Model of frames	**model_of_frames**	**model box**	

model of plot frames to plot.

Section: View to plot

The fields and buttons used in this section have the following functions.

Field Description	Parameter name	Type	Pop-Up
View to plot	**view_name**	**model box**	

view in which data to plot resides.

Section: Plotter parameters

The fields and buttons used in this section have the following functions.

Field Description	Parameter name	Type	Pop-Up
Plotter type	**plotter_type**	**plotter box**	

a valid plotting option is selected.

Field Description	Parameter name	Type	Pop-Up
Plot file stem	**plot_stem**	**plotter box**	

plot file name. The appropriate extension is added dependant on the plotter type selected.

Clean plot models beforehand

Field Description	Parameter name	Type	Pop-Up
	plot_model_clean	**choice box**	**do not clean** **prompt for clean** **always clean**

whether to clean (delete the elements in) any resultant plot models that may already exist, before generating the plot(s). This parameter is only applicable if plotting to a model or models. Note that if the models are cleaned using this parameter, any non-plot or locked elements found in the models will not be cleaned from the models, and the plot job will be cancelled.

Use drawing numbers in plot file names use_drawing_numbers_in_filenames tick box

Please continue to the next section 26.9.2 Notes - Plot Frame.

26.9.2 Notes - Plot Frame

This is documented for all the PPF Editors in 26.2.4 Notes.

Please continue to the next section 26.9.3 Plot to Models - Plot Frame.

26.9.3 Plot to Models - Plot Frame

This is documented for all the PPF Editors in 26.2.5 Plot to models.

Please continue to the next section 26.9.4 Plot Frame Title Block.

26.9.4 Plot Frame Title Block

This is documented for all the PPF Editors in 26.2.6.1 Title Block Section in PPF Editors.
For more general information about a title block, see 26.2.6 Title Block.

Return to 26.9 Plot Frame and PPF Editor.

26.9.5 Buttons at Bottom of Plot Frame PPF Editor

This is documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

Return to 26.9 Plot Frame and PPF Editor.

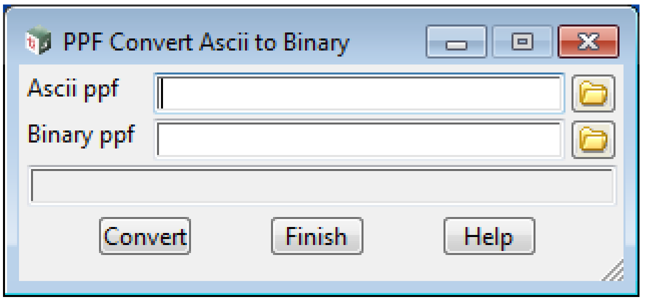
26.10 Convert Ascii PPF to Binary

Position of option on menu: **Plot =>Plot and PPF Editors =>Convert Ascii to Binary**

The **Convert ascii to binary** option is for converting the old text plot parameter files to the new binary plot parameter file format.

Note: Binary PPFs are stored *within* the project (not in the folder containing the project as the Text PPFs were).

Selecting the **Convert ascii to binary** displays the **PPF Convert Ascii to Binary** panel:



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Ascii ppf	file box		

name of the Text plot parameter file to convert.

Binary ppf	button		

convert the Text PPF to the equivalent binary PPF. The binary PPF file will be stored in the current project.

Convert	button		

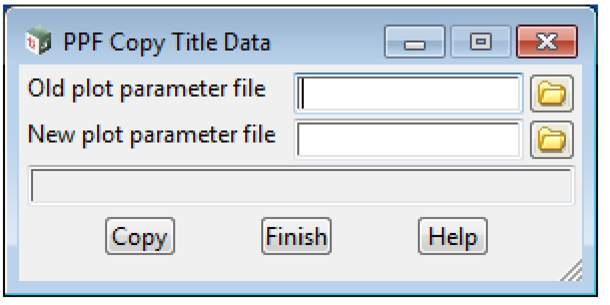
convert the Text PPF to a binary PPF.

26.11 Copy Title Data

Position of option on menu: **Plot =>Plot and PPF Editors =>Copy title data**

The **Copy title data** option is for copying the title data in one binary plot parameter to another binary plot parameter file format.

On selecting the **Copy title data** option, the **PPF Copy Title Data** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description		Type		Defaults		Pop-Up

Old plot parameter file	file box

name of the plot parameter file to copy the title data from.

New plot parameter file	button

name of the plot parameter file to copy the title data to.

Copy	button

copy the title data from one PPF file to another.

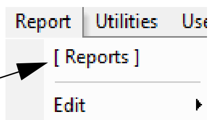
27 Reports

Position of menu: **It is on the main menu as Report**

The **Reports** menu contains options to report on the strings in a model, polygon details (area, centroid), string set outs, string names, crest and sag points and x-falls.

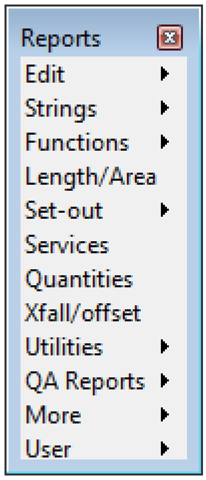
The **Reports** menu is

on Main menu



create floating **Reports** menu

on 12d Model menu and floating Reports menu



edit a .rpt file
report on strings, crest/sag points, names
report on functions
length, area, centroid of strings
point and string set-out information

calculations of quantities
report x-fall between two strings
XML report utilities
QA reports
further reports
Reports User menu

For the option/menu *Edit*, go to 27.1 Edit
Strings 27.2 Strings
Functions 27.3 Functions
Length/area 27.4 Length and Area
Set-out 27.5 Set-Out Reports
Services 27.6 Services
Quantities 27.7 Quantities
X-fall 27.8 X-Fall and Offset Report
Utilities 27.9 Report Utilities
QA reports 27.10 QA Reports
More 27.11 More Reports

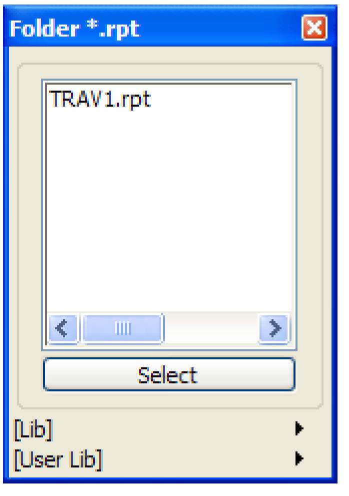
Each menu option will now be discussed.

27.1 Edit

Position on menu: **Report =>Edit**

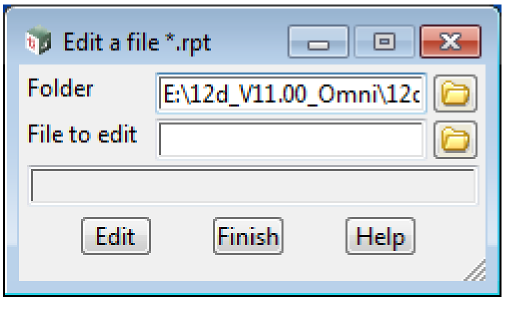
The **Edit** option is used to edit any (printer) reports ending in *.rpt.

On walking right on *Edit*, the list of files ending in *.rpt are displayed.



Double clicking on the report name will bring up the report in the system editor.

Clicking on the *Edit* at the top of the menu brings up the **Edit a file** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Folder	folder box	current folder	folder browser

the folder to look for the report file.

Field Description	Type	Defaults	Pop-Up
File to edit	file box		*.rpt

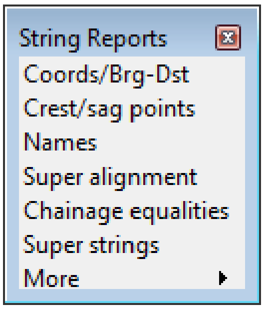
name of the file to bring up in the system editor.

27.2 Strings

Position of menu: **Report =>Strings**

The **Strings** menu contains options to report on selected strings, report the crest/sag points for a string and create a list of all the unique string names in a model or view.

The **Strings** walk-right menu is



For the option *Coords/Brg-Dst*, go to 27.2.1 Coordinates or Bearing-Distance Report

Crest/sag points 27.2.2 Crest/Sag Points Report

Names 27.2.3 Names Report

Super alignment 27.2.4 Super Alignment Report

Chainage Equalities 27.2.5 Chainage Equalities Report

Super strings 27.2.6 Report for Super Strings

More 27.2.7 More Strings Reports.

27.2.1 Coordinates or Bearing-Distance Report

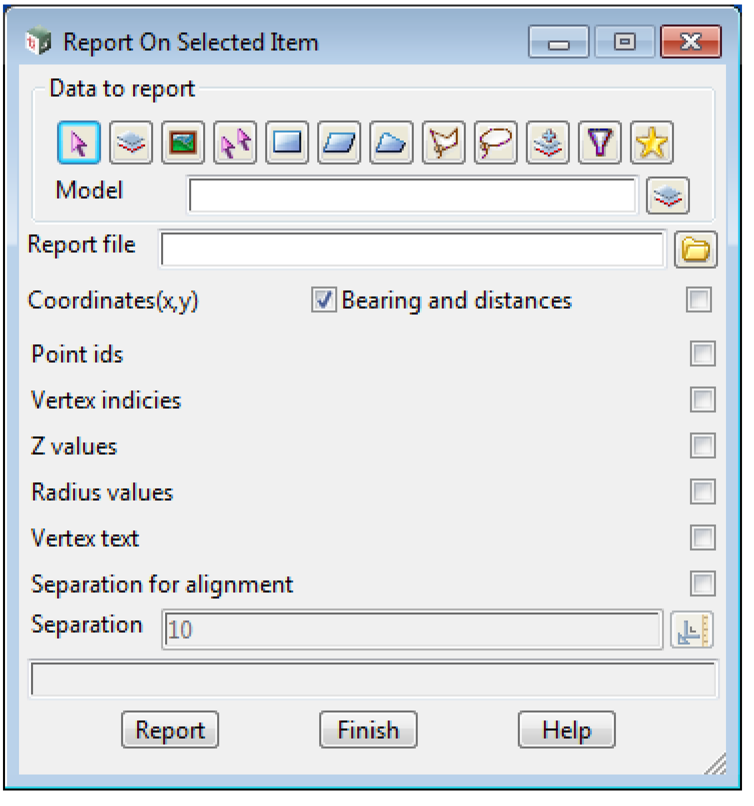
Position of option on menu: **Report =>Strings =>Coords/Brg-Dst**

The **Coords/Brg-Dst** option is used to generate a report on selected items defined by a source box. The report can be of the form of coordinates of each point of a string, or the co-ordinates of the first point of a string and the bearings and distances from each other point of the string to the first point of the string.

For a a Super Alignment string it will report the solved horizontal and vertical geometry (the horizontal and vertical Segments that make up the Super Alignment). If there is a non-zero separation value, then at each chainage that is a multiple of the separation value, the report also includes the chainage, x, y, z, and in and out bearings at he chainage.

For an Alignment string it will report on the HIP's and VIPS. If there is a non-zero separation value, then at each chainages that are multiples of the separation value, the report also includes the chainage, x, y, z, bearing for horizontal and chainage, height (z), grade for vertical.

On selecting the **Coords/Brg-Dst** option, the **Report on Selected Item** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Report file	input		*.rpt

name of the file to report to.

Coordinates(x,y)	tick box	tick	

*if **tick**, the coordinate report parameters will be displayed which will determine what other information as well as the coordinate values will be placed in the report. **NOTE:** If an **alignment string** is part of the selection, the report will include **all** relevant details about the alignment. In this case the report will not use the coordinate report parameters as specified, for the alignment string.*

Bearing and Distances tick box

*if **tick**, the bearing and distance report parameters will be displayed which will determine what other information as well as the bearing and distance values will be placed in the report.*

Coordinate report parameters

if the **Coordinates(x,y)** option is selected, the following parameters will be displayed

Point ids tick box

if selected, any valid point ids will be shown in the report.

Vertex indices tick box

if selected, vertex indices will be shown in the report.

Z Values tick box

if selected, any valid z values will be shown in the report.

Radius values tick box

if selected, any valid radius values will be shown in the report.

Vertex Text tick box

if selected, any valid vertex text values will be shown in the report.

Separation for Alignment tick box

if selected, the separation for alignment box will be enabled.

Separation input box 10

if enabled by ticking the previous tick box, the alignment string information will be reported at a chainage interval given by the separation value.

Report button

run the option and create the report.

For a Super Alignment, the report is the same as **Reports =>Strings => Super alignment** (see 27.2.4 Super Alignment Report).

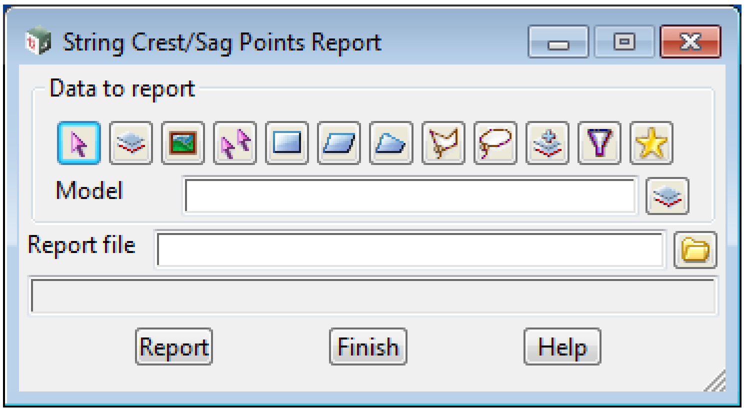
27.2.2 Crest/Sag Points Report

Position of option on menu: **Report =>Strings =>Crest sag points**

The **crest/sag points** option is used to generate a (printer) report on the crests and sags points of a string.

A number of strings can be reported on by selecting them in turn

On selecting the **crest/sag points** option, the **string crest/sag points report** panel is displayed.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Report file	input		*.rpt

name of the file to contain the reports on the crest and sag points of strings.

Pick & Report	button		

as strings are selected, the crest and sag points report is generated and appended to the report file.
The cycle is terminated by clicking RB to raise the **pick ops** *menu and selecting* **cancel** *from it.*

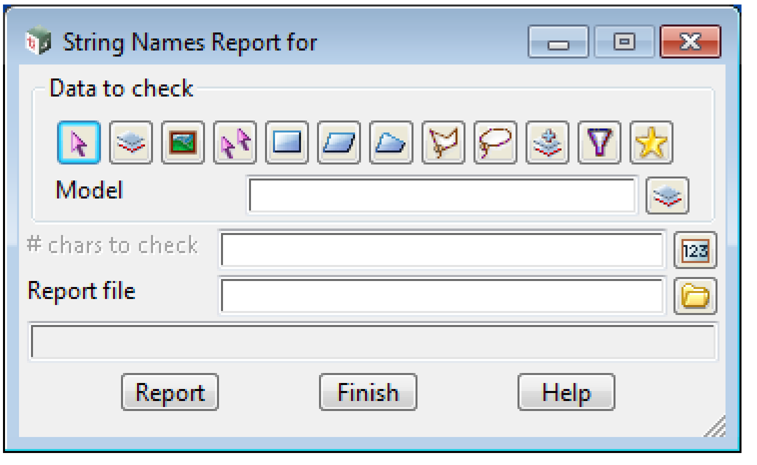
27.2.3 Names Report

Position of option on menu: **Report =>Strings =>Names**

The **names** option is used to report on all the unique strings in a model or on a view.

If the **report** button is selected, then all the strings in the model/view given by the model/view to report field will be checked and all unique names, plus a frequency count, will be written to the report file.

Selecting **Names** displays the **String Names Report for** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

# chars to check	input		

*if **non blank**, the number of characters to be used in the string name when checking for uniqueness.*
*If **blank**, then the entire string name is used.*

Report file	file box		*.rpt files

name of the file for the report.

Report	button		

report on all the unique string names in model/view.

27.2.4 Super Alignment Report

Position of option on menu: **Report =>Strings =>Super alignment**

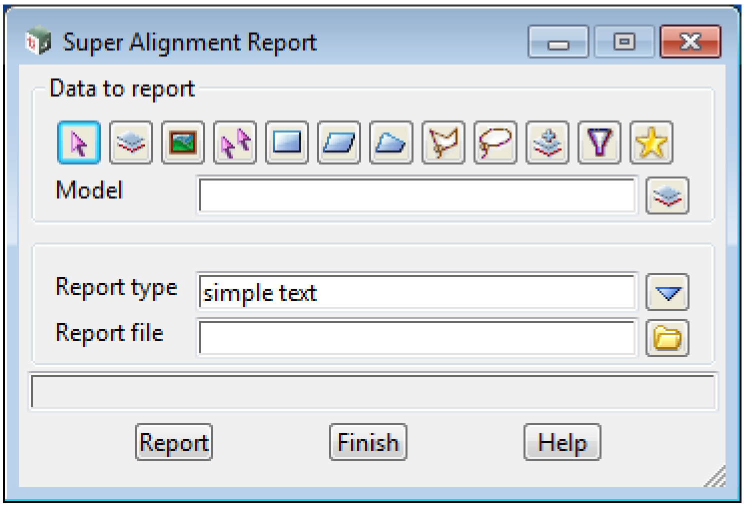
Position of option on menu: **Strings =>SA tools =>Report**

Report on the Super Alignment that gives information on the horizontal and vertical components.

For a Super Alignment string it will report the solved horizontal and vertical geometry (the horizontal and vertical Segments that make up the Super Alignment).

If there is a non-zero separation value, then at each chainages that are multiples of the separation value, the report also includes the chainage, x, y, z, in and out bearing for horizontal vertices, and chainage, height (z) and in and out grade for vertical vertices.

On selecting the **Super alignment** option, the **Super Alignment Report** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source.			
Data source			
type of data source.			
Report type	choice box	simple text	html tables, pdf tables, original xml, csv ip tables, simple text, crests and sags
type of report			
Report file	input		*.rpt
name of the file to report to. See below for definition of the report and an example.			
Report	button		
run the option and create the report.			

The Super Alignment report is made up of 5 parts:

(a) General Information

The type of transition curve.

Whether the super alignment is closed or not.

The start chainage for the string and the chainage length (2d length) of the string.

(b) Horizontal Vertex Data

The **Horizontal Vertex Data** section of the report gives information about each of the *horizontal vertices* of the underlying ***horizontal segment geometry***.

Note: "Solving" a super alignment takes all the constraints and produces a string of vertices with segments of type Line, Arc or Transition between each pair of adjacent vertices.

So the **Horizontal Vertex Data** report gives the (x,y,z) coordinates of each of the vertices of the solved horizontal geometry with the type of segment going into the vertex (**In Seg**), and the type of segment going out of the vertex (**Out Seg)**.

The **In Direction** is the angle at the vertex of the segment going into the vertex, and the **Out Direction** is the angle at the vertex of the segment going out of the vertex.

If the *In* and *Out Direction* are the same, then the two segments are *tangential* at the vertex and there will be a *Yes* in the **Tan** column, otherwise there will be a *No* in the **Tan** column.

In Seg

The type of the segment going into the critical point (In Segment) at the chainage - Line, Arc, Leading Spiral (LSpiral), Trailing Spiral (TSpiral)

Out Seg

The type of the segment going out of the critical point (Out Segment) at the chainage - Line, Arc, Leading Spiral (LSpiral), Trailing Spiral (TSpiral)

Tan - yes or no

yes if the In Segment and Out Segment are tangential. That is, the In Direction and Out Direction are the same.

no if the In Segment and Out Segment are not tangential. That is, the In Direction and Out Direction are different.

Chainage

chainage of the critical point

X, **Y** and **Z Coordinates** at that chainage

In Direction

the angle of the In Segment at the critical point. Measured in dms, counterclockwise from the positive x-axis.

Out Direction

the angle of the Out Segment at the critical point. Measured in dms, counterclockwise from the positive x-axis.

In Radius

the radius of the In Segment at the critical point (or blank if on a Line).

Out Radius

the radius of the Out Segment at the critical point (or blank if on a Line).

(c) Horizontal Geometry Data

How each of the horizontal parts is defined.

(d) Vertical Vertex Data

The **Vertical Vertex Data** section of the report gives information about each of the *vertical vertices* of the underlying ***vertical segment geometry***.

Note: "Solving" the vertical of a super alignment takes all the constraints and produces a 2d string in the (Chainage, height) plane, of vertices with segments of type Line, Arc or Parabola between each pair of adjacent vertices.

So the **Vertical Vertex Dat**a report gives the (ch,z) coordinates of each of the vertices of the solved vertical geometry with the type of segment going into the vertex (**In Seg**), and the type of segment going out of the vertex (**Out Seg)**.

The **In Grade** is the grade at the vertex of the segment going into the vertex, and the **Out Grade** is the grade at the vertex of the segment going out of the vertex.

If the *In* and *Out Grade* are the same, then the two segments are *tangential* at the vertex and there will be a *Yes* in the **Tan** column, otherwise there will be a *No* in the **Tan** column.

In Seg

The type of the segment going into the critical point (In Segment) at the chainage - Line, Arc, Parabola

Out Seg

The type of the segment going out of the critical point (Out Segment) at the chainage - Line, Arc, Parabola

Tan - yes or no

yes if the In Segment and Out Segment are tangential. That is, the In Grade and Out Grade are the same.

no if the In Segment and Out Segment are not tangential. That is, the In Grade and Out Grade are different.

Chainage

chainage of the critical point

Level

height (z value) at that chainage

In Grade

the grade of the In Segment at the critical point.

Out Grade

the grade of the Out Segment at the critical point.

In VCL Radius

the radius of the parabola or arc of the In Segment at the critical point (or blank if on a Line).

Out VCL Radius

the radius of the parabola or arc of the Out Segment at the critical point (or blank if on a Line).

(e) Vertical Geometry Data

How each of the vertical parts is defined.

Old Report - V9

The Super Alignment report is made up of 5 parts:

(a) General Information

The date the report was produced and the string and model name for the string.

The type of transition curve.

Whether the super alignment is closed or not.

The start chainage for the string and the chainage length (2d length) of the string.

(b) A report for the critical points, and the horizontal chainage increment of the string giving the

Point Type at the chainage (eg Straight, Tangent-Curve, Curve, Spiral-Curve etc)

Chainage at that point.

X, **Y** and **Z Coordinates** at that chainage

Instantaneous **Bearing** at that chainage

Instantaneous **Radius** at that chainage (or blank if on a straight)

(c) Horizontal Vertex Data

The **Horizontal Vertex Data** section of the report gives information about each of the *horizontal vertices* of the underlying ***horizontal segment geometry***.

Note: "Solving" a super alignment takes all the constraints and produces a string of vertices with segments of type Line, Arc or Transition between each pair of adjacent vertices.

So the **Horizontal Vertex Dat**a report gives the (x,y,z) coordinates of each of the vertices of the solved horizontal geometry with the type of segment going into the vertex (**In Seg**), and the type of segment going out of the vertex (**Out Seg)**.

The **In Bearing** is the bearing at the vertex of the segment going into the vertex, and the **Out Bearing** is the bearing at the vertex of the segment going out of the vertex.

If the *In* and *Out Bearings* are the same, then the two segments are *tangential* at the vertex and there will be a *Yes* in the **Tan** column, otherwise there will be a *No* in the **Tan** column.

(d) Horizontal Geometry Details

How each of the horizontal parts is defined.

(e) Vertical Vertex Data

The **Vertical Vertex Data** section of the report gives information about each of the *vertical vertices* of the underlying ***vertical segment geometry***.

Note: "Solving" the vertical of a super alignment takes all the constraints and produces a 2d string in the (Chainage, height) plane, of vertices with segments of type Line, Arc or Parabola between each pair of adjacent vertices.

So the **Vertical Vertex Dat**a report gives the (ch,z) coordinates of each of the vertices of the solved vertical geometry with the type of segment going into the vertex (**In Seg**), and the type of segment going out of the vertex (**Out Seg)**.

The **In Grade** is the grade at the vertex of the segment going into the vertex, and the **Out Grade** is the grade at the vertex of the segment going out of the vertex.

If the *In* and *Out Grade* are the same, then the two segments are *tangential* at the vertex and there will be a *Yes* in the **Tan** column, otherwise there will be a *No* in the **Tan** column.

(f) Horizontal Geometry Details

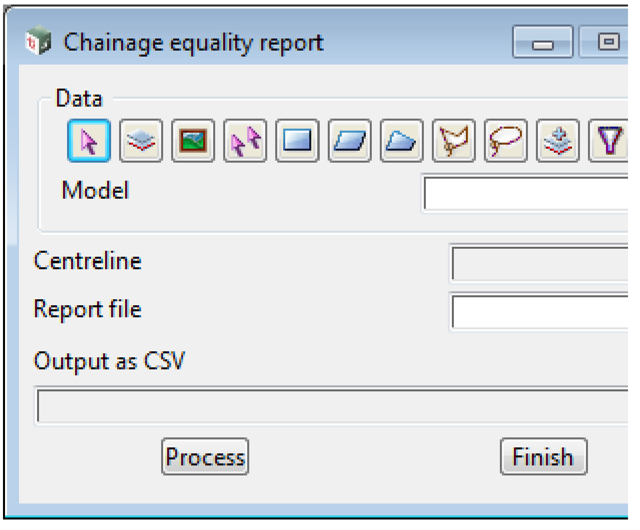
How each of the vertical parts is defined.

27.2.5 Chainage Equalities Report

Position of option on menu: **Report =>Strings =>Chainage equalities**

This option is under development.

On selecting the **Chainage equalities** option, the **Chainage Equality Report** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Centreline string select

name of the super alignment to report on.

Report File file select

name of the file to report to.

Output as CSV tick box

if tick, write the report out as a CSV file

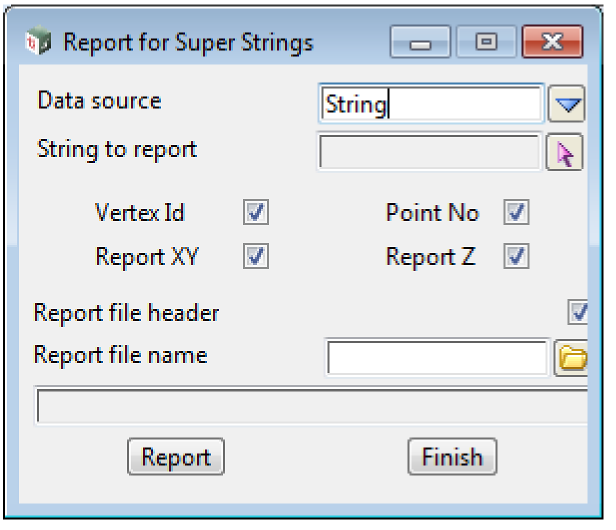
Report button

run the option and create the report.

27.2.6 Report for Super Strings

Position of option on menu: **Report =>Strings =>Super strings**

This option reports on information in the super string.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Vertex index	tick box	tick	

if tick, vertex indices are reported.

Point id	tick box	tick	

if tick, point ids are reported.

Report XY	tick box	tick	

if tick, x and y values are reported.

Report Z	tick box	tick	

if tick, z values are reported.

Report file header	input box	tick	

if tick, a header including the date and model name and string names is included.

Report file name	input box		

name of the report.

Report	button		

Run the option.

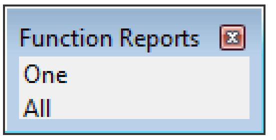
27.2.7 More Strings Reports

There are currently no options on this menu.

27.3 Functions

Position of menu: **Report =>Functions**

A report can be made on a function. The **function** walk-right menu is

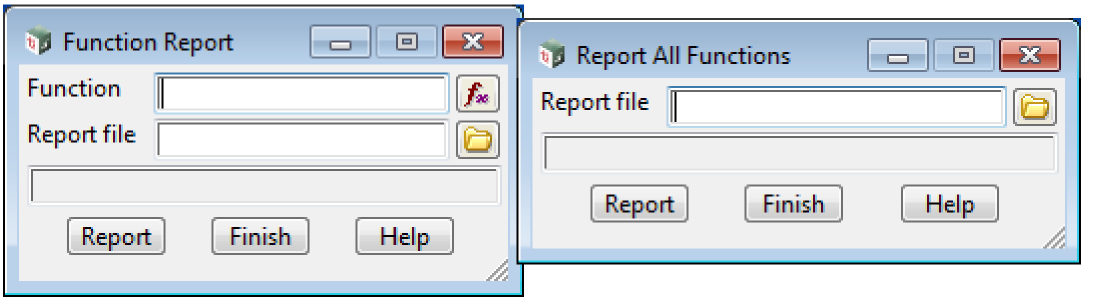


27.3.1 Report a Function, Report all Functions

Position of option on menu: **Report =>Functions =>One**

Position of option on menu: **Report =>Functions =>All**

On selecting the **report** or **report all** option, the **function report/ report all functions** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Function	function box		available functions

name of the function to be reported.

Report file	file box		*.rpt files

name of the file to write the report to.

Report	button		

after selecting this button, a report on the function/ all functions is produced.

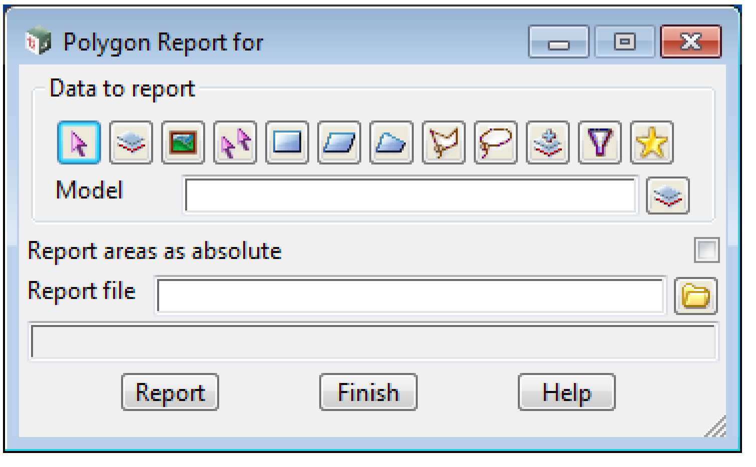
27.4 Length and Area

Position of option on menu: **Report =>Length/Area**

The **Length/area (Polygons)** option creates a report containing the following information for each selected string:

- string name
- if the string is closed or not
- length of the string
- area of the string (if not closed, join first and last points). A polygon area is positive if the vertices of the polygon go in a clockwise direction, or negative if the vertices go in an anti-clockwise direction.
- centroid co-ordinates

On selecting the Length/Area option, the Polygon Report for panel is displayed.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Report areas as absolute tick box

A polygon area is positive if the vertices of the polygon go in a clockwise direction, or negative if the vertices go in an anti-clockwise direction.

if ticked, report all areas as positive.

Report file	input		*.rpt

file for the polygon reports.

Report	button		

produce a polygon report for all strings selected in the Data source.

27.5 Set-Out Reports

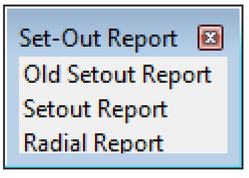
Position of menu: **Report =>Set-out**

The **Set out** report options are for reporting the bearing and distance from a selected instrument station to individual points, strings, models of strings or views of strings.

In the *Setout report*, a backsight stations can be selected and the bearing of the **line** from the instrument station to the backsight station reported. Individual backsight points or strings of backsight points can be selected for reporting.

In the *Radial report*, the report can be sorted by point number, bearing or distance.

The **set outs** walk-right menu is



old set out report from V5.0
set out report for strings
set out report sorted by name, distance or bearing

For the option *Old setout report*, go to 27.5.1 Old Setout Report
Setout report 27.5.2 Setout Report
Radial report 27.5.3 Radial Report

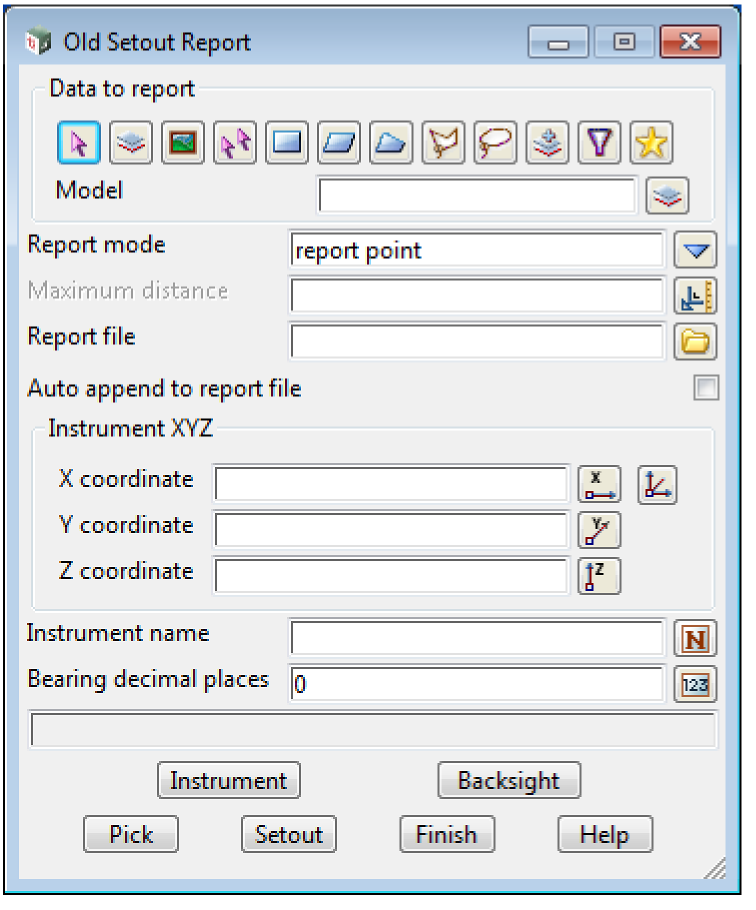
The menu options will now be discussed.

27.5.1 Old Setout Report

Position of option on menu: **Report =>Set out =>Old setout report**

The setout report from ***12d Model*** V5. This option has been rewritten for ***12d Model*** V6 and is called **Setout Report**.

On selecting the **Old setout report** option, the **Old Setout Report** panel is displayed.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Report mode	input		report points, report string

*if **report points**, report selected points. Otherwise report on all points in the selected string.*

Maximum distance	input		

*if **non-blank**, any points further that the maximum distance from the instrument station will not be reported on. If **blank**, all selected points will be reported on*

Report file	input		

file for the backsight and setout reports

Instrument XYZ/name output

co-ordinates/name of the current instrument station

Bearing decimal places input

number of decimal places to report the bearings to

Instrument button

the required instrument station is selected and its name and position are reported in the instrument XYZ *and* instrument name *panel fields.*

Backsight button

a backsight is selected and written to the report file.

Pick button

*After pick is chosen, a set out report is written to the report file for any selected strings. If the report mode is **report point**, only the individual point is reported. If the report mode is **report string**, all the points in the string are reported.*
*The cycle is terminated by clicking RB to raise the **pick ops** menu and selecting **cancel** from it.*

Setouts button

produce a set out report for all the strings in the model/view given in the model/view *field.*

How to Use the Panel and Panel Messages

(a) Enter the report file name and maximum distance.

(b) The instrument station is chosen by activating the **station** button and selecting the required station point. It will then be reported in the file

(c) Any backsight points to be reported can then be chosen by picking the **backsight** button and selecting the backsight point.

(d) To report on individual strings or points, set the report mode to either point or string. The **pick** button is then activated and the individual points or strings selected. The cycle is terminated by clicking RB to raise the **pick ops** menu and selecting **cancel** from it.

To report on all the strings in a model/view, give the model/view in the model/view field, and select the **setout** button.

Note

The instrument station can be changed at any time by selecting the **station** button and picking the new station.

All backsight and set outs will then be taken from the new instrument station.

27.5.2 Setout Report

Position of option on menu: **Report =>Set out =>Setout report**

In the *Setout report*, a backsight stations can be selected and the bearing of the **line** from the instrument station to the backsight station reported. Individual backsight points or strings of backsight points can be selected for reporting.

The instrument station can be changed at any time and new backsight and set outs reported.

The **set out** option prints the following information:

instrument station

string name, point number, x, y, z

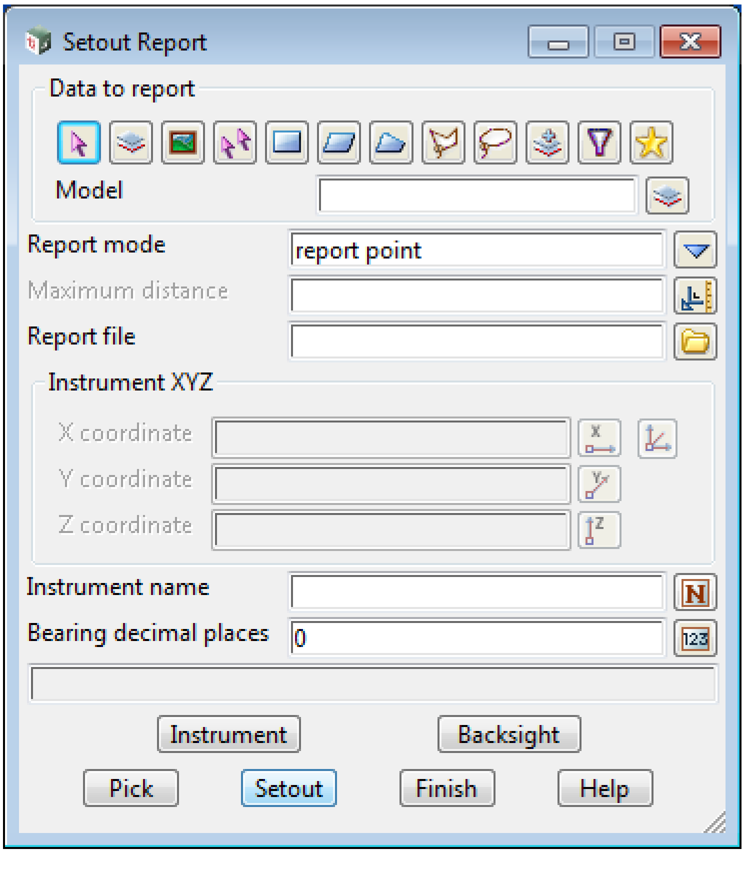
backsight point

string name, point number, x, y, z, bearing to the line joining the instrument and backsight, horizontal distance, height difference between instrument station and the backsight

point set-out point

string name, point number, x, y, z, bearing, horizontal distance, height difference between instrument station and the point

On selecting the **Setout report** option, the **Setout Report** panel is displayed.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Report mode choice box report points, report string

*if **report points**, report selected points. Otherwise report on all points in the selected string.*

Maximum distance input

*if **non-blank**, any points further that the maximum distance from the instrument station will not be reported on. If **blank**, all selected points will be reported on*

Report file file box

file for the backsight and setout reports

Instrument XYZ/name output

co-ordinates/name of the current instrument station

Bearing decimal places input

number of decimal places to report the bearings to

Instrument button

the required instrument station is selected and its name and position are reported in the instrument XYZ *and* instrument name *panel fields.*

Backsight button

a backsight is selected and written to the report file.

Pick button

*After pick is chosen, a set out report is written to the report file for any selected strings. If the report mode is **report point**, only the individual point is reported. If the report mode is **report string**, all the points in the string are reported.*
The cycle is terminated by clicking RB to raise the **Pick ops** *menu and selecting* ***Cancel*** *from it.*

Setouts button

produce a set out report for all the strings in the model/view given in the model/view *field.*

How to Use the Panel and Panel Messages

(a) Enter the report file name and maximum distance.

(b) The instrument station is chosen by activating the **station** button and selecting the required station point. It will then be reported in the file

(c) Any backsight points to be reported can then be chosen by picking the **backsight** button and selecting the backsight point.

(d) To report on individual strings or points, set the report mode to either point or string. The **pick** button is then activated and the individual points or strings selected. The cycle is terminated by clicking RB to raise the **pick ops** menu and selecting **cancel** from it.

To report on all the strings in a model/view, give the model/view in the model/view field, and select the **setout** button.

Note

The instrument station can be changed at any time by selecting the **station** button and picking the new station.

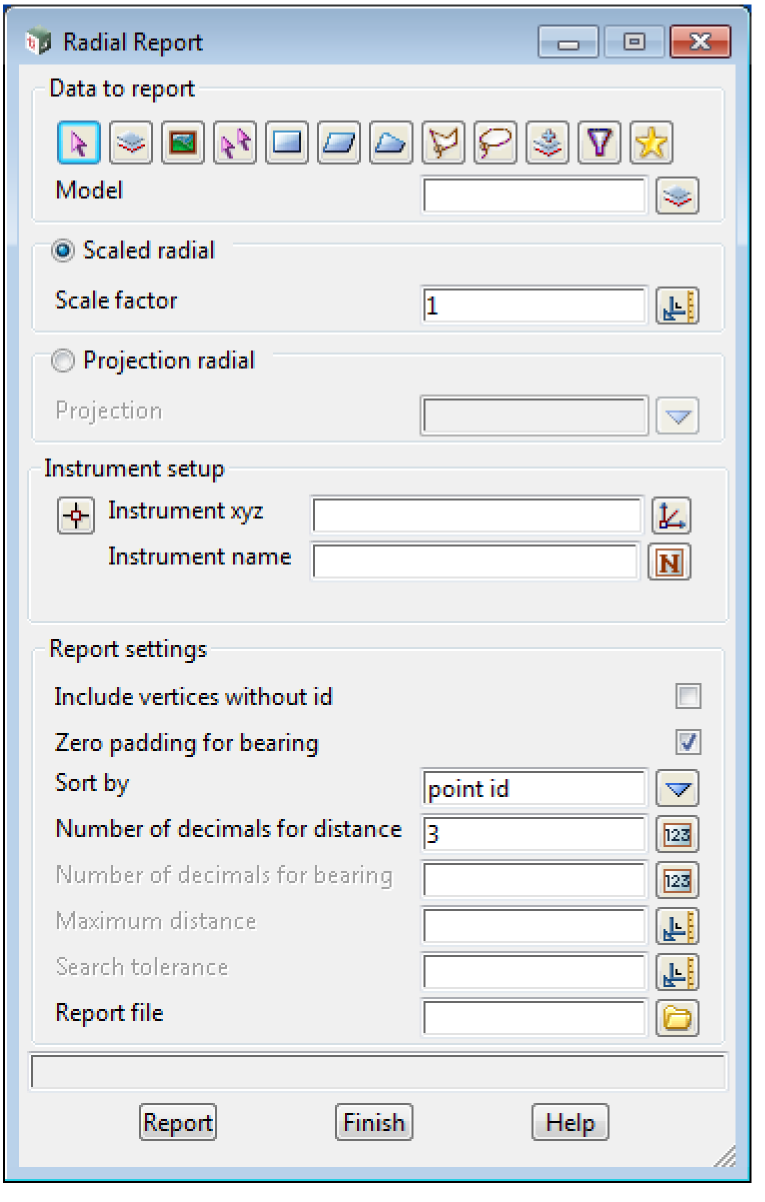
All backsight and set outs will then be taken from the new instrument station.

27.5.3 Radial Report

Position of option on menu: **Report =>Set out =>Radial report**

The radial report reports the bearing and distance from the Instrument to selected vertices. the report can be sorted by point id, bearing or distance.

Selecting **Radial report** brings up the **Radial Report** panel.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Scaled radial radio button

if selected, the report uses a fixed scale factor.

Scale factor input 1

*if **scaled radial is** selected, the fixed scale factor to use*

Projection radial radio button

if selected, the report uses a projection for calculating distances

Projection projection box available projections

*if **projection radial** is selected, the selected projection is used when calculating distances*

Instrument setup

*when the instrument point is selected, the **Instrument co-ordinates** and **name** is displayed n the* Instrument xyz *and* Instrument name *fields.*

Report settings

Include points without id tick box

*if **tick**, vertices with a non blank point id are included in the report.*
*if **not tick**, only vertices with non blank point id are included in the report.*

Zero padding for bearing tick box

*if **tick**, include extra zeros for minutes and seconds.*

Sort by choice box point id point id, bearing, distance

*if **point id**, the report is sorted by the point id's on the vertex.*
***bearing** , the report is sorted by the bearing to the point.*
***distance** , the report is sorted by the distance to the point.*

Number of decimals input 3

number of decimal places for reporting co-ordinates

Maximum distance input

*if **non-blank**, any vertices further that the maximum distance from the instrument station will not be reported on. If **blank**, all vertices points will be reported on*

Search tolerance input

when a vertex is found, any vertices with the same point id within the search distance of the vertex are not reported. Also no vertices closer to the instrument point that this distance will be reported.

Report file file box

file for the setout reports

Report button

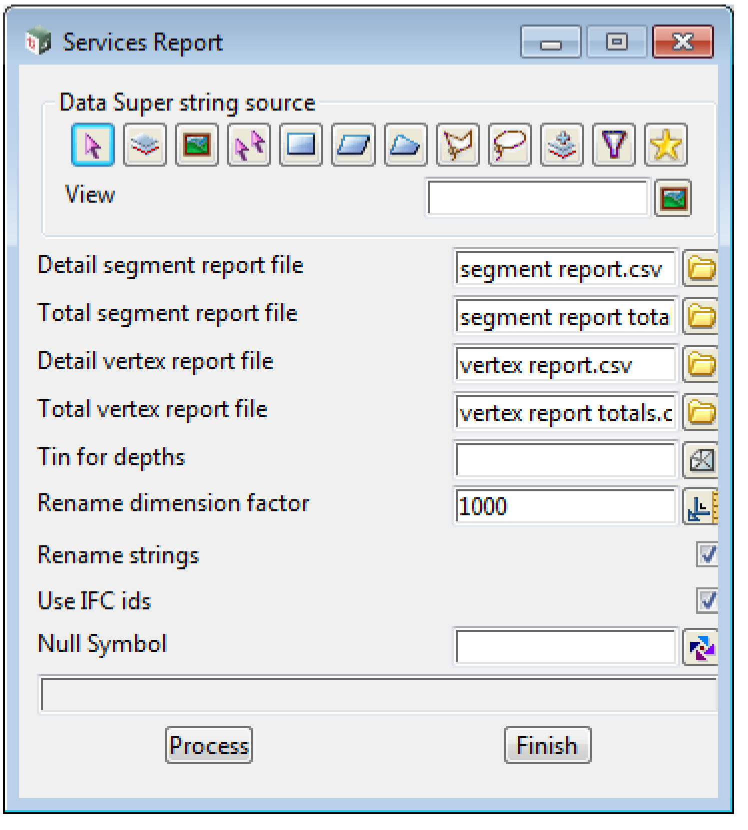
produce the report

27.6 Services

Position of option on menu: **Report =>Services**

Selecting **Services** brings up the **Services** panel.

This section of documentation is a work in progress and will be updated in subsequent releases.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

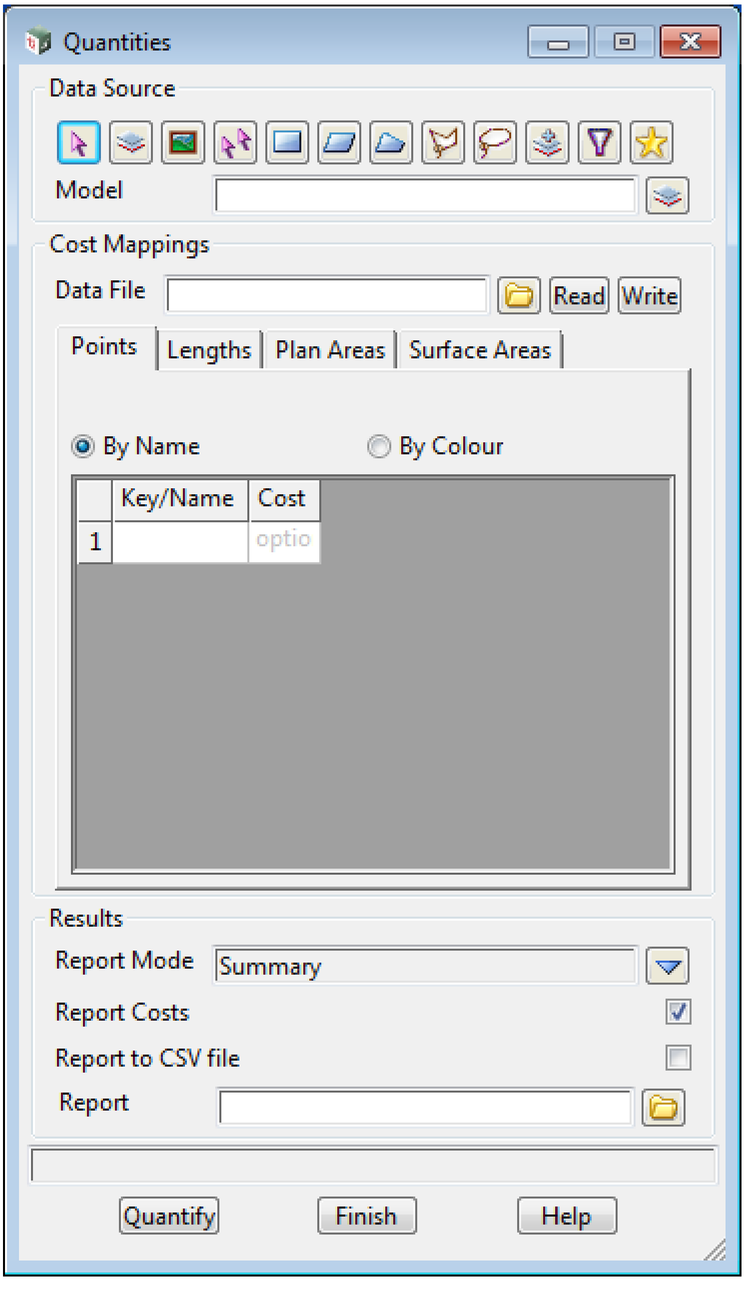
Field Description	Type	Defaults	Pop-Up
Data segment report file	file box	segment report.csv	available .csv files
Total segment report file	file box	segment report totals.csv	available .csv files
Detail vertex report file	file box	vertex report.csv	available .csv files
Total vertex report file	file box	vertex report totals.csv	available .csv files
Tin for depths	tin box		available tins
Rename dimension factor	measure box	1000	At Point, Point to Point, String from Point, String to Point

Rename strings	tick box	ticked	
Use IFS ids	tick box	ticked	
Null symbol	symbol box		available symbols

27.7 Quantities

Position of option on menu: **Report =>Quantities**

Selecting **Quantities** brings up the **Quantities** panel.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

type of data source.

Data file file box

set up file for the costing data - file is read/written using the ***Read/Write*** *buttons.*

Costing tabs

Points tab and grid

By name **By colour**

for any string selected by the key/name or colour, the number of vertices in the string is multiplied by the cost and the total added to the quantities report.

Lengths tab and grid

By name **By colour**

for any string selected by the key/name or colour, the plan or 3d length of the string is multiplied by the cost and the total added to the quantities report.

Plan Areas tab and grid

By name **By colour**

for any string selected by the key/name or colour, the plan area of the string is multiplied by the cost and the total added to the quantities report.

Surface Areas tab and grid

By name **By colour**

for any string selected by the key/name or colour, the surface area of the string within the given tin is multiplied by the cost and the total added to the quantities report.

Report mode choice box Summary Summary, Full

produce the quantity report.

Report costs tick box

if tick, the cost used for each calculation is included in the report.

Report to CSV file tick box

if tick, the report is written as a CSV file

Report file box

name of the quantities report file

Quantify button

produce the quantity report.

27.8 X-Fall and Offset Report

Position of option on menu: **Report =>Xfall/offset**

The **x-fall** report option reports on the horizontal and vertical offsets and the cross-fall between two strings.

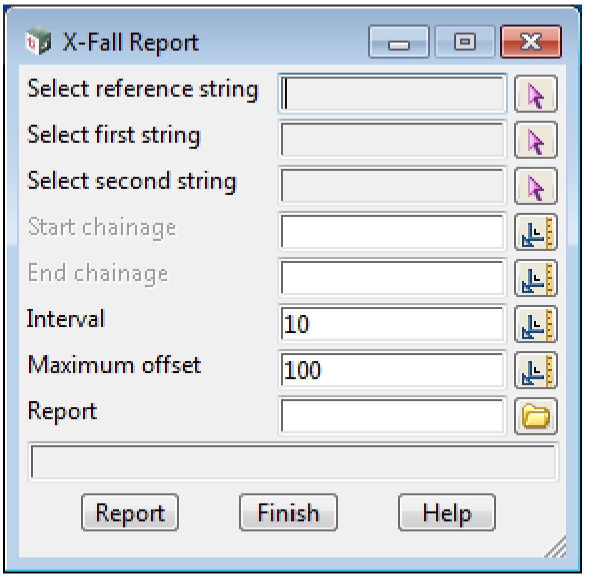
The offsets are calculated as follows:

(a) a reference string is selected which is used to define chainages.

(b) lines perpendicular to the reference string are taken at regular chainages and intersected (in plan) with the first and second strings.

(c) the horizontal and vertical offsets and the cross-fall between the two strings is calculated at the intersection points.

On selecting the **X-fall** option, the **X-Fall Report** panel is displayed.



The fields and buttons in this panel are used as follows

Field Description	Type	Defaults	Pop-Up
Start/End chainage	input		

if blank, the start/end chainage of the reference string is used.
if non-blank, the given chainage is used as the start/end chainage.

Interval	input		

chainage interval to calculate values at.

Maximum offset	input		

if non-blank, the maximum distance to search from the reference string to find the 1st and 2nd strings.

Report file	file box		*.rpt

file for the x-fall report

Ref/1st/2nd	button		

select the reference/first/second string.

Report	button		

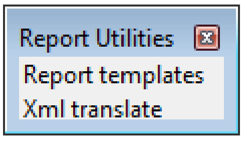
produce a offset and x-fall report between the first and second strings.

27.9 Report Utilities

Position of menu: **Report =>Utilities**

This section of documentation is a work in progress and will be updated in subsequent releases.

The **Utilities** walk-right menu is



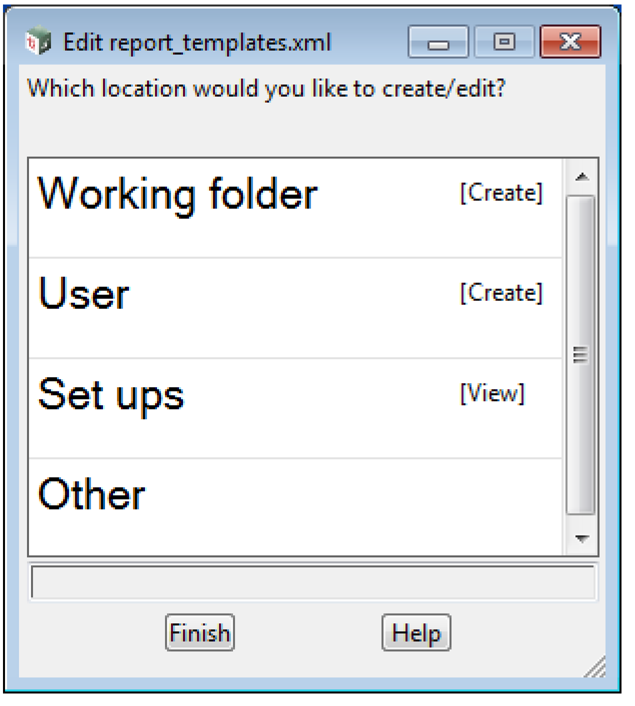
For the option *Report templates*, go to	27.9.1 Report Templates
XML translate	27.9.2 XML Translate

27.9.1 Report Templates

Position of option on menu: **Report =>Utilities =>Report templates**

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting **Report templates**, the **Edit** panel is displayed.

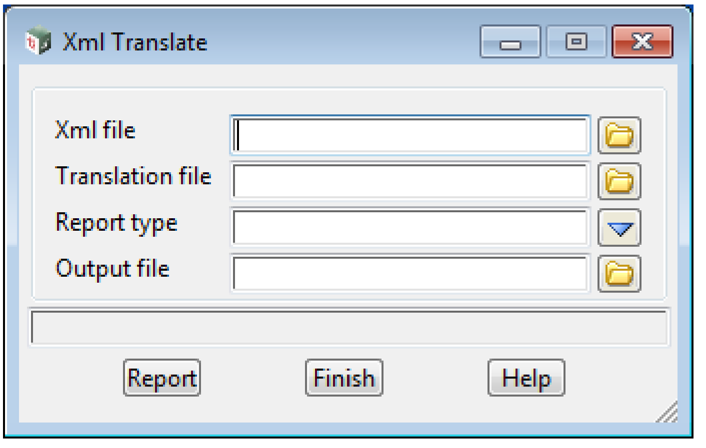


27.9.2 XML Translate

Position of option on menu: **Report =>Utilities =>XML translate**

This section of documentation is a work in progress and will be updated in subsequent releases.

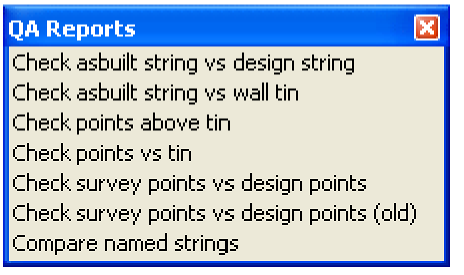
On selecting **XML translate**, the **XML Translate** panel is displayed.



27.10 QA Reports

Position of menu: **Report =>QA Reports**

The QA options are for checking surveyed strings against design strings or tins.



For *Check asbuilt string vs design string*,go to 27.10.1 Check As built String vs Design String

Check asbuilt string vs wall tin 27.10.2 Check Asbuilt String vs Wall Tin

Check points above tin 27.10.3 Check Points Above a Tin

Check points vs tin 27.10.4 Check Points vs Tin

Check survey points vs design points 27.10.6 Check Survey Points vs Design Points (3).

Check survey points vs design points 27.10.5 Check Survey Points vs Design Points (Old).

Compare name strings 27.10.7 Compare Named Strings

27.10.1 Check As built String vs Design String

Position of option on menu: **Report =>QA Reports =>Check asbuilt string vs design string**

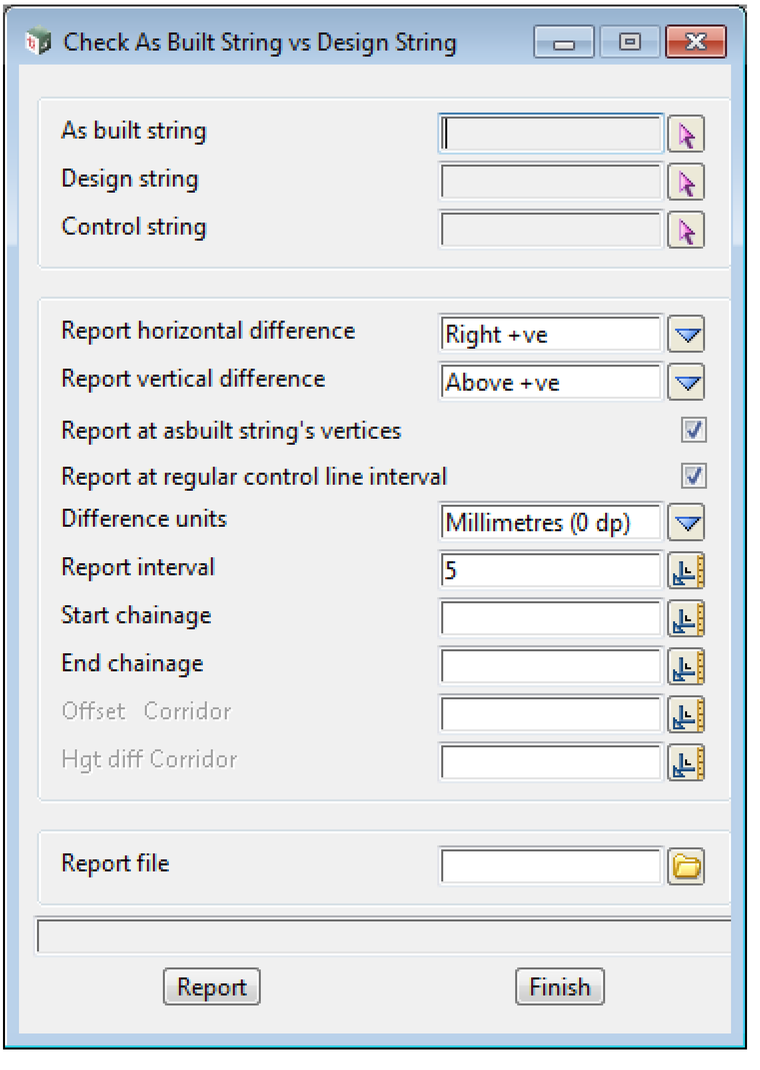
This panel is used to check the horizontal and vertical differences between two strings (usually "as built" and design). A control string is selected to provide the chainage and line to cut the two strings and calculate the difference along. The control string can be one of the two strings.

The corridors are an optional setting for where multiple cuts of the as built and design strings are possible.

E.g. If string crosses over itself or turns through more than 90° a section normal to the control string could cut it more than once.

If the user sees warning messages such as "> 1 cut" then use these settings to filter out the multiple cuts.

Selecting the **Check asbuilt string vs design string** brings up the **Check As Built String vs Design String** panel.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
As built string	string select		
string to compare			
Design string	string select		

string to compare

Control string string select

string to use to define chainage and right angles. The line at right angles cuts the "as built" and "design" strings and is used to calculate the horizontal and vertical differences.

Report horizontal difference choice box Right +ve None, Right +ve, Right -ve

*if **None*** *Don't report horizontal distances.*

*if **Right +ve*** *Horizontal differences are reported with differences to the right reported as +ve*

*if **Right -ve*** *Horizontal differences are reported with differences to the right reported as -ve*

Report vertical difference choice box Above +ve None, Above +ve, Above -ve

*if **None*** *Don't report horizontal distances.*

*if **Above +ve*** *Vertical differences are reported with differences above reported as +ve*

*if **Above -ve*** *Vertical differences are reported with differences above reported as -ve*

Report at asbuilt string's verticestick box tick

if tick, the differences are reported at the vertices of the as built string.

Report at regular control line intervaltick box tick

if tick, the differences are reported at the chainage interval given in the "Report interval" box.

Difference units choice box Millimetres (0 dp) Millimetres (0 dp)
Millimetres (1 dp)
Metres (3 dp)
Metres (4 dp)

*if **Millimetres (0 dp)** In the report, differences are printed out as Millimetres with 0 decimal places*

*if **Millimetres (1 dp)** In the report, differences are printed out as Millimetres with 1 decimal place*

*if **Metres (3 dp)*** *In the report, differences are printed out as Metres with 3 decimal places*

*if **Metres (4 dp)*** *In the report, differences are printed out as Metres with 4 decimal places*

Report interval input box 5

chainage interval of the control string to report the differences at.

Start chainage input box

start chainage of the control string to start reporting differences.

End chainage input box

end chainage of the control string to stop reporting differences.

Offset Corridor input box

If this value is set a cut offset greater than this from the design string is ignored.

Hgt diff Corridor input box

If this value is set a cut hgt difference greater than this from the design string is ignored

Report file input box

name of the report file.

Report button

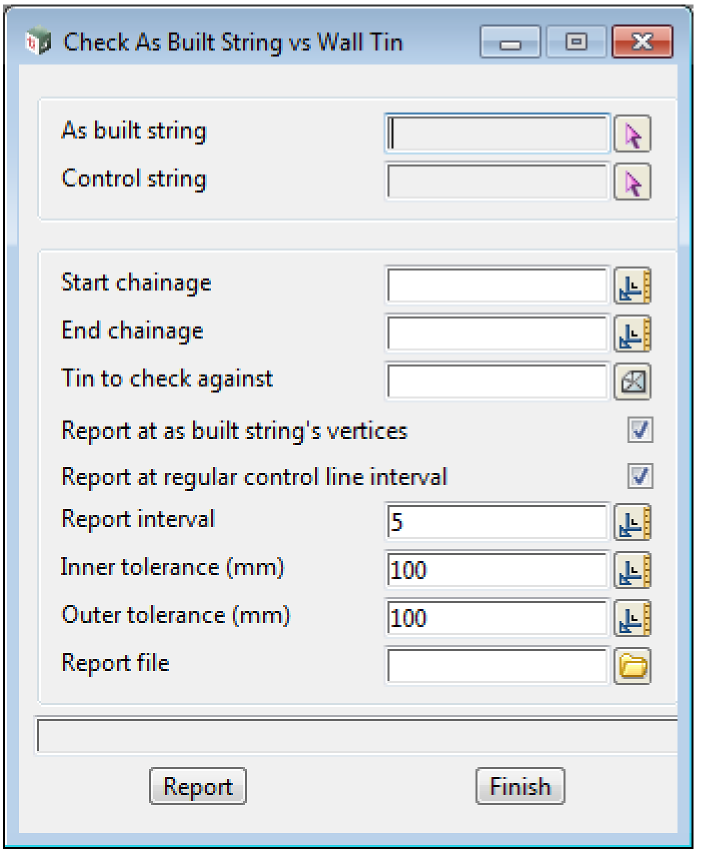
run the option.

27.10.2 Check Asbuilt String vs Wall Tin

Position of option on menu: **Report =>QA Reports =>Check asbuilt string vs wall tin**

This panel is used to check the horizontal difference between a string (usually the “as built”) and a tin (usually a wall tin). A control string is selected to provide the chainage and bearing to project a horizontal line to cut the string and the tin and calculate the horizontal difference along. The control string can be the “as built” string.

Points that are different by a given inner and outer tolerance are flagged in the report.



The fields and buttons used in this panel have the following functions:

Field Description | Type | Defaults | Pop-Up

As built string string select

string to compare against the wall tin.

Control string string select

string to use to define chainage and right angles. The horizontal line at right angles cuts the “as built” string and “tin to check against” tin that is used to calculate the horizontal differences.

Start chainage input box

start chainage of the control string to start reporting differences.

End chainage input box

end chainage of the control string to stop reporting differences.

Tin to check against input box available tins

tin to compare the as built string with.

Report at as built string's verticestick box tick

if tick, the differences are reported at the vertices of the as built string.

Report at regular control line intervaltick box tick

if tick, the differences are reported at the chainage interval given in the "Report interval" box.

Report interval input box 5

chainage interval of the control string to report the differences at.

Inner tolerance (mm) input box 100

if the inner horizontal distance between the string and the wall is greater that this value (in units times 1000) then it is flagged in the report.

Outer tolerance (mm) input box 100

if the outer horizontal distance between the string and the wall is greater that this value (in units times 1000) then it is flagged in the report.

Report File input box

name of the report file.

Report button

run the option.

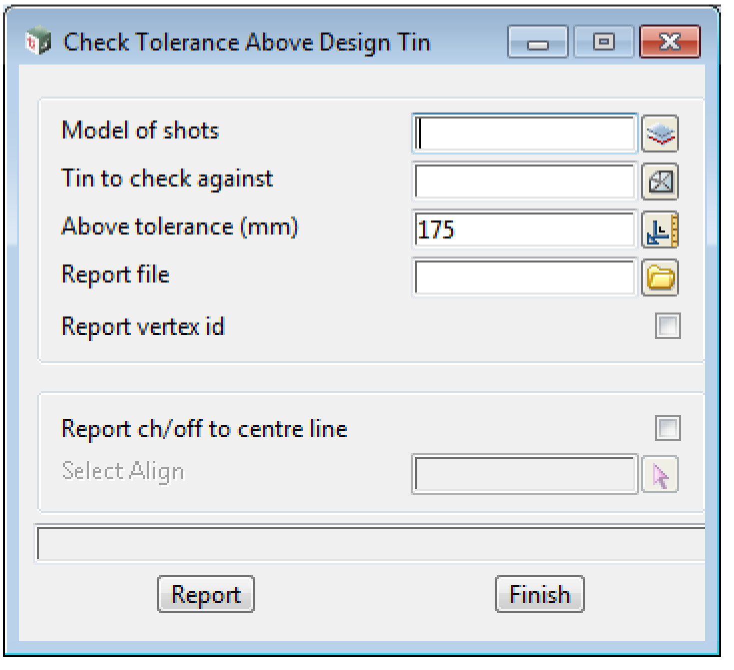
27.10.3 Check Points Above a Tin

Position of option on menu: **Report =>QA Reports =>Check points above tin**

This panel is used to check the z-value of points against the z-value of a tin at the same (x,y) locations and only report on those above the tin. To check points above and below a tin, go to the next section 27.10.4 Check Points vs Tin.

A z-tolerance above the tin is given and all points above the tin and outside the tolerance are especially flagged in the report.

Optionally the report can also include the chainage and offset of the points from a selected alignment string.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Model of shots	model box		

model of points to check the z-value against the tin.

Tin to check against	tin box		

tin to check the z-values against

Above tolerance (mm)	input box	175	

*if the z-value of the point is **above** the tin and the difference of the z-value of the point and the tin (times 1000), is greater than this amount then it is flagged in the report.*

Report file	file box		

name of the report file.

Report ch/off to centre line	tick box		

if tick, the chainage and offset of the points from the selected alignment string are included in the report.

Select align	string select		

select the alignment string to calculate offset and chainage from.

Report

run the option.

27.10.4 Check Points vs Tin

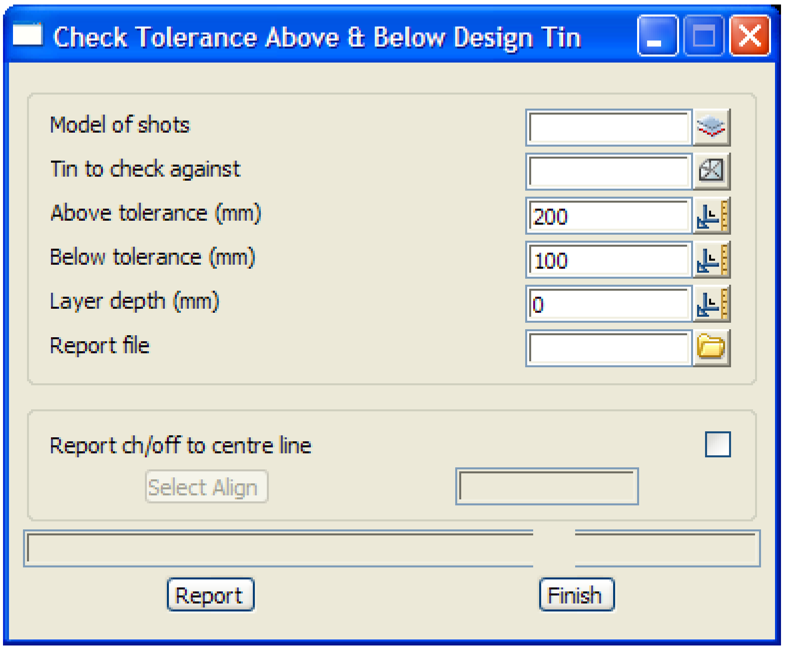
Position of option on menu: **Report =>QA Reports =>Check points vs tin**

For **Check points above tin**, go to 27.10.3 Check Points Above a Tin.

This panel is used to check the z-value of points against the z-value of a tin at the same (x,y) locations, or if a **Layer depth** is given, the z-values of points are checked against the tin *minus* the layer depth.

Separate z-tolerances are supplied for ***above*** and ***below*** the tin and points outside either tolerance are especially flagged in the report.

Optionally the report can also include the chainage and offset of the points from a selected alignment string.



The fields and buttons used in this panel have the following functions:

Field Description   Type   Defaults   Pop-Up

Model of shots   model box

model of points to check the z-value against the tin.

Tin to check against   tin box

tin to check the z-values against

Above tolerance (mm)   input box   175

*if the z-value of the point is **above** the tin and the difference of the z-value of the point and the tin (times 1000), is greater than this amount then it is flagged in the report.*

Below tolerance (mm)   input box   175

*if the z-value of the point is **below** the tin and the absolute value of the difference of the z-value of the point and the tin (times 1000), is greater than this amount then it is flagged in the report.*

Layer depth   input box   0

this value is subtracted form the z-value of the tin before the comparison is made with the z-value of the point.

Report file   file box

name of the report file.

Report ch/off to centre linetick box

if tick, the chainage and offset of the points from the selected alignment string are included in the report.

Select align string select

select the alignment string to calculate offset and chainage from.

Report

run the option.

27.10.5 Check Survey Points vs Design Points (Old)

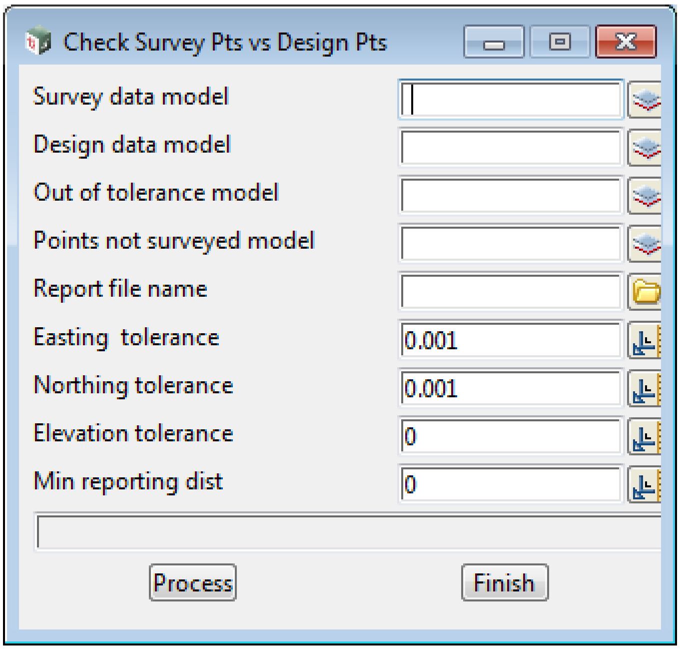
Position of option on menu: **Report =>QA Reports =>Check survey points vs design points (old)**

This option is used to check surveyed points against the design points.

Separate tolerances are given for Eastings (x), Northings (y) and Elevations (z).

Any design points that have not been surveyed are noted and copies of points out of tolerance and/or points not surveyed can be automatically made.

NOTE - if a ***radial*** search distance is required in (x,y), go to the next section 27.10.6 Check Survey Points vs Design Points (3).



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Survey data model	model box		available models

model of points to be compared against the design points.

Design data model	model box		available models

points to be compared against.

Out of tolerance model	model box		available models

copies of any points out of tolerance are added to this model.

Points not surveyed model input box

copies of any points from the design model that have not been surveyed.

Report file name	input box		

name of the report.5

Easting tolerance	input box	0.001	

tolerance in the x direction.

Northing tolerance	input box	0.001	

tolerance in the y-direction.

Elevation tolerance	input box	0

tolerance in the z-direction.

Min reporting dist	input box	0

Process	button

run the option.

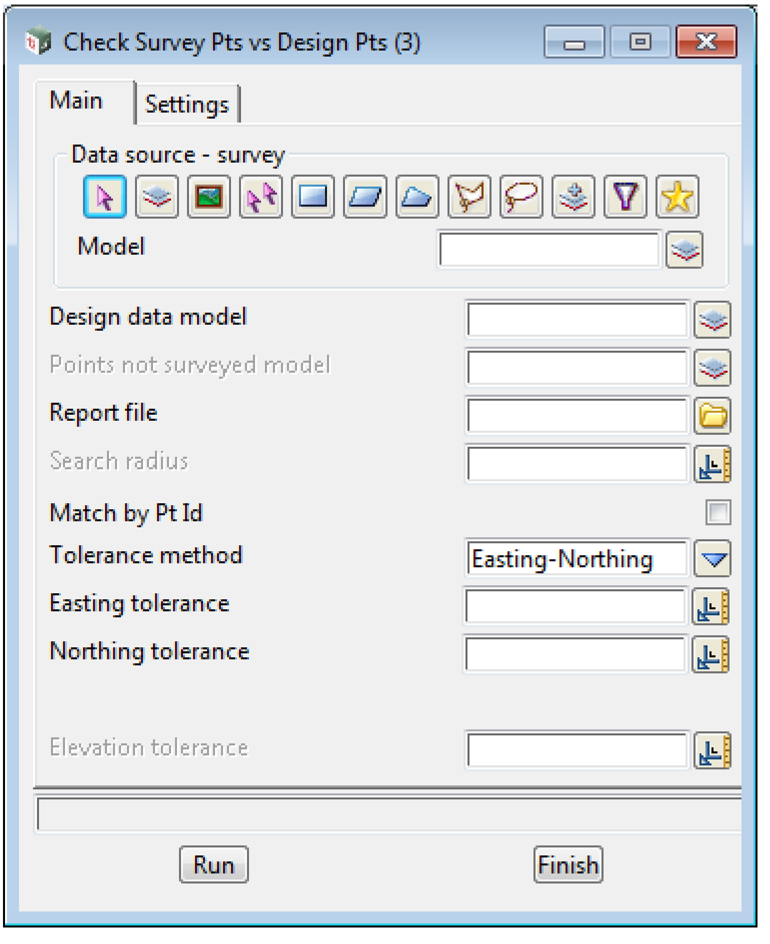
27.10.6 Check Survey Points vs Design Points (3)

Position of option on menu: **Report =>QA Reports =>Check survey points vs design points**

This option is used to check surveyed points against the design points.

The (x,y) search distance can be either one radial distance, a separate x and y distance or separate chainage and offset distances.

Any design points that have not been surveyed are noted and can be optionally copied to a model.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up

Main Tab

Data source type - survey — Defaults: Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source — Type: input

source of data to be processed.

Design data model — Type: model box — Pop-Up: available models

Model containing design points for comparison against.

Points not surveyed model	input box		

Copies of any points from the design model that have not been surveyed.

Report file	file box		

Name of report file for results

Search radius	measure box		At Point, Point to Point, String from Point,String to Point

if set surveyed/design points are matched when less than this distance apart.

Match by Pt Id	tick box		

if ticked surveyed/design points are matched by point id.

Tolerance method	choice box	Easting-Northing	Easting-Northing, Distance,Chainage-Offset

*if **Chainage-Offset**, separate chainage and offset tolerances relative to a selected string are given to check against.*

*if **Easting-Northing**, separate Easting (x) and Northing (y) tolerances are given to check against.*

*if **Distanc**e, the test is for a radial distance, not a separate tolerances.*

Easting tolerance	measure box		At Point, Point to Point, String from Point, String to Point

The tolerance in the x-direction

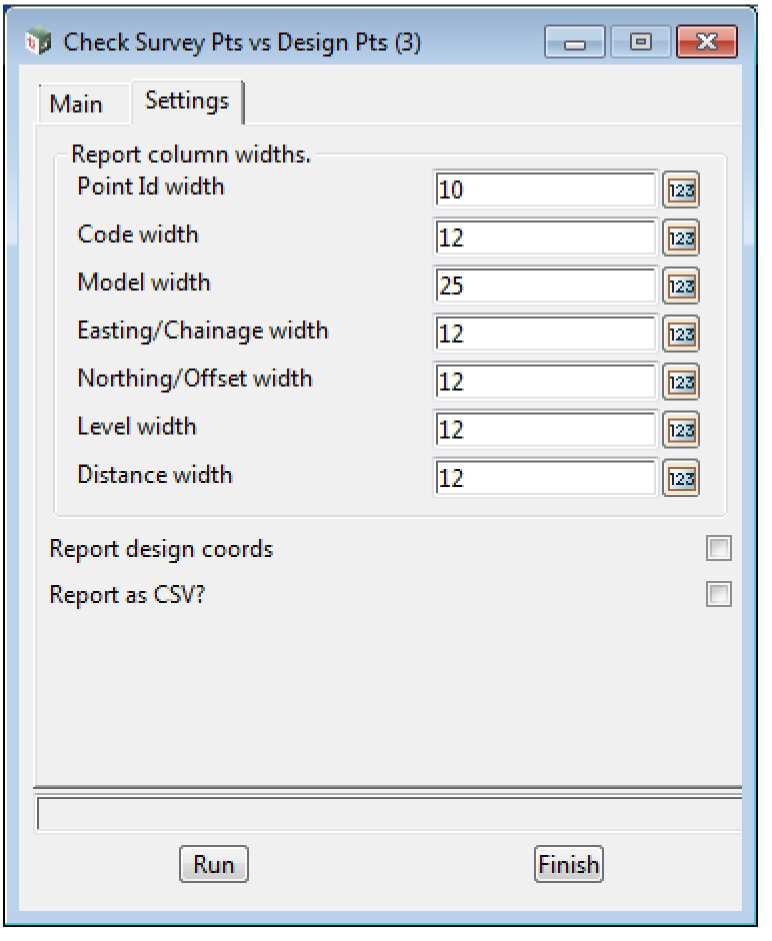
Northing tolerance	measure box		At Point, Point to Point, String from Point, String to Point

The tolerance in the y-direction

Elevation tolerance	measure box		At Point, Point to Point, String from Point, String to Point

The tolerance in the z-direction

Settings Tab



This tab allows some settings in controlling the report.

Report Column Widths

Point Id width input 10

Width of point id column.

Code width input 12

Width of code column, (0 removes column)

Model width input 25

Width of model column, (0 removes column)

Easting /Chainage width input 12

Width of easting/chainage column.

Northing /Offset width input 12

Width of northing/offset column.

Level width input 12

Width of level column.

Distance width input 12

Width of distance column.

Report design coords

if ticked design coordinates will be written to the report file

Report as CSV?

If **Report as CSV?** *is ticked then the column width settings are ignored and the report written as a comma delimited 'CSV' file suitable for exports to spreadsheets and others.*

If **Report as CSV?** *is not ticked then the reported is formatted with the column width figures in mind.*

Run button

run the option.

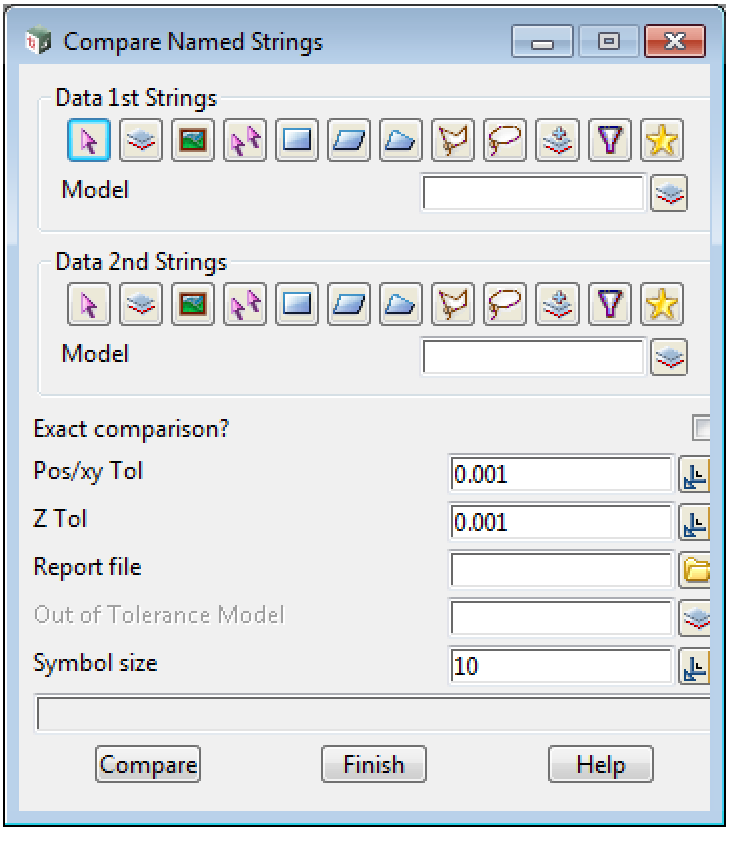
27.10.7 Compare Named Strings

Position of option on menu: **Report =>QA Reports =>Compare named strings**

The **compare named strings** panel is a utility to check for changes in a string and highlights these changes. It would typically be used when a revised design is released to highlight where the actual changes are.

Strings are matched by name, there must only be one string of the same name in each of the data sources.

Selecting **Compare named strings** brings up the **Compare Named Strings** panel.



The fields and buttons used in this panel have the following functions:

Field Description Type Defaults Pop-Up

Data 1st Strings

the data source for the 1st set of strings.

data selection type - for a full description go to 4.19.3 Data Source.

Data 2nd Strings

the data source for the set of strings to compare to the 1st set of strings.

data selection type - for a full description go to 4.19.3 Data Source.

Exact comparison? tick box

if ticked the strings are compared vertex by vertex

if unticked the points in the 2nd string are dropped to the first string and the comparison is done by offset and height difference.

Pos/xy Tol measure box

The distance between vertices or the difference in offset before the point is considered different.

Z Tol measure box

The height difference between the strings before the point is considered different.

Report file file box

The file to which the results of the comparison are written, contains the strings compared, the number of name matches if not matched or unique and the details of differing points.

Out of Tolerance Model model box

Any points outside the nominated tolerances can be written to this model.

Symbol size input

Points in the ***out of tolerance model*** *have a diamond of this real world size drawn around them to highlight the points.*

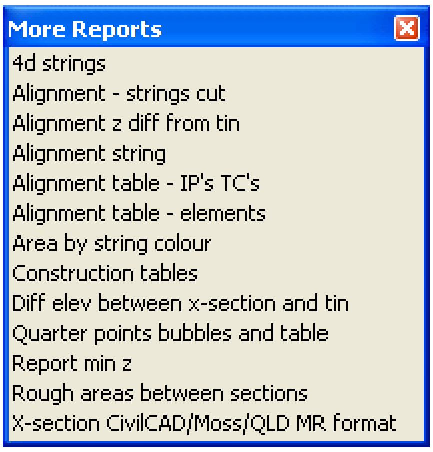
Compare button

Compares the two data sources

27.11 More Reports

Position of menu: **Report =>More**

More miscellaneous reports.



report on 4d strings
report the strings that an alignment cuts
give the differences from a tin to a string
report on an alignment string
create alignment report and/or table giving IP's and CT's
create alignment report and/or table giving elements
give plan areas summed by string colour
give the differences from the points on a section to a tin
report and/or table of quarter points for an arc
report the minimum values on a x-section
report of areas between sections

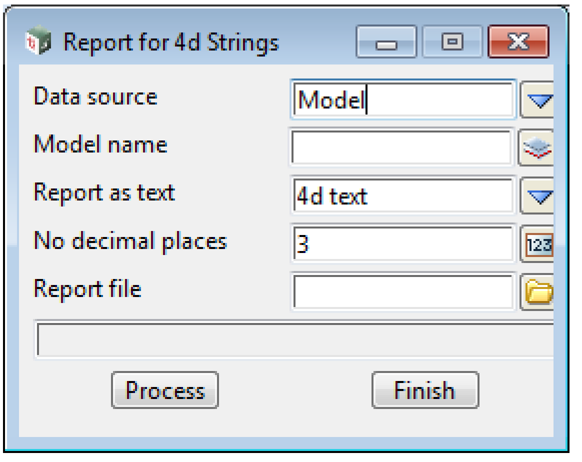
For the option/menu *4d string*, go to	27.11.1 Report for 4d Strings
Alignment - strings cut	27.11.2 Alignment - Strings Cut
Alignment z diff from tin	27.11.3 Report Z Differences from Alignment to Tin
Alignment string	27.11.4 Alignment Report
Alignment table - IP's TC's	24.16.15 Tabulate Alignment - IP's and CT's
Alignment table - elements	24.16.16 Tabulate Alignment - Elements
Area by string colour	27.11.7 Total of Plan Area by String Colour
Diff elev between x-sections and tin	27.11.8 Report Z Differences From X-Sections to a Tin
Quarter points bubble and table	17.18.3 Setout Lip Line
Report min z	27.11.10 Report Minimums Z-Value on a Cross Section
Rough areas between sections	27.11.11 Report Rough Areas
Super string	27.2.6 Report for Super Strings
X-section CivilCAD/Moss/Qld MRD format	27.11.12 X-Sections Report

The menu options will now be discussed.

27.11.1 Report for 4d Strings

Position of option on menu: **Report =>More =>Report for 4d strings**

This panel is used to create a report for 4d strings where the x y and z values are printed out for each point plus either the 4d text for the point or the name of the string (repeated for each point).



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source	choice box	model	string, model, view

data source type.

Model/View/String	data source		

Data source to do report of 4d strings on.

Report as text	file	4d text	string name 4d text

if 4d text, the 4d text for the point is written out after the x, y and z values.

If string name, the string name is written out after the x, y and z values.

No decimal places	input	3	

number of decimal places to use in the x, y and z values.

Report file	file		

name of the report file.

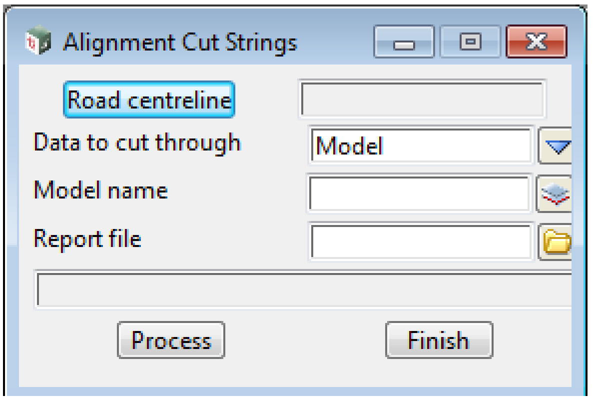
Process	button		

run the option.

27.11.2 Alignment - Strings Cut

Position of option on menu: **Report =>More =>Alignment - strings cut**

This option is used to create a report of the position and angle that strings make where they cut a selected alignment string.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Road centreline	string select		

select the alignment string to report the cuts for.

Data source	choice box	Model	String/Model/View

source of the data

Data

method a specifying data

Report file	input box		*.rpt files

name of the report file.

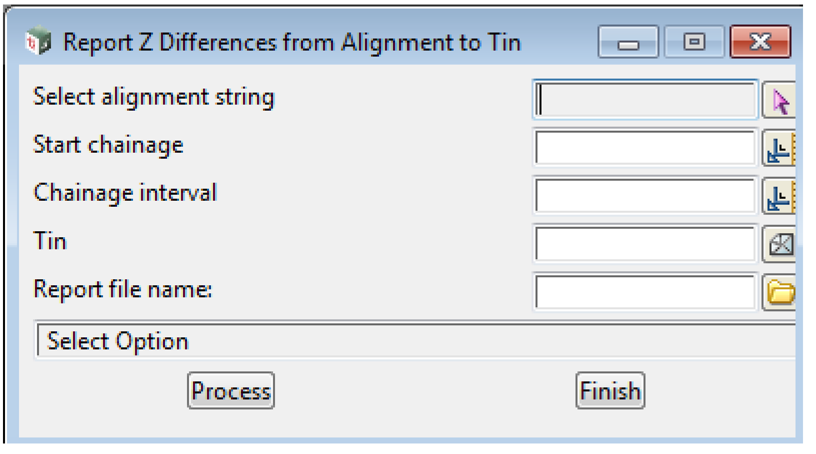
Process	button		

run the option.

27.11.3 Report Z Differences from Alignment to Tin

Position of option on menu: **Report =>More =>Report z differences from alignment to tin**

This panel is used to create a report of the difference in z-values between an alignment string and a tin. The differences are reported at a given chainage interval along the alignment string.



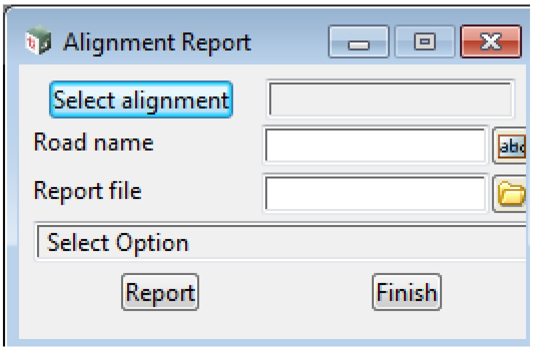
The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Select alignment string	string select		
select the alignment string to report z-differences for.			
Chainage interval	input box		
interval to report on.			
Tin	input box		available tins
tin to get z-values from.			
Report file name	input box		*.rpt files
name of the report file.			
Process	button		
run the option.			

27.11.4 Alignment Report

Position of option on menu: **Report =>More =>Alignment string**

This panel is used to report the tangent points and centres of arcs for an alignment string.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Select alignment string	string select		

select the alignment string to report on.

Report file name	input box		

name of the report file.

Report	button		

run the option.

27.11.5 Alignment Table - IP's, TC's

Position of option on menu: **Report =>More =>Alignment table - IP's and TC's**

Create table of IP and CT points for an alignment string.

This panel has already been documented.

See 24.16.15 Tabulate Alignment - IP's and CT's in 24 Drafting

27.11.6 Alignment Table - Elements

Position of option on menu: **Report =>More =>Alignment table - elements**

Create table of horizontal elements for an alignment string.

This panel has already been documented.

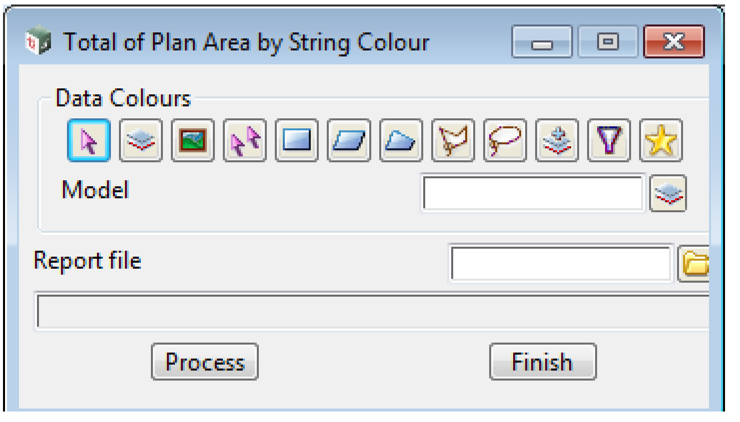
See 24.16.16 Tabulate Alignment - Elements in 24 Drafting

27.11.7 Total of Plan Area by String Colour

Position of option on menu: **Report =>More =>Area by string colour**

This panel is used to calculate the sum of the plan area of all strings of the same colour. This is especially useful for calculating the plan areas of faces produced for slope areas, volumes etc.

A report giving the total plan area for each different colour is produced.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source	data source	model	model, view

Type of data to calculate areas for.

Model/View data source

Data source to calculate the areas and sum by colour.

Report file input box

Report giving the total plan areas of the strings for each colour.

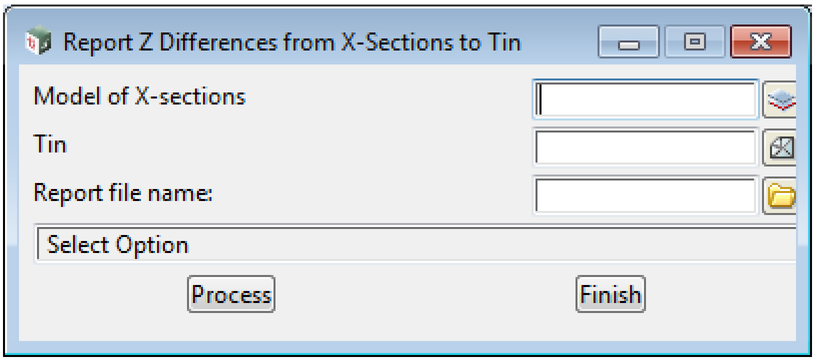
Process button

Run the option

27.11.8 Report Z Differences From X-Sections to a Tin

Position of option on menu: **Report =>More =>Diff elev between x-section and tin**

This panel is used to report the z differences between the points on cross sections and the corresponding z-values from a tin.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Model of X-Sections	model box		available models

model of cross sections to report on.

Tin	tin box		

tin to get z-values from.

Report file name	file box		

name of the report file.

Process	button		

run the option.

27.11.9 Quarter Points Report

Position of option on menu: **Report =>More =>Quarter points bubbles and table**

This option is used to create bubbles and/or a report for the critical horizontal and vertical points and quarter points (by chord or by chainage) for any arcs in an alignment string.

This option has already been documented as

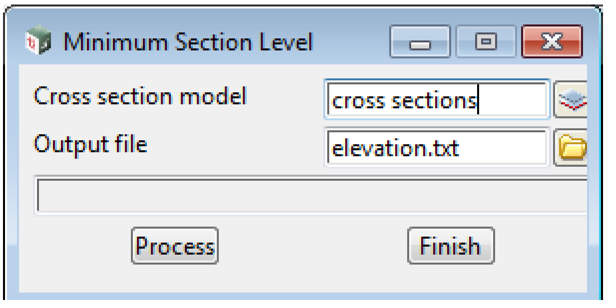
Survey =>Setout =>Setout lip line

in the section 17.18.3 Setout Lip Line.

27.11.10 Report Minimums Z-Value on a Cross Section

Position of option on menu: **Report =>More =>Report min z**

This panel creates a report giving the minimum z-value on a cross section.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Cross section model	model box		

model of cross sections to report on.

Output file	file box		*.txt files

file to write section names and minimum z-values to.

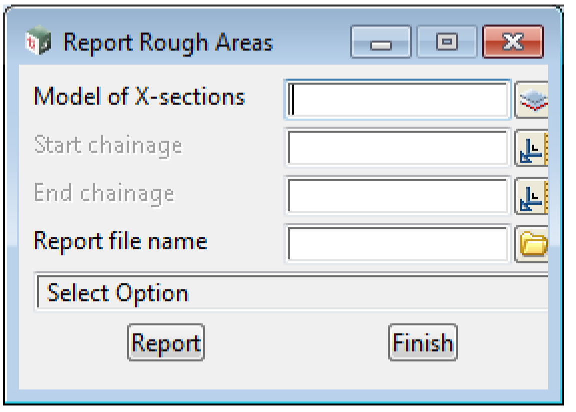
Process	button		

run the option.

27.11.11 Report Rough Areas

Position of option on menu: **Report =>More =>Rough areas between sections**

This panel is used to



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Model of x-sections	input box		

xxxxx

Start chainage	input box		

xxxxx

End chainage	input box		

xxxxx

Report file name	input box		

name of the report file.

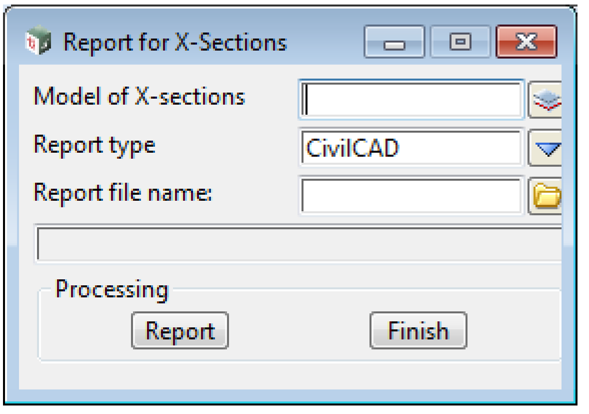
Report	button		

run the option.

27.11.12 X-Sections Report

Position of option on menu: **Report =>More =>X-section CivilCAD/Moss/QLD MR format**

This panel is used to write out cross sections in a variety of formats.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Model of x-sections	input box		available models

model of cross sections to write out.

Report type	file box	CivilCAD	CivilCAD, Moss MainRoad Qld, Brief

format of the report.

Report file name	input box		

name of the report file.

Report	button		

run the option.

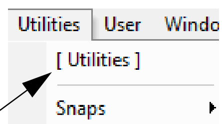
28 Utilities

Position of menu: **It is on the main menu as Utilities**

The **Utilities** menus contains a collection of useful operations that don't easily fit under any of the other menus.

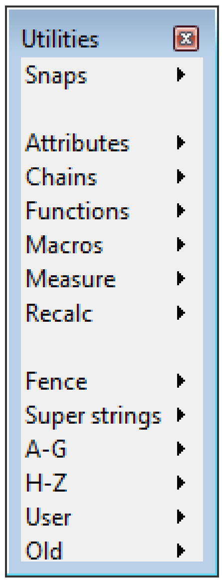
For ease of selection, the frequently used utilities are placed on the first level of the menu. All the other utilities are split alphabetically between two walk-right menus - the utilities walk-right menus for A-G and H-Z.

on Main menu



create floating **Utilities** menu

on 12d Model menu and floating Utilities menu



snaps

edit, create, delete, *etc.* for attributes
edit, create, delete, *etc.* for chains
edit, create, delete, *etc.* for functions
compiling and running macros.

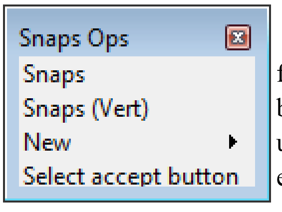
H-Z	28.10 Utilities H-Z
Old	28.11 Old

28.1 Snaps

Position of menu: **Utilities =>Snaps**

The **snaps** option allows the user to set snapping modes for use during pick operations. The snapping modes have been discussed in detail in the 4.13 Snaps section.

The **Snaps** walk-right menu provides a full snap menu, abbreviated snap menus laid out either horizontally or vertically, and a snaps cogo menu for creating special point positions using co-ordinate geometry commands.



full snaps menu
brief snaps laid out vertically
under development
equivalent to middle mouse button (accept)

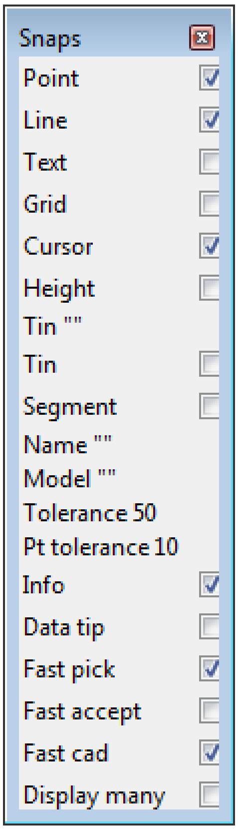
For the option

Snaps, go to	28.1.1 Snaps
Snaps (Vert)	28.1.2 Snaps (Vert) and H Toolbar
Cogo	28.1.3 Snaps Cogo
New	28.1.5 Snaps New
Select accept button	28.1.4 Select accept button

28.1.1 Snaps

Position of option on menu: **Utilities =>Snaps =>Snaps**

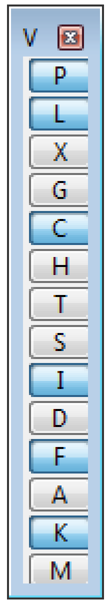
The **Snaps** menu provides tick boxes to turn the various snap modes on or off and options to set tin, string and model names. Any combination of snap modes and names can be set.



Snaps menu

point snap on/off
line snap on/off
text snap on/off
grid snap on/off
allow cursor point on/off
ask for z value at each point in edits
name of tin to snap to
tin snap on/off
turn segment snap on/off
restriction on string names
restriction on model names
set snap tolerance
set point snap tolerance
bring up info panel on/off
turns data tips on/off
turns fast pick on/off
turns fast accept on/off
K - accept results of snaps CAD without MB
picks bring up selection grid

Snaps V menu



The snaps are set on or off using the toggles on the **Snaps H** toolbar, or the tick boxes on the **Snaps** or **Snaps V** menu.

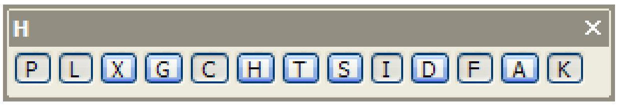
For more information on what all the snaps in the Snaps menu are, go to the 4.13 Snaps and 4.13.2 Setting Snaps section.

28.1.2 Snaps (Vert) and H Toolbar

Position of option on menu: **Utilities =>Snaps =>Snaps (Vert)**

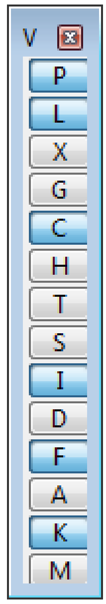
The **Snaps (vert)** menu provides the same tick boxes as the **Snaps** menu to turn the various snap modes on or off, however the snap descriptions are abbreviated to one character to reduce the menu size. There is also the **H** toolbar which is a horizontal version of the Snaps menu.

The **H** toolbar and Snaps (vert) menu are H toolbar which is



The **Snaps** are

P Point snap (on)
L Line snap (on)
X Text snap (off)
G Grid snap (off)
C Cursor snap (on)
H Height snap (off)
T Tin snap (off)
S Segment snap (off)
I Info snap (on)
D Data tip (off)
F Fast accept (on)
A Fast accept (off)
K Construction snap (on)
M Show selection grid on picks



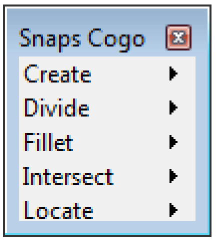
For more information on snaps, go to the 4.13 Snaps and 4.13.2 Setting Snaps section.

28.1.3 Snaps Cogo

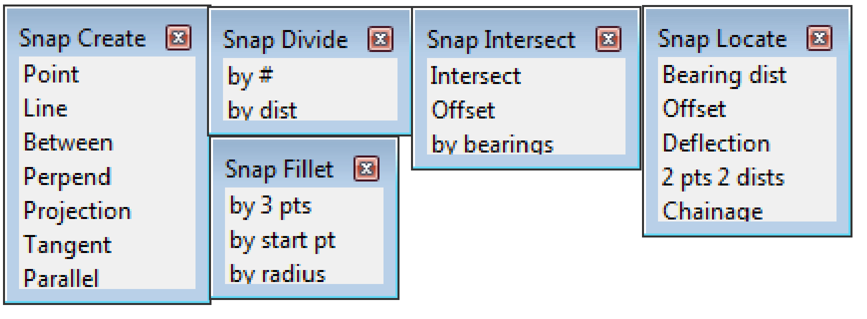
Position of menu: **Utilities =>Snaps =>Cogo**

The **Snaps cogo** options are used to create the point required for any 12d Model select operation. For example, selecting the next point in **append** in an editor. The result of the **Snaps cogo** is returned to the **select operation** as the selected point.

Walking right on the **cogo** option brings up the **Snaps cogo** menu



and the walk-right menus for each of the **Snaps cogo** menu items are



Note on Combining Snaps Cogos

When using a snaps cogo option, another select is often required and it is permissible to use other snaps cogo option to create the point for that select.

For example, the required point is the point halfway between two other points **dropped perpendicularly** onto an arc.

Such a combined result can be achieved using **Snaps cogo** however the order of selecting the **snaps cogo** options may at first seem to be the reverse of what is required.

For the above example, the snaps cogo **perpen** must be selected before the **between** option.

This is because when the **perpen** snap cogo option is selected, it asks the user to **select** the point to drop and it is then that the snaps cogo **between** option is used to find the midpoint of two selected point. The result of the **between** then becomes the point to drop for the **perpen**.

If the **between** option had been selected first, the resultant midpoint would have been returned as the selected point and that select completed.

28.1.4 Select accept button

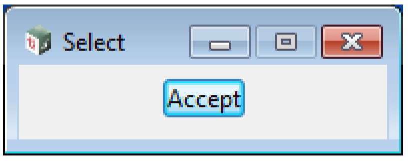
Position of menu: **Utilities =>Snaps =>Select accept button**

Instead of selecting (MB) to accept a string selection, you can click (LB) on the **Accept** button.

This option is usually used for tablet computers without a middle mouse button.

LB = the left mouse button

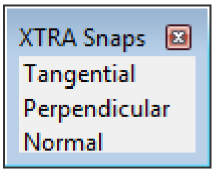
MB = the middle mouse button



28.1.5 Snaps New

Position of menu: **Utilities =>Snaps =>New**

The **XTRA Snaps** menu is currently under development.

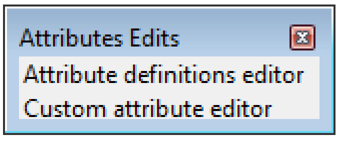


28.2 Attributes

Position of menu: **Utilities =>Attributes**

This section of documentation is a work in progress and will be updated in subsequent releases.

The **Attributes** walk-right menu is:



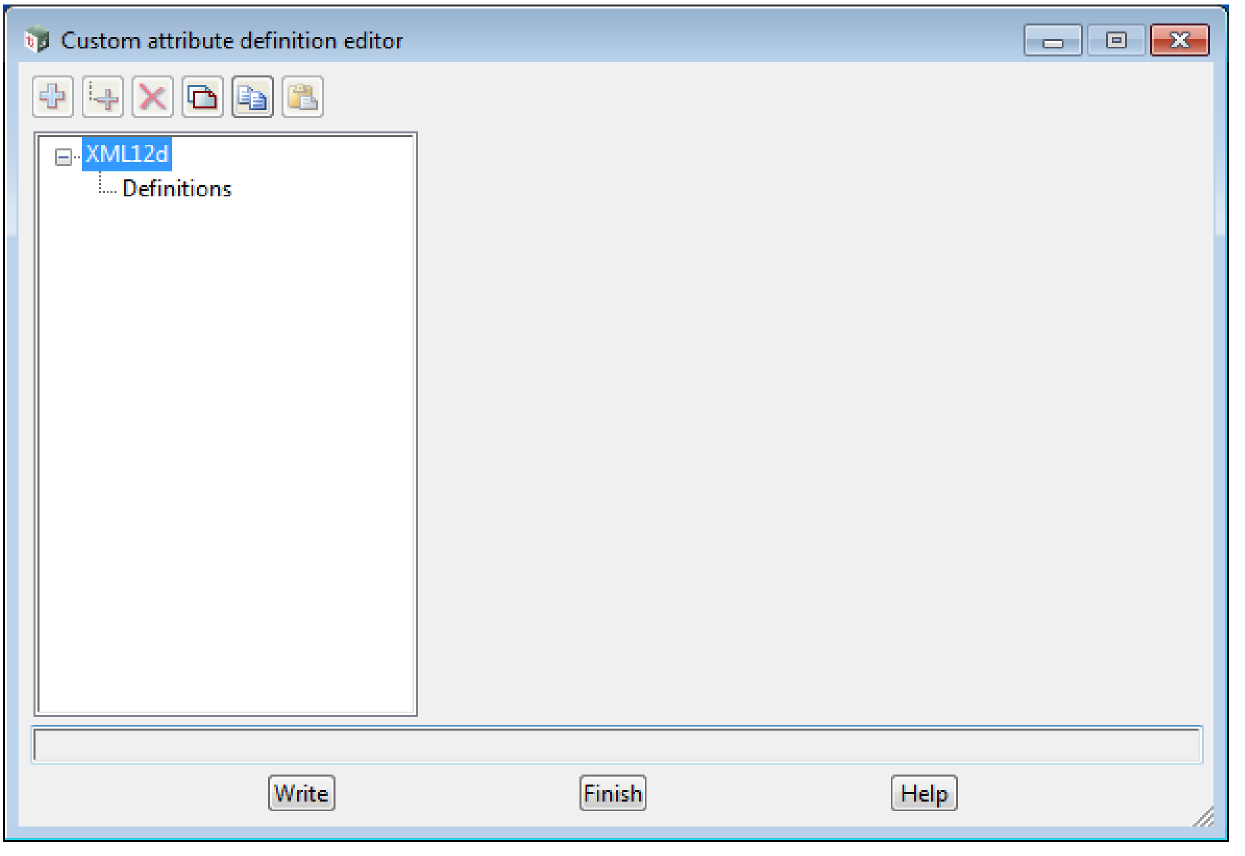
edit attribute definitions
edit custom attributes

For the *Attribute definitions editor*, go to 28.2.1 Attribute Definitions Editor
Custom attribute editor 28.2.2 Custom Attribute Editor

28.2.1 Attribute Definitions Editor

Position of option on menu: **Utilities =>Attributes =>Attributes Edits =>Attribute definitions editor**

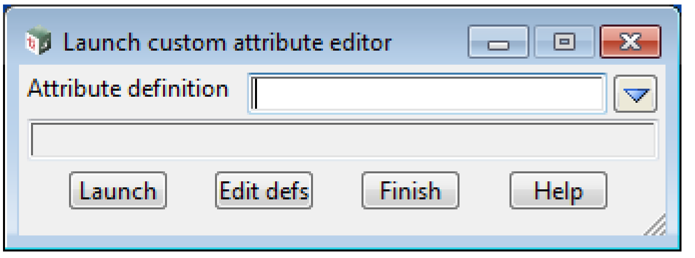
This section of documentation is a work in progress and will be updated in subsequent releases.



28.2.2 Custom Attribute Editor

Position of option on menu: **Utilities =>Attributes =>Attributes Edits =>Custom attribute editor**

This section of documentation is a work in progress and will be updated in subsequent releases.



28.3 Chains

Position of menu: **Utilities =>Chains**

12d Model has many different built in objects, from simple strings, through to complex super alignments with computators, drainage networks, super tins and Apply MTF functions.

However as complex as these objects are, no software can foresee every situation met in surveying and civil design, both now and into the future.

12d Model provides two tools to help users extend the supplied ***12d Model*** functionality and automate simple and complex tasks within a company. They are the

(a) the ***12d Model Programming Language*** (12dPL) - a full programming language so users can write complex tailored options and functions (called macros)

and

(b) ***chains***.

Chains are a relative simple method for users to combine and run existing ***12d Model*** functions and options. Anyone who can use ***12d Model*** can create and run a chain.

In its simplest form, a ***Chain*** is a list of items that are run in the order that they appear in the list. Things that can be run in a *Chain* include:

(a) ***12d Model*** functions

(b) other chains

(c) super alignment resolves

(d) plot parameter files

(e) most ***12d Model*** options

(f) most screen layout files

(g) most macros, and certainly those that don't have a panel

(h) an external command line

(i) some special hardwired chain commands such as delete a tin, delete all tins, delete a model, delete all models, clean a model, delete a file and compare files.

For more sophisticated applications, chains can also

(a) create ***12d Model*** views and add and remove models from the views

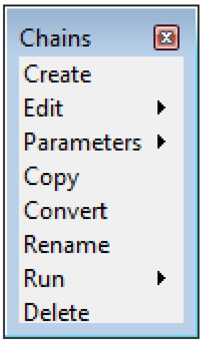
(b) minimise, maximise, redraw and delete views

(c) include flow control using tests, labels and go to's

(d) be parametrised and run with user supplied parameter values

So a *chain* can be as simple as running a list of functions.or as complex and making decisions inside the chain, thus creating user defined ***Super Objects***.

The **Chains** walk-right menu is



create a chain
edit a chain
parameterise a chain
copy a chain
convert a chain
rename a chain
run a chain
delete a chain

For the option

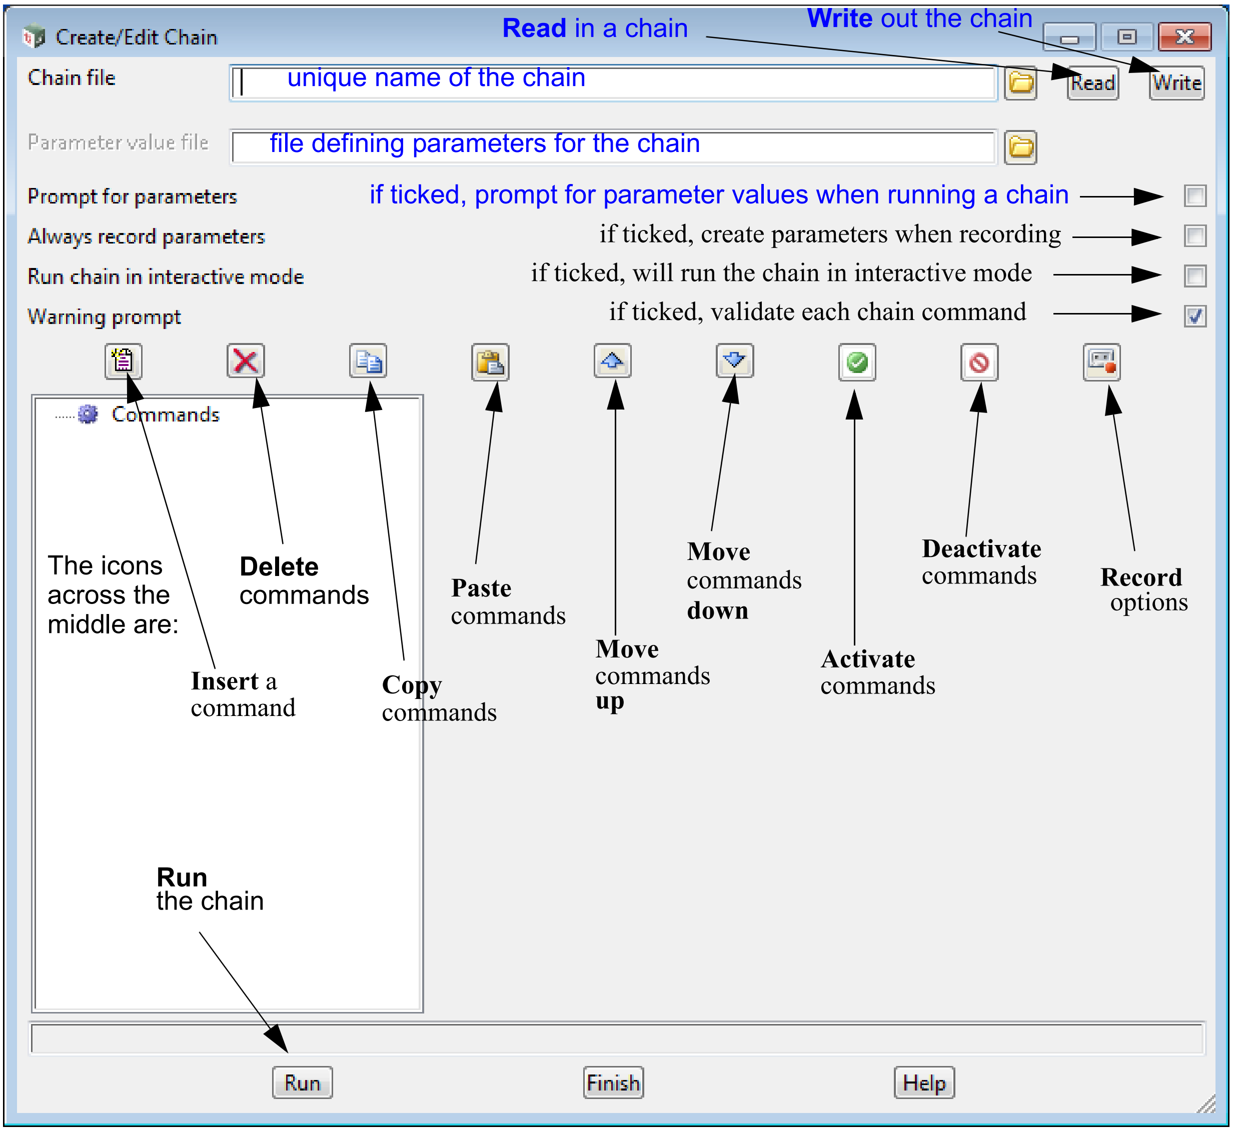
Create	28.3.1 Create/Edit a Chain
Edit	28.3.3 Edit a Chain
Parameters	28.3.4 Chain Parameters
Copy	28.3.6 Copy a Chain
Convert	28.3.7 Chain Conversion
Rename	28.3.8 Rename a Chain
Run	28.3.9 Run a Chain
Delete	28.3.10 Delete a Chain

28.3.1 Create/Edit a Chain

Position of option on menu: **Utilities =>Chains =>Create**

The **Create/Edit** option creates new chains but can also edit an existing chain, or run an existing chain.

Selecting **Create** brings up the **Create/Edit Chain** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chain file	file box	blank	available *.chain, *.rcn files

name of the file for the chain.

*To **create** a new chain, a unique name is typed into the **Chain file** box and the **Write** button clicked.*

*To **edit** an existing chain, enter the name of the existing chain into the **Chain file** box and then click on the **Read** button.*

*The chain is then built up by inserting commands using the **Insert** icon.*

Read	button

when pressed, read in the given chain file

Write button

when presses, write out all the chain commands in the list to the given chain file.

*After each item is added to the chain, click on **Write** to save the updated chain.*

Parameter value file file box blank existing parameter files

*if **not blank**, the file to use for mapping parameters and values in the Chain.*

*If **blank**, no parameter file is used*

For more information, go to the section 28.3.4 Chain Parameters.

Prompt for parameters tick box

*if **ticked**, when a with parameters chain is run, the table of parameters is displayed on the screen before running the chain so that any required modifications can be made before the chain is run.*

*If **not ticked,** any values for parameters are taken from the parameter value file.*

Always record parameters tick box

*If **ticked** and the user records panels or options, the recorder will attempt to record parameters.*

Run chain in interactive mode tick box

*if **ticked**, run the chain in **Interactive Mode**. See* 28.3.2 Interactive Mode.
*If **not ticked**, the chain runs normally.*

Important Note and Warning

***Run chain in interactive mode** has no connection to the* **Run in interactive mode** *that is available when many panels are recorded in a chain. When a recorded panel in the chain has* **Run in interactive mode** *ticked on, then when that panel runs in the chain, the panel is displayed and the user can change values in the panel fields and then run/not run the panel. When the panel is closed the chain continues running.*

Warning prompt tick box

*if **not ticked**, validations of the inserted commands are not performed straight away. For example, if you press **Insert** many times, you won't get the warning prompt "Some changes you have made are invalid. Do you wish to change nodes and discard your changes?". Also a confirmation prompt does not come up when you delete commands from the chain.*

*if **ticked**, inserted commands are validated and warning messages and error messages will be generated.*

Icons

Insert icon

inserts commands into the chain. For more information on the commands, go to 28.3.1.1 Inserting a Chain Command

Delete icon

deletes the highlighted commands in the chain

Copy icon

copies the highlighted commands in the chain so that they can be pasted back into this chain or another chain.

Paste icon

pastes the copied commands into this chain, or into another opened chain.

Move up icon

move the highlighted commands up one position in the chain

Move down icon

move the highlighted commands down one position in the chain

Activate icon

activate any of the highlighted commands that are deactivated

Deactivate icon

deactivate all of the highlighted commands

Record icon

record one or more options. For more information on Record, go to 28.3.1.2 Record Icon and the Recorder Toolbar

Button at Bottom

Run button

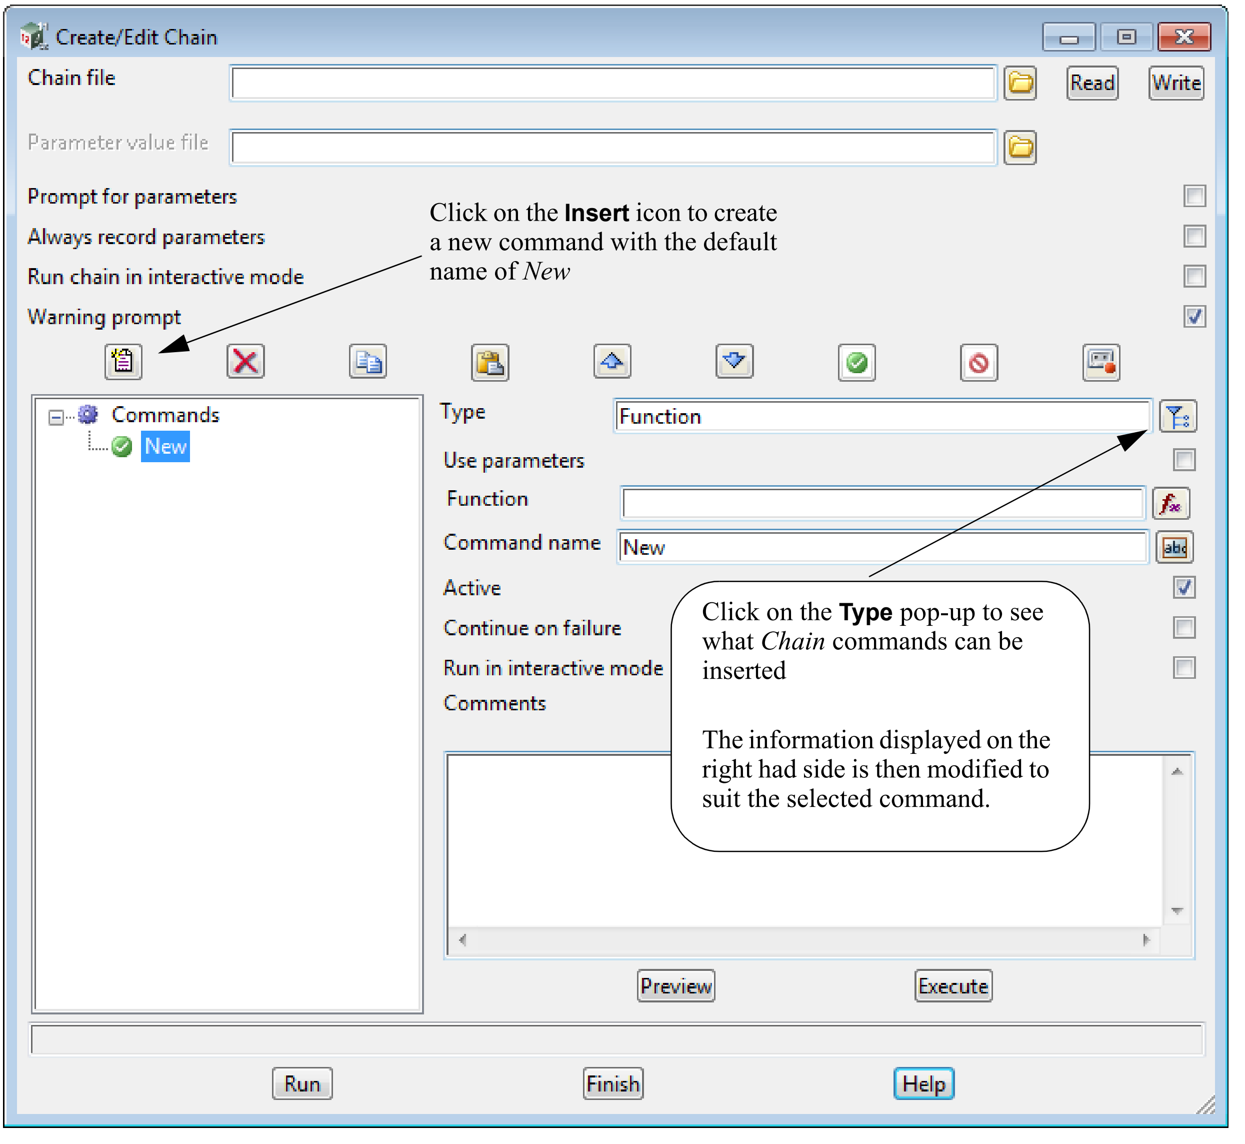
run the chain.

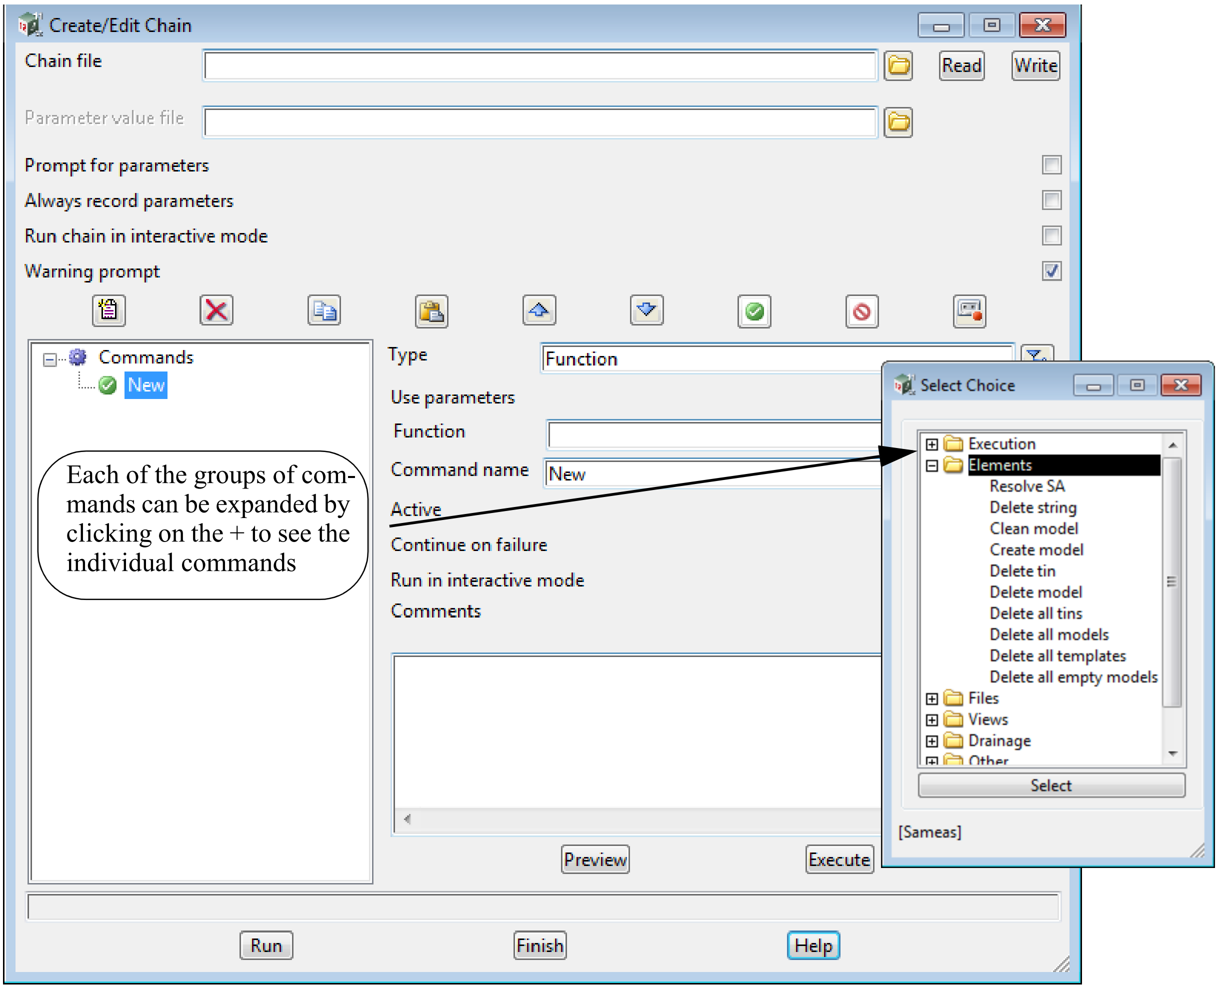
Continue to the next subsection 28.3.1.1 Inserting a Chain Command or the next section 28.3.3 Edit a Chain or return to 28.3 Chains.

28.3.1.1 Inserting a Chain Command

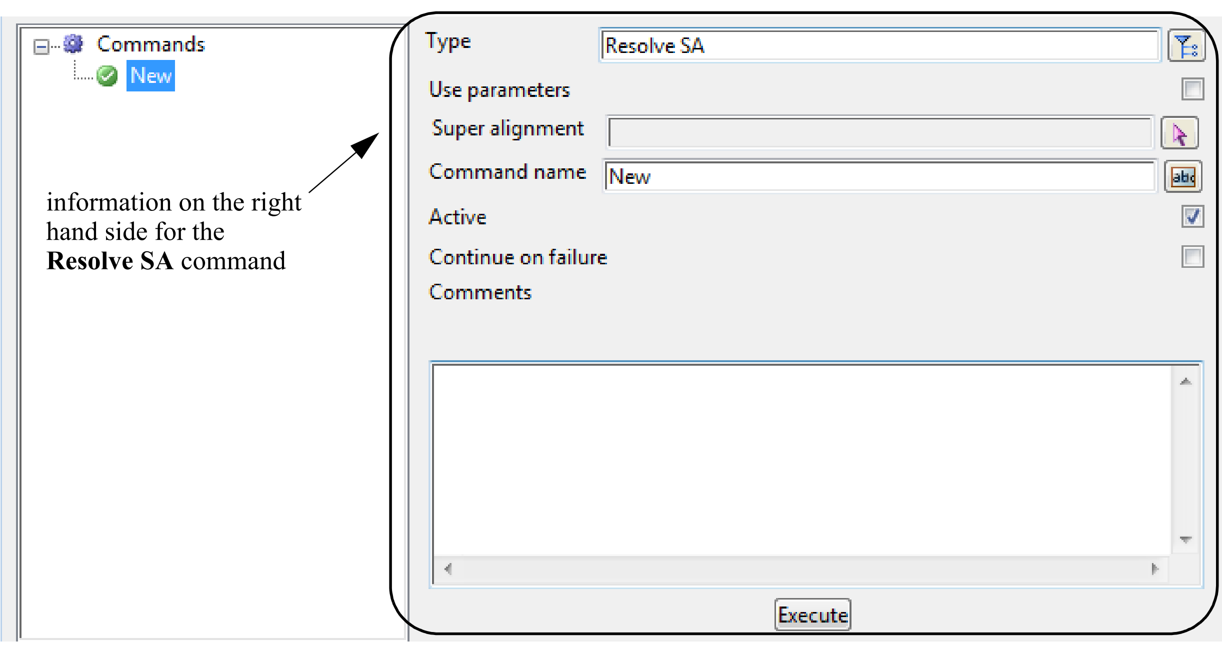
The chain is built up by *inserting commands* using the ***Insert*** icon.

Clicking on the ***Insert*** icon inserts a new command with the default name of **New** into the chain. The ***Type*** of the command is then selected on the right hand side of the panel. The specific information needed for defining that type of new command is then displayed on the right hand side of the panel.





Selecting a command will update the right hand side of the panel with information for that particular command. For example, for the **Resolve SA** command:



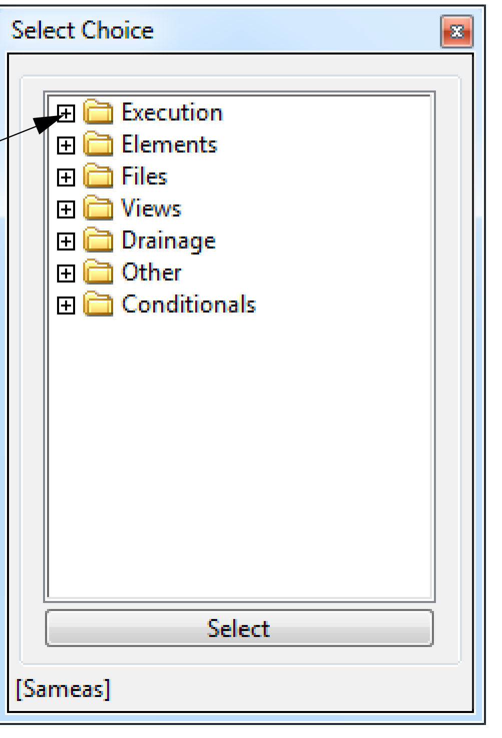
After each Command is added to the chain, or a Command modified, click on **Write** to save the updated chain.

For all the available **Chain Commands** that can be **Inserted**, see 28.3.1.1.1 Chain Commands.

Continue to the next section 28.3.1.1.1 Chain Commands or return to 28.3 Chains.

28.3.1.1.1 Chain Commands

Click on the + to expand the Command group



For the *Chain* commands under the group

Execution, go to	28.3.1.1.1.2 Execution
Elements	28.3.1.1.1.3 Elements
Files	28.3.1.1.1.4 Files
Views	28.3.1.1.1.5 Views
Drainage	28.3.1.1.1.6 Drainage
Other	28.3.1.1.1.7 Other
Conditionals	28.3.1.1.1.8 Conditionals

28.3.1.1.1.1 Common Fields in Commands

The common fields used in the right hand side of the **Create/Edit Chain** panel for the Chain commands are:

Field Description Type Defaults Pop-Up

Use parameters tick box

*If **ticked**, parameters can be used within the commands.*

Note that only some chain commands have a **Use Parameters** *tick.*

Command name text box

the name to give the command - this is what is displayed in the Chain list.

As information is filled in for a command, a default Command name composed of the command and some extra information from the command fields (for example the name of the super alignment) is created and written into the Command name field.

The Command name does not have to be unique and can be changed at any time.

*Clicking on the **abc** icon on the end of the* **Command name** *field will regenerate the automatic Command name and write it in the* **Command name** *field.*

*When you **rerecord** a command, the* **Command name** *is **not** modified but left as it was before rerecording.*

Active tick box

*if **ticked**, the command is run when the chain is run.*

*If **not ticked**, the command is not run when the chain is run.*

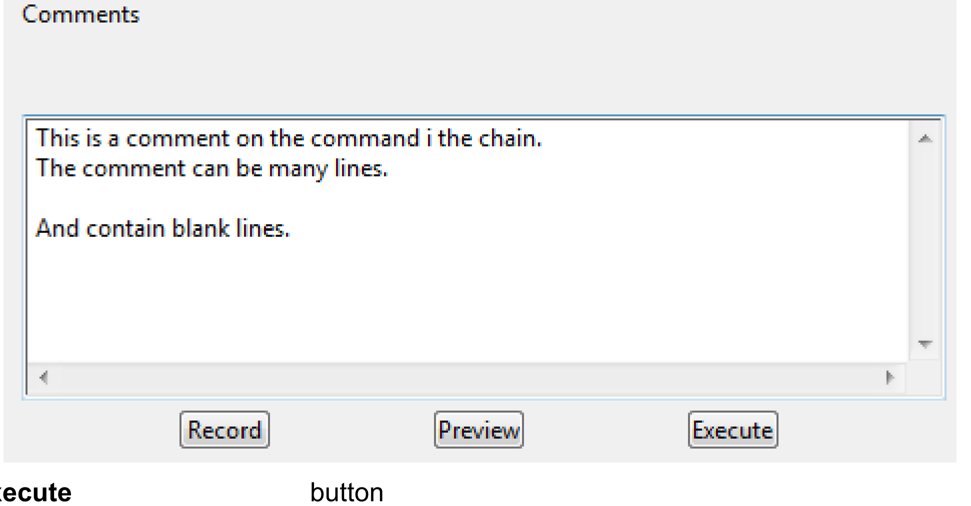
Continue on failure tick box

*if **ticked** and there is an error when running the command, processing continues to the next command in the Chain.*

*If **not ticked** and there is an error when running the command then the Chain terminates.*

Comments text box

any information typed into this box is kept as a Comment for current Chain command being displayed.



Execute button

run the current chain command. This button is not on all commands.

When a chain is running, messages and error messages are written to the ***Output window***.

Important Note - each time a command is inserted or modified, the **Write** button must be clicked to write out the modified chain.

Return to 28.3.1.1.1 Chain Commands or 28.3 Chains.

28.3.1.1.1.2 Execution

For the description of the common fields on most Chain Command panels, see 28.3.1.1.1.1 Common Fields in Commands*. These include the fields* **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute**.

Option

run a **12d Model** *option. Note that not all options can be run in a chain.*

Option *is also used to record the option that it runs.*

For more information, go to 28.3.1.1.2.1 Execution >Option.

Option - Manual

run a **12d Model** *option in Manual Mode. Note that not all options can be run in a chain.*

Option - Manual *is also used to record the option that it runs.*

For more information, go to 28.3.1.1.2.2 Execution >Option - Manual.

Screen layout file

run an existing screen layout file. Note - not all slf's can be run.

For more information, go to 28.3.1.1.2.3 Execution >Screen Layout File.

Function

recalc a 12d function

For more information, go to 28.3.1.1.2.4 Execution >Function.

Delete function

delete a function.

It will optionally ***clean*** *all the strings created by the function.*

Delete all functions

delete all functions

It will optionally ***clean*** *all the strings created by all the functions.*

Chain

run an existing chain.

Macro

run a **12d Model** *macro that doesn't have a panel*

For more information, go to 28.3.1.1.2.5 Execution >Macro.

Plot

run a plot parameter file.

For more information, go to 28.3.1.1.2.6 Execution >Plot.

Shell command

run an external program, Microsoft command line etc.

For more information, go to 28.3.1.1.2.7 Execution >Shell Command.

Continue to the next section 28.3.1.1.1.3 Elements or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.1.3 Elements

For the description of the common fields on most Chain Command panels, see 28.3.1.1.1.1 Common Fields in Commands. *These include the fields* **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute**.

Resolve SA

resolve a selected super alignment.

Clicking on the Resolve command highlights the selected super alignment.

Delete string

delete a selected string

Clean model

clean the given model

Create model

creates a new model of the specified name

Delete tin

delete the given tin

Delete model

delete the given model

Delete all tins

delete all tins in the project

Delete all models

delete all models in the project

Delete all templates

delete all templates in the project

Delete all empty models

delete all empty models in the project

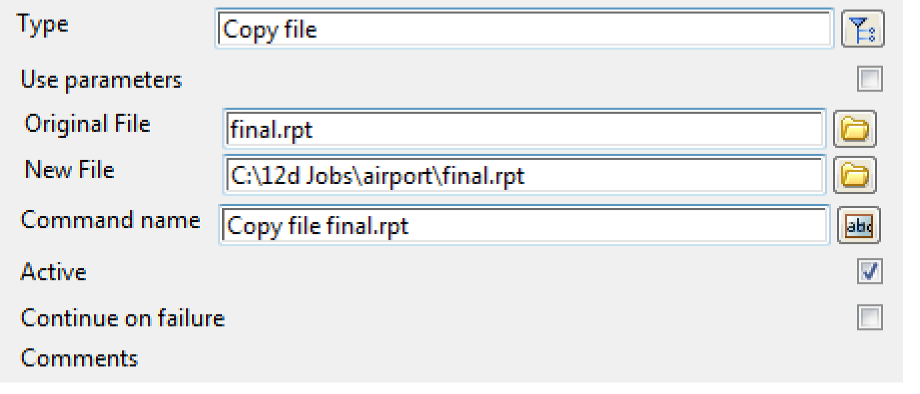
Continue to the next section 28.3.1.1.1.4 Files or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.1.4 Files

For the description of the common fields on most Chain Command panels see [28.3.1.1.1.1 Common Fields in Commands]. *These include the fields* **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute**.

Copy file

copy the given file to a user given file name (which included the full path name).



The file being copied will overwrite an existing file.

Delete file

deletes the specified file

Compare

compare two text files and write the results out to a **Report** *file.*

If the Report file already exists, the **Write mode** *determines if it is overwritten or appended to.*

Continue to the next section [28.3.1.1.1.5 Views] or return to [28.3.1.1.1 Chain Commands] or [28.3.1.1 Inserting a Chain Command].

28.3.1.1.1.5 Views

For the description of the common fields on most Chain Command panels see 28.3.1.1.1.1 Common Fields in Commands*. These include the fields* **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the button* **Execute***.*

Redraw all views

redraws all views.

Redraw a view

redraws a given view.

Fit view

do a fit on a given view.

Minimise view

minimise a given view.

Maximise view

maximise a given view.

Restore a view

restore a minimised view.

Create view

creates a new view of the given name and optionally position in the View Area.

For more information, go to 28.3.1.1.2.8 Views >Create view.

Delete view

delete a view of a given name.

Add model to view

adds the given model to a given view.

Remove model from view

remove a given model from a given view.

Remove all from view

removes all the models from a given view.

Dump view image

dump an image of a given view.

For more information, go to 28.3.1.1.2.9 Views >Dump view image.

Change view colour

change the background colour of a given view.

Continue to the next section 28.3.1.1.1.6 Drainage or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.1.6 Drainage

For the description of the common fields on most Chain Command panels see 28.3.1.1.1.1 Common Fields in Commands*. These include the fields* **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the button* **Execute***.*

Drainage analysis

runs drainage analysis on a given model

Drainage analysis- dynamic

runs dynamic drainage analysis on a given model

Set pit details

sets the pit details for a given model

Regrade pipes

regrades the pipes in a given model

Continue to the next section 28.3.1.1.1.7 Other or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.1.7 Other

For the description of the common fields on most Chain Command panels see 28.3.1.1.1.1 Common Fields in Commands*. These include the fields* **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the button* **Execute***.*

Comment

creates a cosmetic comment - no action is performed.

Halt

stop running the chain

Prompt

places a Prompt and returns a value to a chain parameter.

For more information, go to 28.3.1.1.2.10 Other >Prompt.

Sleep

puts the chain asleep for a given number of seconds.

Write output window

writes a one line message to the Output Window.

Clear output window

clears the Output Window.

Dump slx image

writes out the image of the panel than an SLX creates.

For more information, go to 28.3.1.1.2.11 Other >Dump slx image.

Print parameter

prints out information about a chain parameter to the Output Window.

For more information, go to 28.3.1.1.2.12 Other >Print parameter.

Save project

save the current project to disk.

Continue to the next section 28.3.1.1.1.8 Conditionals or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.1.8 Conditionals

How the Conditionals work is described in 28.3.1.1.1.9 Chain Flow Control and Conditional Commands.

Label

create a labelled line in the chain. See 28.3.1.1.1.9 Chain Flow Control and Conditional Commands.

Goto

jump to a labelled line. See 28.3.1.1.1.9 Chain Flow Control and Conditional Commands.

If Model Is Empty

test if a model of a given name is empty.

If Model Exists

test if a model of a given name exists

If Tin Exists

test if a tin of a given name exists

If Function Exists

test if a function of a given name exists

If File Exists

test if a file of a given name exists

If View Exists

test if a view of a given name exists

If Parameter Equals

test if a given parameter has a certain value

For more information, go to 28.3.1.1.2.13 Conditionals >If Parameter Equals.

Return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

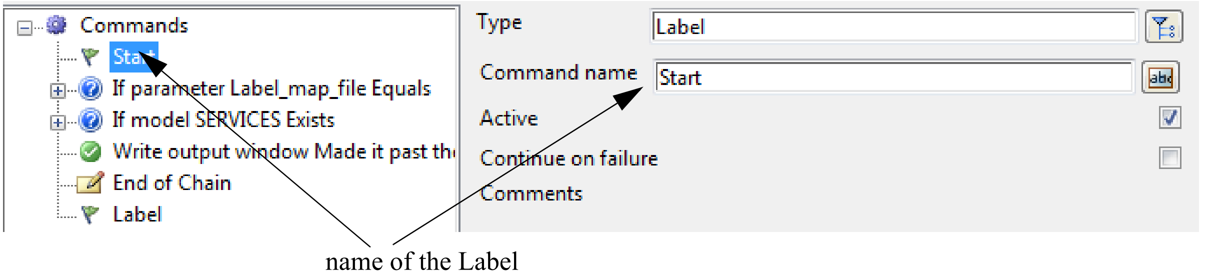
28.3.1.1.1.9 Chain Flow Control and Conditional Commands

The commands in a Chain are normally processed in the order that they are listed in the Chain.

However this order can be changed by using the **Goto** and **Label** commands, and the commands given in the **Conditionals** group (see 28.3.1.1.1.8 Conditionals).

Label

The **Label** command has a user given name and acts as a reference line in a chain. Goto's and Conditionals can change the processing order of the Chain so that the next command processed is the one after the ***Label*** and processing continues on from there.

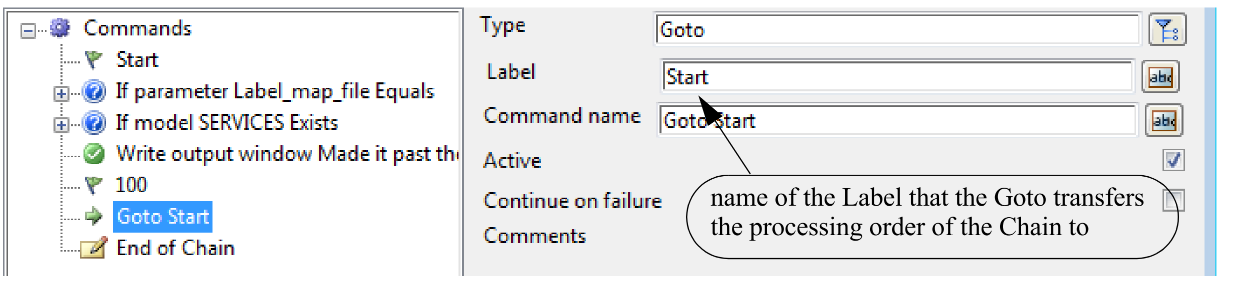


The name of a *Label* must be unique within the Chain.

When run the *Label* command doesn't do anything and processing moves onto the command after the *Label* command.

Goto

The **Goto** command changes the processing order of the Chain so that next command processed is the one after the given ***Label***.



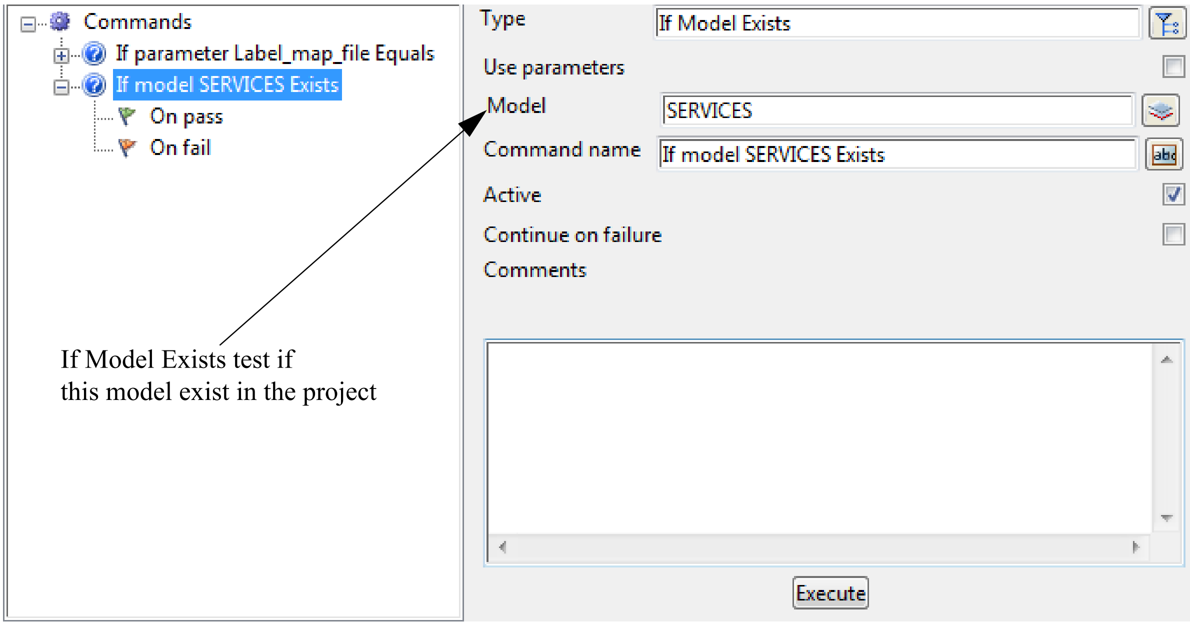
Conditionals

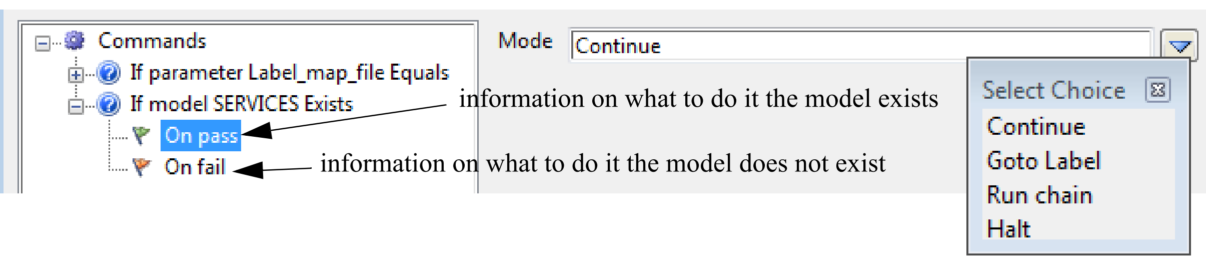
A **Conditional** consists of a test and the two nodes **On pass** and **On fail.**

Each **Conditional** commands performs a specific test and

(a) if the test is passed then the action on the **On pass** line is performed

(b) if the tests fails then the action on the **On fail** line is performed

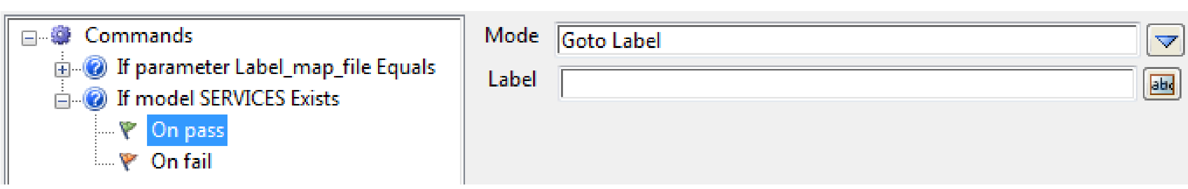




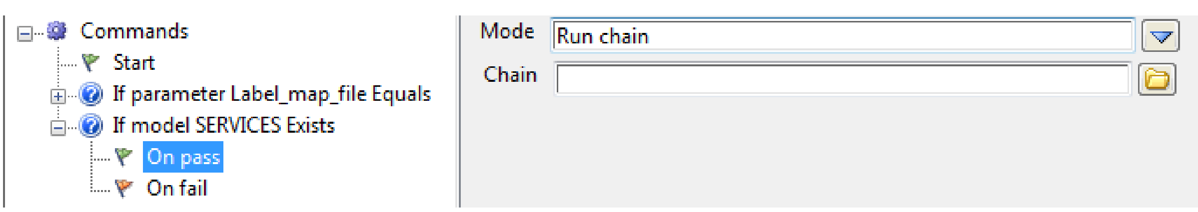
The choices for both the **On pass** and **On fail** are the same and are:

Continue *- run the next command in the Chain*

Goto Label *- the next command to run is the one after the given Label.*



Run chain *- run the given Chain. The next command in the Chain is then run.*



Halt *- stop running the chain.*

Return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

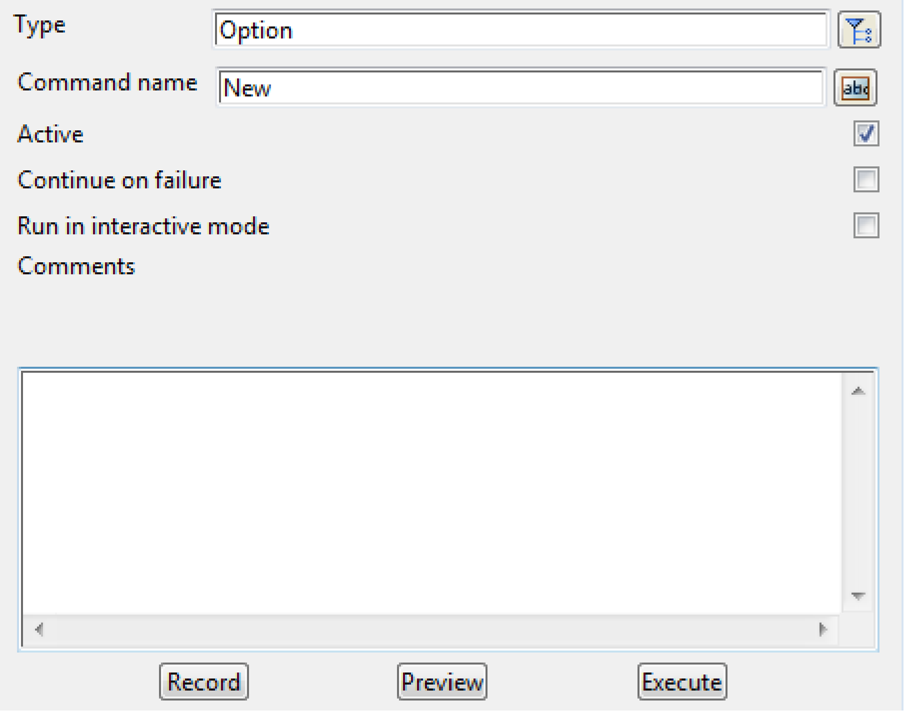
28.3.1.1.2 Additional Information on Some Chain Commands

See

- 28.3.1.1.2.1 Execution >Option
- 28.3.1.1.2.2 Execution >Option - Manual
- 28.3.1.1.2.3 Execution >Screen Layout File
- 28.3.1.1.2.4 Execution >Function
- 28.3.1.1.2.5 Execution >Macro
- 28.3.1.1.2.6 Execution >Plot
- 28.3.1.1.2.7 Execution >Shell Command
- 28.3.1.1.2.8 Views >Create view
- 28.3.1.1.2.9 Views >Dump view image
- 28.3.1.1.2.10 Other >Prompt
- 28.3.1.1.2.11 Other >Dump slx image
- 28.3.1.1.2.13 Conditionals >If Parameter Equals

28.3.1.1.2.1 Execution >Option

The **Option** command records any ***12d Model*** panel or **12d** PL's (macros) that can be recorded.



After this command is selected, the **Record** button must then be pressed to start a "one option" record cycle. The option to be recorded is then started up and run so that it is recorded.

The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Option***

Run in interactive mode	tick box		

*if **ticked**, when the command runs, the panel will be displayed.*

At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

*If **not ticked**, the command will run without being displayed and allowing for changes to be made.*

Important Note and Warning

*The **Run in interactive mode** for a **panel** has no connection to the* **Run chain in interactive mode** *for the Chain.*

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

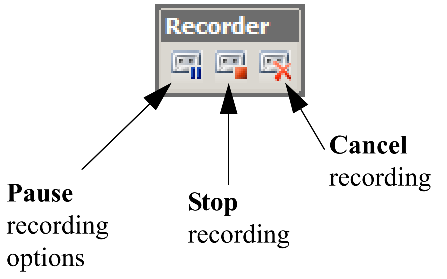
Buttons at bottom

See Record button
Preview button
Execute button

Record button

Clicking on the **Record** *button starts a "one option" record cycle.*

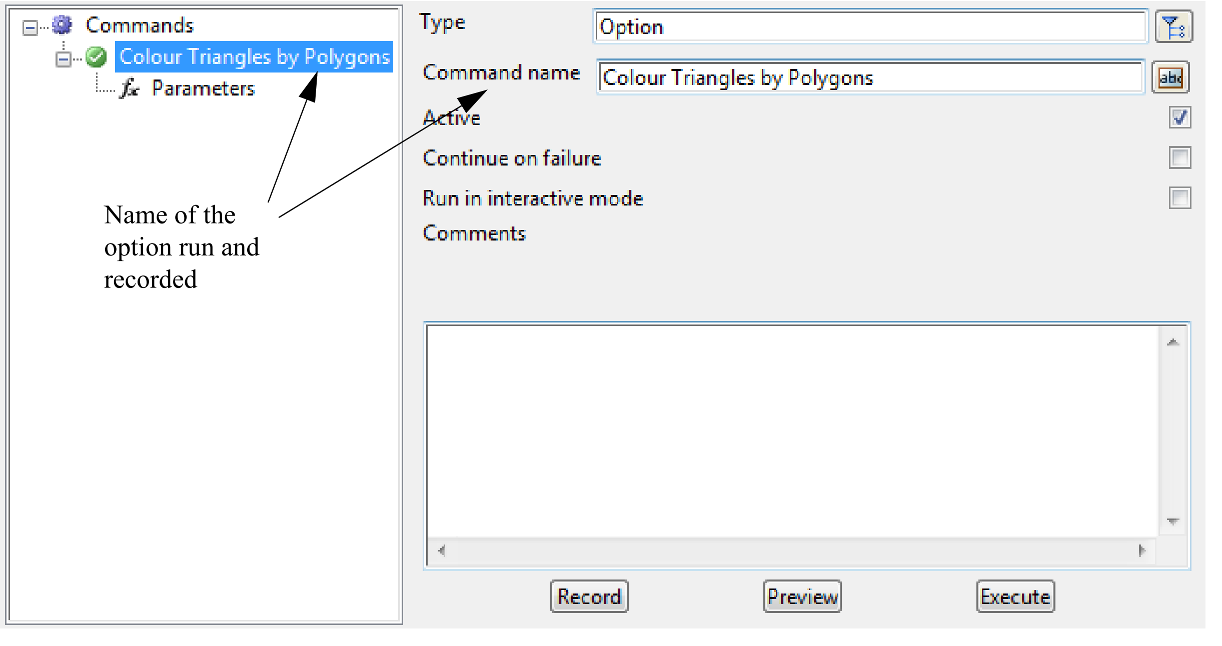
The **Recorder** *toolbar is placed on the screen but no button has to be pressed because the Record is already running. However the buttons* **Stop** *and* **Cancel** *can be pressed to terminate the recording.*



Now ***run*** *the* ***12d Model*** *panel option or macro that you wish to record.*

Once the option has run, the **Recorder** *panel is automatically removed, and the recorded option's details recorded in the* **Option** *command and the* **Command name** *of the* **Option** *is set to the name of the option that was run.*

The **Create/Edit Chain** *panel is then opened and displayed the* **Option** *command that was just recorded.*



Click on the **Write** *button at the bottom of the* **Create/Edit Chain** *panel to save the modified chain.*

Important Notes on Recording

1. CAD commands ***can not*** *be recorded.*

2. Many Macros ***can not*** *be recorded. But if* **Option** *won't work, then* **Option - Manual** *may. See* 28.3.1.1.2.2 Execution >Option - Manual.

3. Not all 12d panels can be recorded. For example, if a screen layout file can not be created for an option, then it can't be recorded. When recording, the ***12d Model*** *panel option must be filled in and run. This may restrict what options can be recorded. But if* **Option** *won't work,* **Option - Manual** *may. See* 28.3.1.1.2.2 Execution >Option - Manual. *If you still find a panel won't record, please leave a note about that panel on the 12d Model Forum.*

Preview button

the **Preview** *button brings up the panel with all the information filled in for those panel fields* ***that can be validated****. So sometimes* **Preview** *can not display all the command information.*

Preview *is for display only and on its own can't be used to modify the details of the command.*

However, if it is a ***recorded option*** *and there is a* **Record** *button on the command, it can be done in conjunction with the* **Record** *button.*

So to change the values in a ***recorded*** *option, select* **Preview** *to bring up the recorded option with all the information filled in.*

Then hit the **Record** *button on the* **Option** *command, make the required changes to the displayed option, and run the panel again.*

This will record the new information ***in place of the existing information****.*

Click on the **Write** *button at the bottom of the* **Create/Edit Chain** *panel to save the modified chain.*

Execute button

run the current chain command.

Option Parameters

To define or modify parameters used in an option, click on the **+** beside the option name in the chain (or double click on the option name) and the Parameters node for the option will be displayed.

For more details on option parameters, go to 28.3.4.3 How to Create Chain Parameters.

Special Notes on Recording Options

1. Use Unique String Names for String Selects

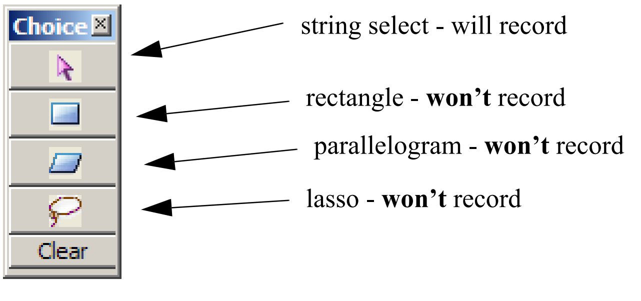
String selects on panels record the ID and the name of the string, and the model ID and the name of the model containing the string.

When the option is run in the chain, the string is first searched for using the model and string id's but if that fails then a string of the recorded name is searched for in the recorded model name.

If the string name is unique in the model then the correct string will be selected. If there is more than one string with the same name in the model, then the first string of that name that is found will be used.

2. Polygon Selects

String selects can be recorded for a *Polygon box* but ***Rectangle***, ***Parallelogram*** **or** ***Lasso*** can **not** be recorded.



Continue to the next section 28.3.1.1.2.2 Execution >Option - Manual or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.2 Execution >Option - Manual

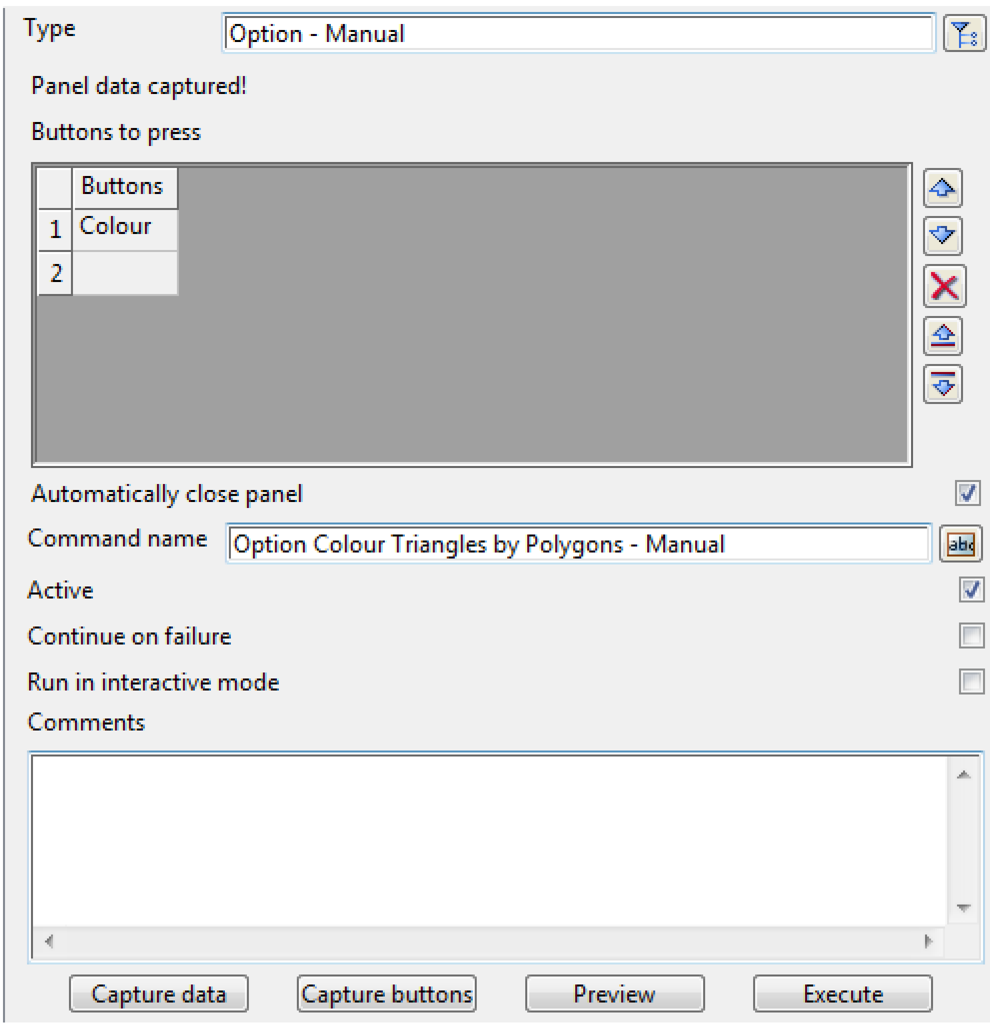
The **Option - Manual** command records an option but with additional information that is used when the command is run in the chain. For example, recording that certain buttons are to be pressed in a certain order.

This is useful for more complex panels, or panels that **require multiple button presses**. It is also useful for **recording macros**.

Unlike the **Option** command, the panel must already be on the screen with the appropriate fields filled in **before** it can be recorded.

The **Option - Manual** command records an option in two parts:

1. The panel to use (the data)
2. The buttons to press and the order they should be pressed



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

the chain command - this command is ***Option - Manual***

Buttons to press	grid		

displays the list of buttons in the panel that are to be pressed and in the order that they are to be pressed. The buttons are added to the list by using the **Capture button** *button.*

For information about grids, see 4.19.6 Grids in Panels.

Automatically close panel tick box

*if **ticked**, when the panel is run in the chain, the panel is automatically closed after all the captured buttons are pressed.*

*if **not ticked**, the panel is not automatically closed. If a **Finish** button has not been captured and hence not pressed when the panel is run in the chain, the panel will remain on the screen (open) after the command is finished.*

Run in interactive mode tick box

*if **ticked**, when the command runs, the panel will be displayed.*

At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

*If **not ticked**, the command will run without being displayed and allowing for changes to be made.*

Important Note and Warning

*The **Run in interactive mode** for a **panel** has no connection to the* **Run chain in interactive mode** *for the Chain.*

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Capture data button

after pressing **Capture data**, *the cursor is moved over the panel that is to be captured. The panel will be highlighted with a yellow border to indicate which panel will be selected.*

Clicking LB will select the highlighted panel and the panel and all the panel field values will be recorded.

Unlike the **Option** *command, the panel must already be on the screen with the appropriate fields filled in **before** pressing* **Capture data**.

Also unlike the **Option** *command the panel is not run.*

*Instead after the panel has been selected, the panel **buttons** that need to be pressed for running the panel are recorded in the order that they need to be pressed.*

Capture buttons button

after pressing **Capture buttons**, *the cursor is moved over the panel buttons on the selected panel, and the panel button will be highlighted with a yellow border to indicate which button will be selected.*

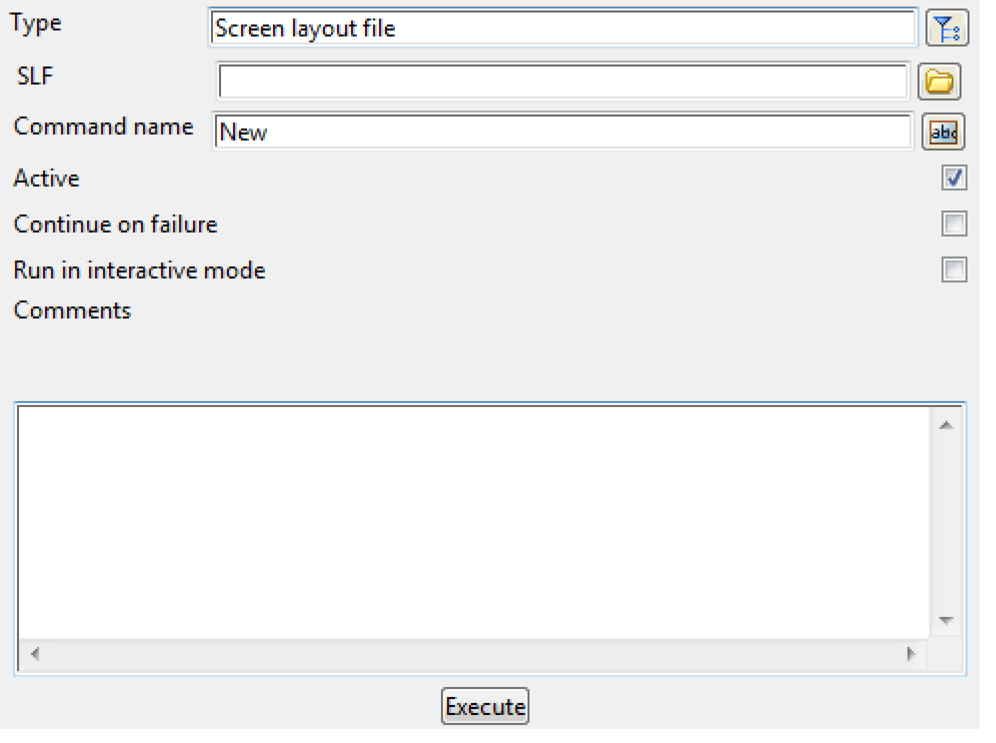
Clicking LB will select the highlighted button and the name of the button will be added to the bottom of the **Buttons to press** *grid.*

To select another panel button, click on **Capture buttons** *again.*

Continue to the next section 28.3.1.1.2.3 Execution >Screen Layout File or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.3 Execution >Screen Layout File

The **Screen layout file** command displays the first panel stored in an SLF file and runs it by pressing the panels designated '**run button**'.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Screen layout file.***

SLF	file		

the slf file to run the first panel from.

Run in interactive mode	tick box		

*if **ticked**, when the command runs, the panel will be displayed.*

At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

*If **not ticked**, the command will run without being displayed and allowing for changes to be made.*

Important Note and Warning

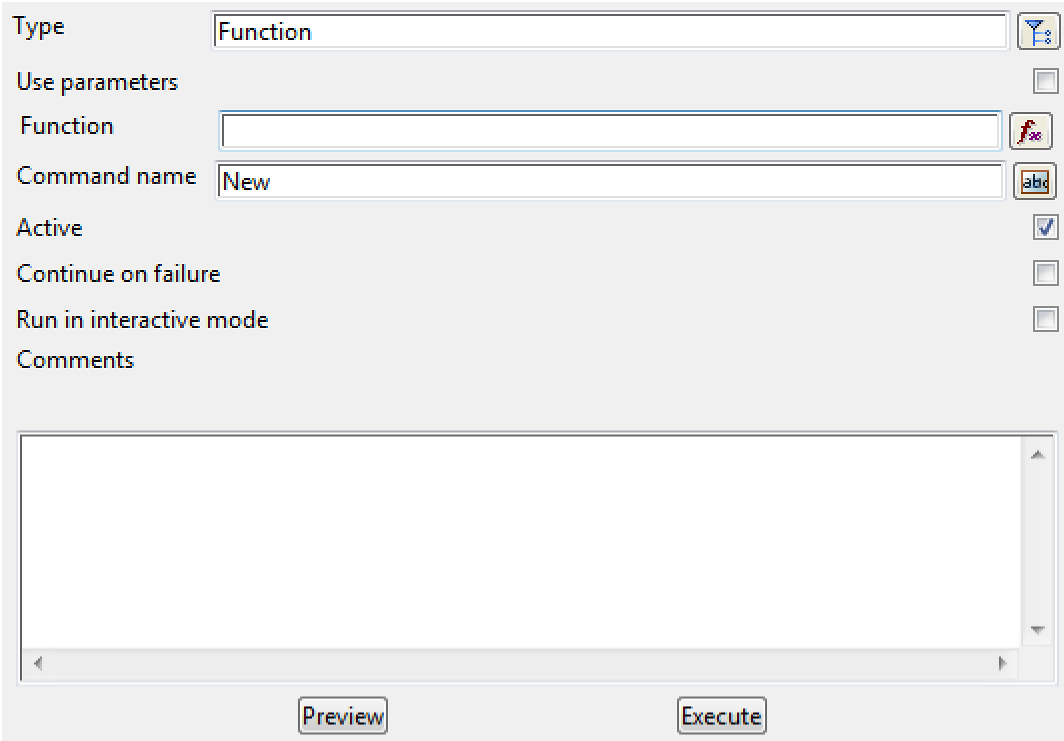
*The **Run in interactive mode** for a **panel** has no connection to the* **Run chain in interactive mode** *for the Chain.*

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

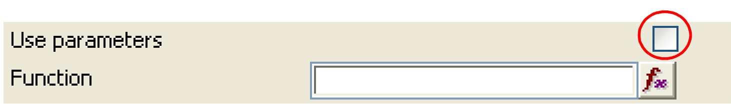
Continue to the next section 28.3.1.1.2.4 Execution >Function or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.4 Execution >Function

The **Function** command recalcs an existing function.



If **Use parameters** is ***not ticked***, the **Function** field is displayed. This requires the selection of an existing function to recalc.



If **Use parameters** is ***ticked***, the **Function parameter** field is displayed. This requires the selection of a function parameter. See 28.3.4 Chain Parameters for more details.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Function.***

Field Description	Type	Defaults	Pop-Up
Function	function box		available functions

the function to recalc.

Field Description	Type	Defaults	Pop-Up
Run in interactive mode	tick box		

*if **ticked**, the function will not be recalced. Instead, the editor for the function will be displayed (if one is available).*

At this point all the data in the panel fields may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

*If **not ticked**, the command will run without being displayed and allowing for changes to be made.*

Important Note and Warning

*The **Run in interactive mode** for a **panel** has no connection to the* **Run chain in interactive mode** *for the Chain.*

Preview button

the **Preview** *button brings up the panel with all the information filled in for those panel fields in the function **that can be validated**. So sometimes* **Preview** *can not display all the command information.*

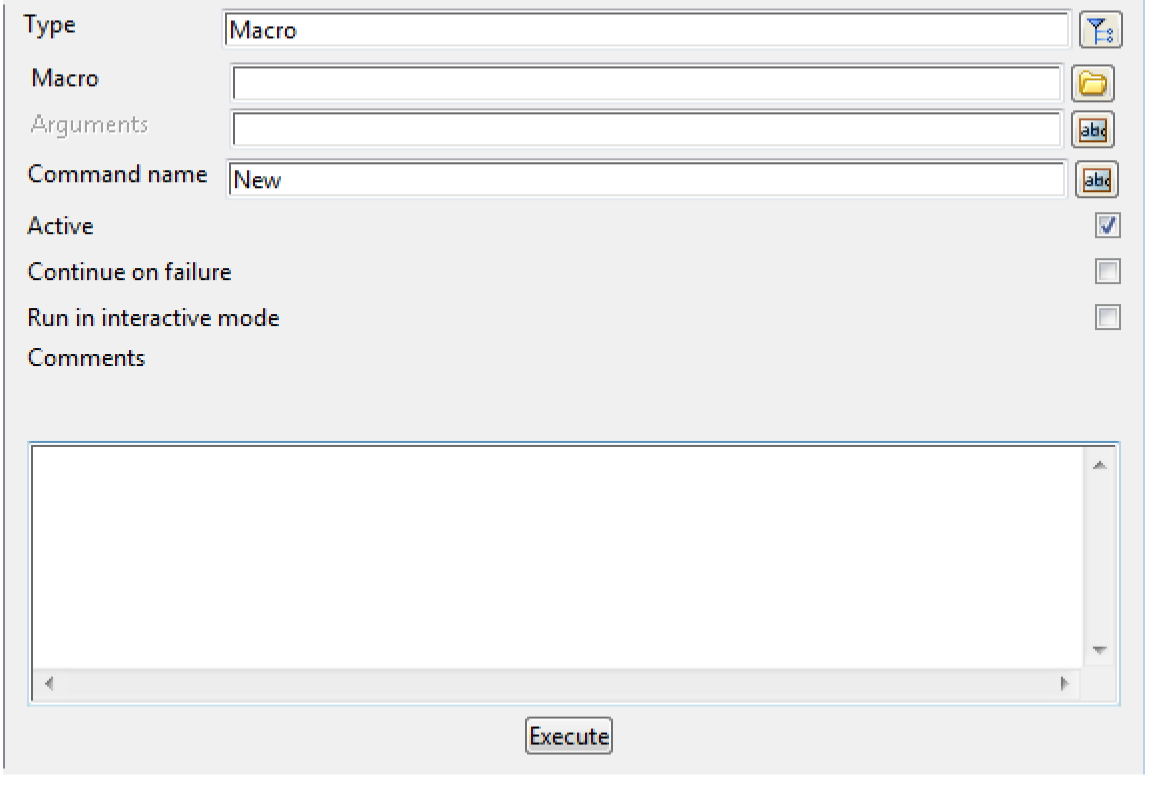
Preview *is for display only and on its own can't be used to modify the details of the command.*

For the description of the fields **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the buttons* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.5 Execution >Macro or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.5 Execution >Macro

The **Macro** command runs a macro with a set of optional arguments



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Macro**.*

Macro	file box		*.4do files

the macro to run.

Arguments	input		

an optional set of arguments to pass to the macro.

***Note** that Chain Parameters can be passed as argument to the Macro. See* 28.3.5.5 Chain Parameters as Macro (12dPL's) Arguments

Run in interactive mode	tick box		

if the macro creates a panel, it must be run in interactive mode.

*If **ticked**, if it is a panel macro (i.e. brings up a panel), the macro will be run in Interactive mode and the panel will be displayed. If it is not a panel macro, the macro will run as normal.*

At this point all the data in the panel fields may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

*If **not ticked**, the command will run without being displayed and allowing for changes to be made.*

Important Note and Warning

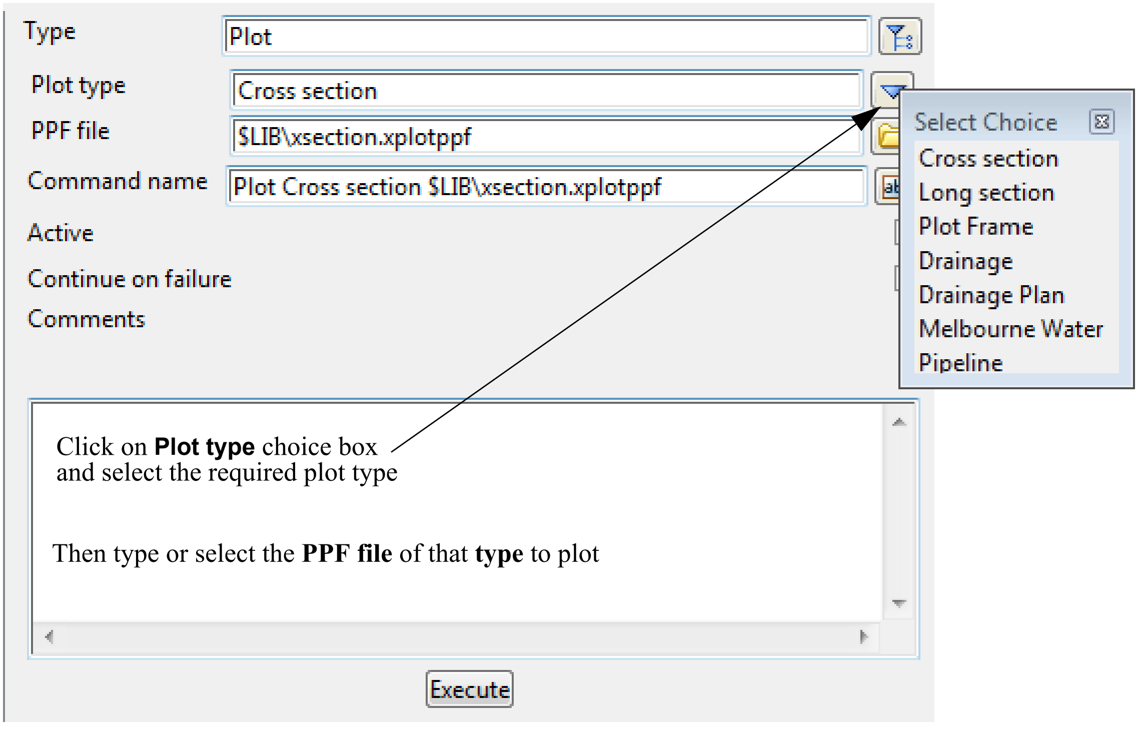
*The **Run in interactive mode** for a **panel** has no connection to the* **Run chain in interactive mode** *for the Chain.*

For the description of the fields **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands*.*

Continue to the next section 28.3.1.1.2.6 Execution >Plot or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.6 Execution >Plot

The **Plot** command plots a given ppf file.

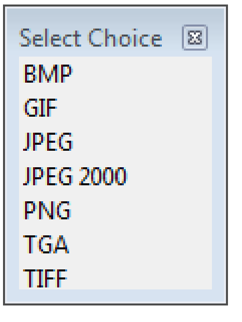


The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Plot***

Plot type	Plot type box		



type of plot to create.

Plot type	plot type box		

name of the view to create. If the name already exists then it is an error.

PPF file	PPF file box		available PPF's for the Plot type

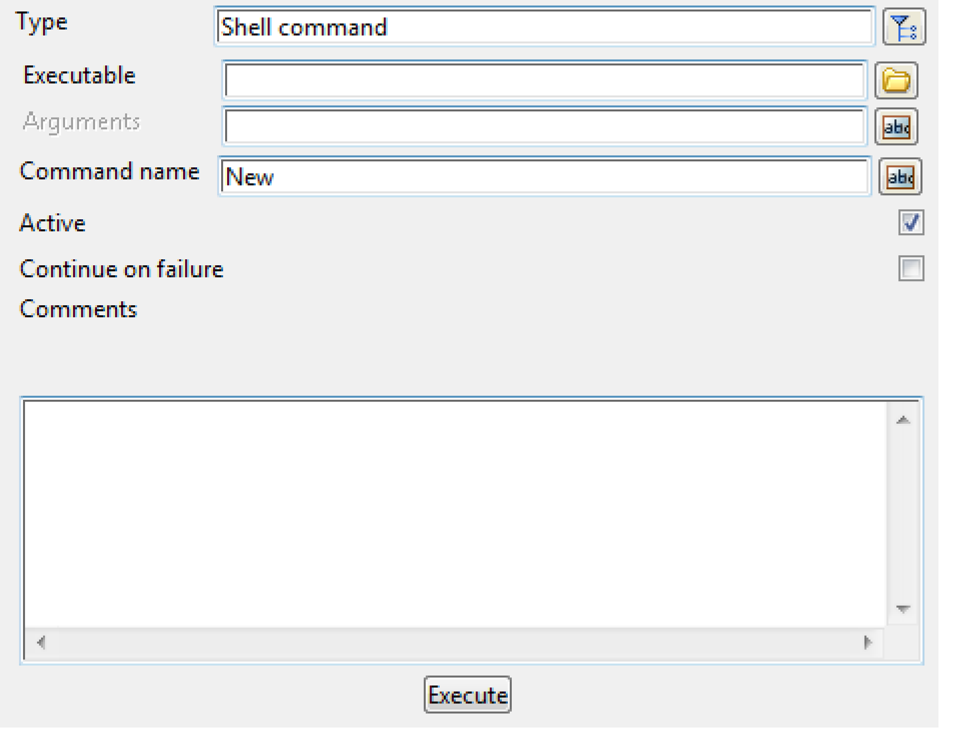
the PPF to use to create the plot.

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.7 Execution >Shell Command or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.7 Execution >Shell Command

The **Shell command** commands run an external program, Microsoft command line *etc*.



The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

the chain command - this command is ***Shell command***

Executable	file browse box		

name of the file to execute.

Arguments	text box		

if ***not blank****, the text is passed as arguments to the* **Executable**.

Also the value of a Chain parameter can be used as an argument passed to the **Executable** *program.*

*The parameter name is enclosed in square brackets (**[** and **]**) and then surrounded by double quotes (**"**)*

"[parameter_name]"

and this is entered in the **Arguments** *field in the place of the argument of the* **Executable** *that it replaces.*

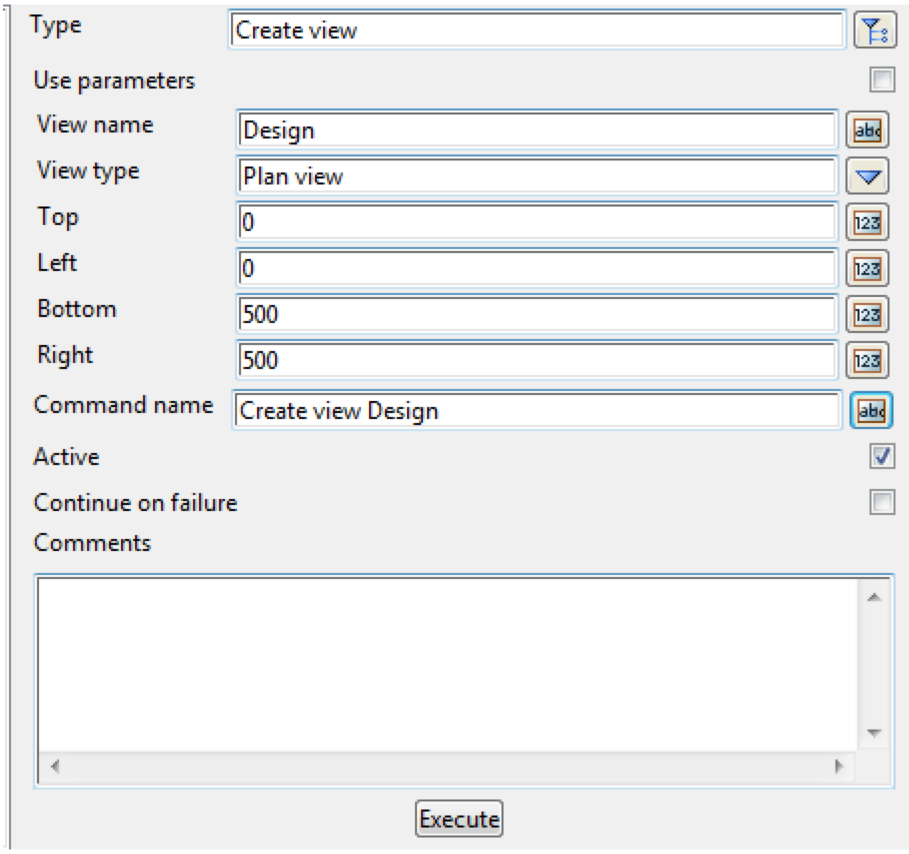
For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.8 Views >Create view or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.8 Views >Create view

The **Create view** command creates view of a given name and type.

It can also optionally give the Top Left and Bottom Right to position and size the view.



The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Create view***

View name	text box		

name of the view to create. If the name already exists then it is an error.

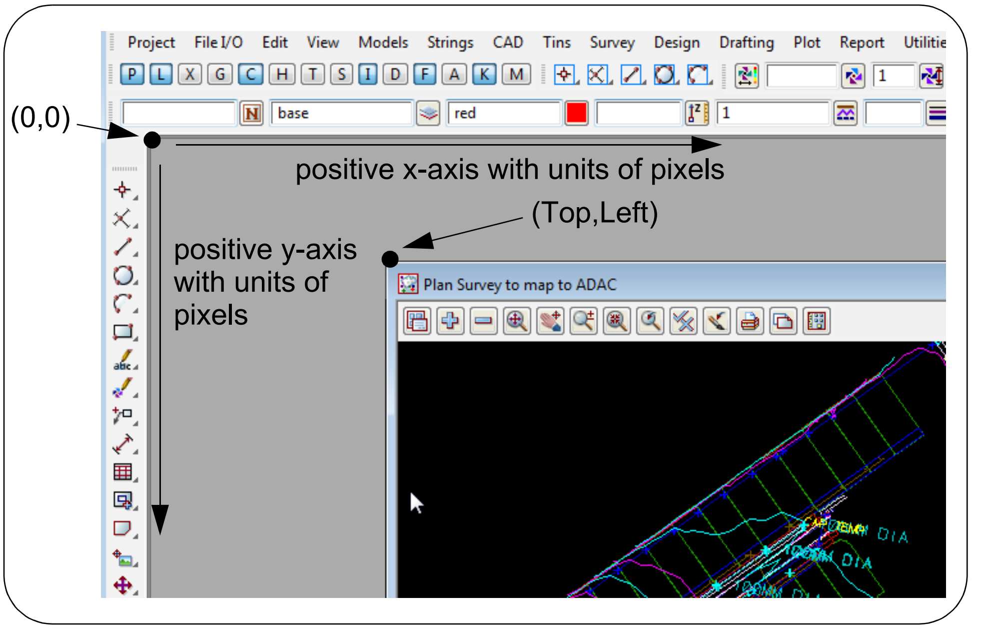
View type	view types box		available view types

the type of view to create

Top/Left/Bottom/Right	integer box		

if not blank, the value in pixels of the top left hand and bottom right corners of the of the created view.

*The coordinate system has (0,0) at the Top Left of the **12d Model** View area, and the X-axis going across the screen and the Y-axis going down the screen. The units are pixels.*

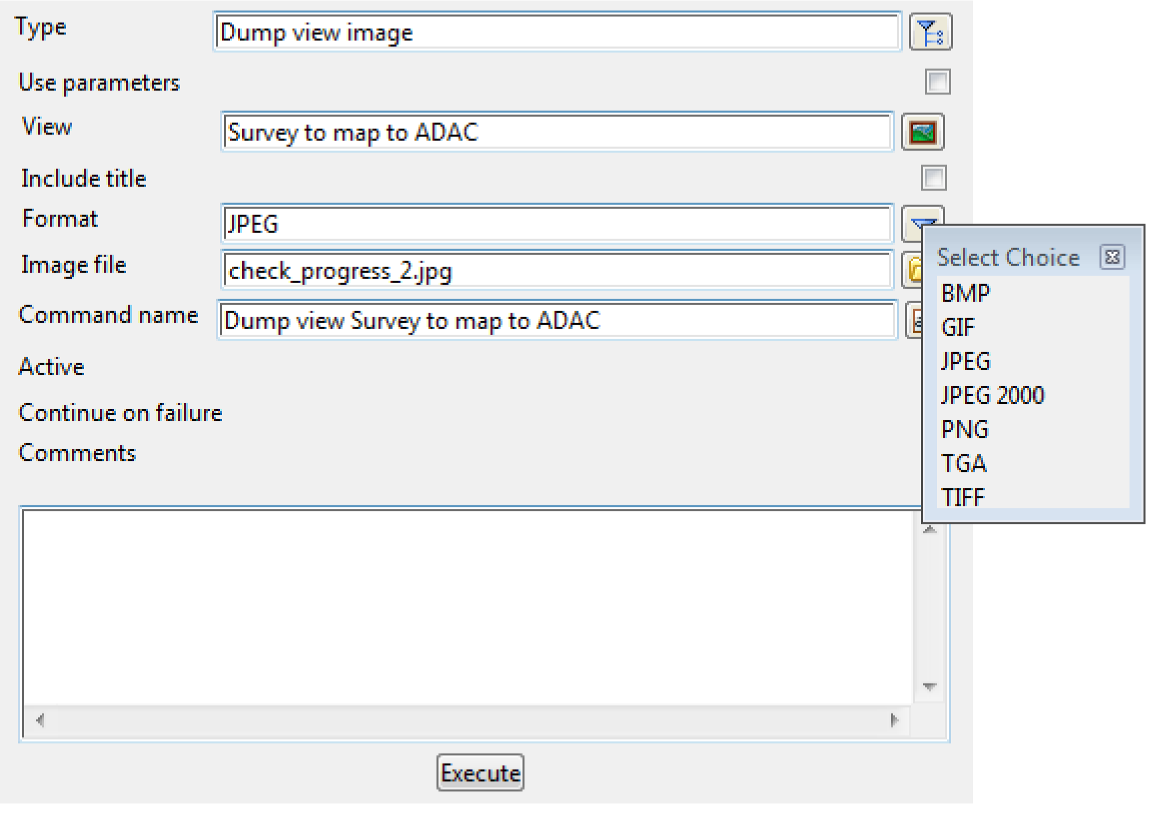


For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.9 Views >Dump view image or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.9 Views >Dump view image

The **Dump view image** command write out an image of the given view.



The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Dump view image***

View	View box		available views

name of the view to write out an image of file of.

Include title	tick box		

*if **ticked**, the title of the view and the icons on the view are included in the image.*

*If **not ticked**, the title of the view and the icons on the view are **not** included in the image.*

Format	choice box		

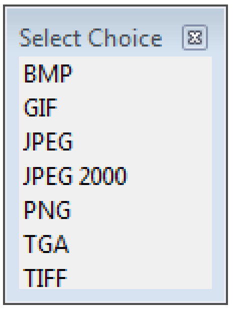


image format to use.

Image file	file box		

the image is written out to this file.

For the description of the fields **Use Parameters***,* **Command name***,* **Active***,* **Continue on failure** *and* **Comments***, and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands*.*

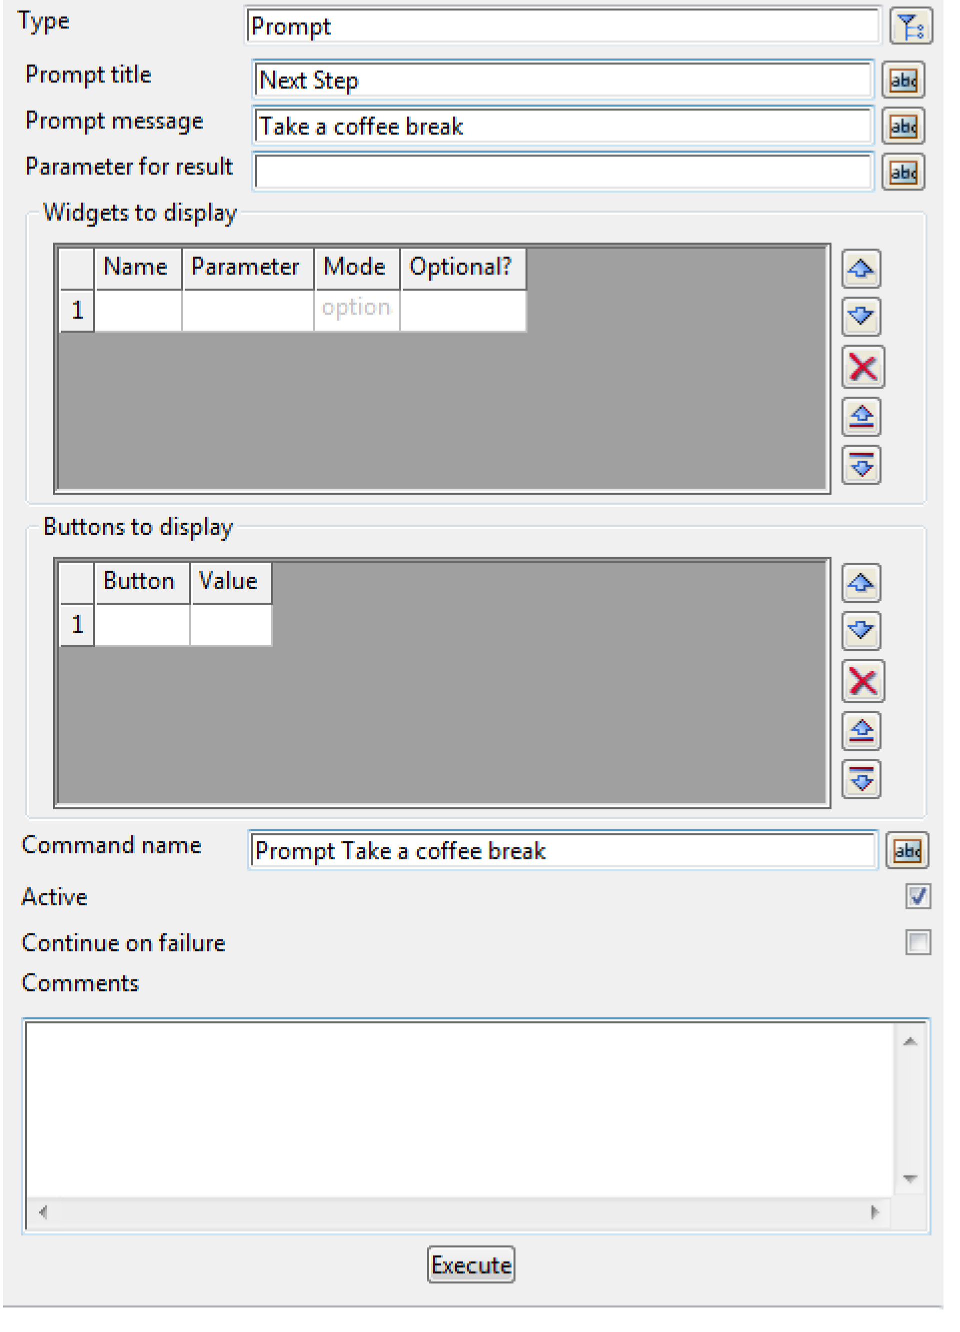
Continue to the next section 28.3.1.1.2.10 Other >Prompt or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.10 Other >Prompt

The **Prompt** command is used to display a user defined Prompt or panel, with user defined text, optional widgets and buttons.

Each button assigns a value to a given parameter, which may be used later in the chain to provide flow control or change data.

All Prompts come up in the same place.



The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **Prompt***

Prompt title	text box		

the title to display at the top of the Prompt

Prompt message text box

the message to display

Parameter for result text box

the parameter to store the result of the Prompt in

Widgets to display - grid

An optional list of widgets to display on the panel to capture more information. The widget must be stored in an existing parameter, defined in the chain's PVF file. The type of parameter will determine the type of widget displayed.

For information about grids, see 4.19.6 Grids in Panels.

Name text box

the name of the widget

Parameter parameter box list of parameters for the chain

the parameter that the widget is created for and will set once the prompt is closed. The parameter must be one of the parameters for the chain.

Mode

Optional? tick box

*if **yes**, the widget will be optional and the user will not need to fill it in when the prompt is displayed.*

*if **no** or **blank**, the widget will not be optional and the user will be required to fill in the widget.*

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Buttons to display - grid

a set of buttons to display on the Prompt panel, each with a name and a return value.

For information about grids, see 4.19.6 Grids in Panels.

Name

the name of the button

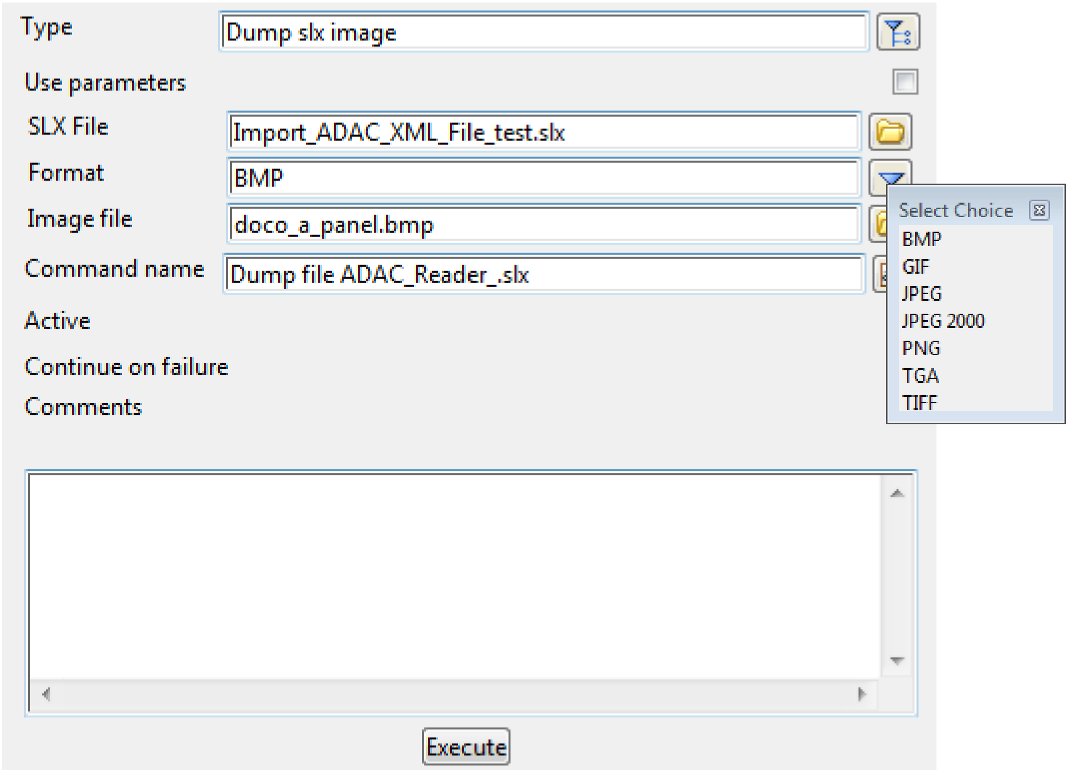
Value

if the button is pressed, the value to assign to the parameter **Parameter for result**.

Continue to the next section 28.3.1.1.2.11 Other >Dump slx image or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.11 Other >Dump slx image

The **Dump slx image** command write out an image of the panel that the SLX creates.



The fields and buttons have the following functions.

Field Description Type Defaults Pop-Up

Type chain command box

*the chain command - this command is **Dump slx image***

SLX File file box available *.slx commands

name of the slx file to read in and display the panel it describes, and then write out an image for.

Format choice box

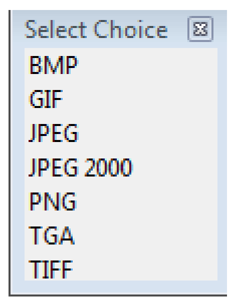


image format to use.

Image file file box

the image is written out to this file.

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.12 Other >Print parameter or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.12 Other >Print parameter

The **Print parameter** command writes out information about a chain parameter to the Output Window.

It prints out in the format

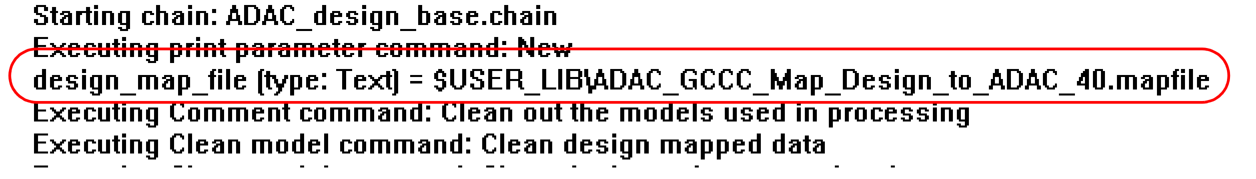
parameter_name [type:*parameter_type*] = *parameter_value*

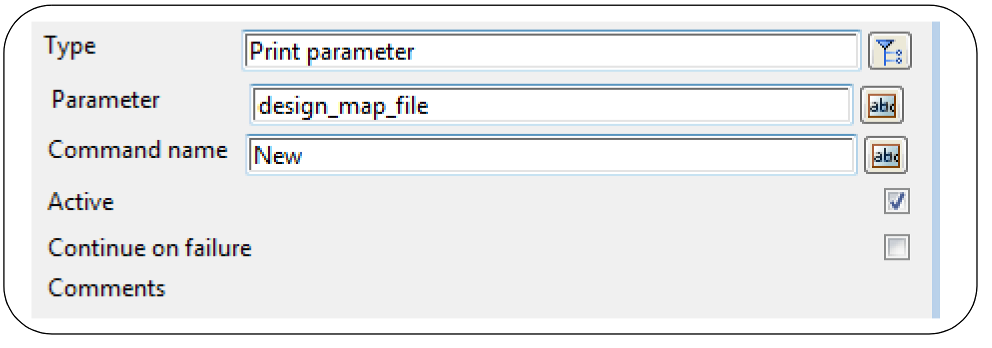
(a) the name of the parameter

(b) the type of the type

(c) the value of the parameters where the *Print parameter* command is processed in the Chain

As an example, for a parameter *design_map_file,* this would print to the ***Output Window***:





The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

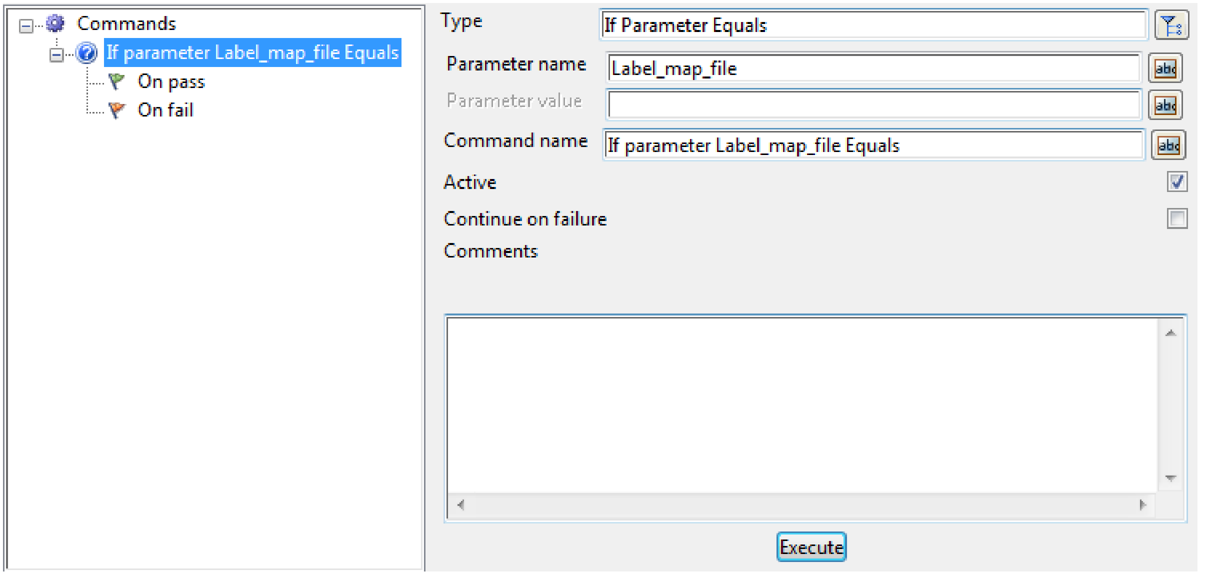
*the chain command - this command is **Print parameter***

For the description of the fields **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.13 Conditionals >If Parameter Equals or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

28.3.1.1.2.13 Conditionals >If Parameter Equals

The **If Parameter equals** command tests if a Chain Parameter has a certain value.



The fields and buttons have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	chain command box		

*the chain command - this command is **If Parameter Equals***

Parameter name	parameter box		parameters in this chain

*the name of a parameter from the **Parameter value file** that is to be tested for having a user given value. The pop-up lists all the parameters in the **Parameter value file** for the Chain.*

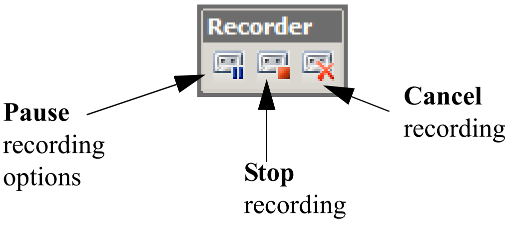
The action of the **On Pass** *and* **On fail** *nodes are described in* 28.3.1.1.1.9 Chain Flow Control and Conditional Commands.

For the description of the fields **Command name**, **Active**, **Continue on failure** *and* **Comments**, *and the button* **Execute** *see* 28.3.1.1.1.1 Common Fields in Commands.

Return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.

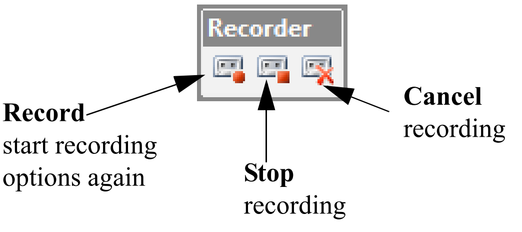
28.3.1.2 Record Icon and the Recorder Toolbar

Clicking on the **Record** icon removes the **Create/Edit Chain** panel and brings up the **Recorder toolbar** with icons to ***Pause***, ***Stop*** and ***Cancel*** the recording.

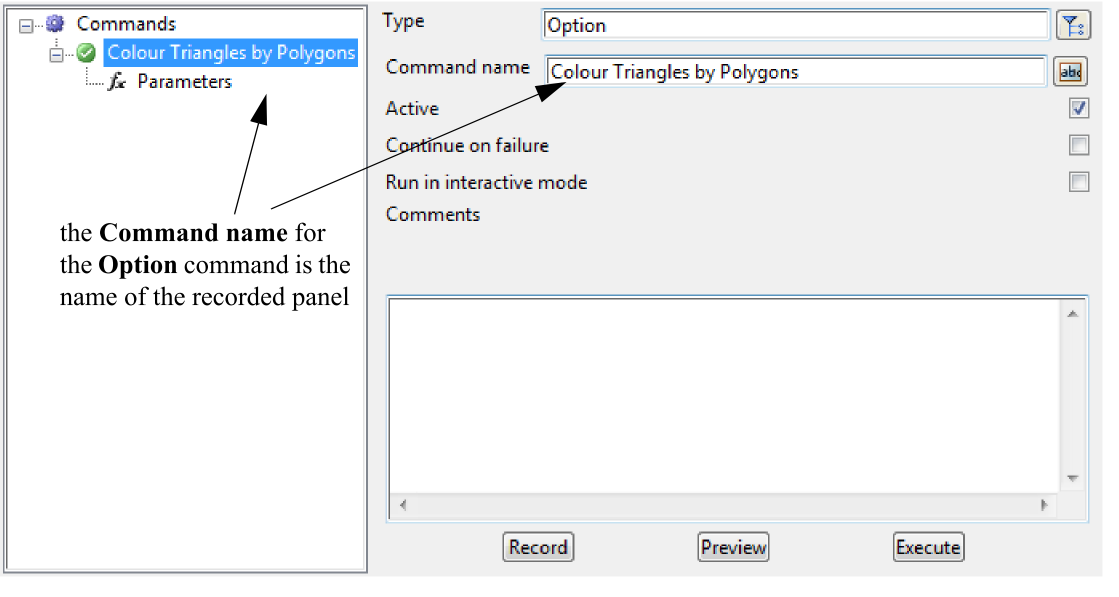


The ***Recording*** process is already underway and you simply ***run*** the ***12d Model*** panels and recordable macros that you wish to record and then press the **Stop** icon.

Pressing **Pause** causes the recording process is interrupted and the **Pause** icon on the Recorder toolbar changes to **Record**. Other options can be run and recording only resumes when **Record** is pressed on the **Recorder** toolbar.



For each recorded panel or macro, an ***Option*** command is added to the list of commands in the chain and its **Command name** is the name of the recorded panel or macro.



When ***Stop*** is pressed, the **Recorder** toolbar is **removed** and the **Create/Edit Chain** panel for the chain is opened on the screen with the new ***Option*** commands added to the command list.

Click on the **Write** button at the bottom of the **Create/Edit Chain** panel to then update the chain.

Note that in **Create/Edit Chain** panel the **Command name** can be modified by clicking on the command in command list in the **Create/Edit Chain** panel and then changing its ***Command name*** field. Click on the **Write** button at the bottom of the **Create/Edit Chain** panel to update the chain.

For more information on recording panel and the buttons **Record**, **Preview** and **Execute**, go to 28.3.1.1.2.1 Execution >Option.

28.3.2 Interactive Mode

Chains support an **Interactive Mode**, meaning that the user is allowed to influence the flow of commands or the data input into the chain.

There are two types of Interactive Mode: **Chain Interactive Mode** and **Command Interactive Mode:**

(a) **Chain Interactive Mode**:

This is toggled via the Run chain in inter.eactive mode tick box on the **Chain Edit/Create** panel. See 28.3.1 Create/Edit a Chain

Then when the chain is run, the **Interactive toolbar** is displayed and the chain will pause for user input. See 28.3.2.1 Interactive Toolbar and Chain Interactive Mode for more details.

(b) **Command Interactive Mode**:

Several commands now support and interactive mode which means that instead of running without the user seeing the command, a command with interactive mode ticked on will pause the chain, display the panel, and allows the user to change panel values and be run or not tun. This applies in the case of panels, functions and macros.

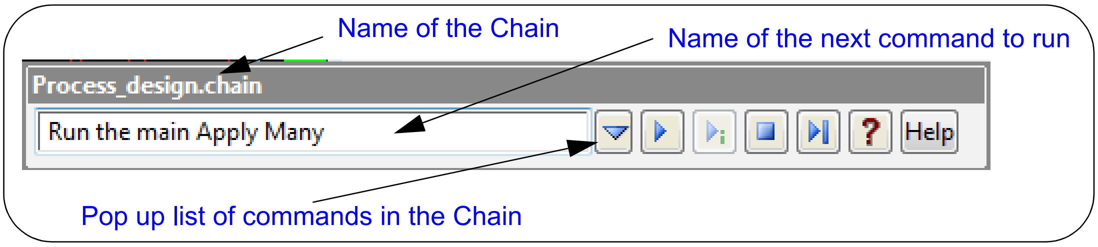
So in these cases, any panels associated with them, and the data they were recorded with, will be displayed and the panel will wait for user input before continuing. See 28.3.2.2 Commands Interactive Mode.

Important Note

The **Chain Interactive Mode** and the **Command Interactive Mode** are totally separate and not related in any way. However when running a **Chain in Interactive Mode**, for each command that supports **Command Interactive Mode**, the user can run the command as is, or **force it** to run in **Command Interactive Mode**.

28.3.2.1 Interactive Toolbar and Chain Interactive Mode

When running a ***Chain*** in **Interactive Mode**, the **Interactive toolbar** is placed on the screen and the chain pauses and ***waits for the user*** to say run the command. The user can even choose a different command to run, and continue running from that command on.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Choice box	choice box		all commands in the Chain

choose the command from the Chain that is placed in the **Interactive** *toolbar ready to be run next.*

Play button button

plays the command displayed in the **Interactive** *toolbar.*

Play + i button button

plays the command displayed in the **Interactive** *toolbar in the* ***Command Interactive Mode*** *regardless of the commands own* **Run in interactive mode** *field. See* 28.3.2.2 Commands Interactive Mode.

This button is only available when the command can be run in Command Interactive Mode. For example a ***Comment*** *command can* ***not*** *be run in Command Interactive Mode.*

Stop button button

stops running the Chain but the **Create/Edit Chain** *panel for the Chain is left on the screen.*

Fast forward button button

runs the chain to the end. The **Create/Edit Chain** *panel for the Chain is left on the screen.*

Fx button

 *bring up the* **Chain Parameters Editor** *panel with the* ***Parameter value file*** *for the Chain loaded into it.*

Help button

display the context sensitive help.

28.3.2.2 Commands Interactive Mode

Running a command in **Command Interactive Mode** will do one of several things, depending on the type of the command:

1. If it is a recorded **Option**, the panel will be presented to the user and the user can change values in the panel fields.

   The user either runs the panel or doesn't run the panel, and then selects the **Finish** button or closes the panel with the X icon.

   If the chain is being run from the **Interactive** toolbar, the Chain then moves on and displays the next command in the Chain in the **Interactive** toolbar.

   If the chain is not being run from the **Interactive** toolbar, the Chain then moves on and runs the next command in the Chain.

2. If it is a **Function** command, the chain will attempt to open the function editor.

   The user either runs the function or doesn't run the function, and then selects the **Finish** button or closes the panel with the X icon.

   If the chain is being run from the **Interactive** toolbar, the Chain then moves on and displays the next command in the Chain in the **Interactive** toolbar.

   If the chain is not being run from the **Interactive** toolbar, the Chain then moves on and runs the next command in the Chain.

28.3.3 Edit a Chain

Position of option on menu: **Utilities =>Chains =>Edit**

Position of option on menu: **Utilities =>Recalc =>Edit chain**

Editing an existing chain on either menu can be done two ways.

The **Edit** walk-right menu displays all the chains in the project and double clicking on a chain in the list will bring up the **Create/Edit Chain** panel (see 28.3.1 Create/Edit a Chain for more information).

Another way of editing a chain is by using the **Recalc Chain** panel (yes the **Recalc Chain** panel) that comes up by:

(a) If the **Chain** menu is being displayed by walking right on **Utilities =>Chains =>Edit** on the top **Main Menu** then the **Edit** menu will be displaying with **[Edit]** written on the top. Clicking on **[Edit]** will bring up the **Recalc Chain** panel

If the **Chain** menu is being displayed by walking right on **Utilities =>Recalc =>Edit chains** on the top **Main Menu** then the **Edit** menu will be displaying with **[Edit chain]** written on the top. Clicking on **[Edit chain]** will bring up the **Recalc Chain** panel

(b) If the **Chain** or **Recalc** menu has been torn from the **Main Menu** on the top then the **Recalc Chain** panel comes up if you click on **Utilities =>Chains =>Edit** without walking right or **Utilities =>Recalc =>Edit chain** without walking right.

The **Recalc Chain** panel can run an existing chain, edit an existing Chain or create a new chain.

For information on the **Recalc Chain** panel see 28.3.9 Run a Chain.

Continue to the next section 28.3.4 Chain Parameters or return to 28.3 Chains.

28.3.4 Chain Parameters

The basic usage of chains is to record and playback a set of panels and other chain commands.

The user can have interactive with the command running in the chain by running the Chain in Interactive Mode (see 28.3.2 Interactive Mode) and/or running selected commands in Command Interactive Model (see 28.3.2.2 Commands Interactive Mode).

However even though these options allow you to change values in some panels as the chain runs, this has to be done again every time the chain is run.

To allow for more power and in the way values in the panels fields are changed, **Chain Parameters** were introduced.

Chain Parameters can be used in place of actual values in the panels and the parameters can be given different values each time the chain is run.

For example, you may have a chain that triangulates a data set and creates and labels contours for the created tin. And to make the chain more flexible, you want to give the name of the created tin and contour models each time the chain is run but don't want to do it by hand.

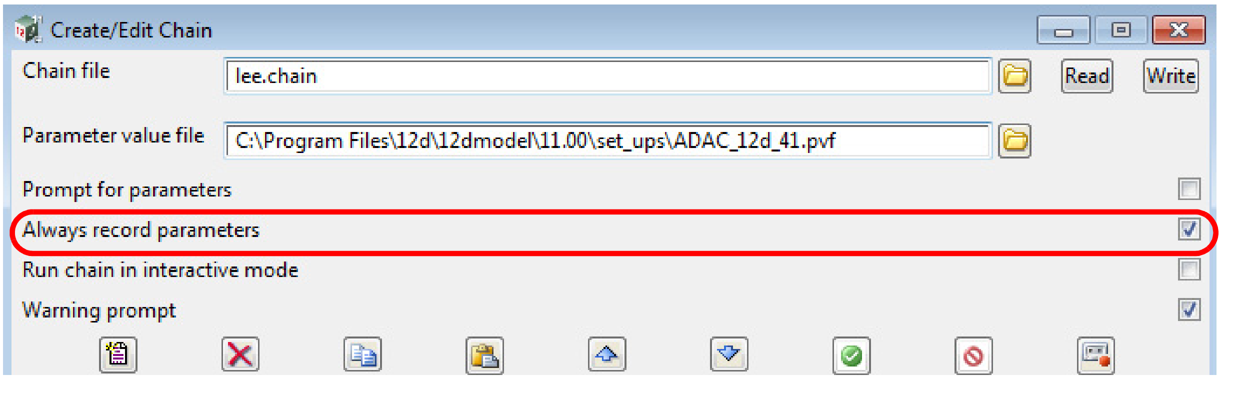
Or you may want to just give the name of the tin and have the names of the contour models derived from the given tin name.

Chain Parameters are used to give the chain this added flexibility.

When Chain Parameters are created, the actual values for the parameters used are stored in a separate **parameter value file** (*.pvf) and so the values of all the parameters can be changed by running the chain with a ***different*** parameter value file.

The Chain Parameters and their values can be defined when the panel is created using the **Option** command, or done separately within the chain itself. Or a commination of both.

To create parameters straight away, have the **Always record parameters** field ticked **on** before starting to record an Option.

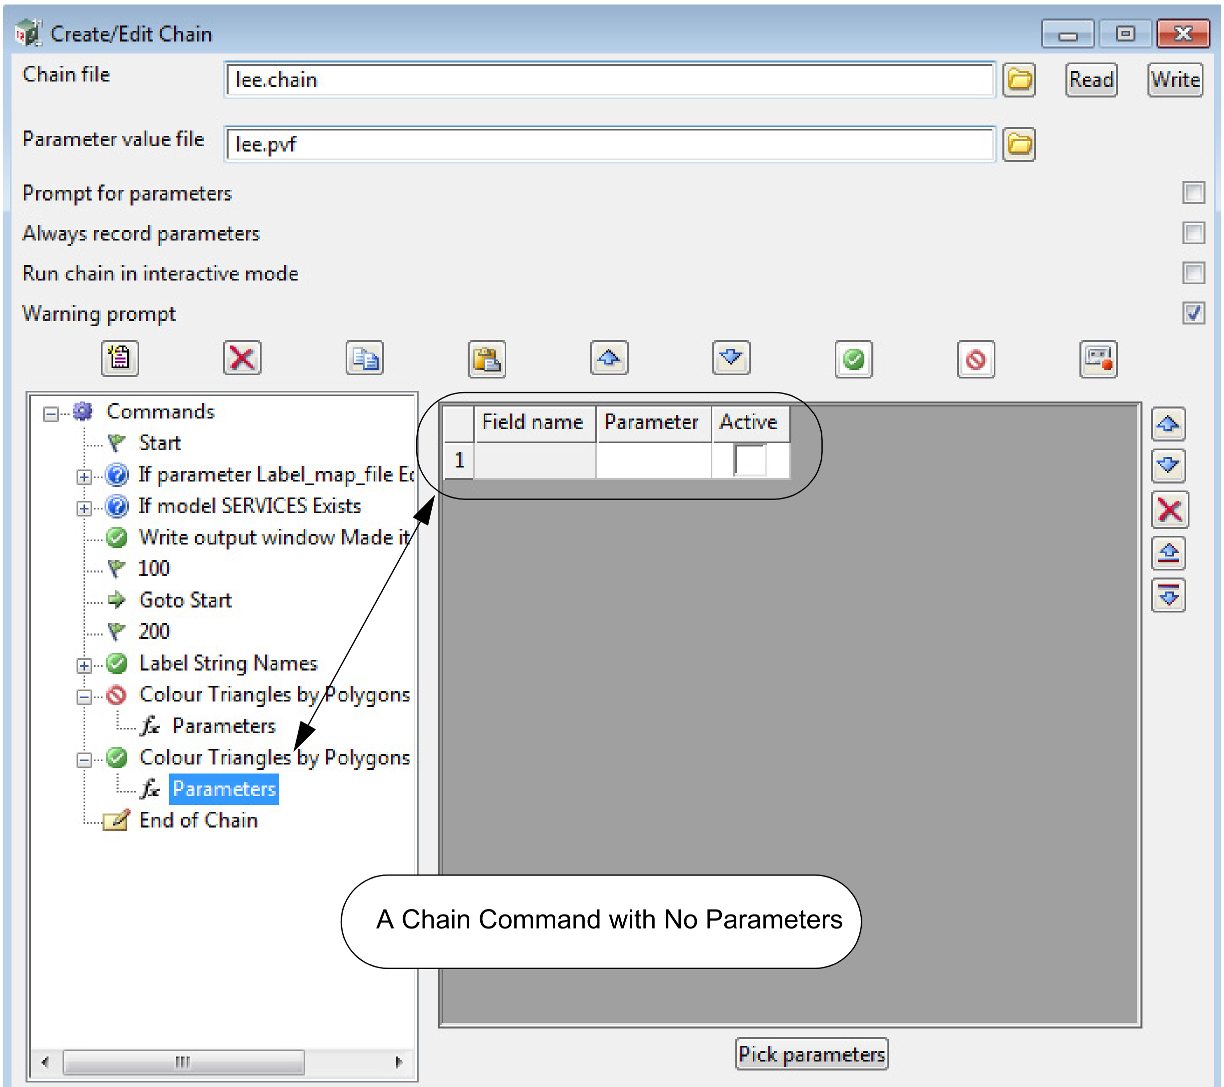


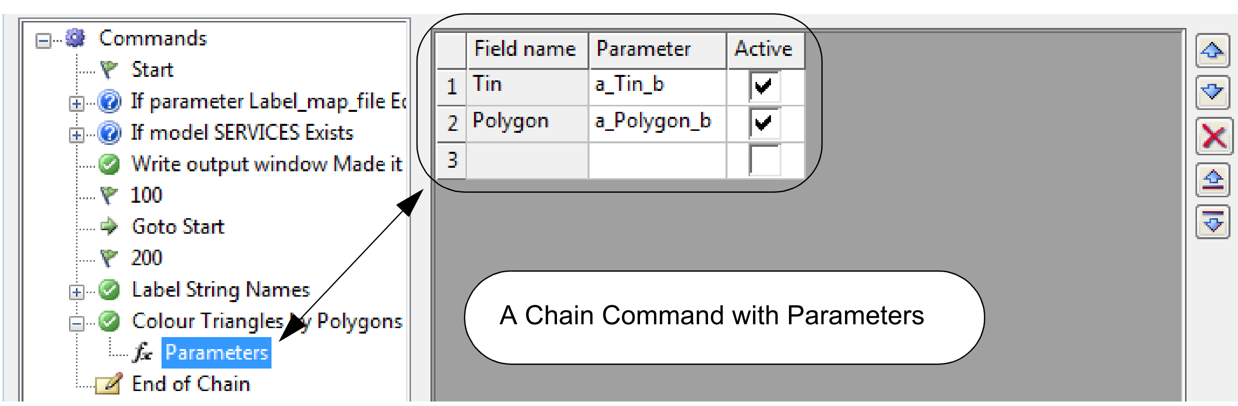
After the option is finished and the recording stops, the **Record Option Parameters** panel is displayed and is used to select the fields you wish to parameterise. See 28.3.4.2 Record Option Parameters Panel.

For information on how to create parameters separately to the recording process, or how to modify existing parameters, see 28.3.4.1 Creating and Modifying Parameters Outside the Recording Process.

28.3.4.1 Creating and Modifying Parameters Outside the Recording Process

For a command in the **Create/Edit Chain** panel, to create parameters separately to the recording process, or to modify existing parameters, click on the **+** to the left of the command in the command list and then on the *Parameter line*. The Parameters are then displayed on the right hand side of the panel.





The fields and buttons used in this panel have the following functions.

Field Description Type Defaults Pop-Up

Parameter grid

the parameter grid holds information about each defined parameter in the chain.

Field name display only

the name of the panel field to be parameterised. This is written to when a field is selected by the **Pick parameters** *buttons. This is read only.*

Parameter text box

the name the user gives the parameter. This can also be modified.

Note that the parameter name can only be alphanumeric and underscores. No spaces are allowed in the name

Active tick box

if ***ticked****, this row is used.*
If ***not ticked****, the row is not used and acts like a comment.*

Buttons at Bottom

Pick parameters

this is used to define more parameters for the option by picking a field from the recorded panel to use as a parameter.

To create a new parameter for the command, click on the **Pick parameters** button. This will bring up the **Record Options Parameter** panel which is used to pick new parameters.

For a description of the **Record Options Parameter** panel and information on how to use it to pick parameters, see 28.3.4.2 Record Option Parameters Panel.

Highlighted rows in the grid can be deleted using the X icon.

New rows are created using the **Pick parameters** button.

If a *Parameter* is not to be used at this time, ***untick*** the **Active** column.

Parameters within options are defined as *Parameter Mappings.*

A parameter mapping maps from a specific field to a named parameter. When an option command runs and fills out a particular field, it will look for the appropriate parameter mapping to that field to use as the value for the field.

To create parameters without recording, or modify them, click on the Parameters under the expanded Option command in the chain editor. All the mappings from parameters to the fields they represent will be listed here.

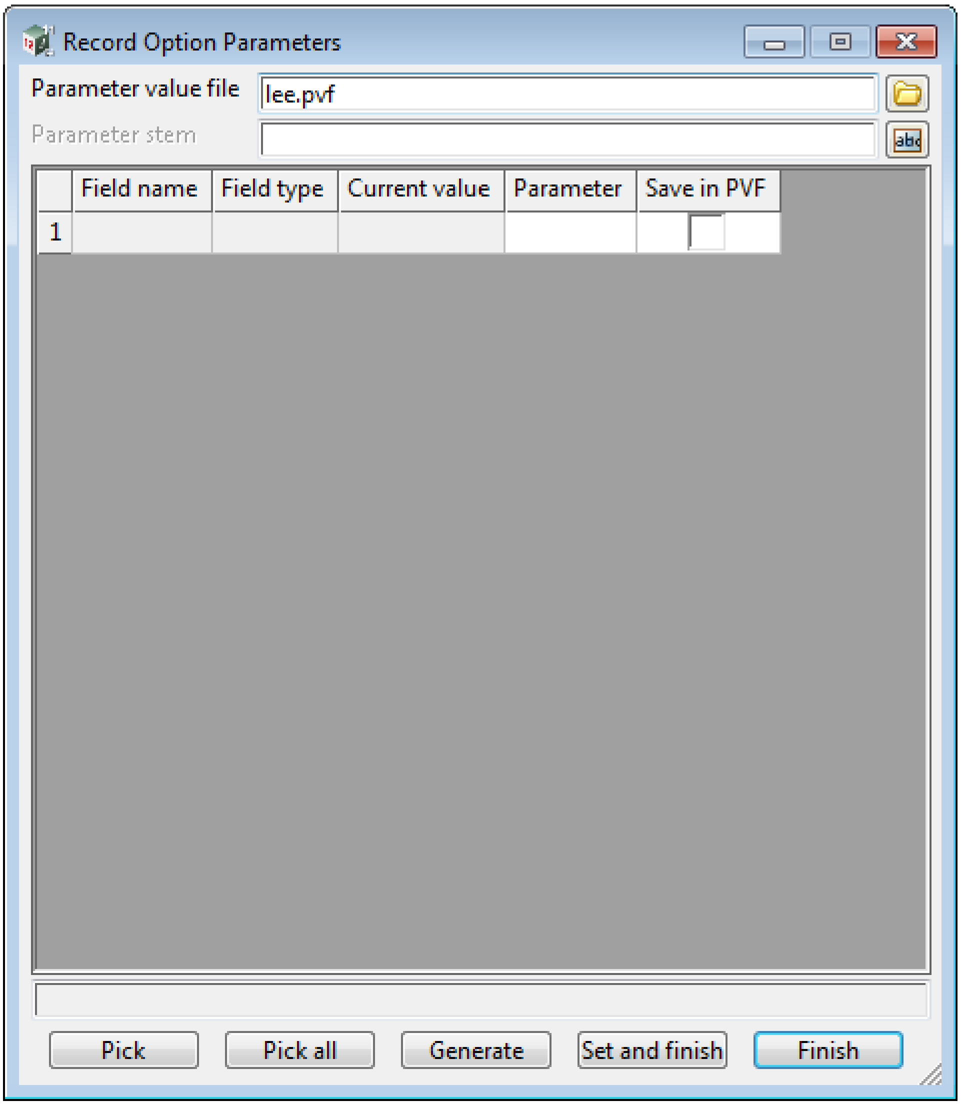
28.3.4.2 Record Option Parameters Panel

The **Record Option Parameters** panel is displayed:

(a) as soon as a recording is finished if the **Always record parameters** field ticked **on** in the **Create/Edit Chain** panel.

or

(b) by clicking on the **Pick parameters** button when the *Parameters* line is clicked on for a command in the **Create/Edit Chain** panel.



The fields and buttons for this panel will now be described but how you use the panel to select parameters is given in the section 28.3.4.3 How to Create Chain Parameters

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Parameter value file	parameter value file box		available *.pvf files

the name of the field on the panel that is being parameterised.

Parameter stem	text box		

*pretext and postext written in the form pre_text*post_text and it is used on the value that is going to be written in the* **Parameter** *column in the grid when it is created by the* **Generate** *button.*

*Note that if there are any spaces in the pre_text*post_text, then each space will be replaced by an underscore in the parameter name.*

Parameter grid name

the parameter grid holds information about each defined parameter in the chain.

Field name display only

the name of the panel field to be parameterised. This is written to when a field is selected by either the **Pick** *or* **Pick all** *buttons. This is read only.*

Field type display only

the type of the parameterised field. This is written to when a field is selected by either the **Pick** *or* **Pick all** *buttons This is read only.*

Current value display only

the value that the panel field had at the time of recording. This is read only.

Parameter text box

the name of the parameter. If **Generate** *is pressed, then this is automatically created from the* **Parameter stem** *and the name of the Field in the panel.*

Note that the parameter name can only be alphanumeric and underscores. Not spaces are allowed in the name

Save in PVF tick box

*if **ticked**, this row is saved in the* **parameter value file**.
*If **not ticked**, the row is not saved in the* **parameter value file**.

However in both cases the information is saved with the chain.

Buttons at Bottom

Pick

pick a field from the recorded panel to use as a parameter

Pick all

automatically pick all fields to be used as parameters

Generate

generate names for the parameters, using the optional parameter stem

Set and finish

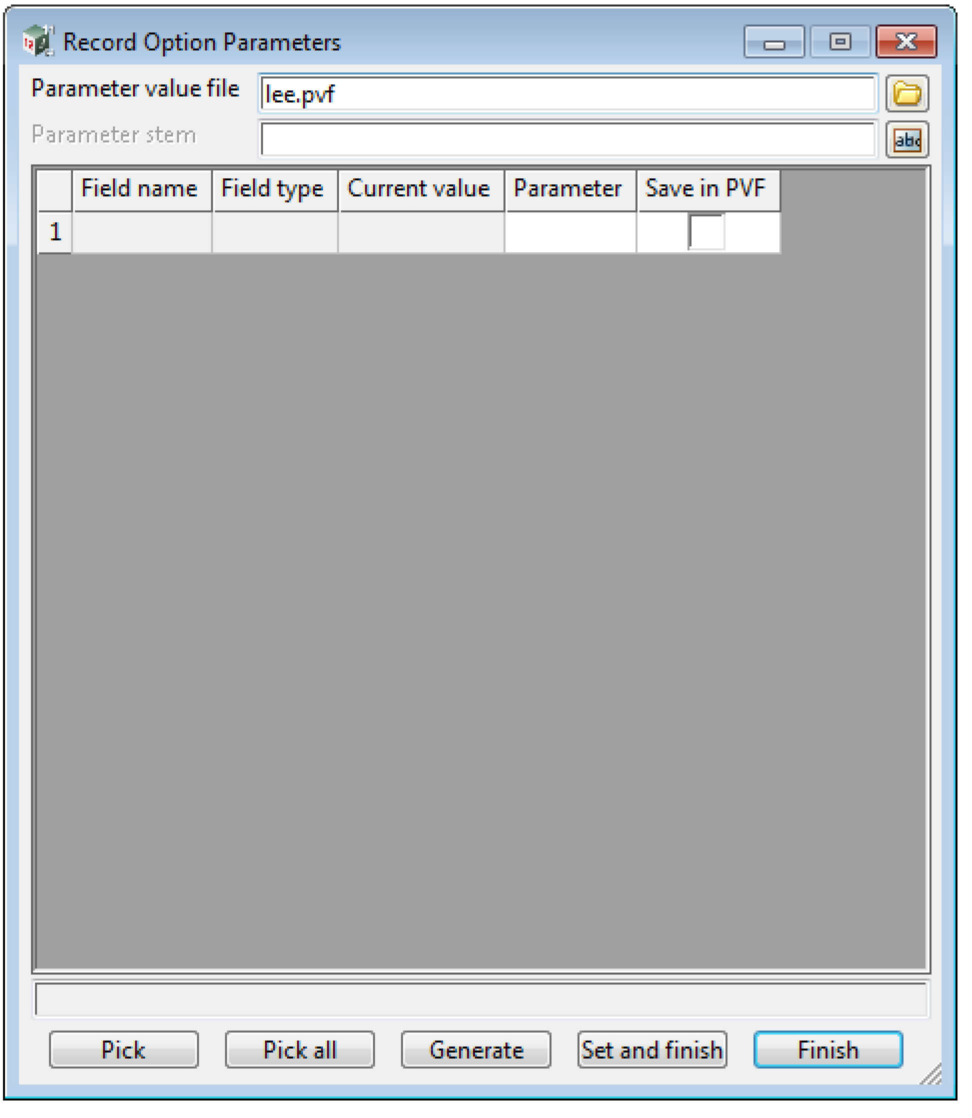
save the recorded parameters and finish the panel.

For information on how to use this panel to select parameters is given in the section 28.3.4.3 How to Create Chain Parameters.

28.3.4.3 How to Create Chain Parameters

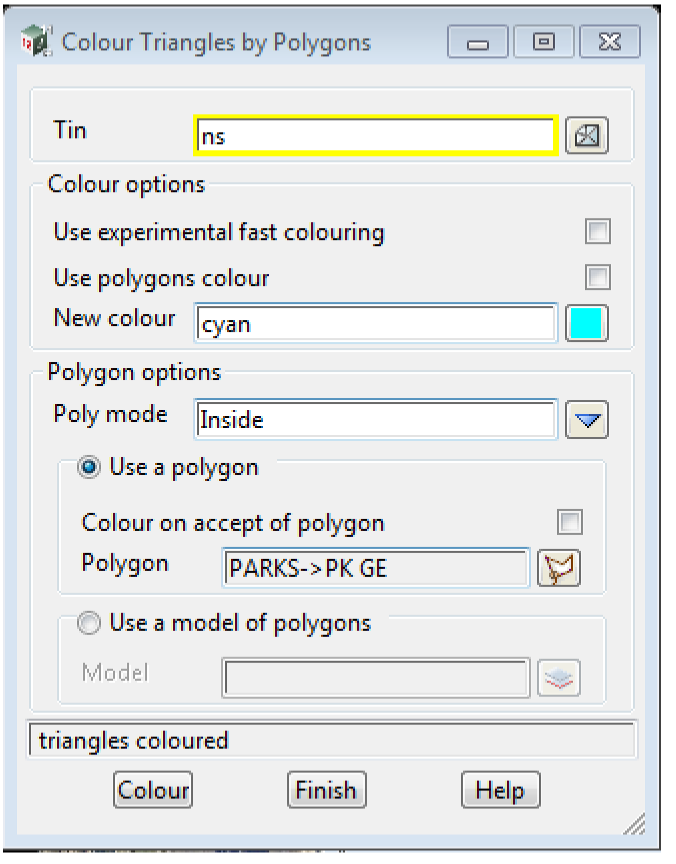
The **Record Option Parameters** is used to create ***Chain Parameters*** and this section describes that process in detail.

Note - information on each field and button in the panel is given in the section 28.3.4.2 Record Option Parameters Panel.

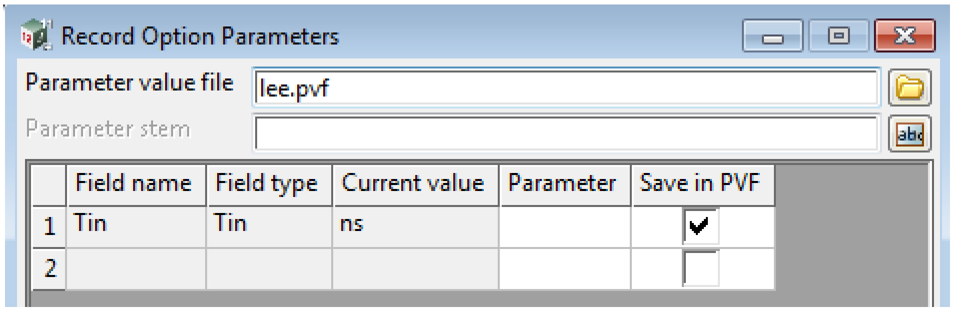


The **Pick** or the **Pick All** buttons can then be used to select the fields that are to be parameterised.

After **Pick** is pressed, as you move over the panel that was just recorded, the fields of the panel that the cursor is over is highlighted with a yellow rectangle.



Clicking when a particular field is highlighted writes the name, type and current value of the field to the next blank line in the grid of the **Record Option Parameters** panel.



The name that you want to call the parameter is then typed into the **Parameter** column and the **Save in PVF** column ticked or not ticked.

If another panel field is to be parameterised, then press the **Pick** button and repeat the process.

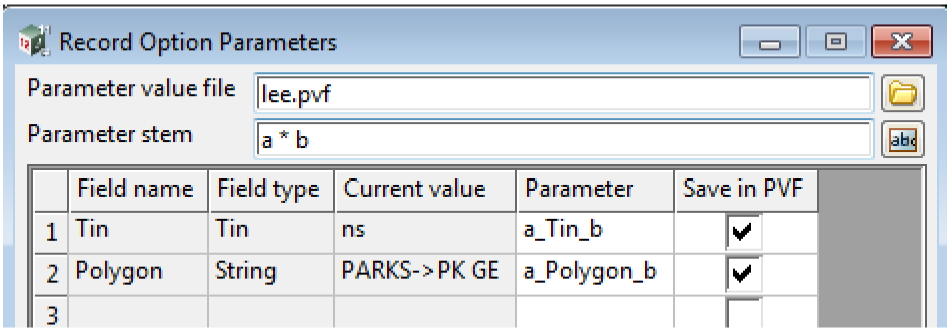
When all the fields to be parameterised have been selected, click on **Set and finish**.

The **Record Option Parameters** panel is then removed from the screen. Click on Finish to remove the panel that was recorded.

Click on the **Write** button on the top right hand side of the **Create/Edit Chain** panel to update the chain in the file, and also if there is one, update the **Parameter value file**.

Note that sometimes the name of the command is not updated until **Write** is pressed.

Another way to create the **Parameter** names is to click on **Generate**. The **Parameter stem** is then applied to the name of the field on the panel to create the **Parameter** name.

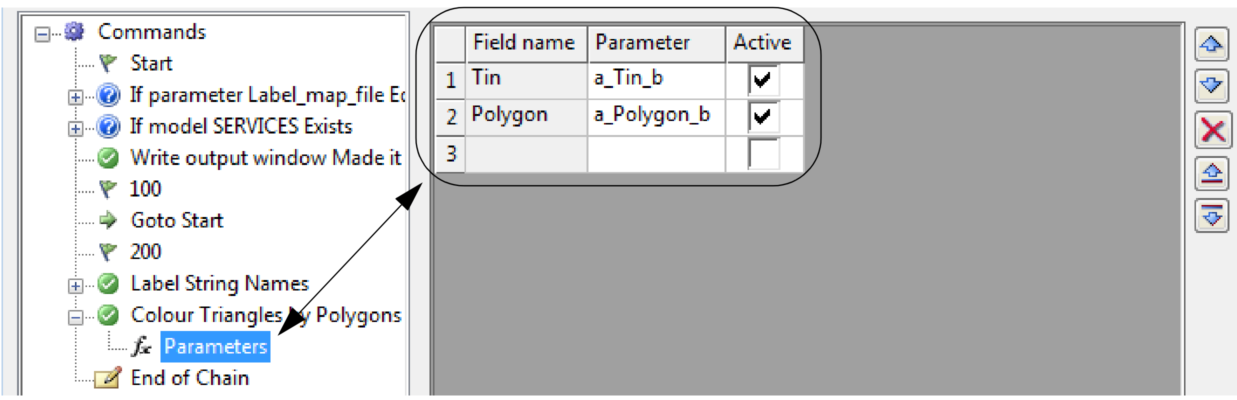


Note that a parameter name can not contain spaces so any spaces are replaced by underscores.

Finally if all panel fields are to be selected as parameters then press the **Generate all** button.

Also if you want to do most parameters but not all, it is often quicker to click on **Generate all** and then delete the few that you don't want from the **Record Option Parameters** panel.

The parameters for a command can be seen by clicking on the + to the left of the command in the command list and then clicking on the Parameter line that is displayed. The Parameters are then displayed in the right hand side of the panel.



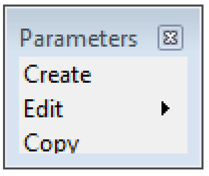
If the *Parameter* is not to be used at this time, ***untick*** the **Active** column.

Return to 28.3.4.2 Record Option Parameters Panel or 28.3.4.3 How to Create Chain Parameters.

28.3.5 Creating/Editing Parameter Value Files

Position of option on menu: **Utilities =>Chains =>Parameters**

These options Create, Edit and Copy Chain pvf files (parameter value files).



selecting Create opens the parameter editor
walk right on Edit, lists parameter files to edit
used to copy a Chain Parameter Value File from one file to another.

For the option:

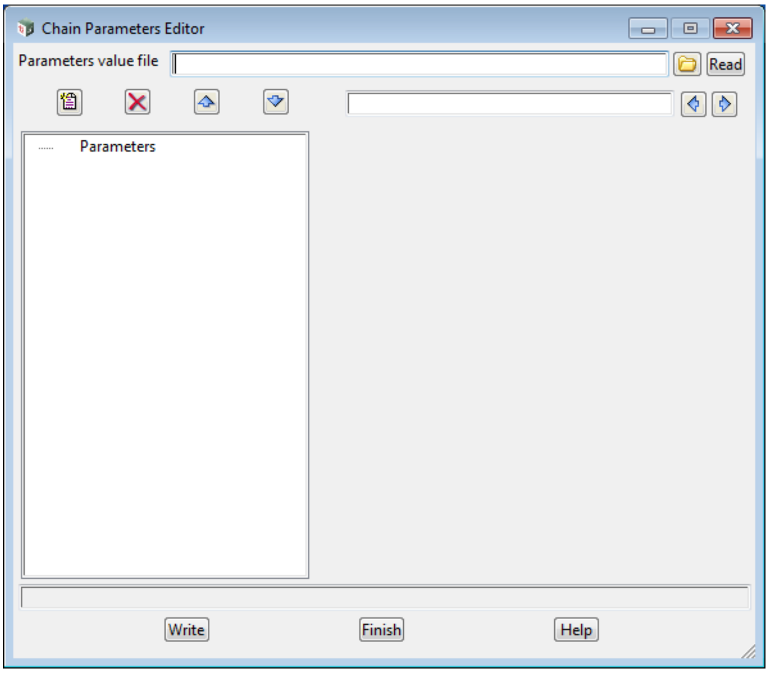
Create, go to	28.3.5.1 Creating a Chain Parameters Value File
Edit	28.3.5.2 Editing a Chain Parameters Value File
Copy	28.3.5.3 Copy a PVF

Chains can also be used

28.3.5.1 Creating a Chain Parameters Value File

Position of option on menu: **Utilities =>Chains =>Parameters =>Create**

Selecting **Create** brings up the **Chain Parameters Editor** panel which is used to both create and edit chain parameters.



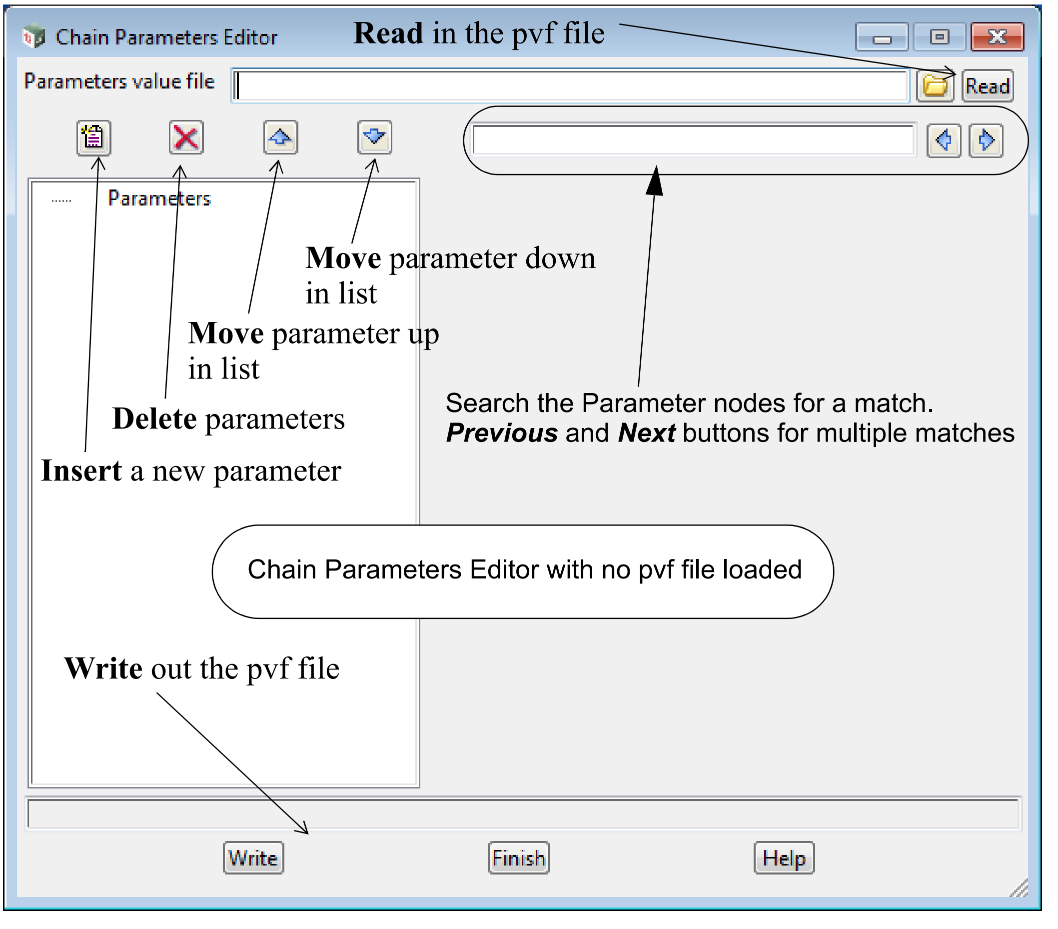
For information about this panel, see 28.3.5.2 Editing a Chain Parameters Value File

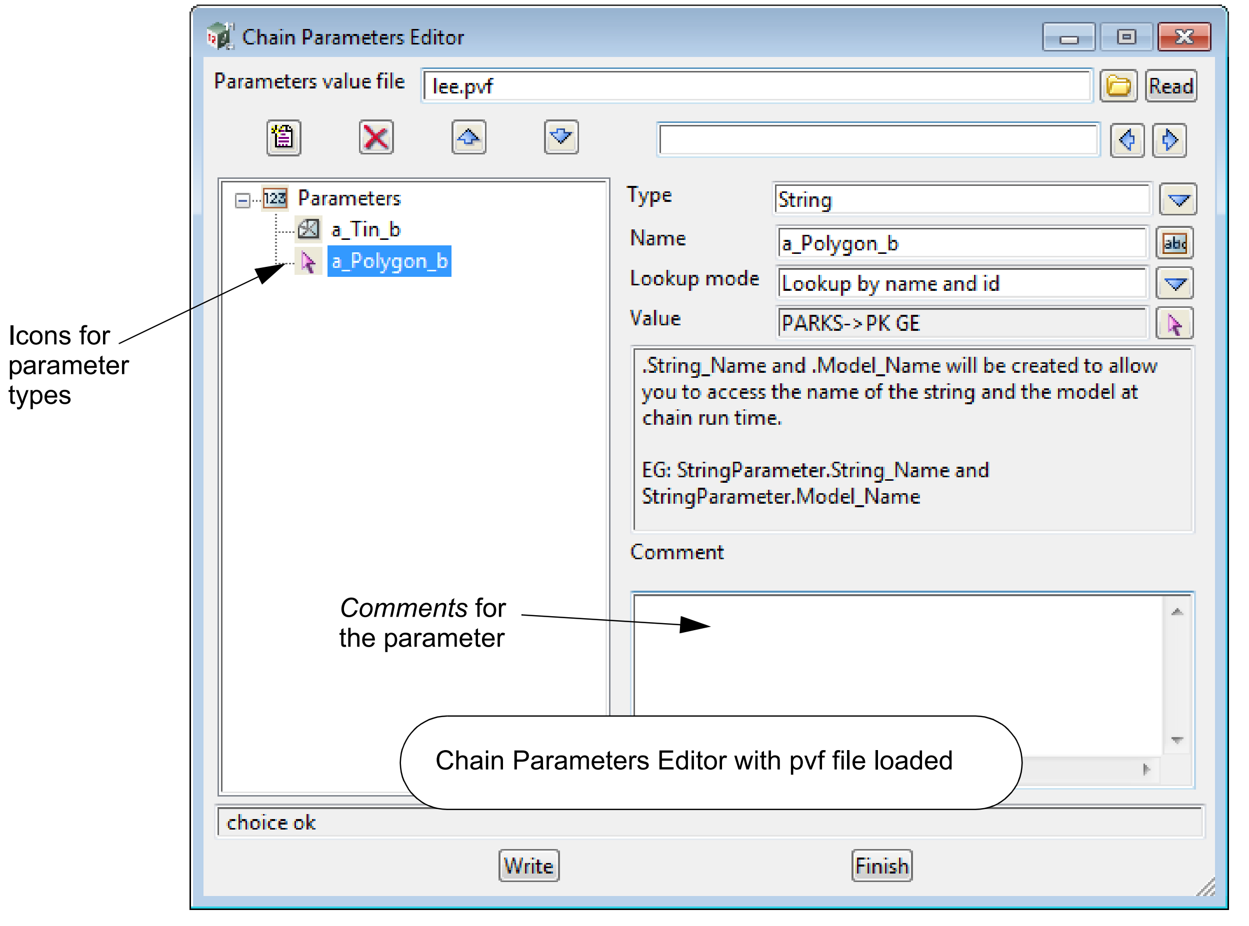
28.3.5.2 Editing a Chain Parameters Value File

Position of option on menu: **Utilities =>Chains =>Parameters =>Edit**

The **Edit** option is a walk-right which lists the existing parameter files. Clicking on a file in this list, brings it up in the **Chain Parameters Editor** panel with the selected pvf file already loaded into the panel.

Or if the **Parameter** menu is a floating menu, clicking on **Edit** without walking right will bring up the **Chain Parameters Editor** panel without a pvf file already loaded. This can then be used to create a new pvf file or selected and load an existing pvf file.





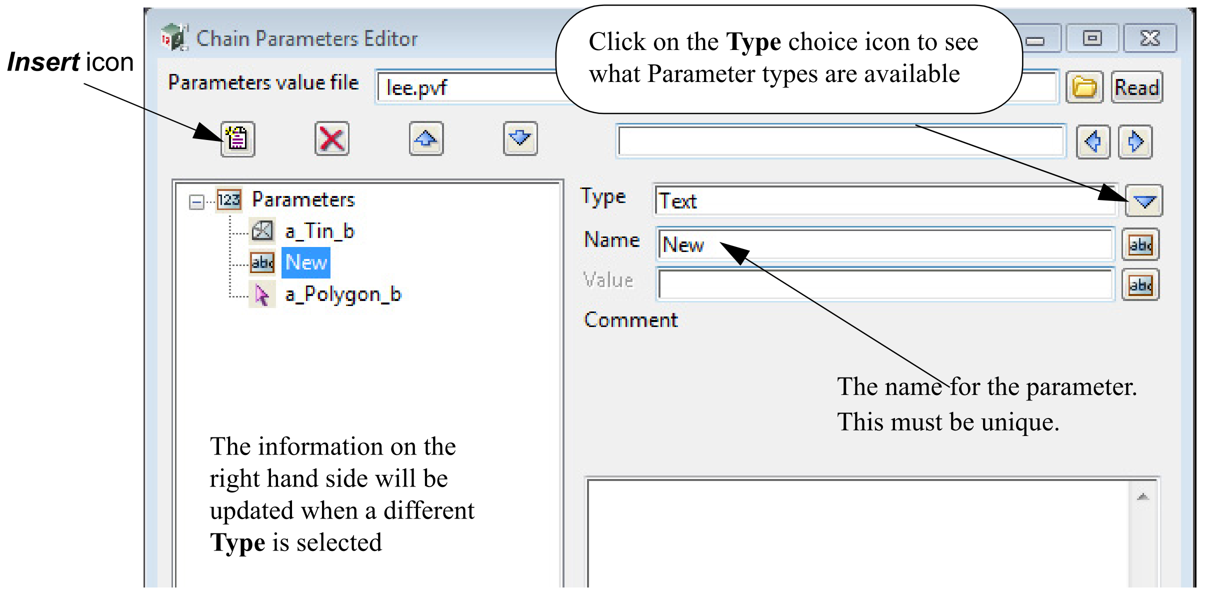
Chain Parameters Editor with pvf file loaded

See:

Inserting a parameter 28.3.5.2.1 Inserting a Parameter
Searching 28.3.5.2.2 Searching for Parameter Values

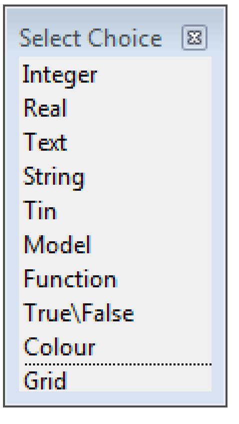
28.3.5.2.1 Inserting a Parameter

Clicking on the ***Insert*** icon insert a new parameter into the list of parameters under the current highlighted parameter. The new parameter is given the default **Type** Text and name **New**.



The correct type for the new parameter is then selected in the **Type** field and the information required for that type of parameter is then displayed in the right hand side of the panel.

The types of parameters available are:

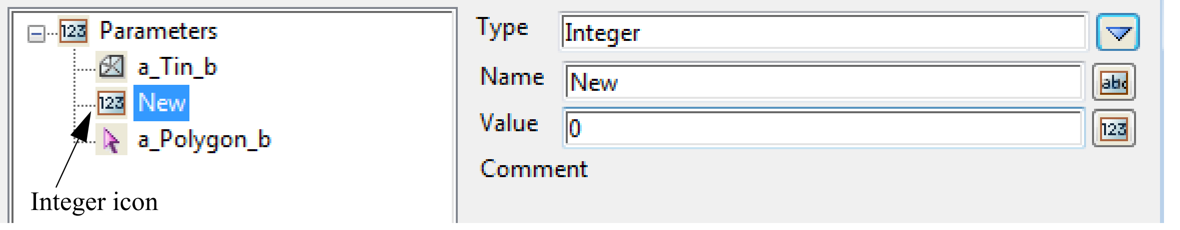


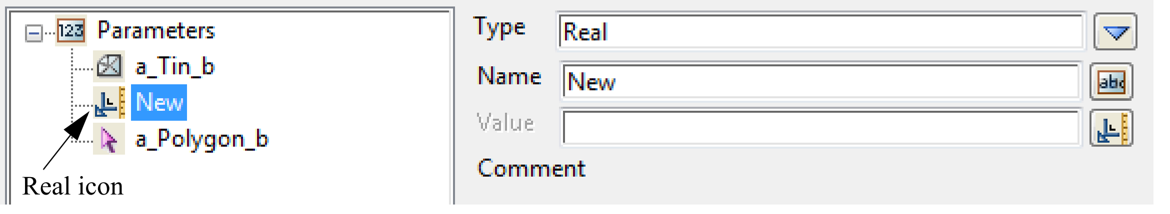
See:

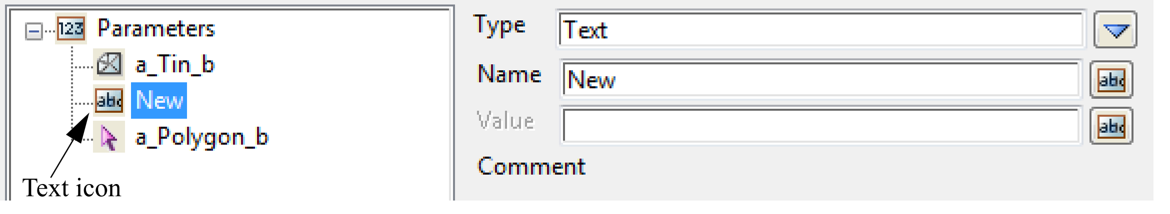
Integer	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
Real	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
Text	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
String	28.3.5.2.1.2 String Parameter
Tin	28.3.5.2.1.3 Tin Parameter
Model	28.3.5.2.1.4 Model Parameter
Function	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
True\False	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
Colour	28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters
Grid	28.3.5.2.1.5 Grid Parameter

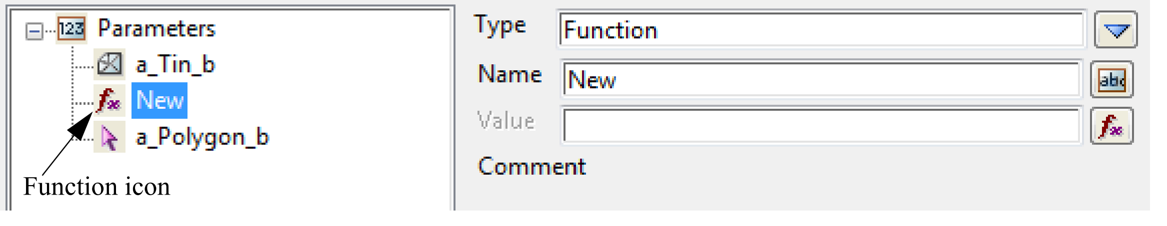
28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters

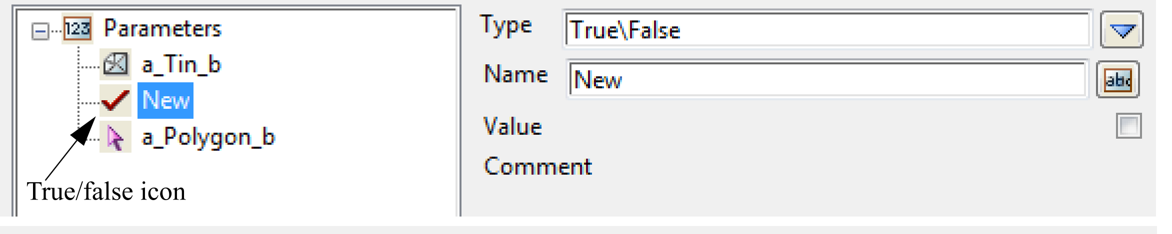
The information needed for all these parameter types is virtually the same.

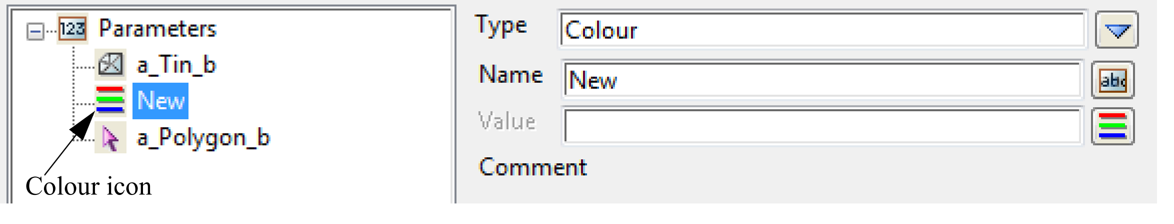












The fields and buttons used in the right hand side of the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	choice box		parameter types

*the type of the parameter. In this case it will be **Integer**, **Real**, **Text**, **Function, True/False** or **Colour**.*

*The icon displayed on the left of the parameter name in the Parameter list under the Parameter node will match the **Type**.*

Name text box

the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the **Write** *button is pressed.*

Value integer, real, text, function, tick box, colour

the value of the parameter. This must match the type of the parameter (integer, real, text, function, true/false tick box, colour).

For **Type** ***True/False***, **Value** *is a tick box and* ***ticked*** *means* ***True*** *and* ***unticked*** *means* ***False***.

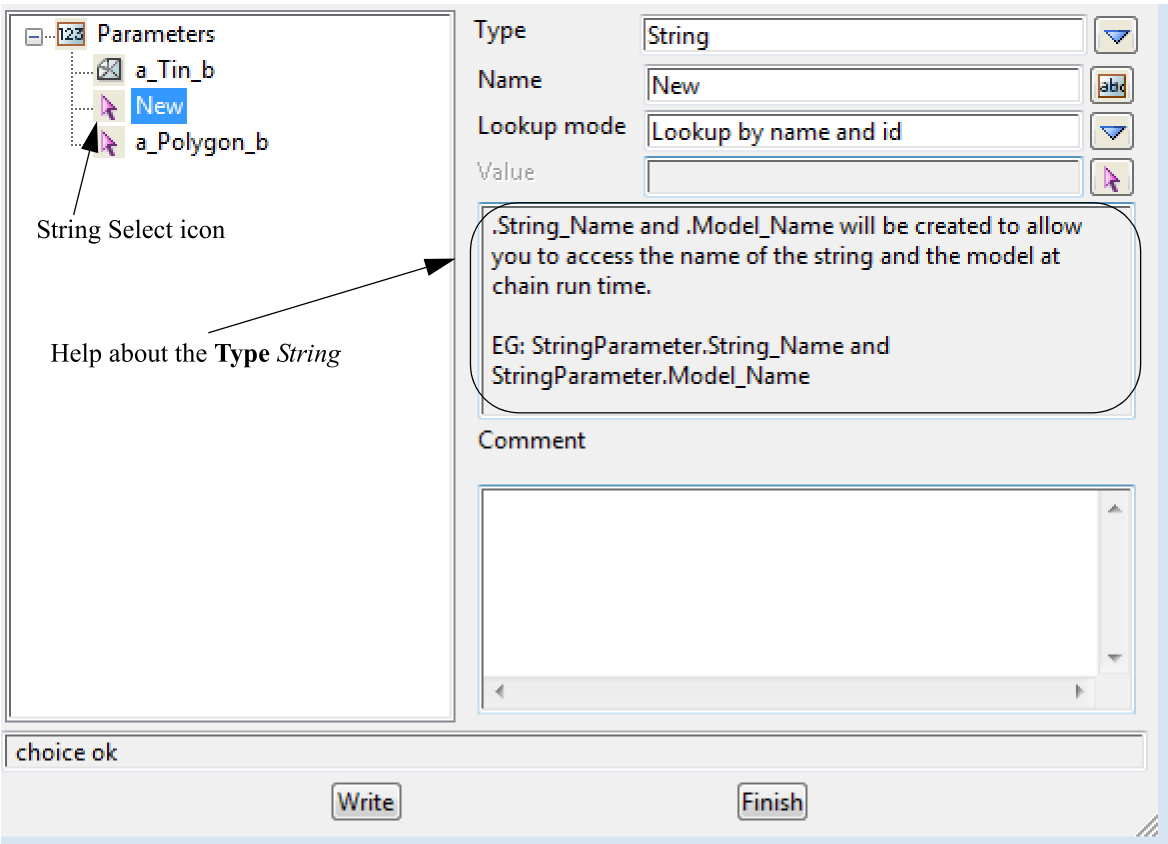
Comment comment box

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.2 String Parameter or return to 28.3.5.2.1 Inserting a Parameter.

28.3.5.2.1.2 String Parameter

The information needed for the parameter of type **String** is given on the right hand side of the panel when ***String*** is selected for **Type**.



The fields and buttons used in the right hand side of the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	choice box		parameter types

*the type of the parameter. In this case it is **String**.*

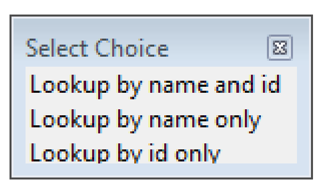
*The **Select String** icon displayed on the left of the parameter name in the Parameter list under the Parameter node.*

Name	text box		

the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the **Write** *button is pressed.*

Lookup mode	choice box		



*if **Lookup by name and id**, the string to use is searched for by string id first and if the string id does not exist, then by string name. If the search becomes by name and there is more than one string with the name then the first one found is selected. THIS NEEDS TO BE EXTENDED FOR name and model*

*if **Lookup by name only**, the string to use is searched for by string name only. If there is more than one string with the name then the first one found is selected. THIS NEEDS TO BE EXTENDED FOR name* *and model*

*if **Lookup by id only**, the string to use is searched for by id only. THIS NEEDS TO BE EXTENDED FOR name and model*

Value string select box

a string is selected by clicking on the string select icon on the right of the field and then selecting a string. The string name and id, and the model name and id that the string is in, are saved with the parameter.

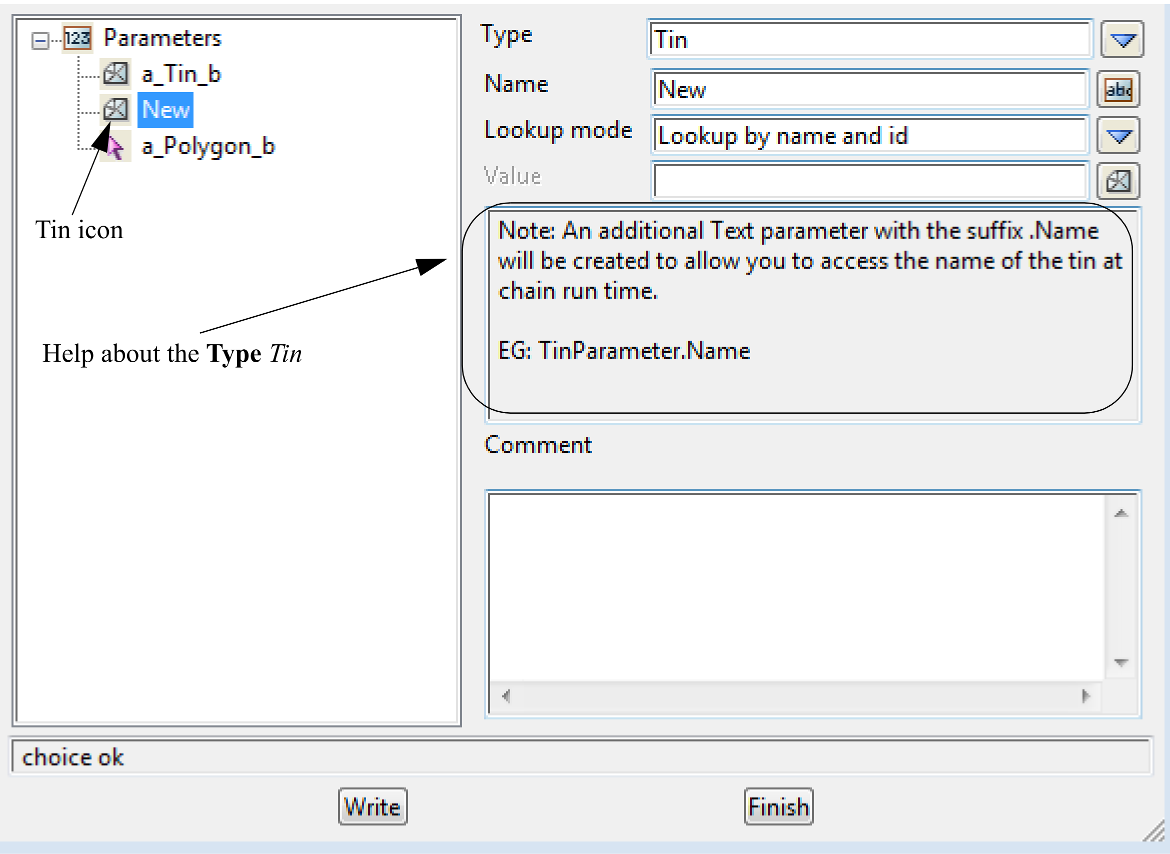
Comment comment box

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.3 Tin Parameter or return to 28.3.5.2.1 Inserting a Parameter.

28.3.5.2.1.3 Tin Parameter

The information needed for the parameter of type **Tin** is given on the right hand side of the panel when ***Tin*** is selected for **Type**.



The fields and buttons used in the right hand side of the panel have the following functions.

Field Description | Type | Defaults | Pop-Up

Type | choice box | | parameter types

*the type of the parameter. In this case it is **Tin**.*

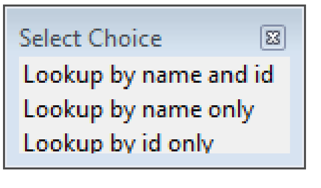
*The **Tin** icon displayed on the left of the parameter name in the Parameter list under the Parameter node.*

Name | text box

the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the **Write** *button is pressed.*

Lookup mode | choice box



*if **Lookup by name and id**, the tin to use is searched for by tin id first and if the tin id does not exist, then by tin name.*

*if **Lookup by name only**, the tin to use is searched for by tin name only.*

*if **Lookup by id only**, the tin to use is searched for by id only.*

Value tin box

the name of the tin. The tin name and id are saved with the parameter.

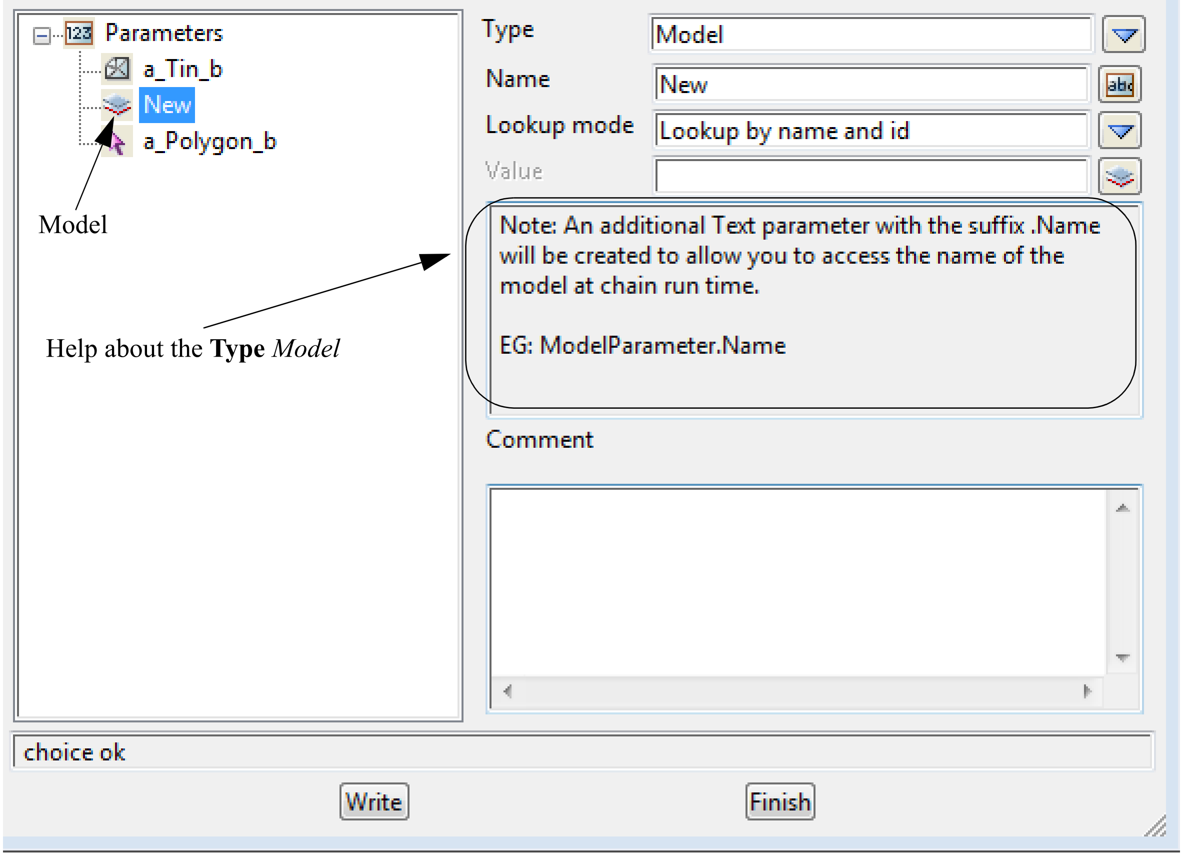
Comment comment box

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.4 Model Parameter or return to 28.3.5.2.1 Inserting a Parameter.

28.3.5.2.1.4 Model Parameter

The information needed for the parameter of type **Model** is given on the right hand side of the panel when ***Model*** is selected for **Type**.



The fields and buttons used in the right hand side of the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	choice box		parameter types

*the type of the parameter. In this case it is **Model**.*

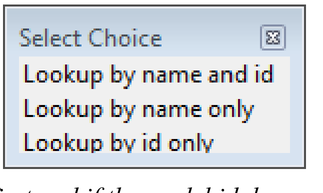
*The **Model** icon displayed on the left of the parameter name in the Parameter list under the Parameter node.*

Name	text box		

the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the **Write** *button is pressed.*

Lookup mode	choice box		



*if **Lookup by name and id**, the model to use is searched for by model id first and if the model id does not exist, then by model name.*

*if **Lookup by name only**, the model to use is searched for by model name only.*

*if **Lookup by id only**, the model to use is searched for by id only.*

Value tin box

the name of the model. The model name and id are saved with the parameter.

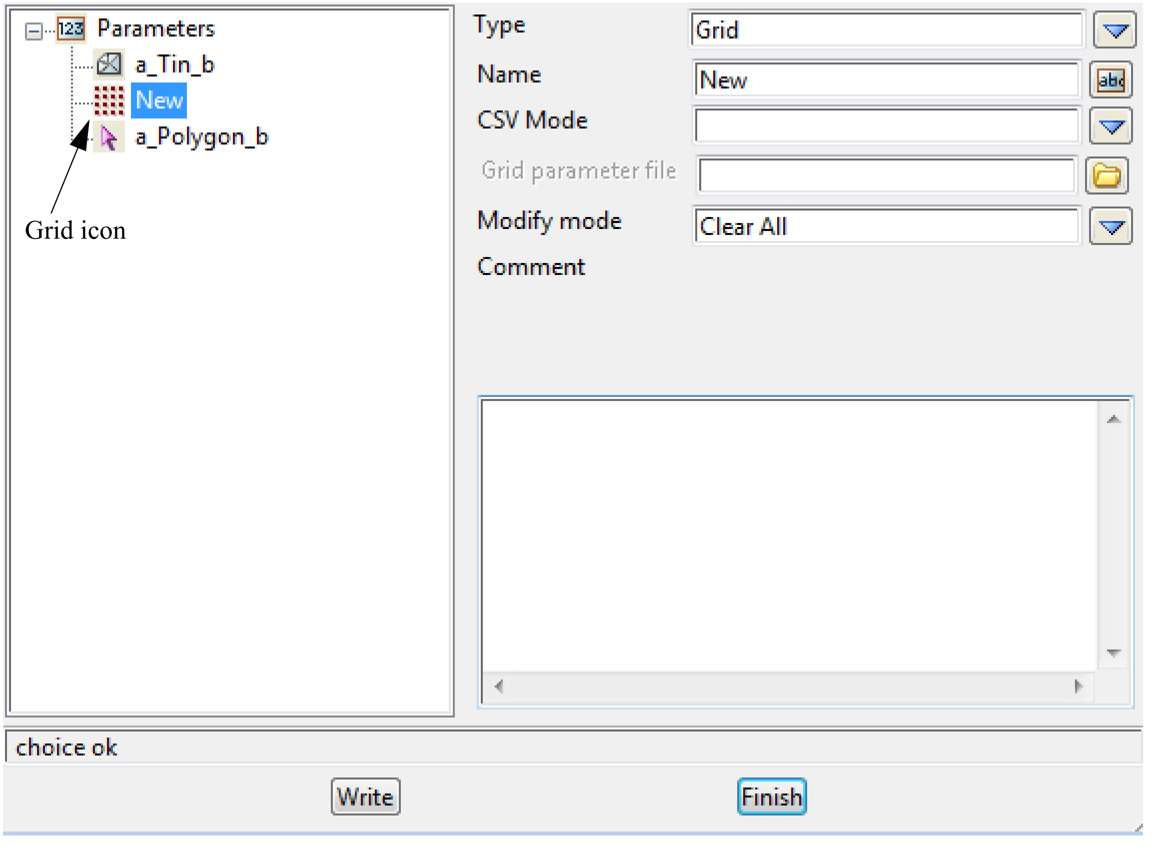
Comment comment box

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.5 Grid Parameter or return to 28.3.5.2.1 Inserting a Parameter.

28.3.5.2.1.5 Grid Parameter

The information needed for the parameter of type **Grid** is given on the right hand side of the panel when ***Grid*** is selected for **Type**.



The fields and buttons used in the right hand side of the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Type	choice box		parameter types

*the type of the parameter. In this case it is **Grid**.*

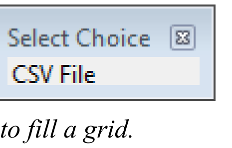
*The **Grid** icon is displayed on the left of the parameter name in the Parameter list under the Parameter node.*

Name	text box		

the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the **Write** *button is pressed.*

CSV mode	choice box		

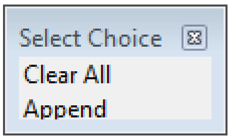


*if **CSV file**, a CSV (comma separated value) file, which defines the values to fill a grid.*

Grid parameter file	file box		all files in working area

the name of the CSV file.

Modify mode choice box



*if **Clear All**, all the existing values in the grid are deleted and are replaced by those in the CSV file.*

*If **Append**, any existing value in the grid in the panel that has the same name as one in the CSV file is replaced by the one in the CSV file. All values in the CSV file that do not already exist in the grid in the panel are added to the grid in the panel.*

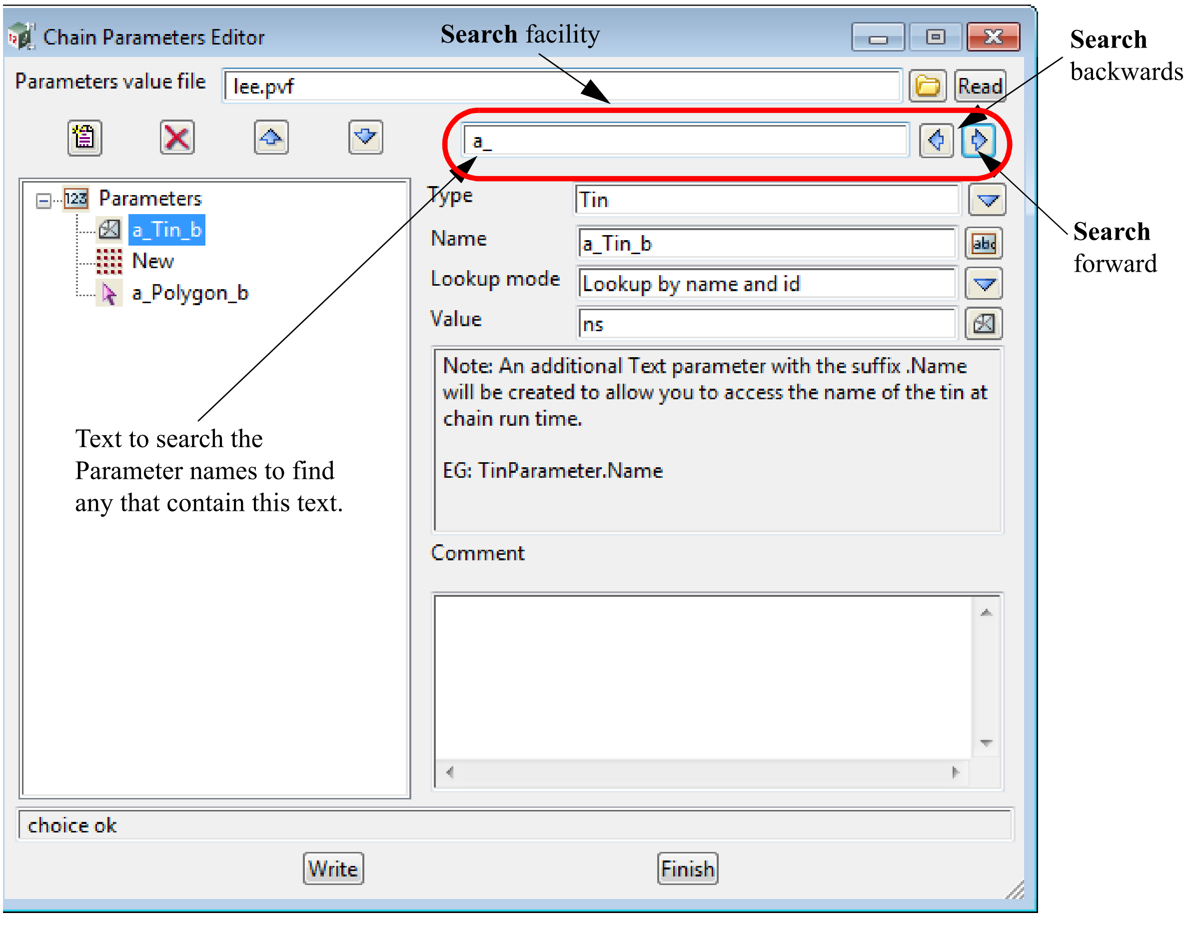
Comment comment box

user comments to be stored with the parameter.

Return to 28.3.5.2.1 Inserting a Parameter.

28.3.5.2.2 Searching for Parameter Values

The **Chain Parameters Editor** panel has a search facility to find any parameter names that contain some user given text.



Text is entered into the search field and if the button for:

Backward search is pressed then the parameter names are searched backwards from the current highlighted node until a name containing the text is found. The parameter node of the found name is highlighted so that information for it is displayed in the right had side of the panel. The search stops when the beginning of the parameter nodes is reached.

Forward search is pressed then the parameter names are searched forward from the current highlighted node until a name containing the text is found. The parameter node of the found name is highlighted so that information for it is displayed in the right had side of the panel. The search stops when the end of the parameter nodes is reached.

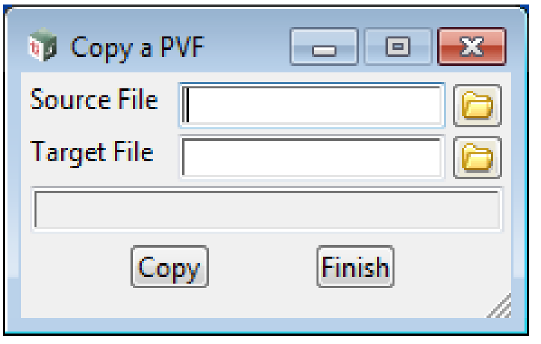
Return to 28.3.5.2 Editing a Chain Parameters Value File.

28.3.5.3 Copy a PVF

Position of option on menu: **Utilities =>Chains =>Parameters=>Copy**

Copy a PVF is used to copy a ***Chain Parameter Value File***.

Selecting **Copy** brings up the **Copy a PVF** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Source File	file box		available *.pvf files
the original PVF file to copy.			
Target File	file box		available *.pvf files
the name of the new copied PVF file.			
Copy	button		
copies the PVF file.			

Continue to the next section 28.3.5.4 Running Chains from User Menus and Toolbars or return to 28.3.5 Creating/Editing Parameter Value Files.

28.3.5.4 Running Chains from User Menus and Toolbars

Chain can be run from a user menu or a user toolbar by using the **Command**:

Command "chain *chain_file_name*"

where *chain_file_name* is the name of the chain.

For User Menus and Toolbars, it is also possible to **substitute** the name of the **parameter value file (pvf)** to use for the chain *chain_file_name* **in place of the pvf mentioned in the chain** *chain_file_name* itself.

The command is

Command "chain *-pvf pvf_file_name chain_file_name*"

where ***pvf_file_name*** is the name of the **pvf** file to use when the chain *chain_file_name* is run from this User Menu or Toolbar.

Note that the

-pvf *pvf_file_name*

is still inside the double quotes (").

Using the ***-pvf*** means that the one base chain can be easily used in user menus and toolbars but with different pvf files.

For example, the chain *ADAC_Survey_base.chain* occurs many times in the "ADAC Survey 4.0 Chains" menu but each time it is run with a different pvf file.

```
Menu "ADAC BRC 4.0 Chains" {
   Button "BRC Survey to ADAC 40 chain" {
      Command "chain -pvf $USER/BRC/ADAC_BRC_40.pvf $LIB/ADAC_survey_base.chain"
   }
   Button "BRC Design to ADAC 40 chain" {
      Command "chain -pvf $USER/BRC/ADAC_BRC_40.pvf $LIB/ADAC_design_base.chain"
   }
}
```

different pvf files

Same chain ADAC_survey_base.chain Run but With Different pvf Files

For more information on User Menus and User Toolbars, see 41.2 User Defined Menus and 41.3 User Defined Toolbars in the Appendix 41 Functions Keys, Menus, Toolbars.

Continue to the next section 28.3.5.5 Chain Parameters as Macro (12dPL's) Arguments or return to 28.3.5 Creating/Editing Parameter Value Files.

28.3.5.5 Chain Parameters as Macro (12dPL's) Arguments

When the Chain Command

Execution >Macro

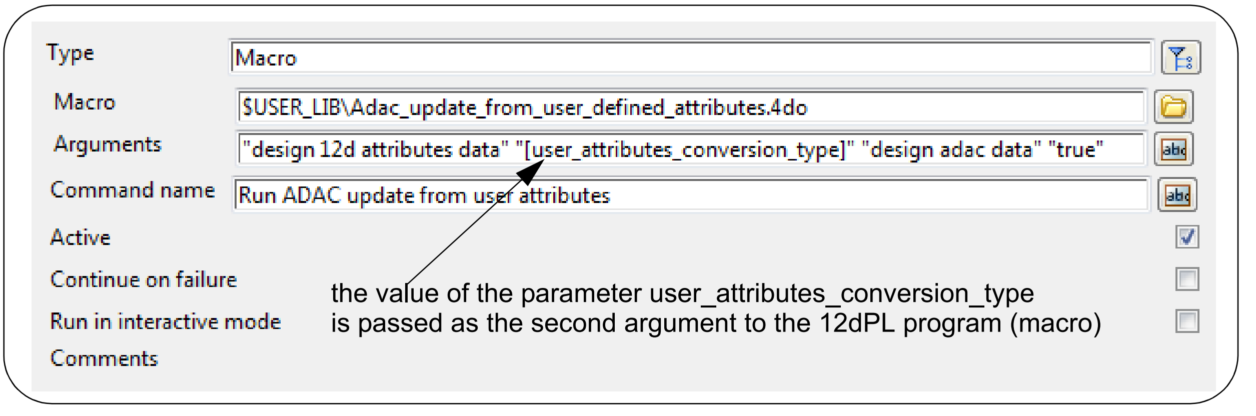
is used to run a 12dPL program (also known as 12PL's or ***12d Model*** macros), the **value** of a **Chain parameter** can be used as an argument passed to a 12dPL program.

This is done via the **Arguments** field in the Macros Command.

The Parameter Name is enclosed in square brackets (**[** and **]**) and then surrounded by double quotes (")

"[parameter_name]"

and this is entered in the **Arguments** field in the place of the argument that it replaces.



For information on the chain command **Macro**, see 28.3.1.1.2.5 Execution >Macro.

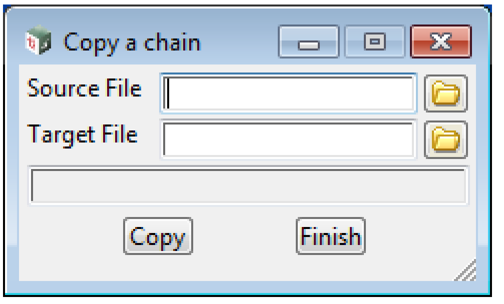
Return to 28.3.5 Creating/Editing Parameter Value Files or 28.3 Chains.

28.3.6 Copy a Chain

Position of option on menu: **Utilities =>Chains =>Copy**

This option copies a chain.

Selecting **Copy** bring up the **Copy a Chain** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Source file	file		available *.chain, *.rcn files

name of the chain to be copied.

Target file	file		

new name for the copied chain.

Copy	button		

Copy the chain.

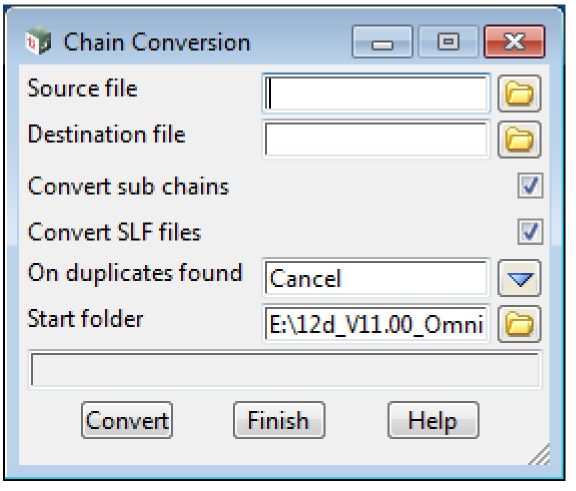
Continue to the next section 28.3.7 Chain Conversion or return to 28.3 Chains.

28.3.7 Chain Conversion

Position of option on menu: **Utilities =>Chains =>Convert**

This option converts a pre-v10 chain **rcn** file to the ***.chain*** format.

Selecting **Convert** brings up the **Chain Conversion** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Source file	file		available *.rcn files

the name of the chain in ***rcn*** *format*

Destination file	file		available *.chain files

the name converted chain in the ***.chain*** *format*

Convert sub chains tick box

if ***ticked****, all sub chains will be converted.*

if ***not ticked****, no sub chains will be converted.*

Convert SLF files

if ***ticked****, all slf files included in the chain will be converted to the new SLX format.*

if ***not ticked****, no slf files will be converted.*

Convert button

converts the source ***rcn*** *file into the new .chain file format.*

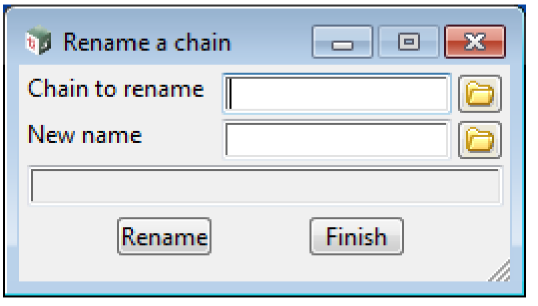
Continue to the next section 28.3.8 Rename a Chain or return to 28.3 Chains.

28.3.8 Rename a Chain

Position of option on menu: **Utilities =>Chains =>Rename**

This option renames an existing chain.

Selecting **Rename** brings up the **Rename a Chain** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chain to rename	file box		available *.chain, *.rcn files
chain to be renamed.			
New name	text box		available *.chain, *.rcn files
new name for the chain.			
Rename	button		
Change the name of the chain.			

Continue to the next section 28.3.9 Run a Chain or return to 28.3 Chains.

28.3.9 Run a Chain

Position of option on menu: **Utilities =>Chains =>Run**

Position of option on menu: **Utilities =>Recalc =>Run chain**

These options can run an existing chain and also create a new chain or edit an existing chain.

Running an existing chain on either menu can be done two ways.

The **Run** or **Run chain** walk-right menu displays all the chains in the project and double clicking on a chain in the list will run the chain.

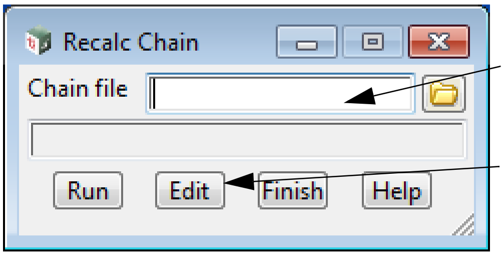
Another way of running a chain is by using the **Recalc Chain** panel that comes up by:

(a) If the menu is being displayed by walking right on **Utilities =>Chains =>Run** on the top **Main Menu** then the **Run** menu will be displaying with **[Run]** written on the top. Clicking on **[Run]** will bring up the **Recalc Chain** panel

If the menu is being displayed by walking right on **Utilities =>Recalc =>Run chain** on the top **Main Menu** then the **Run chain** menu will be displaying with **[Run chain]** written on the top. Clicking on **[Run chain]** will bring up the **Recalc Chain** panel

(b) If any of the menus getting to the **Chain** or **Recalc** menus have been torn from the top **Main Menu** then the **Recalc Chain** panel comes up by clicking on **Utilities =>Chains =>Run** without walking right or **Utilities =>Recalc =>Run chain** without walking right.

The **Recalc Chain** panel can run an existing chain, or edit an existing chain, or create a new chain.



to ***create*** a chain, type in a new name for the chain (the **.chain** will be automatically added)

Clicking on ***Edit*** brings up the **Create/Edit Chain** panel.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chain file	file box		available *.chain and *.rcn files

the name of the chain file to create/edit or run.

If the file does not exist, a new Chain of that name will be created.

Run	button		

if the chain exist then the chain will be run.

Edit	button		

if the chain exist then it will be brought up in the **Create/Edit Chain** *panel for editing.*

Position of option on menu: **Utilities =>Chains =>Edit**

Position of option on menu: **Utilities =>Recalc =>Edit chain**

Editing an existing chain on either menu can be done two ways.

The **Edit** walk-right menu displays all the chains in the project and double clicking on a chain in the list will bring up the **Create/Edit Chain** panel (see 28.3.1 Create/Edit a Chain for more information).

Another way of editing a chain is by using the **Recalc Chain** panel that comes up by:

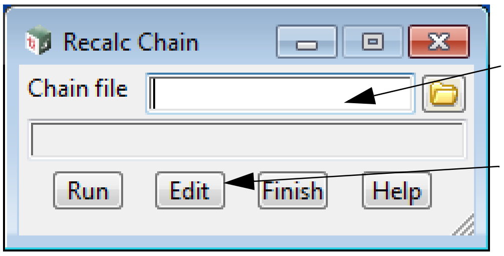
(a) If the **Chain** menu is being displayed by walking right on **Utilities =>Chains =>Edit** on the top

Main Menu then the **Edit** menu will be displaying with **[Edit]** written on the top. Clicking on **[Edit]** will bring up the **Recalc Chain** panel

If the **Chain** menu is being displayed by walking right on **Utilities =>Recalc =>Edit chains** on the top **Main Menu** then the **Edit** menu will be displaying with **[Edit chain]** written on the top. Clicking on **[Edit chain]** will bring up the **Recalc Chain** panel

(b) If the **Chain** or **Recalc** menu has been torn from the **Main Menu** on the top then the **Recalc Chain** panel comes up if you click on **Utilities =>Chains =>Edit** without walking right or **Utilities =>Recalc =>Edit chain** without walking right.

The **Recalc Chain** panel can edit an existing Chain or create a new chain.



to ***create*** a chain, type in a new name for the chain (the **.chain** will be automatically added)

Clicking on ***Edit*** brings up the **Create/Edit Chain** panel.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chain file	file box		available *.chain, *.rcn files

the name of the chain file to create.

Run	button		

if the chain exist then the chain will be run.

Edit	button		

if the chain in **Chain file** *exist then it will be brought up in the* **Create/Edit Chain** panel for editing.

If the chain in **Chain file** *does not exist then it is created and then brought up in the* **Create/Edit Chain** panel for editing.

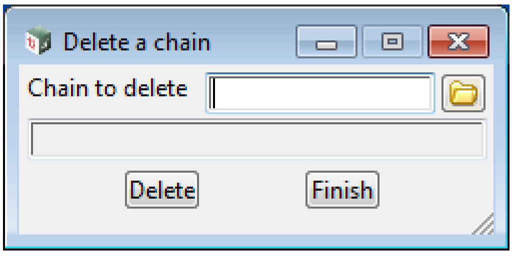
Continue to the next section 28.3.10 Delete a Chain or return to 28.3 Chains.

28.3.10 Delete a Chain

Position of option on menu: **Utilities =>Chains =>Delete**

This option deletes a chain.

Selecting **Delete** brings up the **Delete a Chain** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Chain to delete	folder box		available *.chain,*.rcn files

name of the chain to delete.

Delete	button		

delete the chain given in the **Chain to delete** *field.*

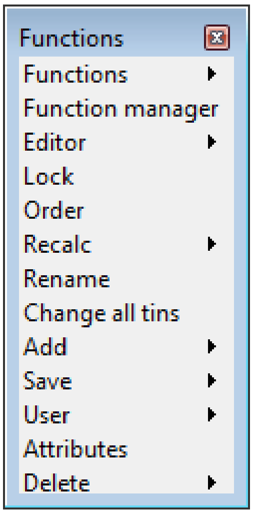
Return to 28.3 Chains.

28.4 Functions

Position of menu: **Utilities =>Functions**

Functions are used in the template and interface options to collect special data together. This allows 12d Model to recognise when some of the data has been modified and that some of the data is no longer valid. It is then possible to re-run the functions (re-calc the functions) and update the modified data.

The **Functions** walk-right menu is



list of functions in the project

modify an existing function
lock a function so it won't recalc
modify the recalc order of functions
recalculate functions
rename a function
change the name of tins in functions
add functions to the project
save a functions to disk

edit attributes of a function
delete functions from disk

The **Functions** walk-right simply lists all the functions that have been defined in the project. The other options in this menu will now be described in more detail.

For the option *Editor*, go to	28.4.1 Editor
Lock	28.4.2 Lock
Order	28.4.3 Order
Recalc	28.4.4 Recalc
Rename	28.4.5 Rename
Change all tins	28.4.6 Change all Tins
Add	28.4.7 Add
Save	28.4.8 Save
Attributes	28.4.9 Attributes
Delete	28.4.10 Delete
Delete many	28.4.10.2 Delete Many Functions

28.4.1 Editor

On walking right on the **Editor** menu option, a list of defined functions appears.

By selecting the highlighted name of a function to be edited, the appropriate function panel filled with the information from the selected function, is displayed

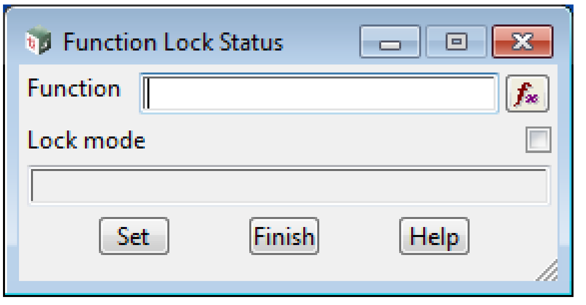
The information in the selected function can then be modified.

Important Note
The defined functions menu also has a **[Same as]** option which is used to select the function to be edited by simply picking **any string** that was created by the function.

28.4.2 Lock

Position of option on menu: **Utilities =>Functions =>Lock**

The function lock option is used to *lock* a function so that it can't be re-calculated.
On selecting the **Lock** option, the **Function Lock Status** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Function	input		available functions

name of the function to lock/unlock.

Lock model	tick box		

display and modifies the lock status for the given function.

If ticked, the function is locked an won't re-calculate.

Set	button		

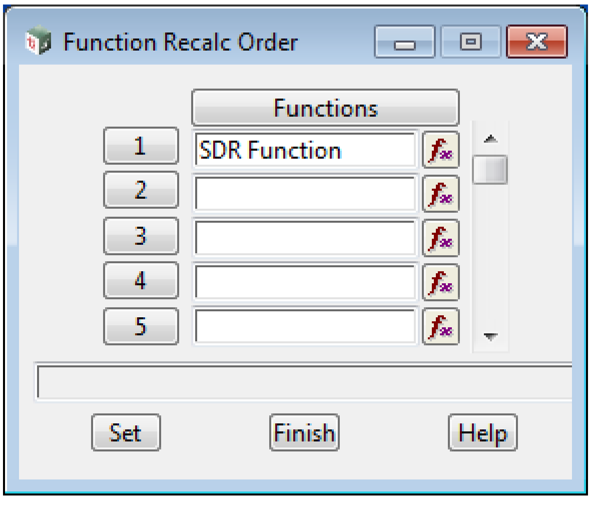
set the lock mode for the selected function.

28.4.3 Order

Position of option on menu: **Utilities =>Functions =>Order**

The default recalculation order for functions is the order in which the functions were created. However, the **Order** option is used to **modify** the function recalc order.

On selecting the **Order** option, the **Function Recalc Order** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Functions	table		available functions

list of functions in their recalculation order. Functions should only appear once in the list.

Set	button		

record the order of functions in the table.

Note - all functions must still exist somewhere in the re-arranged recalc order.

28.4.4 Recalc

Position of option on menu: **Utilities =>Functions =>Recalc**

The **recalc** menu is the same as the menu.

Utilities =>Recalc

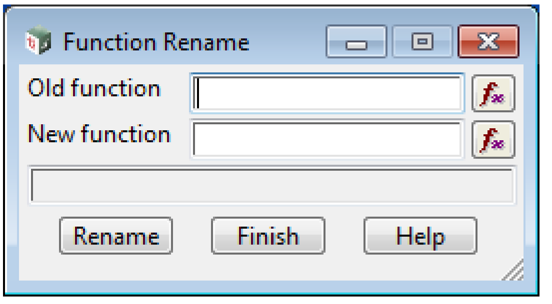
For more information, please go to the section 28.7 Recalc.

28.4.5 Rename

Position of option on menu: **Utilities =>Functions =>Rename**

On selecting the **rename** option, the **function rename** panel is displayed.

This panel can be used to change the names of existing functions



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up

Old function	input		available functions

name of the function to be renamed.

New function	input

new name for the function

Rename	button

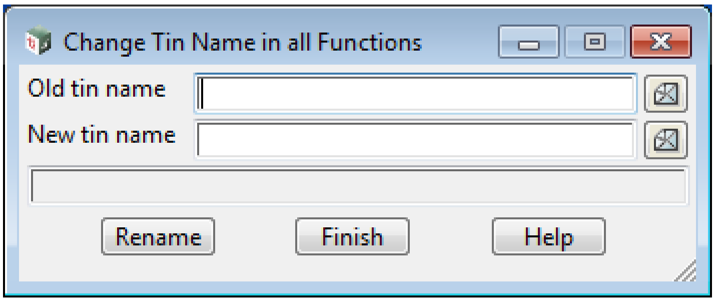
Change the name of the function in the **old function** *field to the name given in the* **new function** *field.*

28.4.6 Change all Tins

Position of option on menu: **Utilities =>Functions =>Change all tins**

Selecting the **Change all tins** option, displays the panel **Change Tin Name in All Functions**.

This panel is used to change the name of a tin in all functions to another tin name.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Old tin name	Tin box		available tins

name of the tin to be renamed.

New tin name	Tin box		available tins

new name for the tin in all functions.

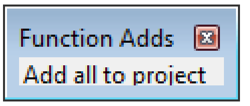
Rename button

Change the name of the tin in the **Old tin name** *field in all functions to the name given in the* **New tin name** *field.*

28.4.7 Add

Position of menu: **Utilities =>Functions =>Add**

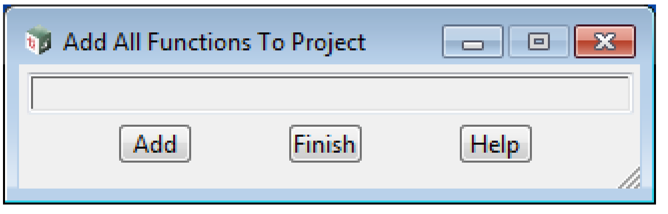
The function **add** option brings up the walk-right menu, **function adds**



Position of option on menu: **Utilities =>Functions =>Add =>Add all to project**

On selecting the **Add all to project** option, the **Add All Functions To Project** panel is displayed.

This panel is used to add all removed functions to the project.

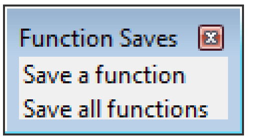


28.4.8 Save

Position of menu: **Utilities =>Functions =>Save**

Functions can be saved on disk so that they can be used for future project work.

The **Function save** walk-right menu is



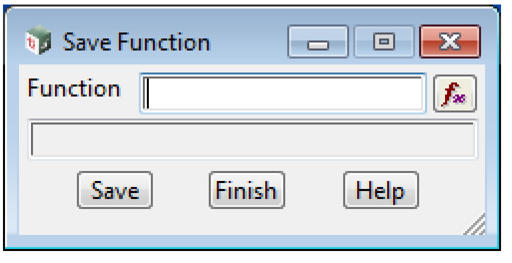
Note - Modified or new functions are automatically saved when a project is saved.

For the option Save a function, go to 28.4.8.1 Save a Function
Save all functions 28.4.8.2 Save All Functions

28.4.8.1 Save a Function

Position of option on menu: **Utilities =>Functions =>Save =>Save a function**

On selecting the **Save a function** option, the **Save Function** panel is displayed.



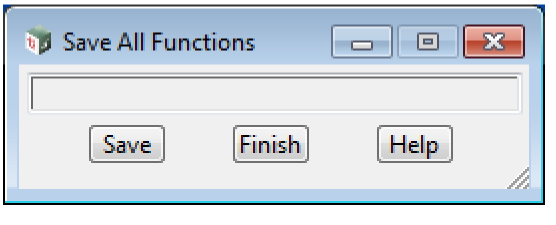
The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Function	input		available functions
name of the function to be saved.			
Save	button		
after selecting this button, the function given in the function field will be saved to disk.			

28.4.8.2 Save All Functions

Position of option on menu: **Utilities =>Functions =>Save =>Save all functions**

On selecting the **Save all** option, the **Save All Functions** panel is displayed.

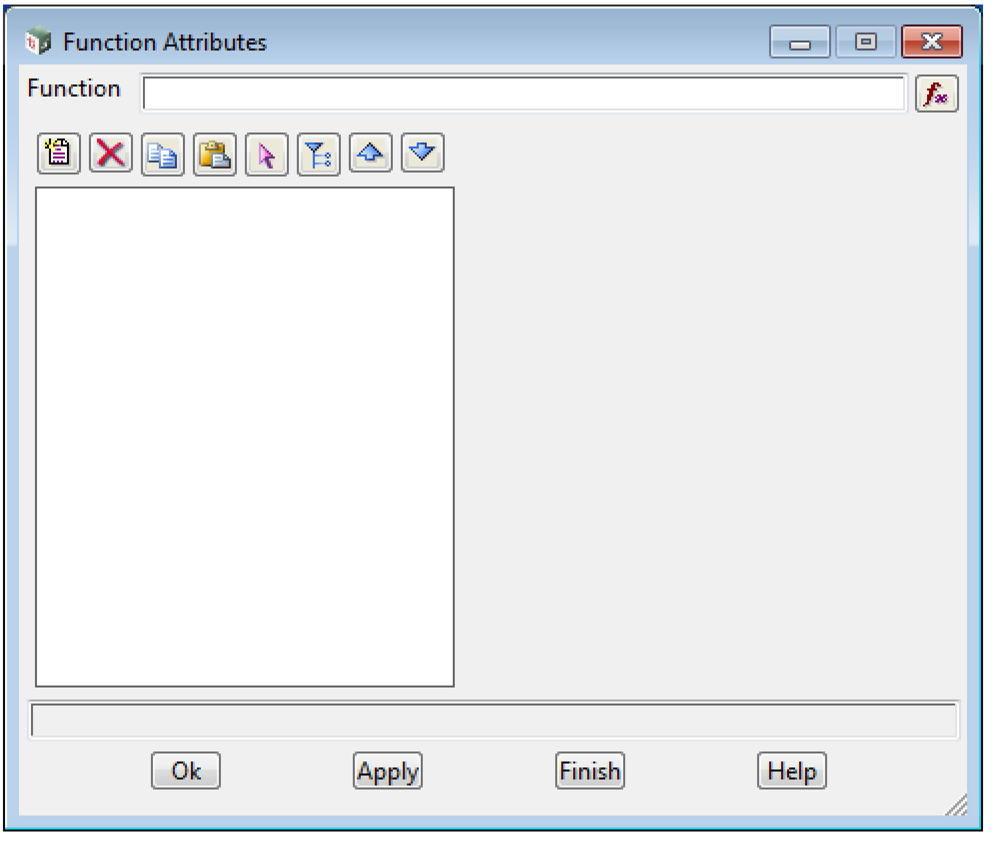


By selecting the **save** button, all functions in the working project will be saved to disk. Unless an error occurs, the panel will be removed after the saving is completed.

28.4.9 Attributes

Position of menu: **Utilities =>Functions =>Attributes**

This section of documentation is a work in progress and will be updated in subsequent releases.



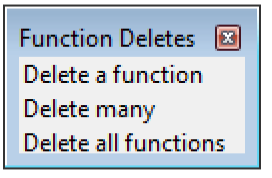
28.4.10 Delete

Position of menu: **Utilities =>Functions =>Delete**

Using the **Delete** option, functions can be deleted from disk so that they no longer can be accessed or take up disk space.

To help protect the user against disasters, when a function is selected for deletion, a **yes-no** pop-up menu is used to confirm that the user did intend deleting the function.

If deletion is confirmed, the selected function is removed from the project and deleted from the disk.
The **Function Delete** walk-right menu is



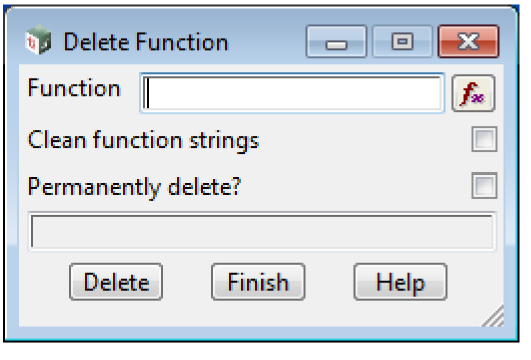
For the option *Delete a function*, go to 28.4.10.1 Delete a Function
Delete many 28.4.10.2 Delete Many Functions
Delete all functions 28.4.10.3 Delete All Functions

28.4.10.1 Delete a Function

Position of option on menu: **Utilities =>Functions =>Delete =>Delete a function**

The **Delete a function** option can be used to delete a function in the working project.

On selecting the **Delete a function** option, the **Delete Function** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Function	function box		all project functions

name of the function to be deleted.

Clean function strings	tick box		

if ***ticked****, delete all the strings created by the function*

Delete	button		

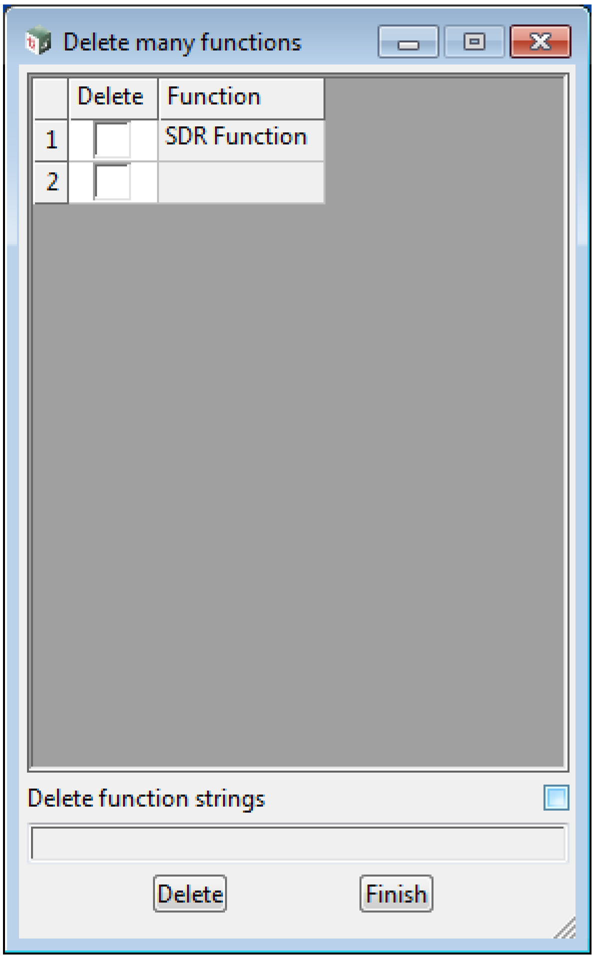
after selecting this button, the function given in the function field will be deleted from the computer disk. A **yes-no** *pop-up is used to confirm that deletion is required.*

28.4.10.2 Delete Many Functions

Position of menu: **Utilities =>Functions =>Delete many**

The **Delete many** option deletes one or more functions in the working project.

Selecting the **Delete many**, displays the **Delete many functions** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Delete	tick box		

*if **ticked**, delete the selected function listed after the tick*

Function	input		all project functions

name of all the functions in the project

Delete function strings	tick box		

*if **ticked**, delete all the strings created by the selected functions*

Delete	button		

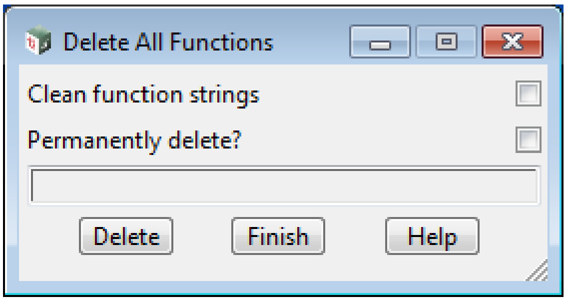
*delete all the **ticked** functions in the function field*

28.4.10.3 Delete All Functions

Position of option on menu: **Utilities =>Functions =>Delete =>Delete all functions**

The **Delete all functions** option will delete all of the functions in the working project.

On selecting the **Delete all functions** option, the **Delete All Functions** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Clean function strings	tick box		

*if **ticked**, delete all the strings created by all the function*

After selecting the **Delete** button, a **yes-no** pop-up is used to confirm that deletion is required. If it is, all functions in the working project will be deleted from disk and unless an error occurs, the panel will be removed.

28.5 Macros

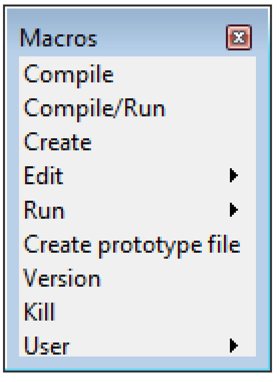
Position of menu: **Utilities =>Macros**

The 12d Solutions Programming Language (12dPL) is a powerful programming language designed to run from within 12d Model. Its main purpose is to allow users to enhance the existing 12d Model package by writing their own programs (12dPLs or macros).

12dPL programs can be compiled from within or outside 12d Model but can only be run from within 12d Model.

The Macros menu has options to compile macros, compile and run or just run macros. A full description of macros is given in the 12d Model Programming Language manual.

The **Macros** walk- right menu is



compile a macro
compile and run a macro
create a macro
edit a macro
run a macro
create file of macro prototypes
version of macro executable
terminates the running of macros

For the option *Compile*, go to	28.5.1 Compile
Compile/run	28.5.2 Compile and Run
Create	28.5.3 Create
Edit	28.5.4 Edit
Run	28.5.5 Run
Create prototypes file	28.5.6 Create Prototype File
Version	28.5.7 Version
Kill	28.5.8 Kill

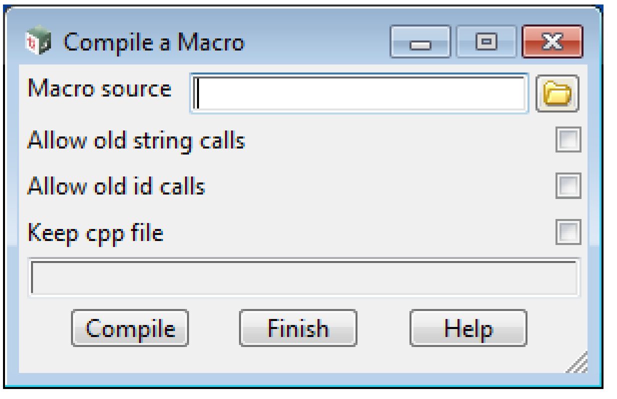
The options will now be described.

28.5.1 Compile

Position of option on menu: **Utilities =>Macros =>Compile**

The **Compile** option is used to compile the 12dPL program source code into a executable program which can then be run from within 12d Model.

On selecting the option, the **Compile a Macro** panel is placed on the screen.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Macro source	input		*.4dm files

the name of the 12dPL program (macro) source file.

Compile	button		

compile the code file given in the **Macro source** *field.*

28.5.2 Compile and Run

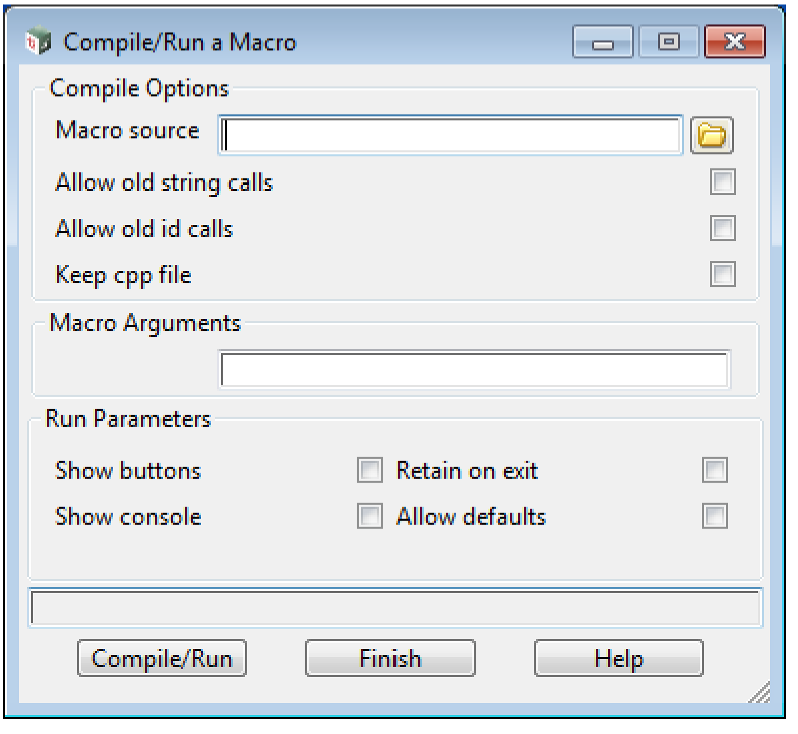
Position of option on menu: **Utilities =>Macros =>Compile/Run**

The **Compile/Run** option compiles the 12dPL program (macro) source code into a executable program, and if there are no errors, runs the program.

When a macro is run, a **macro console** panel is placed on the screen to provide an i/o and message area for the macro. It is possible to bring up the macro console with or without the **restart**, **abort** and **finish** buttons.

When the macro finishes, the macro console can be left on the screen or removed.

Selecting the **Compile/Run** menu option, brings up the **Compile/Run a Macro** panel:



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Macro source	input		*.4dm files

the name of the macro source file.

Macro arguments input

if non-blank, a text line which is passed to the program as an argument line.

Show buttons tick box

if ticked, the macro console panel has **abort**, **restart** *and* **finish** *buttons on it.*

Retain on exit tick box tick

if ticked, the macro console panel remains on the screen after the macro has finished running.

Show console tick box tick

if ticked, the macro console panel is placed on the screen.
if not ticked, the macro console panel is not displayed - used mainly with panels.

Allow defaults tick box

if ticked, the default value for a prompt is displayed in the macro console panel.

Compile/Run button

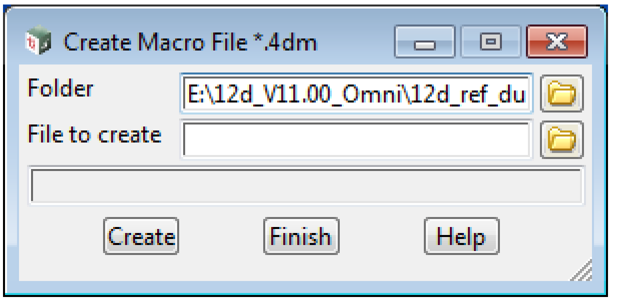
compile the code file given in the **macro source** *field and if the compile is successful, run the program.*

28.5.3 Create

Position of option on menu: **Utilities =>Macros =>Create**

The **Macros=>Create** option is used to create macro files (*.4dm) with the editor pointed to by the EDIT_4D environment variable.

Selecting **Macros=>Create** brings up the **Create Macro File *.4dm** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Folder	input	current folder	

name of the folder to create the .4dm file in.

File to create	input		*.4dm files

name of the file, in **folder***, to create.*

Create	button		

create the file given by the **folder** *and* **file to create** *panel fields. A macro header is set up in the file.*

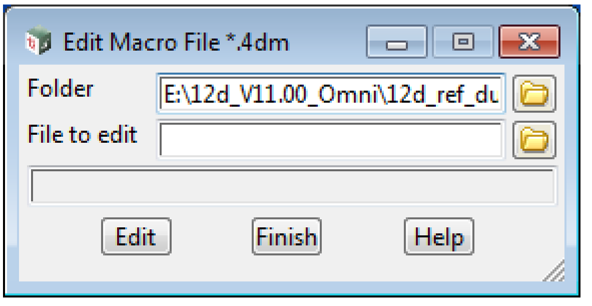
28.5.4 Edit

Position of option on menu: **Utilities =>Macros =>Edit**

The **Macros=>Edit** option is used to edit macro files (*.4dm) with the editor pointed to by the EDIT_4D environment variable.

The **Macros=>Edit** option has two modes of operation - selecting the **macros=>edit** itself, or by activating the **Macros=>Edit** option's walk-right menu, **folder *.4dm**.

Selecting **Macros=>Edit** itself brings up the **Edit Macro File *.4dm** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Folder	input	current folder	

name of the folder for the .4dm file.

File to edit	input		*.4dm files

name of the file, in **folder***, to edit.*

Edit	button		

edit the file given by the **folder** *and* **file to edit** *panel fields. If the file given in the* **file to edit** *field does not exist, then a new file is created which already has each of the macro header set up.*

The **Macros=>Edit** walk-right menu provides a list all the many template files (files ending in .mtf) in the current folder. When a file is selected from the list, it is automatically loaded into the editor.

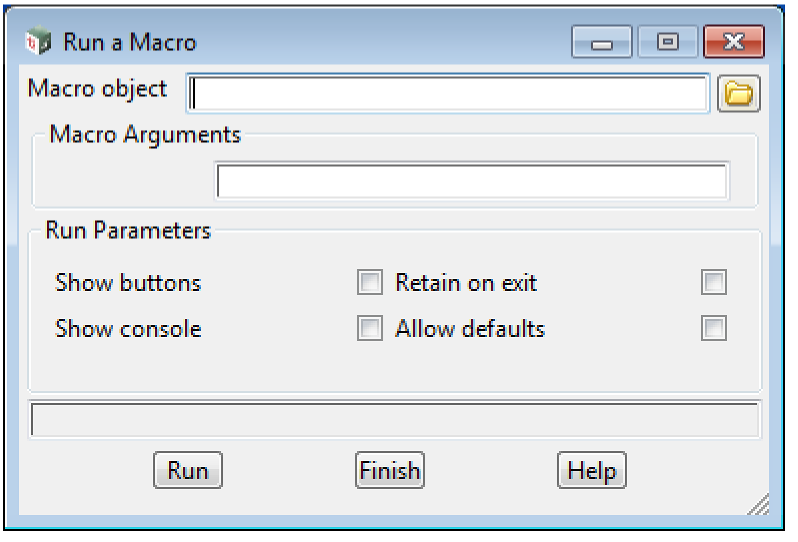
28.5.5 Run

Position of option on menu: **Utilities =>Macros =>Run**

The **Run** option runs an existing macro executable program (produced by the compile process).

Like the **Compile/Run** option, the Run options can run the macro executable with or without buttons on the macro console, and leave or remove the macro console once the macro has been executed.

Selecting the **Run** menu option brings up the **Run a Macro** panel



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Macro object	input		*.4dm files

the name of the macro object or executable program.

Macro arguments	input		

if non-blank, a text line which is passed to the program as an argument line.

Show buttons	tick box		

if ticked, the macro console panel has **abort**, **restart** *and* **finish** *buttons on it.*

Retain on exit	tick box		tick

if ticked, the macro console panel remains on the screen after the macro has finished running.

Show console	tick box	tick	

if ticked, the macro console panel is placed on the screen.
if not ticked, the macro console panel is not displayed - used mainly with panels.

Allow defaults	tick box		

if ticked, the default value for a prompt is displayed in the macro console panel.

Run	button		

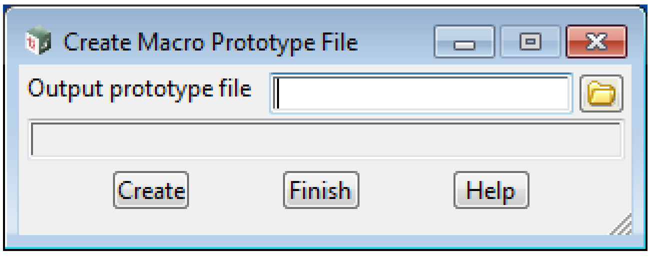
run the executable given in the **macro object** *field.*

28.5.6 Create Prototype File

Position of option on menu: **Utilities =>Macros =>Create prototype file**

The **Create prototype file** option creates a list of the function prototypes for all the ***12dPL*** functions in the ***12d Programming Language*** compiler that is available on your computer.

Selecting the **Create prototypes file** brings up the **Create Macro Prototype File** panel



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Output prototype file	File Box		*.txt files

the name of the file to write the macro function prototypes out to.

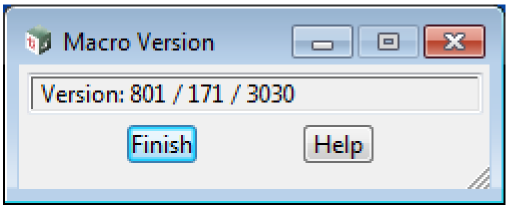
Create	button		

create the file of macro function prototypes.

28.5.7 Version

Position of option on menu: **Utilities =>Macros =>Version**

The **Version** option simply brings up a panel giving information about the macro process.



28.5.8 Kill

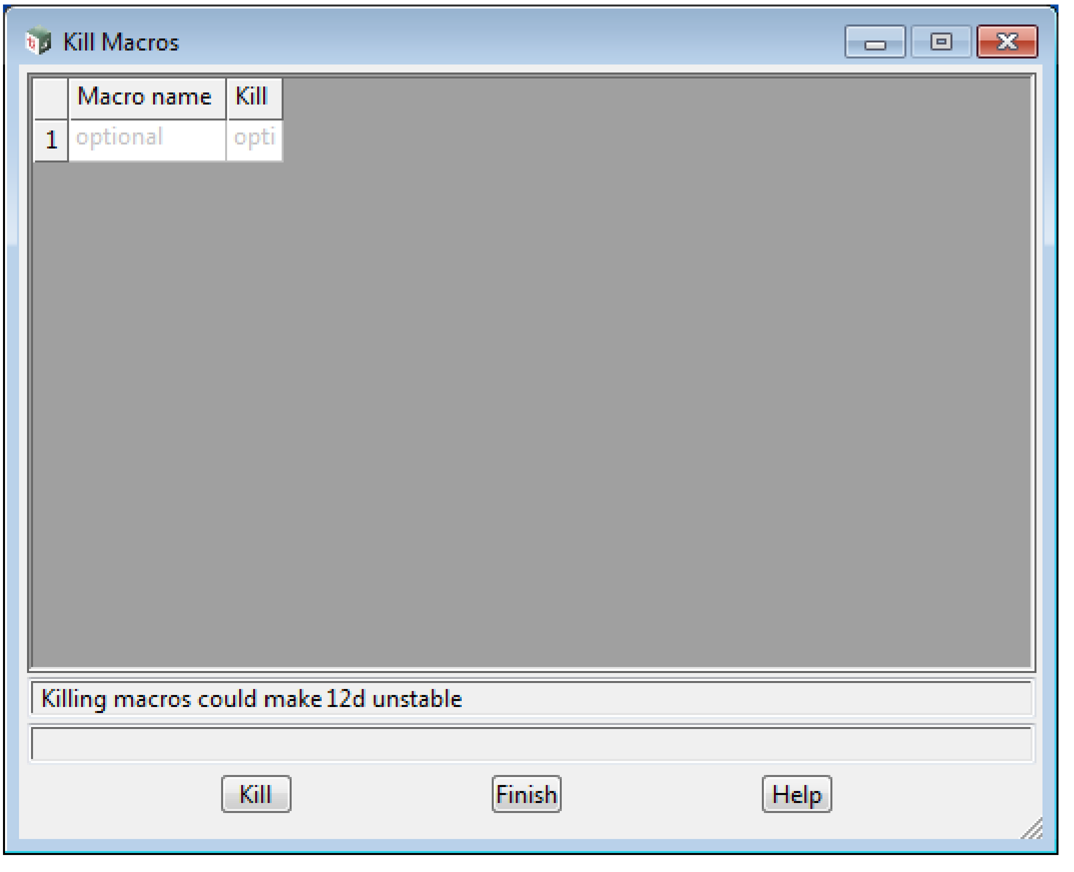
Position of option on menu: **Utilities =>Macros =>Kill**

The **Kill** option is used to terminate selected running macros.

This option is useful in situations such as when the macro writer has omitted a **Finish** button on the macro or has unintentionally made the macro panel invisible.

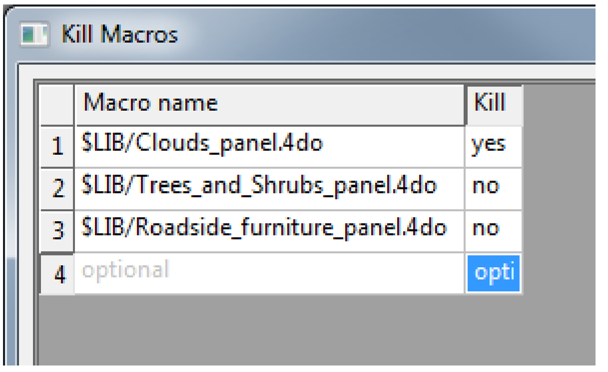
It cannot be used to terminate a macro in an infinite loop because there is no way of getting to the **Kill** option.

On selecting **Kill**, the **Kill Macros** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Macro Grid			
Macro name			
the name of a running macro.			
Kill	choice cell	yes	yes, no
*if **yes**, the macro will be terminated when the **Kill** button is selected.*			



Kill button

*terminates all macros in the grid with **yes** in the* **Kill** *column.*

28.6 Measure

Position of menu: **Utilities =>Measure**

The **Measure** menu contains two options to display the

delta x, delta y, horizontal distance, angle and bearing

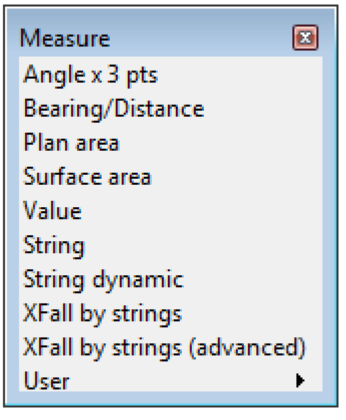
between points, and for a section view, the

delta chainage, delta height, slope distance and % grade

between points are calculated and displayed.

There are also options to calculate the plan area of polygons, the surface area of a tin within a polygon, run measures and dynamic measures and dynamically calculate and display the x-fall between two strings.

The **Measure** walk- right menu is



measure angle by 3 points
distance/bearing with scale option
plan areas
surface area for a tin
any measures
information from a point to a string
information from a position to a string
x-fall between two strings
more information & x-fall between strings

Note

The **Measure** option has another mode of operation. Rather than moving onto the walk-right arrow, if LB is clicked when the **Measure** button is highlighted on the **12d Model=>utilities** menu, the **distance/bearing** panel is displayed on the screen.

For the option *Angle x 3 pts*, go to	28.6.1 Angle by 3 Points
Bearing/distance	28.6.2 Bearing and Distance
Plan area	28.6.3 Plan Area
Surface area	16.11.4 Surface Area
Value	28.6.5 Value
String	28.6.6 String
String dynamic	28.6.7 String Dynamic
Xfall by strings	28.6.8 X Fall by Strings
Xfall by strings (advanced)	28.6.9 X Fall by Strings (Advanced)

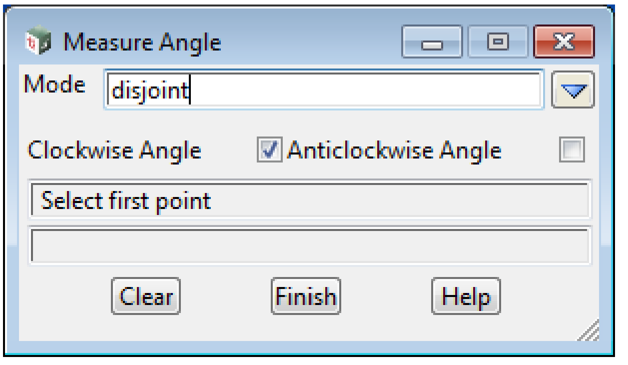
The options in the menu will now be described.

28.6.1 Angle by 3 Points

Position of option on menu: **Utilities =>Measure =>Angle x 3 pts**

The **Angle by 3 pts** option is used to calculate the angle formed by selected three positions. the angle can be expressed as a clockwise or anti-clockwise angle.

On selecting the **Angle x 3 pts** option, the **Measure Angle** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Mode	input	disjoint	disjoint, continuous

In disjoint mode, only the angle between the three selected positions is reported. After the angle is reported, the user can select the 1st point in the sequence.

In continuous mode, after the initial reporting of the angle, the user is prompted for the 3rd point of the new angle to be measured. By default, the previous 2nd point becomes the first point and the previous 3rd point becomes the 2nd point. This allows just one point (the third point) to be selected and the angle reported will change accordingly.

Clockwise angle tick box

if ticked, then the angle is measured in the clockwise (forward) direction.

Anti-clockwise angle tick box

if ticked, then the angle is measured in the anti-clockwise direction.

Clear button

when this button is selected, the sequence is re-initialised.

Note - after two positions are selected, the angle to the cursor position is dynamically calculated and displayed as the cursor moves around the view.

28.6.2 Bearing and Distance

Position of option on menu: **Utilities =>Measure =>Bearing/Distance**

The **Bearing/Distance** option is used to calculate

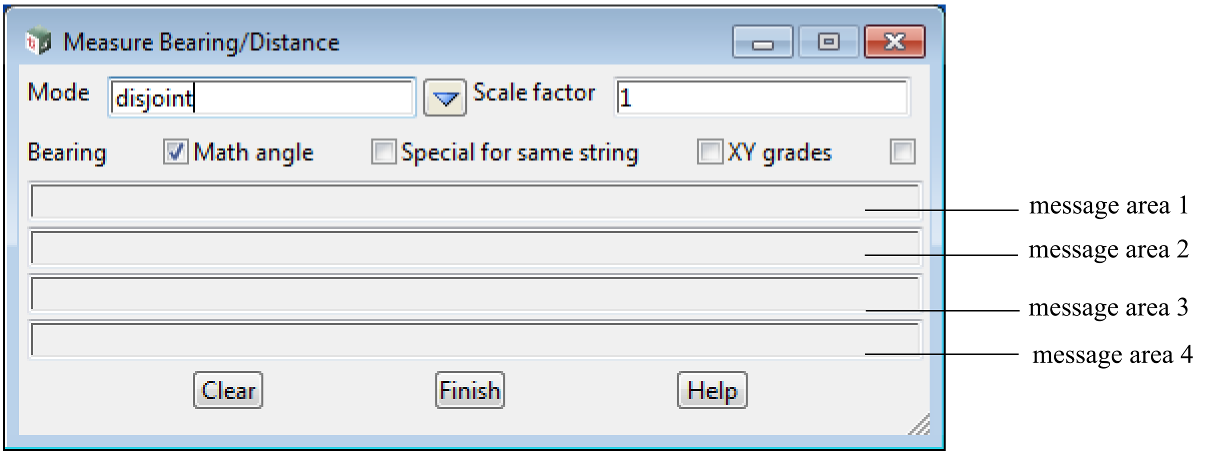
(a) the bearing measured in a clockwise direction between the positive y-axis and the (imaginary) line joining two selected points (when the bearing tick box is selected)

or

the bearing measured in an anticlockwise direction between the positive x-axis and the (imaginary) line joining two selected points (when the **Math angle** tick box is selected)

(b) the distance between two user selected points.

On selecting the **Bearing/Distance** option, the **Measure Bearing/Distance** panel is displayed.



This panel is principally used to display the distances between, and bearing of the line joining, pairs of user selected points.

message area 1 : brg = plane dist = ellipsoid dist =

where brg is the angle measured clockwise from north and is calculated using the coordinate values (Inverse value)

plane dist is the distance calculated using the coordinate values (Inverse value)

ellipsoid dist is the distance calculated by dividing the plane distance by the current scale factor

message area 2: dx = dy = dht = (if applicable)

where dx is the difference in x value between the two coordinates

dy is the difference in y value between the two coordinates

dz is the difference in z value between the two coordinates

If valid height values exist for two consecutive points the grade and slope is also reported

message area 3: grade % = slope =

If the measurement mode is set to continuous, the sum distances will be shown for the route taken

message area 4: Sum plane dist = Sum ellip dist =

where Sum plane dist, is the accumulative length of the route taken calculated using plane distances.

Sum ellip dist, is the Sum plane dist / scale factor.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Mode	input	disjoint	disjoint, continuous

In disjoint mode, only the distance between the two points and the bearing (in degrees, minutes and seconds) of the (imaginary) line connecting the two points are displayed.

In continuous mode, after the initial reporting of the bearing/distance, the user is prompted to select the next point (2nd point). In this case the previously selected second point becomes the first point.

Scale	input/output	1.0	

the scale factor which will be used to convert plane distances to ellipsoid distances.

i.e ellipsoid distance = plane distance / scale factor

Bearing	tick box	ticked	

if ticked, the measured vectors can be displayed as bearings (angles measured from north, clockwise)

Math angle	tick box	un-ticked	

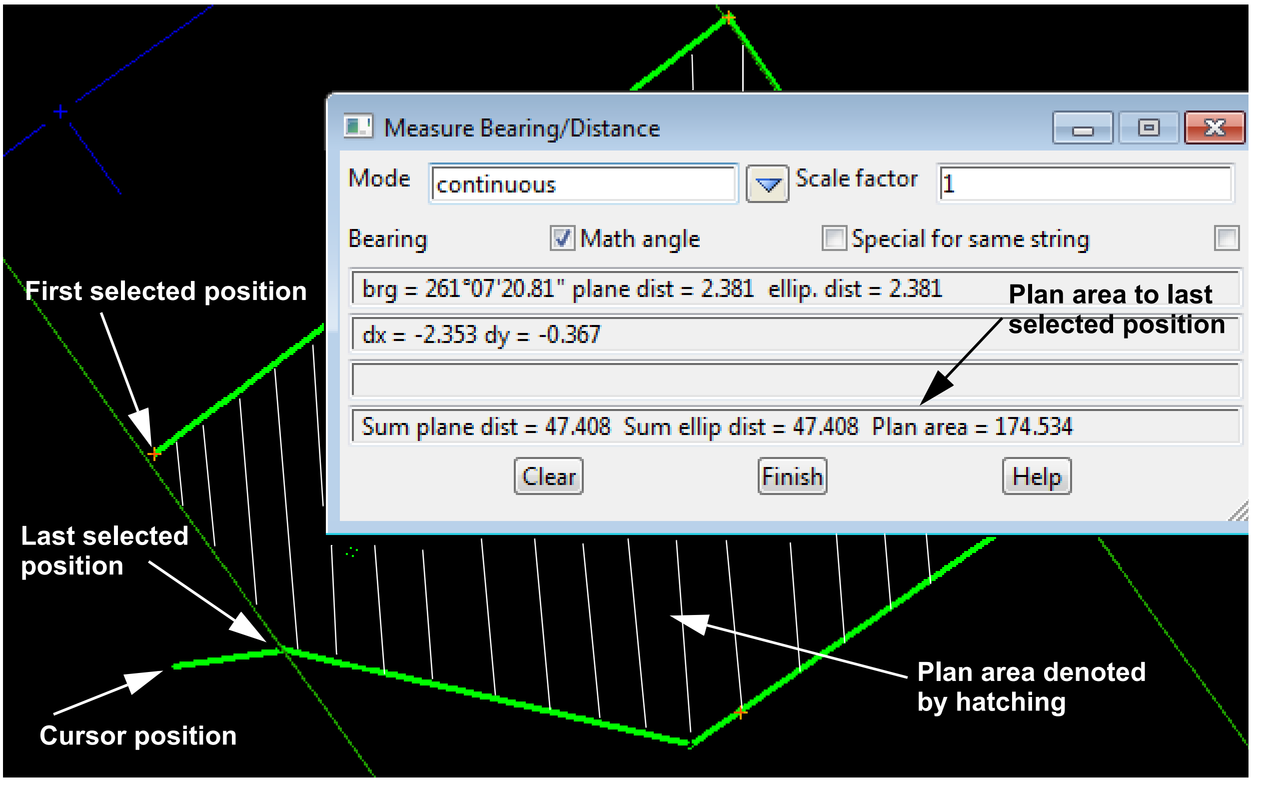
if ticked, the measured vectors can be displayed as a mathematical angle (measured from east in a anti-clockwise direction.

Clear	button		

when this button is selected, the selection sequence is re-initialised.

Note

when in **continuous** mode, each time the next screen position is added to the highlighted figure, the **plan area** is calculated for the closed figure that is constructed by joining the first and last selected screen positions.



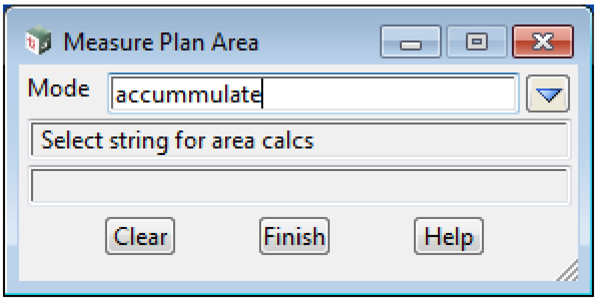
28.6.3 Plan Area

Position of option on menu: **Utilities =>Measure =>Plan area**

The **Plan area** option is used to calculate the plan areas enclosed by strings.

If a string is not closed, the first and last points are considered to be connected to form a polygon.

On selecting the option, the **Measure Plan Area** panel is placed on the screen.



This panel is principally used to display the plan areas of strings selected by the user.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Mode	input	disjoint	disjoint, continuous

*If **disjoint**, only the area of the selected string is displayed. If **continuous**, the total of the areas is also displayed.*

Clear	button

when this button is selected, the total-to-date of the area is reset to zero and the selection sequence begun.

How to Use the Panel and Panel Messages

The measure area cycle consists is as follows:

(a) the string is selected with the mouse.

message area 1	select string for area calcs
message area 2	

(b) repeat step (a) to find more areas and accumulate them. If the accumulator is to be zeroed, simply select the **clear** button again.

The area of the selected string is displayed in message area 2.

If the mode is set to continuous, the accumulated areas (sum) of the selected strings is also displayed.

message area 1	select string for area calcs
message area 2	area = *value* sum = *value*

The cycle can then be repeated for as many strings as needed without leaving the option.

The accumulated total is reset to zero (cleared) by selecting the **clear** button again.

28.6.4 Surface Area

Position of option on menu: **Utilities =>Measure =>Surface area**

The **Surface area** option calculates and reports the surface area of a tin restricted to a user specified polygon.

This option has already been documented as **Tins=>Tin analysis=>Surface area.**

See the section 16.11.4 Surface Area.

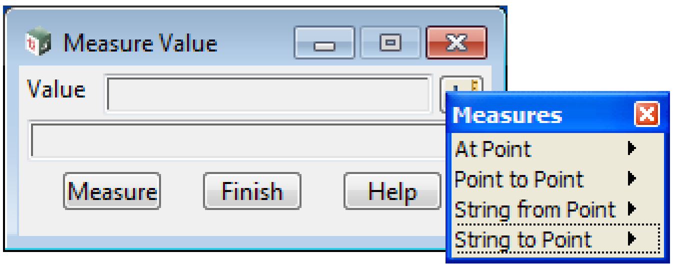
28.6.5 Value

Position of option on menu: **Utilities =>Measure =>Value**

The **Value** option is used to calculate and display any of the measures available in the **Measures** pop-up menu.

The **Measures** are documented under 4.21 Measures.

On selecting the option, the **Measure Value** panel and the **Measures** menu are placed on the screen.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Value	output		

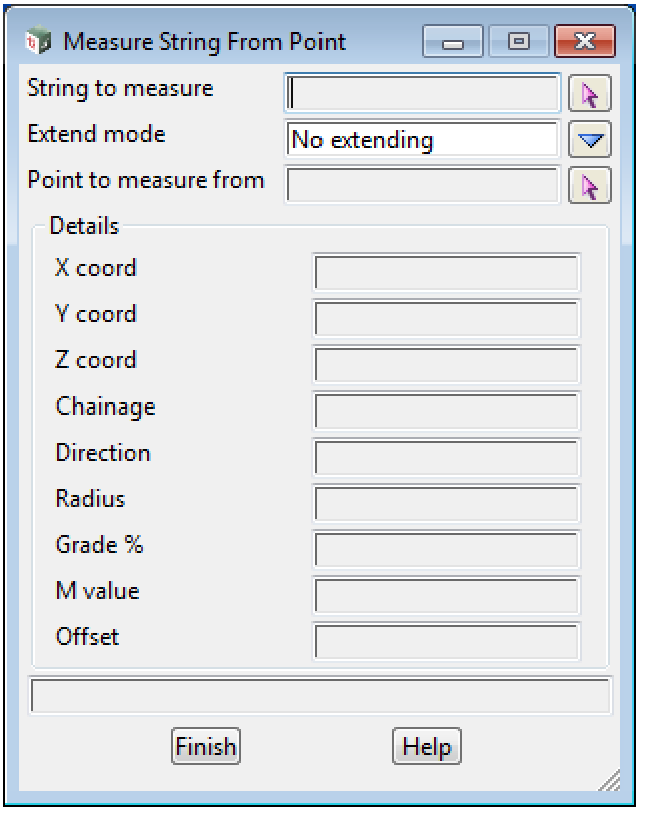
the value calculated by the selected measure option.

28.6.6 String

Position of option on menu: **Utilities =>Measure =>String**

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting **String**, the **Measure String From Point** panel is placed on the screen.

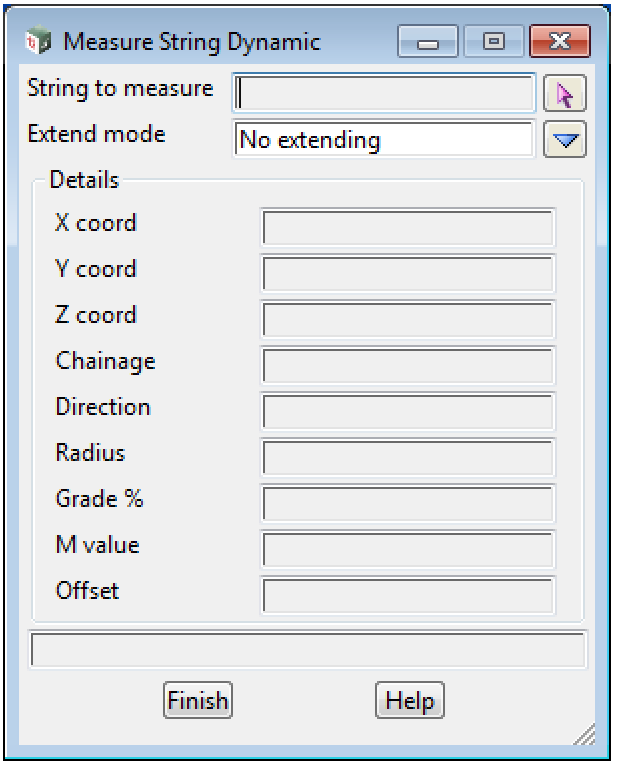


28.6.7 String Dynamic

Position of option on menu: **Utilities =>Measure =>String dynamic**

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting **String dynamic**, the **Measure String Dynamic** panel is placed on the screen.



28.6.8 X Fall by Strings

Position of option on menu: **Utilities =>Measure =>XFall by strings**

In this option, the user selects a reference string to define what is meant by chainage and right angles, and then selects two strings to calculate the x-fall between.

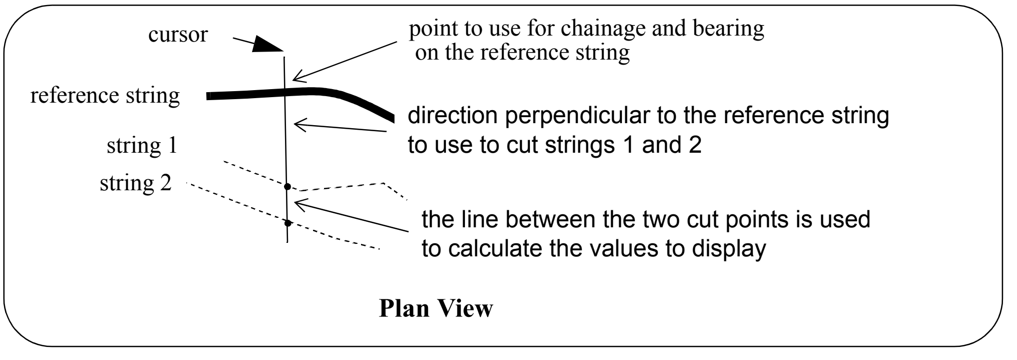
Once the three strings are selected, as the cursor moves around in a plan view, the cursor position is dropped perpendicularly onto the reference string.

At the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts the two selected strings. The xfall, delta width and delta z is then calculated between the cut points on the strings.

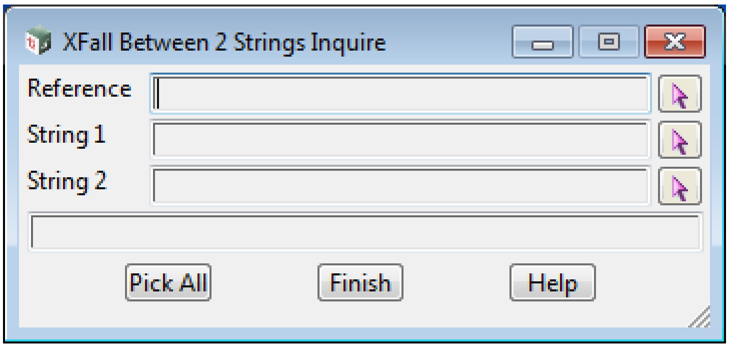
Then the chainage and the xfall are dynamically displayed in the panel message area.

The line joining the two strings is dynamically displayed on the plan view.

The chainage, xfall, delta width and delta z are dynamically displayed in the message area.



On selecting the **Xfall by strings** option, the **XFall Between 2 strings Inquire** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Reference	string-select		

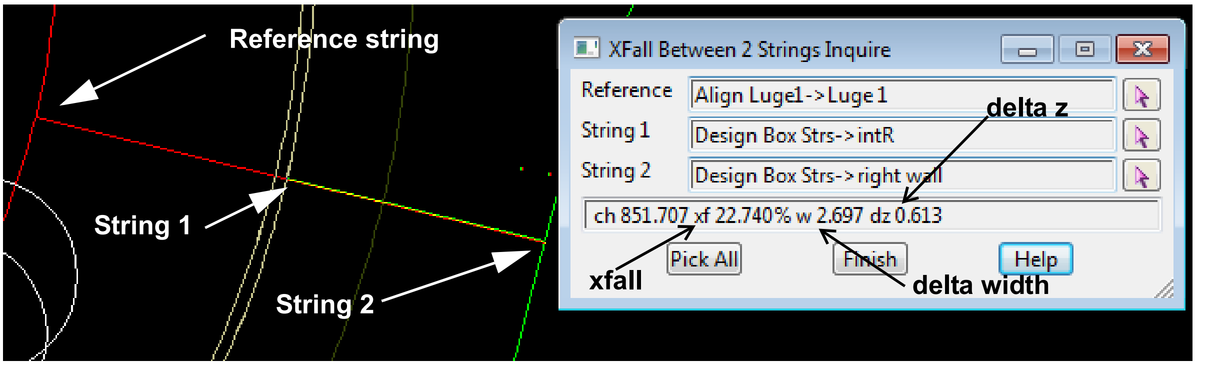
the selected string is used to defined the meaning of chainage and bearing for the inquire. The cursor is dropped perpendicularly onto the reference string and at the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts **string 1** *and* **string 2**. *The xfall, delta width and delta z between the two cut points are then calculate and displayed.*

String 1/2	string-select		

the two strings to calculate x-fall between.

Pick all	button		

if **pick all** *is selected, the user is asked to sequentially select the three strings: reference string, string 1 and string 2. The strings are automatically assigned to the appropriate string-select panel fields.*



28.6.9 X Fall by Strings (Advanced)

Position of option on menu: **Utilities =>Measure =>XFall by strings (advanced)**

In this option, the user selects a reference string to define what is meant by chainage and right angles, and then selects two strings to calculate a variety of values for the reference string and the two strings, and the differences between the values for the two strings.

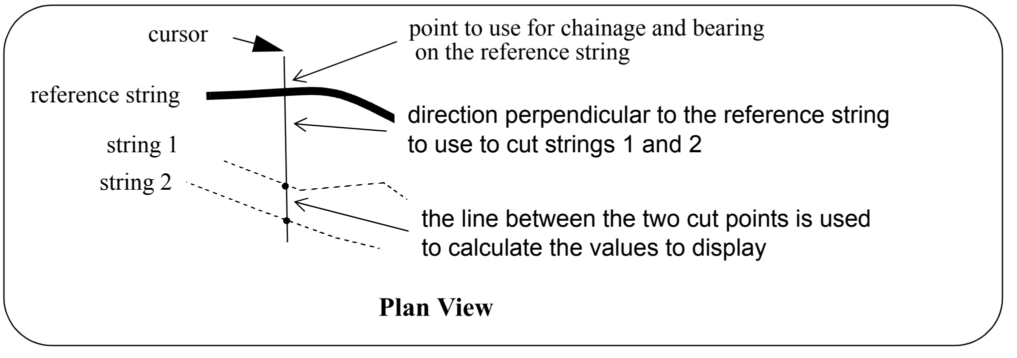
Once the three strings are selected, as the cursor moves around in a plan view, the cursor position is dropped perpendicularly onto the reference string.

At the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts the two selected strings. The xfall is then calculated between the cut points on the strings.

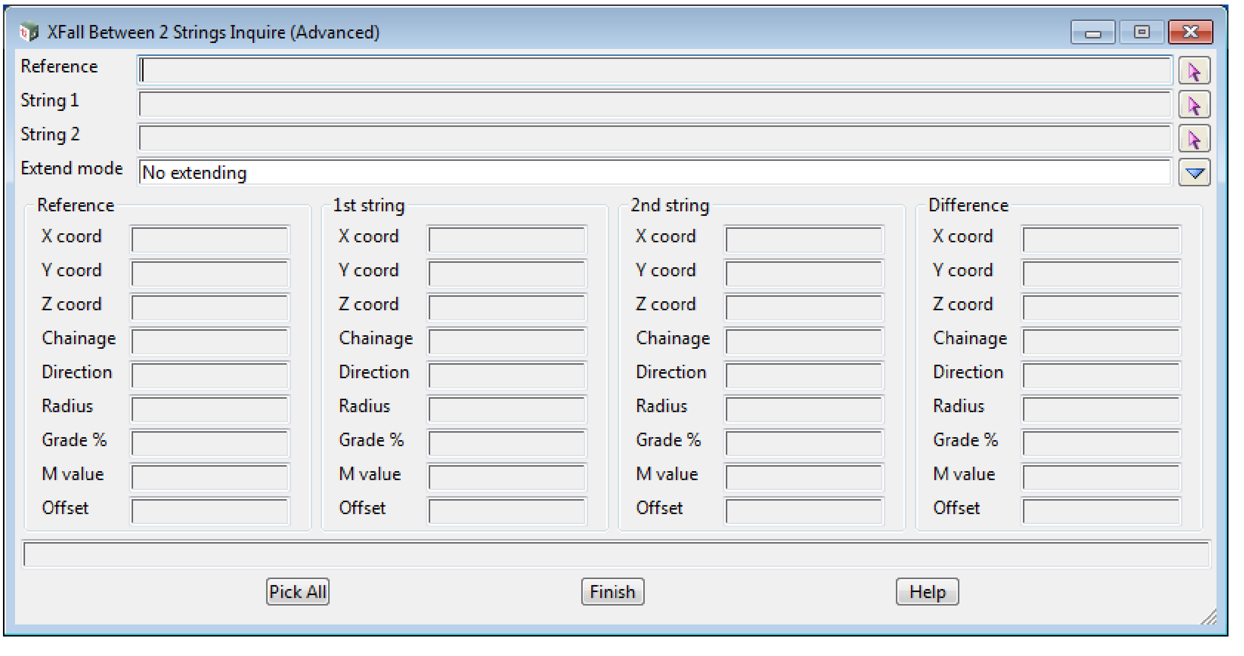
Then the chainage and the xfall are dynamically displayed in the panel message area.

The line joining the two strings is dynamically displayed on the plan view.

Various values for the cut points on the two strings, and the differences of the values between the strings dynamically displayed in the grid.



Plan View



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Reference	string-select		

the selected string is used to defined the meaning of chainage and bearing for the inquire. The cursor is *dropped perpendicularly onto the reference string and at the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts* **string 1** *and* **string 2***. The values are then calculate and displayed for the two cut points and the difference between the values of the cut points.*

String 1/2 string-select

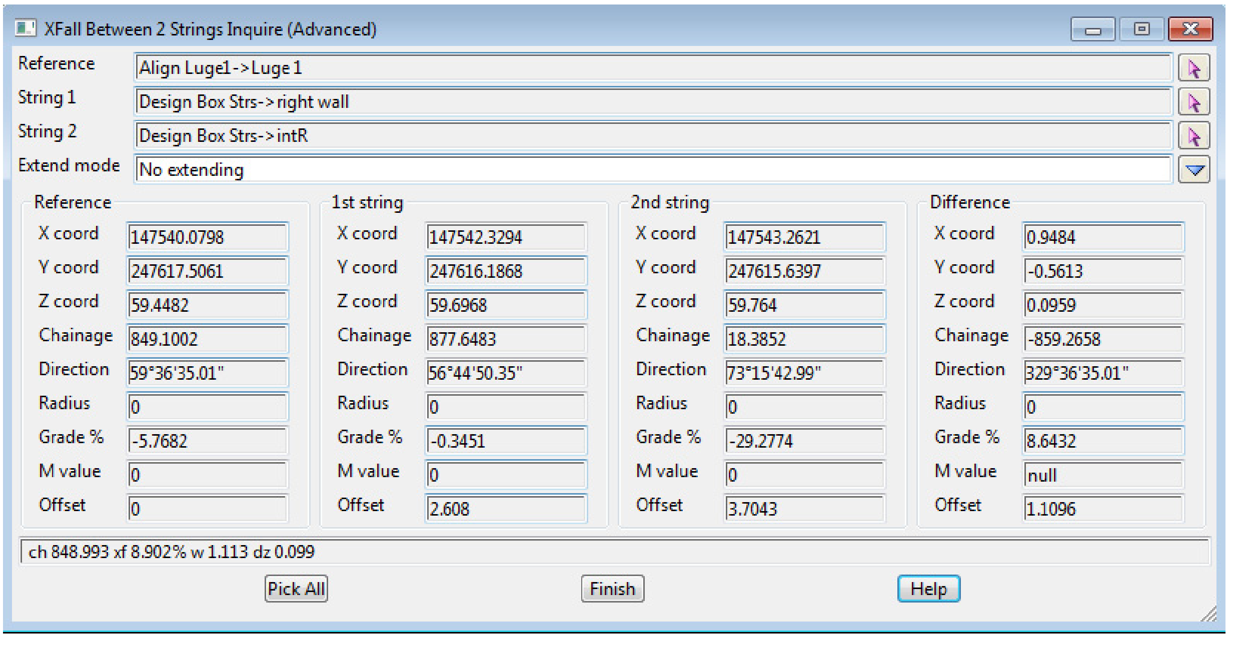
the two strings to calculate value on, and the differences between the values.

Grid output

grid to display the values or the cut point on the two strings and the differences between the values.

Pick all button

For example,



28.7 Recalc

Position of menu: **Utilities =>Recalc**

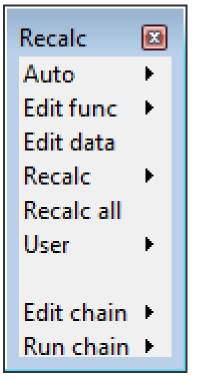
Once a function has been applied, the calculated information is only correct whilst the initial data is not modified in any way. If any modifications are made to the data, then the function must be re-run and all the associated information recalculated and redrawn, and any perspective views associated with the function set with the new eye and target positions, and redrawn.

There are date and time stamps for all string, tin and template information in 12d Model and this enables 12d Model to determine what information has been modified since a function was last run and what re-calculations are required.

The **Recalc** option is designed to **re-run** functions

If LB is clicked whilst the **Recalc** menu option is highlighted, all the template functions with **auto recalc** set **on**, and that have had their initial data modified since their last re-run, will be recalculated and all appropriate information updated. The data will be redrawn on any views that is was on before the recalc.

The **Recalc** walk-right menu has four options:



For the option *Auto*, go to 28.7.1 Auto
Edit func 28.7.2 Editor
Edit data 28.7.3 Edit Data from String
Recalc 28.7.4 Recalc
Recalc all 28.7.5 Recalc All

Edit chain 28.7.6 Edit Chain
Run chain 28.7.7 Run Chain

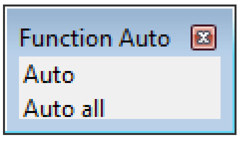
28.7.1 Auto

Position of option on menu: **Utilities =>Recalc =>Auto**

The **Auto** option allows the user to specify whether a function is automatically recalced if another function, tin, template or string that it depends upon, is modified or recalced.

Individual functions or all functions can have auto-recalc mode turned on or off and the default for a new function is **off**.

The **Function Auto** menu is

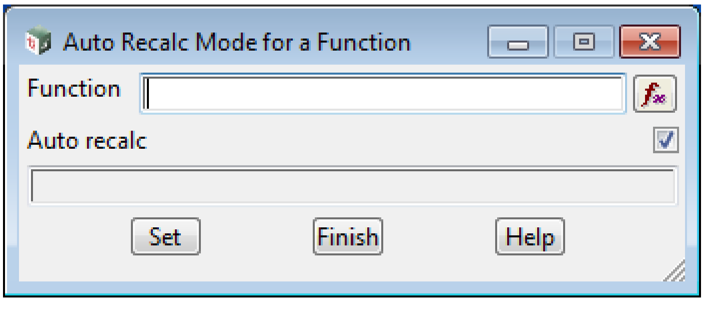


For the option Auto, go to 28.7.1.1 Auto
Auto all 28.7.1.2 Auto all

28.7.1.1 Auto

Position of option on menu: **Utilities =>Recalc =>Auto =>Auto**

Selecting **Auto** displays the **Auto Recalc Mode for a Function** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Function	input		available functions

name of the function to be have auto recalc mode set on/off.

Auto recalc	tick box	tick	

If the tick is on, the specified function will have its ***auto recalc*** *value changed to on.*

If the tick is off, the specified function will have its ***auto recalc*** *value changed to off.*

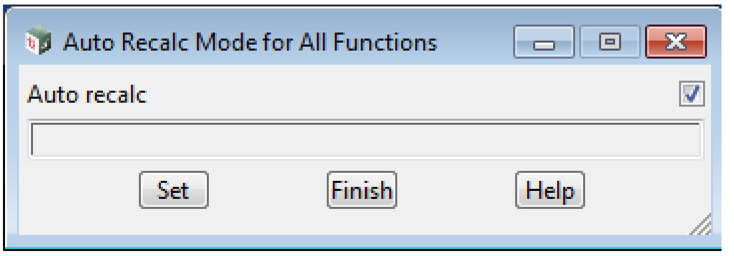
Set	button		

Set the **auto recalc** *mode for the selected function.*

28.7.1.2 Auto all

Position of option on menu: **Utilities =>Recalc =>Auto =>Auto all**

Selecting **Auto all** displays the **Auto Recalc Mode For All Functions** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Auto recalc	tick box	tick	

*If the tick is on, all functions within the project will have their **auto recalc** value changed to on.*

*If the tick is off, all functions within the project will have their **auto recalc** value changed to off.*

Note: the tick is not a global setting within 12d. The use of the option changes every function within the project.

Set	button		

Set the **auto recalc** *mode for all functions.*

28.7.2 Editor

Position of option on menu: **Utilities =>Recalc =>Editor**

The **Recalc=>Editor** option is used to edit functions.

The **Recalc=>Editor** walk-right menu provides a list all the defined functions in the project.

When a function is selected from the list, it is automatically loaded into the appropriate function panel for the selected function, and displayed

The information in the selected function can then be modified.

Important Note
The defined functions menu also has a **[Same as]** option which is used to select the function to be edited by simply picking **any string** that was created by the function. This is documented in the next section 28.7.2.1 Edit Function from String.

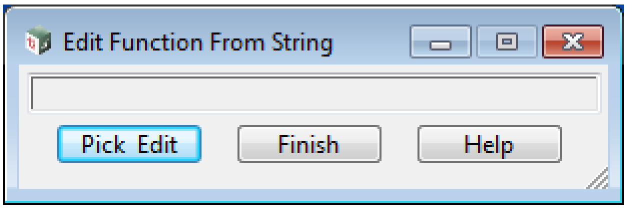
28.7.2.1 Edit Function from String

Position of option on menu: **Utilities =>Recalc =>Editor =>[Same as]**

Position of option on menu: **Utilities =>Recalc =>Recalc =>[Same as]**

The **Edit Function from String** option allows the user to start up the *Function editor* by simply selecting a string that was created by the function.

On selecting the option, the **Edit Function From String** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Pick Edit	button		

select data that was created by a function and the appropriate function editor is then opened.

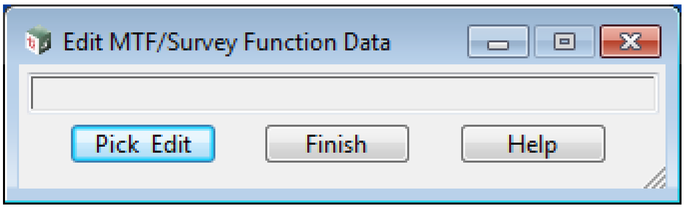
28.7.3 Edit Data from String

Position of option on menu: **Utilities =>Recalc =>Edit data**

The **Edit data** option allows the user to start up the *MTF editor* by simply selecting a string that was created using an Apply Templates function (and hence an MTF file). The MTF file used in the *Apply Templates* function is automatically loaded into MTF editor (go to 20.4.1.1 MTF Edit).

Similarly the **Edit data** option also allows the user to start up the *Survey Field Data editor* by simply selecting a string that was created using a *Survey Data Reduction* function. All the data produced by the *Survey Data Reduction* function is automatically loaded into the *Survey Field Data* editor (go to the section 17.7.5 Survey Field Data Editor).

On selecting the **Edit data** option, the **Edit MTF/Survey Function Data** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Pick Edit	button		

select data that was created by applying an MTF file or a Survey Data Reduction function. The appropriate MTF editor or Survey Field Data editor that created the selected data, is then opened.

For information on the *Survey Field Data Editor*, go to the section 17.7.5 Survey Field Data Editor.

For information on the *MTF Editor*, go to 20.4.1.1 MTF Edit.

28.7.4 Recalc

Position of menu: **Utilities =>Recalc =>Recalc**

The **Recalc** option is used to recalculate a user selected function, and all functions that depend on the function that have auto recalc set on.

The **Recalc** walk-right menu lists all the existing functions and by selecting a function name, the function will be forced to re-run and all appropriate information and views for that function will be updated.

The existing functions menu also has a **[Changed]** option which recalcs all changed functions.

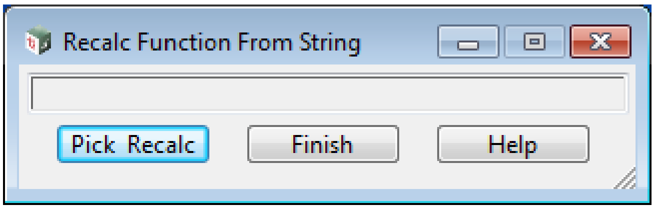
The existing functions menu has a **[Same as]** option which is used to select the function to be recalced by simply picking **any string** that was created by the function. This is documented in the next section 28.7.4.1 Recalc Function from String

28.7.4.1 Recalc Function from String

Position of option on menu: **Utilities =>Recalc =>Recalc =>[Same as]**

The **Recalc Function from String** option allows the user to recalc a function by simply selecting a string that was created by the function.

On selecting the option, the **Recalc Function From String** panel is displayed.



The fields and buttons used in this panel have the following functions.

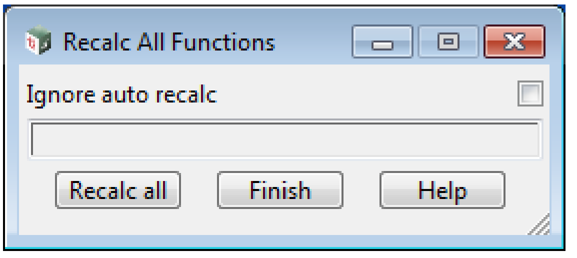
Field Description	Type	Defaults	Pop-Up
Pick Edit	button		

select data that was created by a function and the appropriate function will be recalced.

28.7.5 Recalc All

Position of option on menu: **Utilities =>Recalc =>Recalc all**

The **Recalc all** option re-runs all functions regardless of their date and time stamps.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Ignore auto recalc	tick box		

*if **not ticked**, all functions that have the auto-recalc flag set on are re-calculated.*

*If **ticked**, the auto-recalc flag is ignored and all functions are re-calculated.*

28.7.6 Edit Chain

Position of option on menu: **Utilities =>Recalc =>Edit chain**

The **Recalc=>Edit chain** option is used to edit chains.

The **Recalc=>Edit chain** walk-right menu provides a list all the defined chains in the project.

When a chain is selected from the list, it is automatically loaded into the **Edit/Create Chain** panel ready for editing.

28.7.7 Run Chain

Position of option on menu: **Utilities =>Recalc =>Run chain**

The **Recalc=>Run chain** option is used to run chains.

The **Recalc=>Run chain** walk-right menu provides a list all the defined chains in the project.

When a chain is selected from the list, it is automatically run.

28.8 Fence

Position of menu: **Utilities =>Fence**

It is often necessary to divide strings into those parts that are within a certain region and those parts that are outside the region. In 12d Model, the **Fence** option is the method of achieving this result.

Given a string to be used as a fence, the 12d Model fencing options will process strings in a model/view against the fence and break the strings into the parts inside the fence string and those parts outside the fence string.

Any 2d, 3d or interface line-strings that cut the fence polygon will have points inserted at the intersections with the fence polygon. The z-value at the intersection point will be interpolated from the adjacent points in the line-string.

Point strings do not have any extra points added to them.

Restrictions

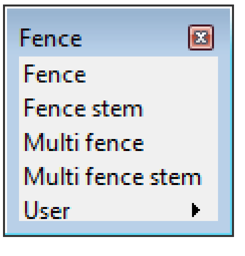
- only 2d, 3d and interface strings can be split using the fence option.
- 4d strings are treated as though they were point strings.
- arcs are considered to be **inside** the fence if the minimum bounding rectangles of the fence and arc overlap.
- alignment, pipeline, drainage, sewer strings are not processed by the fence option

Notes

1. if the fence string is not closed, the first and last points are joined together to form a closed polygon as the fence.
2. a string may be broken into a number of pieces if it wanders in and out of the fence string.
3. the fence string is not processed against itself even if it is in the model or view being fenced.
4. unpredictable results will occur if any strings being fenced lie on top of the fence. If problems occur, parallel the fence in or out by a millimetre.

The **fence** options allows the user to choose a single string to be used as the polygon fence or a number of strings to be used as polygons and process the data against all the strings in one operation.

The **fence** walk-right menu is



For the option *Fence*, go to 28.8.1 Fence
Fence stem 28.8.2 Fence Stem
Multi fence 28.8.3 Multi Fence
Multi fence stem 28.8.4 Multi Fence Stem

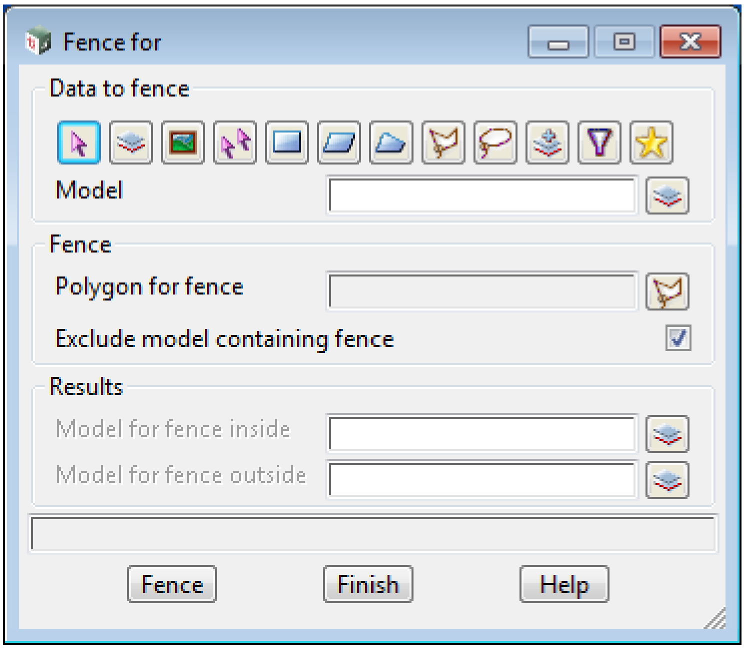
28.8.1 Fence

Position of option on menu: **Utilities =>Fence =>Fence**

In this option, the user selects a single string to be used as a polygon fence. If the string is not closed, the first and last points are joined together to form a polygon.

The **Fence** option will process a selected string or all the strings in a model/view/string against this fence and break the strings into the parts inside the fence string and those parts outside the fence string.

On selecting the **Fence** option and then the appropriate **Data Source** in the panel, the **Fence for** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description Type Defaults Pop-Up

Data source type

data selection type - for a full description go to 4.19.3 Data Source.

Data source

data source for strings to fence.

Polygon for fence string-select

the selected string will be used as the polygon to act as a fence to separate data into an inside and an outside.

Exclude model containing fence tick box ticked

if ***ticked****, no data in the model containing the fence string will be fenced.*
if ***not ticked****, all the appropriate data in the model containing the fence string will be fenced.*

Model for fence inside input available models

if ***non-blank****, name of the model to contain the data inside of the fence string.*
If ***blank****, then no fence inside will be calculated.*

Model for fence outside input available models

if ***non-blank****, name of the model to contain the data outside of the fence string.*
If ***blank****, then no fence outside will be calculated.*

Fence button

on selecting **fence***, the appropriate strings in the data source will be divided by the fence string (selected by the* **poly** *button) into the parts of the strings inside the fence string and the parts of the string outside the fence string. Any line-strings that cut the fence string will have a point inserted at the intersection with the fence string and the z-value for this point interpolated from the points on either side of it in the line-string.*

How to Use the Panel and Panel Messages

(a) Select a fence polygon string by choosing **Polygon to fence**

(b) Fence processing begins on selecting the **Fence** button.

Progress messages - sent to the panel message area
calculating inside-outside
calculating inside
calculating outside
fencing *string name*

Completion message - sent to the panel message area
finished fence

<esc> can be used to abort the fence option.

28.8.2 Fence Stem

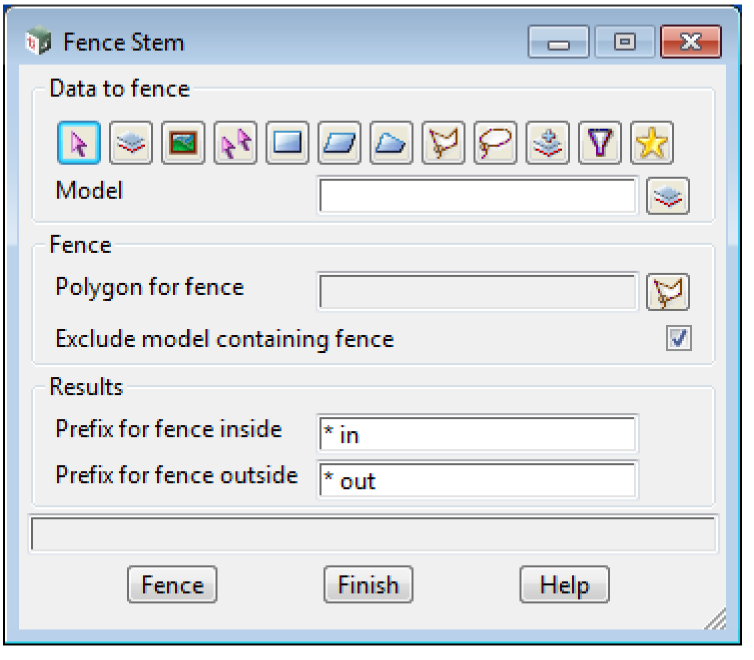
Position of option on menu: **Utilities =>Fence =>Fence stem**

As for the **Fence** option, the user selects a single string to be used as a polygon fence. If the string is not closed, the first and last points are joined together to form a polygon.

The **Fence Stem** option will process a selected string or all the strings in a model/view against this fence and break the strings into the parts inside the fence string and those parts outside the fence string. The inside and outside will then be put into models of the same name as the original model modified by a prefix and/or postfix.

This means that unlike the **Fence** option, when fencing a view with the **Fence Stem** option, the inside/outside for each model on the view goes to distinct models using the prefix/postfix for the inside/outside model names.

On selecting the **Fence Stem** option and then the appropriate **Data Source** in the panel, the **Fence Stem** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

data source for strings to fence.

Prefix for fence inside	input		available models

*if **non-blank**, prefix*postfix to adjust the data model name to be the model to contain the data inside of the fence string.*

*If **blank**, then no fence inside will be calculated.*

Prefix for fence outside	input		available models

*if **non-blank**, prefix*postfix to adjust the data model name to be the model to contain the data outside of the fence string.*

*If **blank**, then no fence outside will be calculated.*

Polygon for fence string-select

the selected string will be used as the polygon to act as a fence to separate data into an inside and an outside.

Exclude model containing fence tick box tick

*if **ticked**, no data in the model containing the fence string will be fenced.*
*if **not ticked**, all the appropriate data in the model containing the fence string will be fenced.*

Fence button

on selecting **Fence***, the appropriate strings in the data source will be divided by the fence string into the parts of the strings inside the fence string and the parts of the string outside the fence string. Any line-strings that cut the fence string will have a point inserted at the intersection with the fence string and the z-value for this point interpolated from the points on either side of it in the line-string.*

<esc> can be used to abort the fence option.

28.8.3 Multi Fence

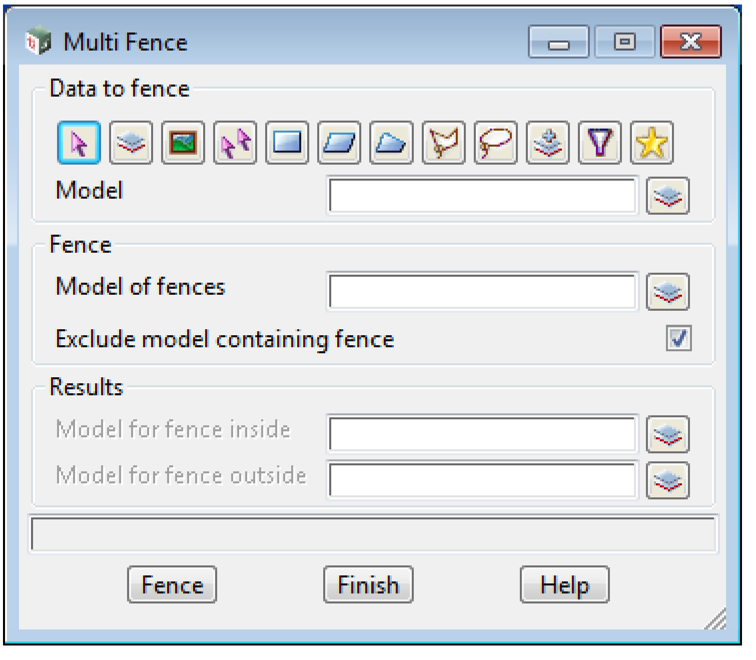
Position of option on menu: **Utilities =>Fence =>Multi fence**

It is often necessary to fence data against more than one polygon.

In the **Multi fence** option, the user provides a model containing all the polygons to be used as fences. The **Multi fence** option will process the selected string or all the strings in a model/view against all the polygons in the polygon model.

The data will be clipped and the **outside** is considered to be those bits are **outside all** of the polygons and the inside is the remainder, *i.e.* the bits **inside any one** of the polygon.

On selecting the **Multi fence** option and then the appropriate **Data Source** in the panel, the **Multi Fence String/Model/View** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

data source for strings to fence.

Model of fences	input		available models

name of the model that contains the polygons to be used as fences.

Model for fence inside	input		available models

name of the model to contain the data that is inside any one of the fences. If this field is blank, then no fence inside will be calculated.

Model for fence outside	input		available models

name of the model to contain the data outside all of the fences. If this field is blank, then no fence outside will be calculated.

Exclude model containing fence	tick box	tick	

if ***ticked****, no data in the model containing the fence string will be fenced.*
if ***not ticked****, all the appropriate data in the model containing the fence string will be fenced.*

Fence button

the appropriate strings in the data source will be divided by the fence polygons (from the model of fences) into the parts of the strings inside any one fence and the parts of the string outside all of the fences. Any line-strings that cut the fences will have a point inserted at the intersection with each fence and the z-value for this point interpolated from the points on either side of it in the line-string.

<Esc> can be used to abort the multi-fence option.

28.8.4 Multi Fence Stem

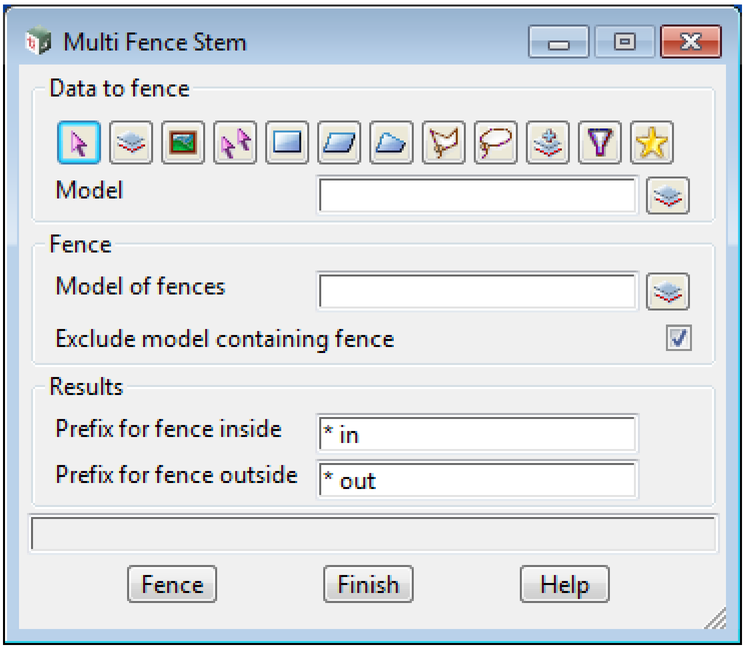
Position of option on menu: **Utilities =>Fence =>Multi fence stem**

It is often necessary to fence data against more than one polygon.

In the **Multi fence stem** option, the user provides a model containing all the polygons to be used as fences. The **Multi fence stem** option will process selected strings or all the strings in a model/view against all the polygons in the polygon model.

The data will be clipped and the **outside** is considered to be those bits are **outside all** of the polygons and the **inside** is the remainder, *i.e.* the bits **inside any one** of the polygon.

On selecting the **Multi fence stem** option and then the appropriate **Data Source** in the panel, the **Multi Fence Stem String/Model/View** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source

data source for strings to fence.

Model of fences	input		available models

name of the model that contains the polygons to be used as fences.

Prefix for fence inside	input		available models

*if **non-blank**, prefix*postfix to adjust the data model name to be the model to contain the data inside of the fence string.*
*If **blank**, then no fence inside will be calculated.*

Prefix for fence outside	input		available models

*if **non-blank**, prefix*postfix to adjust the data model name to be the model to contain the data outside of the fence string.*
*If **blank**, then no fence outside will be calculated.*

Exclude model containing fence tick box tick

*if **ticked**, no data in the model containing the fence string will be fenced.*
*if **not ticked**, all the appropriate data in the model containing the fence string will be fenced.*

Fence button

the appropriate strings in the data source will be divided by the fence polygons (from the model of fences) into the parts of the strings inside any one fence and the parts of the string outside all of the fences. Any line-strings that cut the fences will have a point inserted at the intersection with each fence and the z-value for this point interpolated from the points on either side of it in the line-string.

<Esc> can be used to abort the multi-fence option.

For general information on ***Affine*** and ***Helmert*** Transformations, go to 28.9.1 Coordinate Transformations - Helmert and Affine

28.9.1 Coordinate Transformations - Helmert and Affine

A ***2D Helmert*** transformation is a two dimensional linear transformation consisting of a scaling, a rotation (of both the x-axis and y-axis about the vertical axis) and a 2D- translation (shift) of data. Hence there are four parameters to be specified.

A ***3D Helmert*** transformation is a three dimensional linear transformation consisting of a scaling, three rotations (about the 3 axes), and a 3D-translation (shift) of data. Hence there are 7 parameters to be specified.

A ***2D affine transformation*** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and rotations of the x-axis (about the vertical axis) and of the y-axis (about the vertical axis). Hence there are six parameters to be specified. Unlike the Helmert transformations, rectangles can be skewed by an affine transformation.

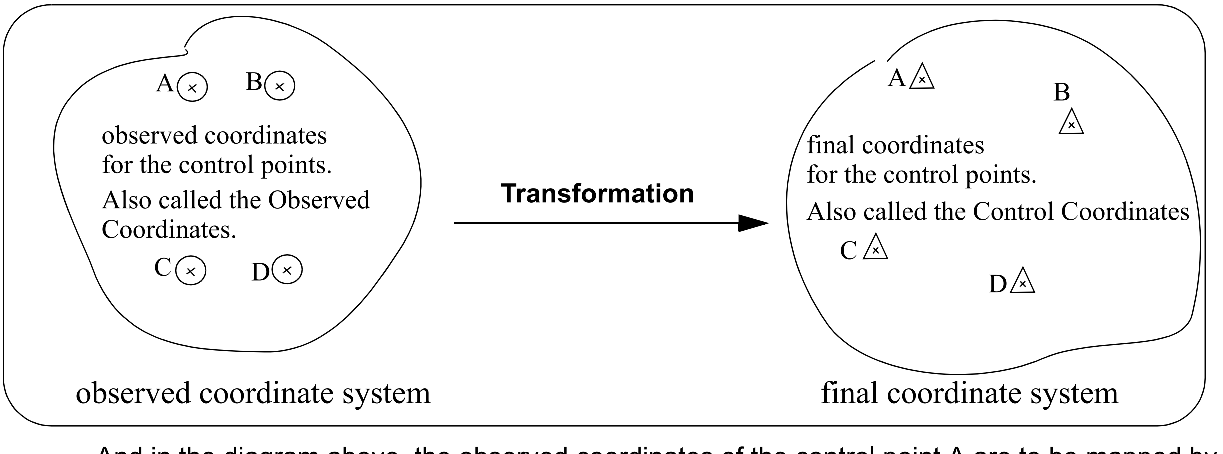
A ***2D orthogonal affine transformation*** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and the same rotation (of both the x-axis and y-axis like the Helmert). Hence there are five parameters to be specified. Unlike the standard affine transformations, rectangles are not skewed by the orthogonal affine transformation.

These types of transformation are often used in civil projects for converting data between a local coordinate system (observed coordinates) and another coordinate system.

The most frequent method of defining all these transformations is not by explicitly giving the transformation parameters but by having both the observed **and** the final coordinates for three or more points (known as the **control points**) and then trying to calculate the transformation parameters from these sets of coordinates.

If the transformation parameters can be successfully calculated from the observed-final coordinate pairs for the control points, then the transformation parameters are then be used to convert the coordinates of any other object in the observed coordinate system to the new final coordinates.

So for this method, the first step is to select **control points** for which the coordinates are known in the final coordinate system and in the local (observed) coordinate system.



And in the diagram above, the observed coordinates of the control point A are to be mapped by the transformation to the coordinates of the control point A in the final coordinate system. And similarly for the points B, C and D.

Note that A is the same point on the ground - it just has a different coordinate in a different coordinate system and hence will appear in a different place in a diagram for each coordinate system.

Usually each control point is selected because

(a) its final coordinates are already known

(b) there is a marker on the ground indicating the exact position of the control point

and

(c) the control point is the area that is being surveyed (observed).

The control point is then surveyed to get its observed coordinates.

Because the final coordinates of the control points are known in advance, the final coordinates of the control point are referred to as the **Control Coordinates**, or **Control Easting** and **Control Northing** and the control point coordinates often referred to as the **Control Point**. The surveyed coordinates of the control point are called as the **Observed Coordinates** or **Observed Easting** and **Observed Northing** (of the control point).

IMPORTANT NOTE - the control points must be selected so that they are spread throughout the area, and the control points must not all be on the one straight line.

The number of parameters to be determined for the transformation ranges from three in a fixed scale 2D Helmert up to seven for a 3D Helmert so there must be enough control points to provide sufficient independent equations to be able to solve for the parameters. Also all survey measurements have errors in them and it is best to have more than the minimum number of required control points to help control errors.

However when there are four or more control-observed point pairs, the system will be over determined. That is, by taking different subsets of the control-observed point pairs, different transformation parameters will result.

In this situation, ***12d Model*** uses **Least Squares** to calculate the transformation parameters from the over determined systems.

Once the transformation parameters have been calculated by Least Squares, for each of the control points the transformation can be applied to the observed coordinates of the control point. The difference between the Control Coordinates and the transformed Observed Coordinates for a control point is called the **residuals** for the transformation.

The ***residuals*** for the least squares solution gives a measure of how good the Least Squares solution was, and for checking purposes, the residuals are displayed in the transformation panel for each of the control-observed point pairs.

As an example of the meaning of the transformation parameters, we'll look at the 2D Helmert transformation.

The 2D Helmert has four parameters:

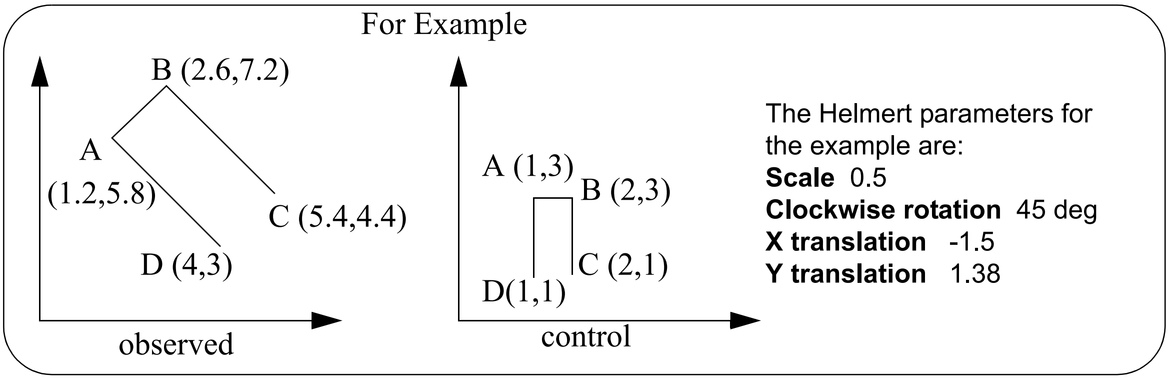
(a) the scale factor for the existing coordinates with respect to the new coordinates

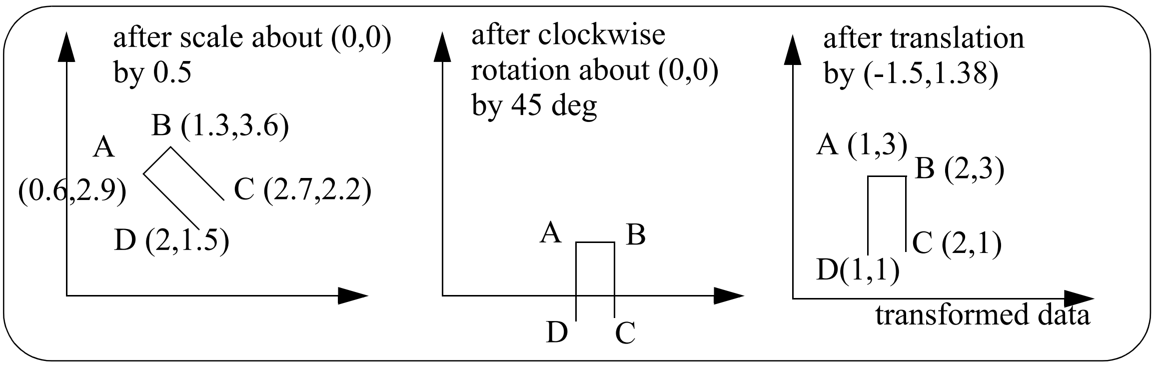
(b) the (z axis) rotation of the existing coordinates to align it with the new coordinates axis

(c) the two (x and y) translations of the existing coordinates after the scalings and rotations have been applied

and the operations to be performed on observed coordinates are:

1. Scale the observed coordinates about (0,0) by the *Scale* factor
2. Then rotate the resulting coordinates about (0,0) in a clockwise direction by the *Clockwise rotation* degrees.
3. Then translate the resulting coordinates by ((X translation, Y translation).



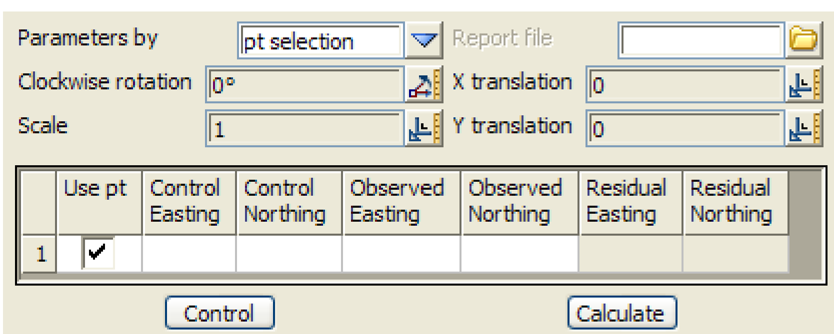


For information about how to select control and observed points in the Affine and Helmert panels, go to the next section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations

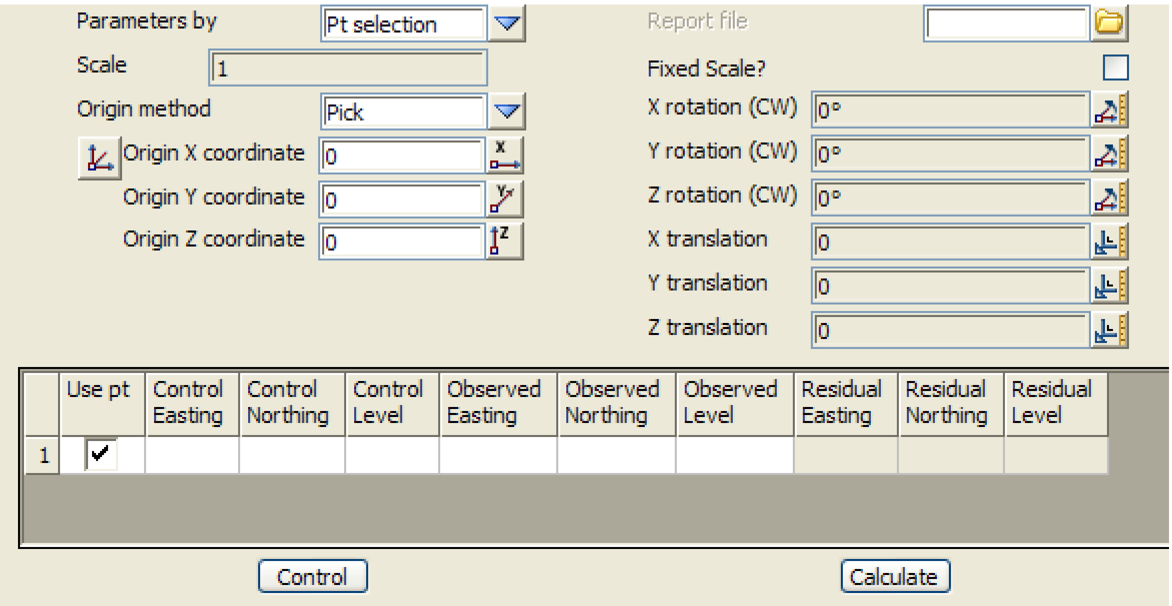
28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations

For the **Affine** and **Helmert** transformations, the parameters can be either typed in or calculated from control-observed point pairs using the method of least squares.

If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels.



Grid for 2D transformations



Grid for 3D transformations

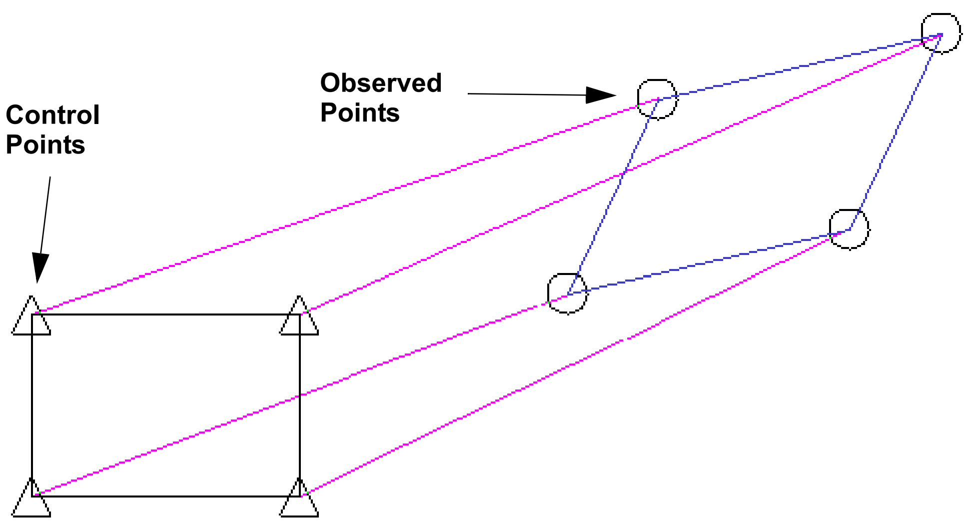
If the **Pt selection** method is chosen, the selection of points is started by selecting the **Control** button.

Note - the default is to select the ***Control Point*** *(the coordinates of the control point in the transformed coordinate system)* and then its associated ***Observed Point*** *(the coordinates of the control point in the observed system)*.

Neither point is accepted until the second point is selected.

However the ***order*** of selection can be ***reversed*** by setting the environment variable **PICK_ORDER_OBSERVED_FIRST_4D** (see 7.6.3 env.4d). The order can then be ***Observed Point first*** and then its associated ***control point with Control Coordinates***.

To help reduce errors, after a control point - observed point pair is selected, the position of the Control Point is shown as a triangle and the position of the associated Observed Point as a circle with a line drawn between the control-observed point pair for clarity



After selecting the **Control** button, the selection starts with the Control (Observed) Point, accepting that point then selecting the corresponding Observed (Control) Point.

After selecting the first pair of points, the second pair is then selected and so on.

The picking is terminated by clicking **RB** and selecting **Cancel** when the next control (observed) point is to be selected.

The coordinates of the Control Points and Observed Points are added to the grid on the selection of two valid points. The **Use pt** field is ticked by default.

Use point column

	Use pt	Control Easting	Control Northing	Observed Easting	Observed Northing	Residual Easting	Residual Northing
1	✔	89621.0175	73418.2203	90542.9037	73734.1936		
2	✔	90014.635	73150.7295	90827.5429	73541.8698		
3	✔	89621.0175	73150.7295	90409.5592	73446.9901		
4	✔	90014.635	73418.2203	90960.8874	73829.0734		
5	✔						

After the selection process is terminated, additional control-observed point pairs can be selected at any time by simply clicking on the **Control** button again. The new control-observed point pairs are added after the existing control-observed point pairs.

If ***Use pt*** is set to tick, the corresponding control-observed point pair is used in the calculations. If ***Use pt*** is not ticked, the corresponding control-observed point pair is ignored and not used.

The **Calculate** button calculates the transformation parameters based on all the control-observed point paris in the grid with the **Use pt** tick box ticked on.

The residuals are placed into the residual columns of the grid and the calculated parameters are placed into the parameters section of the panel.

	Use pt	Control Easting	Control Northing	Observed Easting	Observed Northing	Residual Easting	Residual Northing
1	✔	89621.0175	73418.2203	90542.9037	73734.1936	76.42145	-51.17784
2	✔	90014.635	73150.7295	90827.5429	73541.8698	-76.42145	51.1778
3	✔	89621.0175	73150.7295	90409.5592	73446.9901	-38.60317	-26.98948
4	✔	90014.635	73418.2203	90960.8874	73829.0734	38.60317	26.98953
5	✔						

Residuals columns

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

For information on how the **Affine Transformation works with Rasters,** go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

28.9.1.2 Affine and Helmert Transformations Applied to Rasters

12d Rasters (including ECW rasters) may have transforms applied with any transformation panel with the following constraints:

1. "Replace existing data" is the only output option supported.
2. The set of parameters supplied for the transformation, when applied to the four corners of the

original raster, results in a rectangle.

3. The raster cannot be selected as a string to be transformed, it should be placed in a model on its own and the model selected as the **'Data to change'**.

The raster images themselves will not be altered, only the model information which maps them into world coordinates is changed.

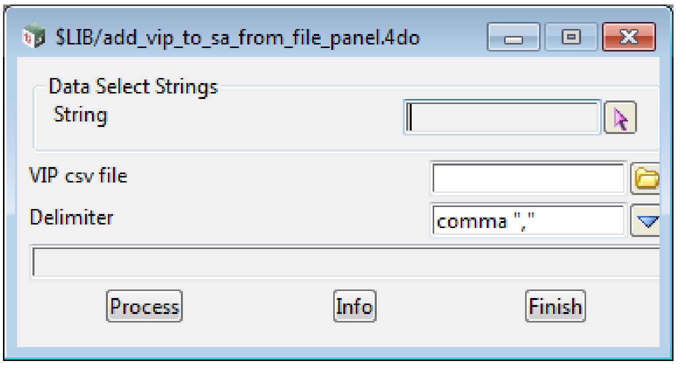
For the Affine panel, this means that different x and y scaling factors may be used, however the two axis rotations must be identical.

28.9.2 Add VIP to SA From File

Position of option on menu: **Utilities =>A-G =>Add VIP to SA from file**

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting **Add VIP to SA from file**, the **Add VIP to SA from file** panel is displayed.



28.9.3 2D Affine

Position of option on menu: **Utilities =>A-G =>Affine**

An affine transformation is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two perpendicular directions and a rotation of the x-axis and the y-axis. Hence there are six parameters to be specified. Unlike the Helmert transformations, rectangles can be skewed by an affine transformation.

So the affine parameters are

(a) the x-scale factor for the observed co-ordinates with respect to the control coordinates

(b) the y-scale factor for the observed co-ordinates with respect to the control coordinates

(c) the rotation of the x-axis of the observed co-ordinates to align it with the control x co-ordinates axis

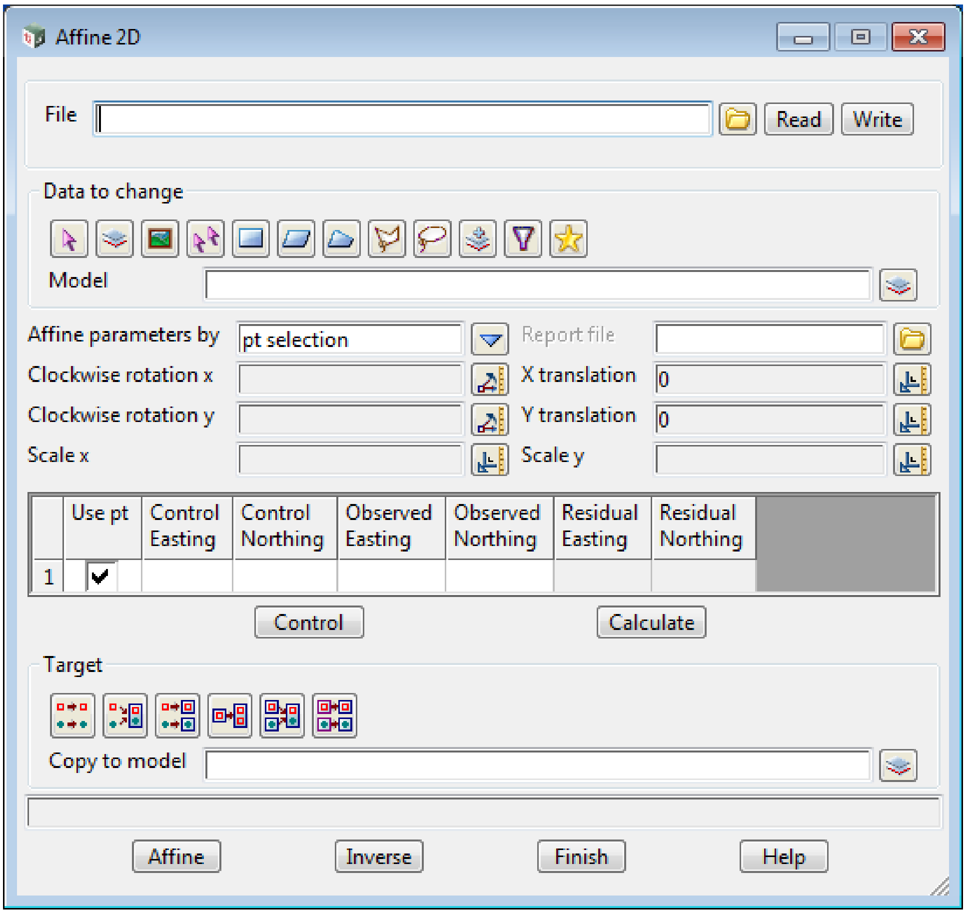
(d) the rotation of the y-axis of the observed co-ordinates to align it with the control y co-ordinates axis

(e) the x and y translation of the existing co-ordinates after the scalings and rotations have been applied

For information on the affine transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the **Affine Transformation works with Rasters,** go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

On selecting **Affine 2D**, the **Affine 2d** panel is displayed.



If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grid on the panel. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
File	file box		*.aaf files

a filename can be specified for reading or writing a file to restore the panel contents for re-use.

Read button

if a valid file exists, the file contents can be loaded into the panel.

Write button

if a valid name is specified, the user can write the input data to a file.

Data to change

Data source type Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.

Affine parameters by	choice	Pt selection	Pt selection Direct entry

the parameter entry method.

***Pt selection** - the control points and their matching observed points are selected by the user after clicking the control button.*

***Direct entry**- the transformation parameter fields are used to type in the parameter data.*

Report file *.rpt files

if not blank, write a report on the Affine transformation.

Rotation x angle box

the rotation of the x-axes of the existing points with respect to the transformed x-axis.

Rotation y angle box

the rotation of the y-axes of the existing points with respect to the transformed y-axis.

Scale x input/output

the x-scale factor for the existing coordinates with respect to the transformed coordinates

Scale y input/output

the y-scale factor for the existing coordinates with respect to the transformed coordinates

X Translation input/output

the x translation of the existing coordinates with respect to the transformed coordinates

Y Translation input/output

the y translation of the existing coordinates with respect to the transformed coordinates

Control button

starts the selection process for choosing more control points. The process is terminated when the calculate button is used.

Calculate button

calculate the Affine parameters from the selected points shown in the grid.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Affine button

apply the affine transformation to the data specified in the source box, and put it into the appropriate target area.

28.9.4 2D Affine - Orthogonal

Position of option on menu: **Utilities =>A-G =>Affine 2D orthogonal**

A ***2D orthogonal affine transformation*** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and the same rotation of both the x-axis and y-axis (about the z axis, like the Helmert). Hence there are five parameters to be specified. Unlike the standard affine transformations, rectangles can not be skewed by the orthogonal affine transformation.

Hence the orthogonal affine parameters are

(a) the x-scale factor for the observed co-ordinates with respect to the control coordinates

(b) the y-scale factor for the observed co-ordinates with respect to the control coordinates

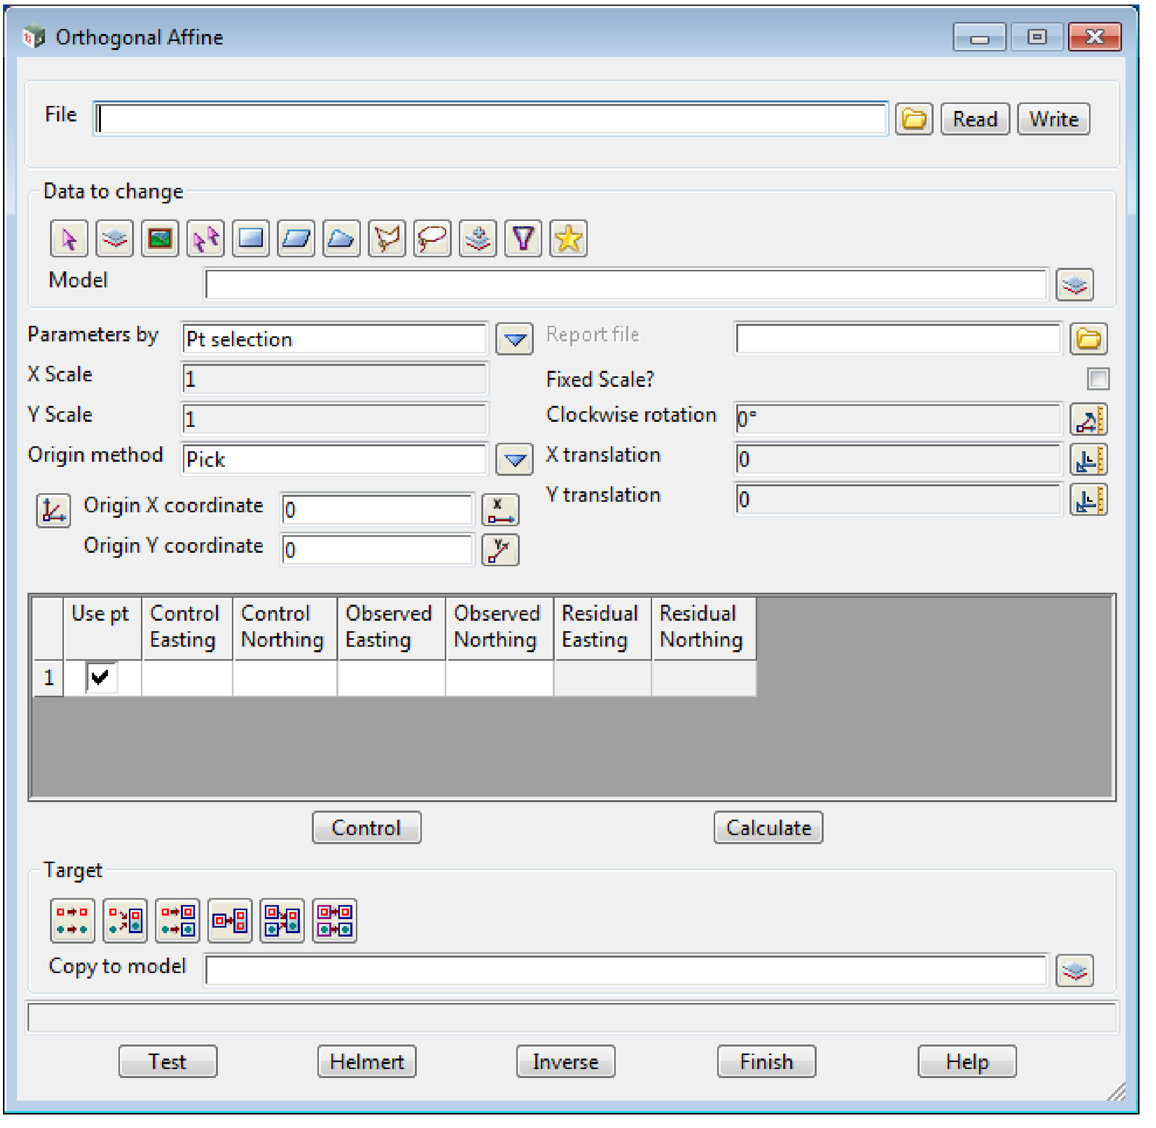
(c) the same rotation of the x-axis and y-axis of the observed coordinates to align it with the control x and coordinate axis

(d) the x and y translation of the observed coordinates after the scalings and rotations have been applied

For information on the affine transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the **Affine Transformation works with Rasters,** go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

On selecting **Affine 2D orthogonal**, the **Orthogonal Affine** panel is displayed.



If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
File	file box		*.ortho_aaf files

a filename can be specified for reading or writing a file to restore the panel contents for re-use.

Read	button		

if a valid file exists, the file contents can be loaded into the panel.

Write	button		

if a valid name is specified, the user can write the input data to a file.

Data to change

Data source type

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Parameters by	choice	Pt selection	Pt selection Direct entry

the parameter entry method.

Report file			*.rpt files

if not blank, write a report on the orthogonal affine transformation.

Clockwise rotation	angle box		

the rotation of both x and y axes of the existing points with respect to the transformed x and y axes.

Fixed scale?	tick box		

if ticked, the x and y scales are typed into the ***X/Y Scale*** *fields and are held fixed when the orthogonal affine parameters are calculated from the selected control-observed point pairs.*

Scale x	input/output		

the x-scale factor for the existing co-ordinates with respect to the transformed coordinates

Scale y	input/output		

the y-scale factor for the existing coordinates with respect to the transformed coordinates

X Translation	input/output		

the x translation of the existing coordinates with respect to the transformed coordinates

Y Translation	input/output		

the y translation of the existing coordinates with respect to the transformed coordinates

Origin method	choice box	Pick	Pick, Obs'd centroid Ctrl centroid

the translation can be reported against another origin than the default (0,0).

Origin X/Y coordinate	input		

the translation parameters are written out with respect to this origin.

Control	button		

restarts the selection process for choosing more control points.

Calculate	button		

calculate the orthogonal affine parameters from the selected points shown in the grid.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Affine	button		

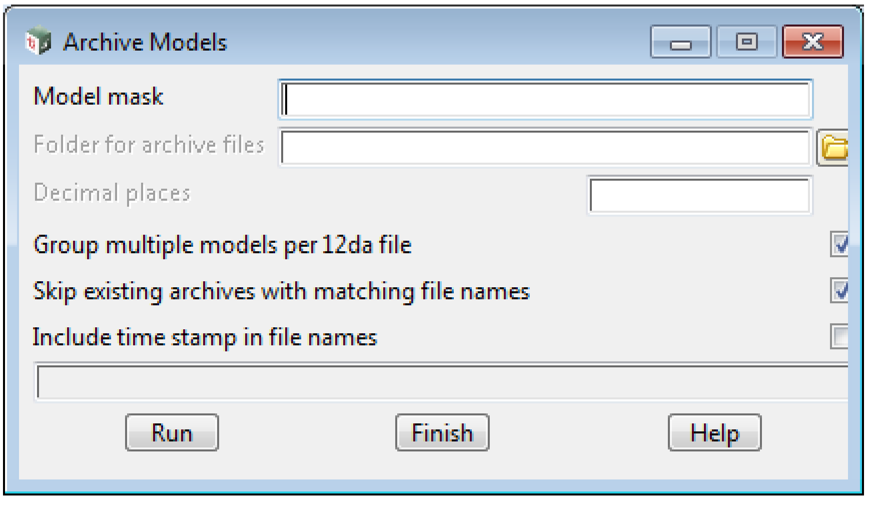
apply the orthogonal affine transformation to the data specified in the source box, and put it into the appropriate target area.

28.9.5 Archive Models

Position of option on menu: **Utilities =>A-G =>Archive models**

This option saves all models matching a specified model mask, to 12da files named in the style: <model name/prefix>[YYYYMMDD HHMMSS].12da

On selecting the **Archive models** option, the **Archive models** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults
Model mask	input text	

specifies the model(s) to archive. Use '' and '?' wildcards to specify multiple models.*

Folder for archive files	folder	

a pre-existing folder to write the 12da files to. If unspecified, will write to backups.4d or working folder, depending on the environment variable $USE_BACKUPS_4D_FOLDER_4D.

Decimal places **integer**

Number of decimal places to use when writing the 12da files. If unspecified, 15 decimal places are used.

Group multiple models per 12da file	tick box	ticked

if ticked, multiple models may be archived per 12da file, based on the matching first word of each model name. (The first word is the prefix of the model name, before the first space.) If not ticked, one model is archived per 12da file.

Skip existing archives with matching file names	tick box	ticked

if ticked, existing 12da files with matching names are left untouched and not re-archived. If not ticked, existing files are overwritten.

Include time stamp in the file names	tick box	not ticked

if ticked, include archive date and time stamp in the file names, in the style:

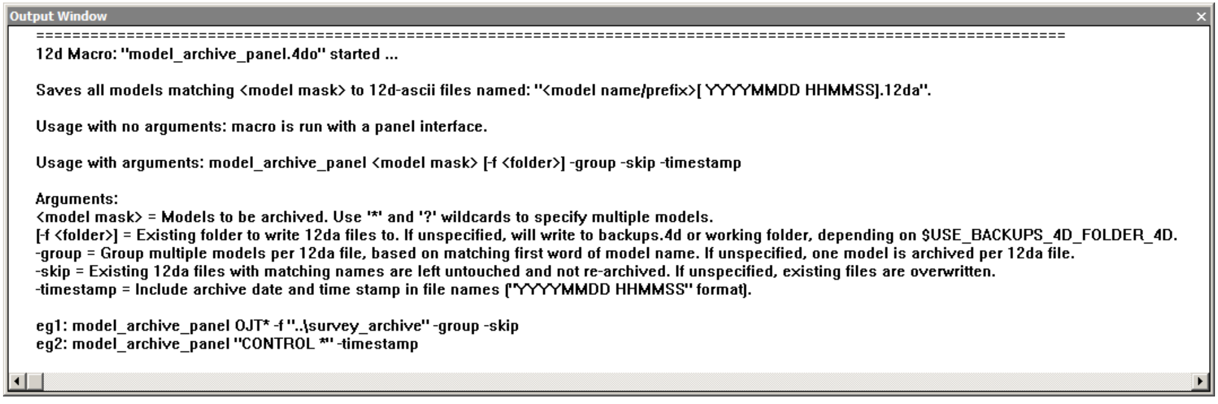
YYYYMMDD HHMMSS

Run	button	

runs the option

Special Note

The **Archive Models** option is a macro, which may optionally be run from a chain via arguments, rather than via an interactive panel. The details of the argument syntax are written to the Output Window, whenever the macro is run without valid arguments, namely:



28.9.6 Cartographic Projections

Position of option on menu: **Utilities =>A-G =>Cartographic**

The **Cartographic** option is used to transform data based on the same datum between

(a) two different cartographic projections (based on the same datum)

(b) longitude and latitude and a cartographic projection (based on the same datum)

(c) a cartographic projection and longitude and latitude (based on the same datum).

The *Cartographic* option has already been documented in the section 17.10.2 Cartographic

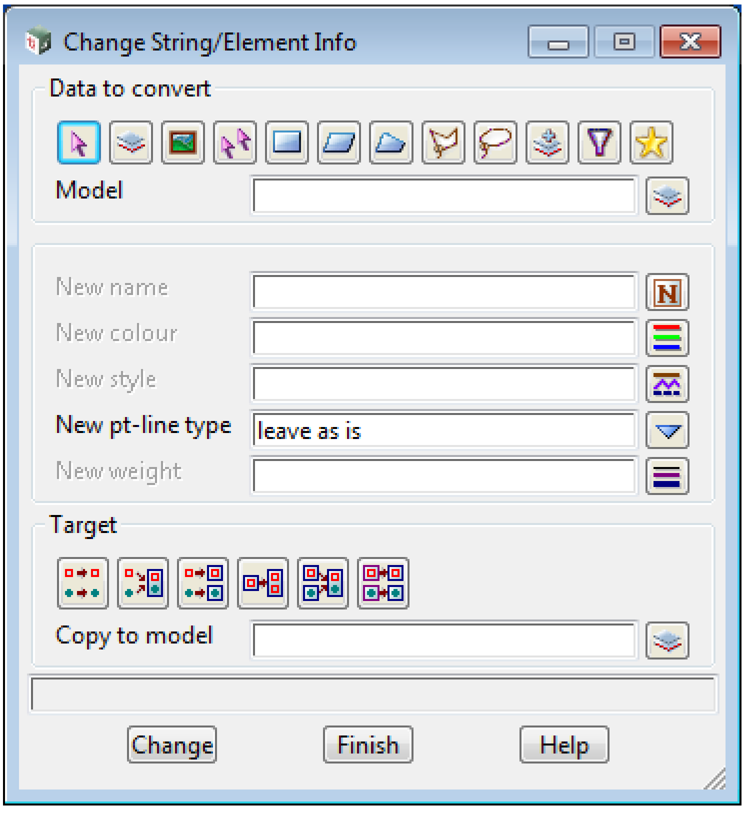
28.9.7 Change

Position of option on menu: **Utilities =>A-G =>Change**

This **Change** option is similar to the **Change** option from the **Strings edits** menu.

For the selected strings, **Change** can modify the colour, name, breakline type, style and model of each string.

On selecting the **Change** option, the **Change String Info** panel is displayed.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be changed.

New name	input		

if non-blank, then the name of the selected strings will be changed to the name given in the **new name** *field.*

New colour	input		available colours

if non-blank, then the colour of the selected strings will be changed to the colour given in the **new colour** *field.*

New style	input		

if non-blank, then the linestyle of the selected strings will be changed to the

given in the **new style** *field.*

New pt-line type input leave as is leave as is, point, line

*if **leave as is**, then the point-line type of the selected string will be not be changed.*
*If **point string** or **line string**, then the point-line type of the selected string will be changed to that type.*

New weight input leave as is leave as is, point, line

if non-blank, then the weight of the selected strings will be changed to the

given in the **new weight** *field.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Change button

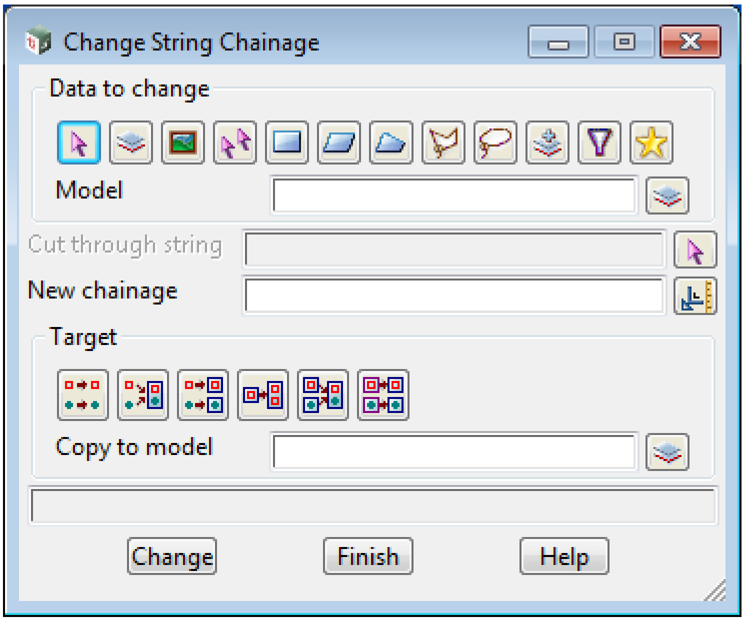
process the Data source of selected strings.

28.9.8 Change String Chainage

Position of option on menu: **Utilities =>A-G =>Change string chainage**

Change string chainage sets the start chainage of the selected strings to a given chainage value.

Selecting the **Change string chainage** brings up the **Change string chainage** panel.



The fields and buttons used in the panel have the following functions.

Field Description Type Defaults Pop-Up

Data to change

Data source type Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.

Cut through string string select

if selected, the position on each string from the ***"Data to change"*** *source box intersects the selected string will have the chainage from* ***"New Chainage"*** *at that position.*

if no string is selected, the field is displayed as optional and the ***"New Chainage"*** *value becomes the start chainage of each string selected from the source box.*

New chainage input

value to set the start chainage of all the selected strings to.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Change button

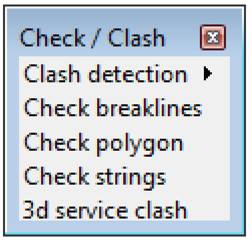
process the selected Data source of strings

28.9.9 Check/Clash

Position of menu: **Utilities =>A-G =>Check/clash**

Check/clash options run checks on strings, and clashes between strings.

The **Check/Clash** walk-right menu is



check for clashing pipes, drainage strings, *etc.*
check for crossing breaklines, duplicate vertices, *etc.*
run checks on a polygon
check strings against a Map File, *etc.*
check strings clashing in 3d

For

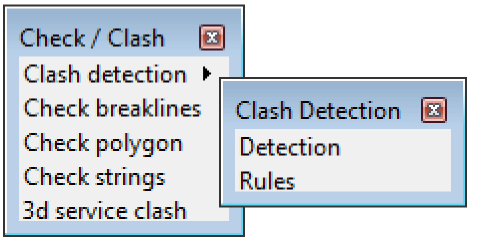
Clash detection	28.9.9.1 Clash Detection
Check breaklines, go to	16.3 Check Breaklines, Duplicate Vertices, Identicals
Check polygon	28.9.9.2 Check Polygon
Check strings	28.9.9.3 Check Strings
3d service clash	28.9.9.4 Strings Clash in 3d

28.9.9.1 Clash Detection

Position of menu: **Design =>Check/clash => Clash detection**
Utilities =>A-G =>Check/clash =>Clash detection

Clash detection checks whether strings clash with each other, and trimeshes of the clash zones can be created. **Rules** can be defined specifying what is a clash.

The **Check/Clash** menu is:



For the options, see

Detection 28.9.9.1.1 Clash Detection
Rules 28.9.9.1.2 Clash Detection Rules

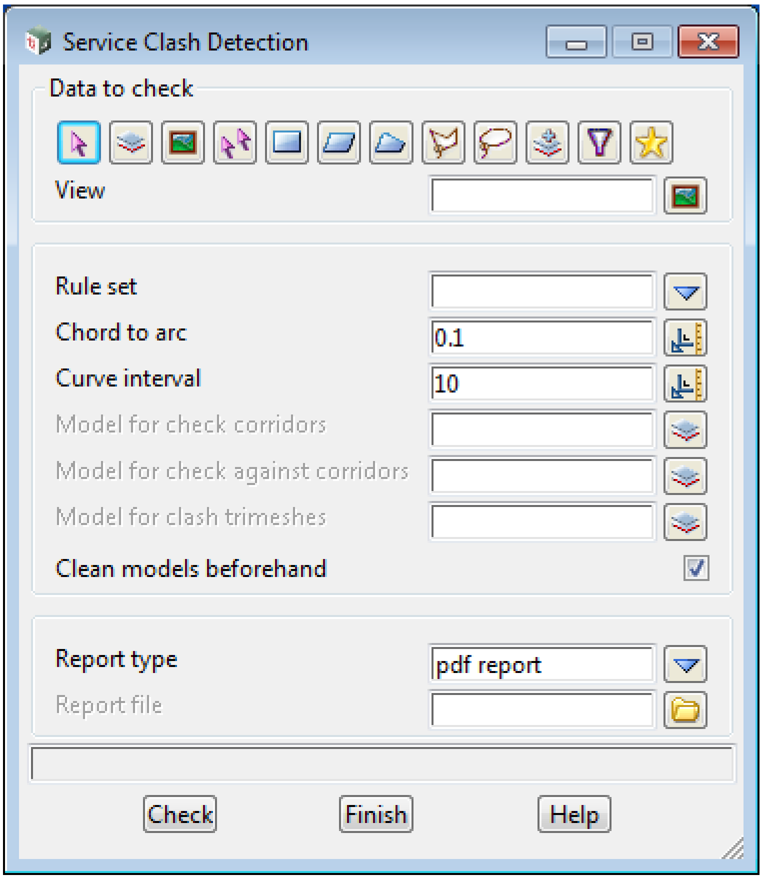
28.9.9.1.1 Clash Detection

Position of option on menu: **Design =>Check/clash => Clash detection =>Detection**
Utilities =>A-G =>Check/clash => Clash detection =>Detection

Service Clash detection checks whether strings clash with each other, and trimeshes of the clash zones can be created. **Rules** can be defined specifying what is a clash. For example, you may only want to know about a horizontal clash, but not a vertical clash, or you may want to know if anything clashes not only with a string but within a user given corridor around the string.

Clashes can be detected between strings of the types Super Pipe with straight line segments and Drainage with straight line segments.

Selecting **Detection** brings up the **Service Clash** panel



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Rule set	choice box		available clash rules

the rules to use in the clash detection. The rules define which models are checked against which models. See 28.9.9.1.2 Clash Detection Rules.

Curve interval	real box	10	

the interval to break curves up when calculating clashes.

Chord to arc real box 0.1

the chord to arc tolerance to use when breaking curves up when calculating clashes.

Model for check corridors model box

*if **not blank**, for all strings in the **Model(s) to check** given in the Rule Set, strings will be created representing the defined corridor.*

Model for check against corridors model box

*if **not blank**, for all strings in the **Model(s) to check against** given in the Rule Set, strings will be created representing the defined corridor.*

Model for clash trimeshes model box available models

*if **not blank**, trimeshes are created to indicate where the clashes occur, and are placed in this model.*

Clean models beforehand tick box

*if **ticked**, the models for check corridors, check against corridors and clash trimesh models are cleaned before processing.*

Report type choice box available xml formats for this panel

the type of report to be generated from the xml file.

New customised report formats can be added by the user. See 4.30 Setting Up XML Reports

Report file file box

*if **not blank**, a report file of this name is created.*

*If **blank**, no report is created.*

Check button

perform the clash checks. Error messages are written to the Output Window as Intelligent Log Lines to help find the problems.

28.9.9.1.2 Clash Detection Rules

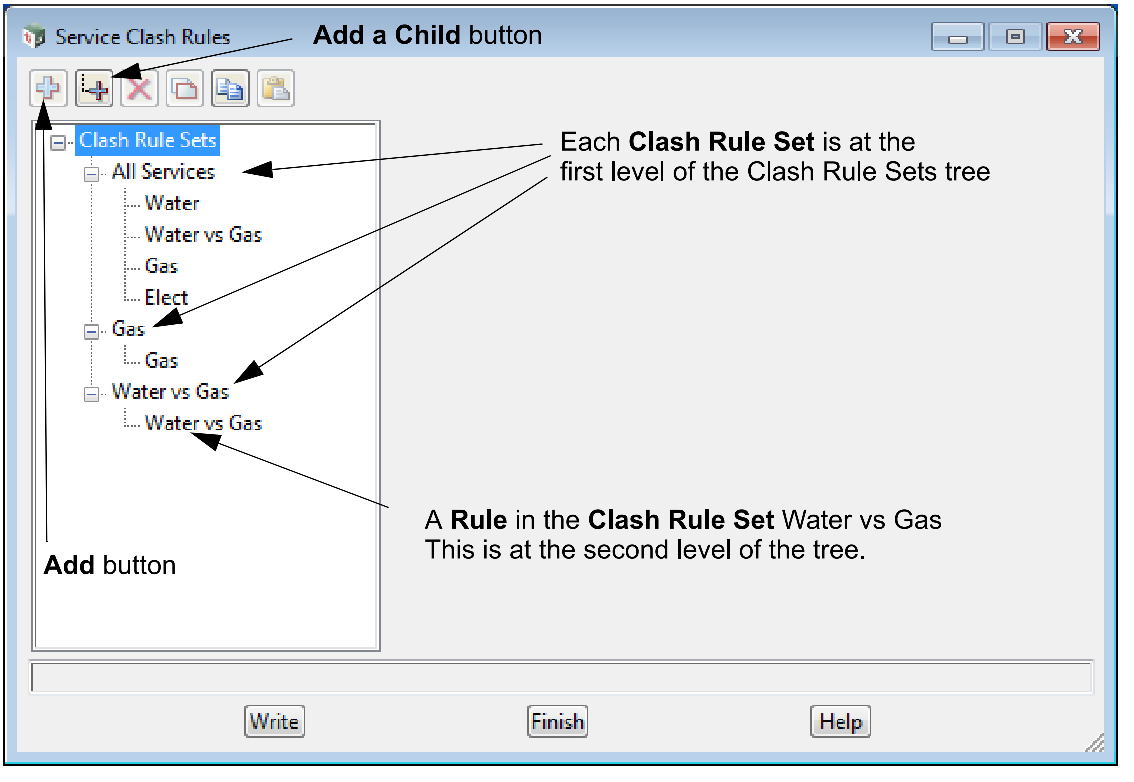
Position of option on menu: **Design =>Check/clash => Clash detection =>Rules**
Utilities =>A-G =>Check/clash => Clash detection =>Rules

The **Service Clash Rules** define what is meant by a "clash".

The **Service Clash Rules** is a tree of Clash Rule Sets and each set has a unique name. The **Service Clash Detection** panel specifies which of the **Clash Rule Sets** is to be used for a particular clash detection run.

The ***Service Clash Rules*** are loaded from a file called ***service_clash_rules.xml*** that is searched for as a standard ***Set_Ups*** file. See 39.2 Files for Setting Up 12d.

Selecting **Rules** brings up the **Service Clash Rules** panel



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up

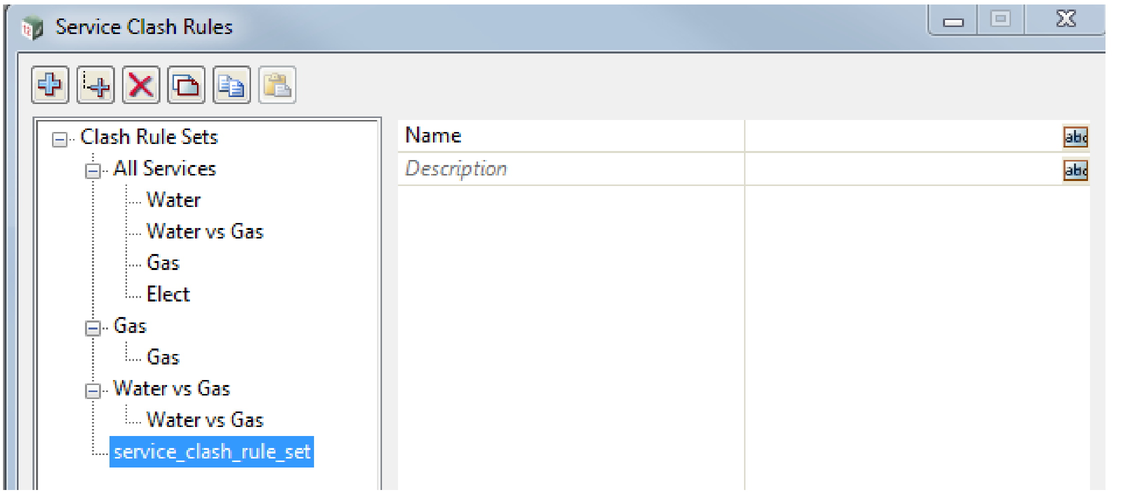
Clash Rule Sets Tree

(a) Clash Rule Set

A **Clash Rule Set** is defined at the first level of the **Clash Rule Sets** tree and each **Clash Rule Set** must have a unique name. One **Clash Rule Set** is selected in the **Service Clash Detection** panel to provide the rules to be used for a particular clash detection run

A new *Clash Rule Set* is created by clicking and highlighting the top level *Clash Rules Sets* and then pressing the **Add Child** button, or by clicking on and highlighting a first level *Clash Rule Set* and then pressing the **Add** button.

A new *Clash Rules Set* with the dummy name **service_clash_rule_set** is then created and a new name must be entered in the **Name** field on the right hand side of the tree. The **Description** is optional.

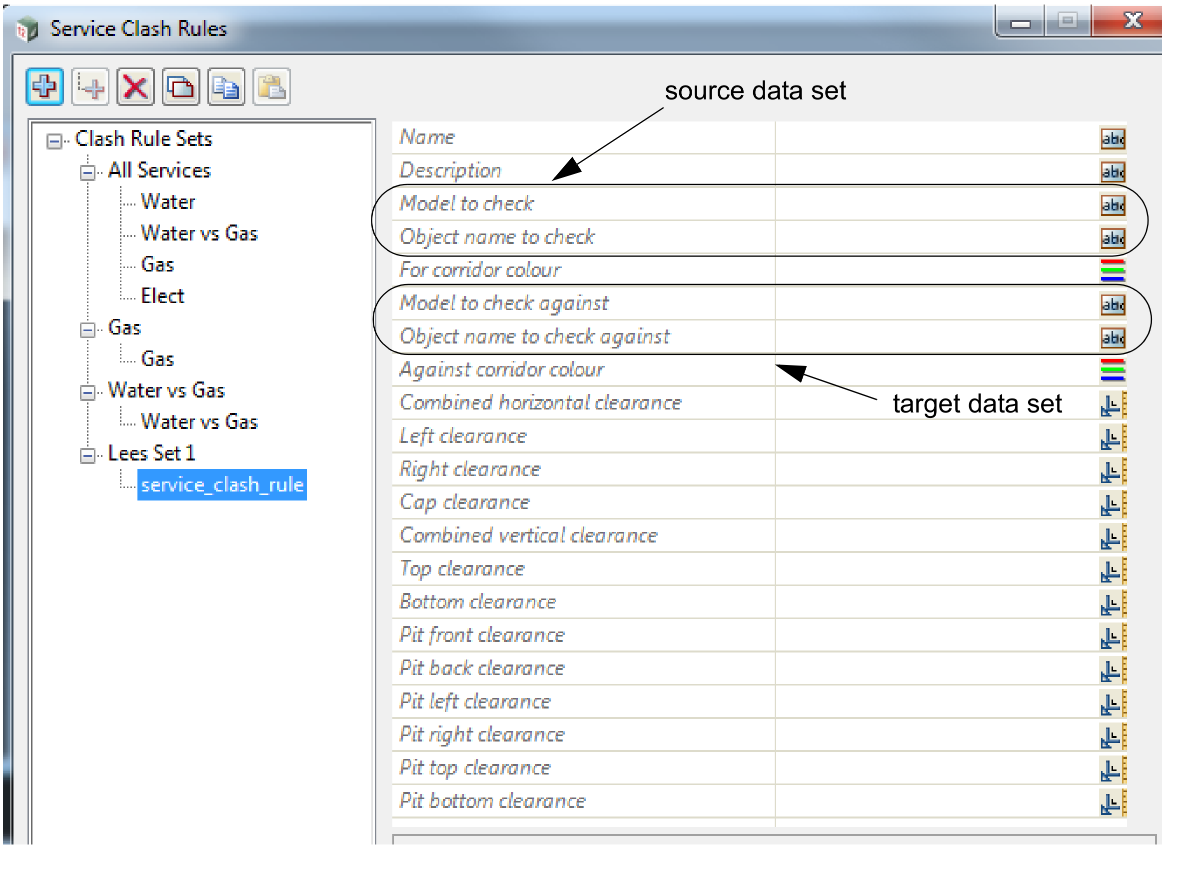


(b) Rules in a Clash Rule Set

The rules for a named Clash Rule Set as defined as second level items under the *Clash Rule Set*. The rules define what is meant by a particular clash.

A new *Rule* is created by clicking and highlighting the named *Clash Rules Set* and then pressing the **Add Child** button, or by clicking on and highlighting a Rule already in the named *Clash Rule Set* and then pressing the **Add** button.

A new *Rule* with the dummy name **service_clash_rule** is then created and a new name must be entered in the **Name** field on the right hand side of the tree. The **Description** is optional.



There must be at least one clash rule in a Clash Rule Set otherwise there is nothing to do. If such a Clash Rule Set is used then no results will be reported.

The Rule defines two separate datasets for each rule - the **Source dataset** containing the elements being checked, and the **Target dataset** containing the elements being checked against. Elements cannot exist in both. They are in either one or the other or neither.

The **Model to check** and **Object name to check** defines the elements that are in the Source data set. Both fields can contain wild cards and wild characters and blank fields will match all elements. That is, blank fields are taken as the wild character *.

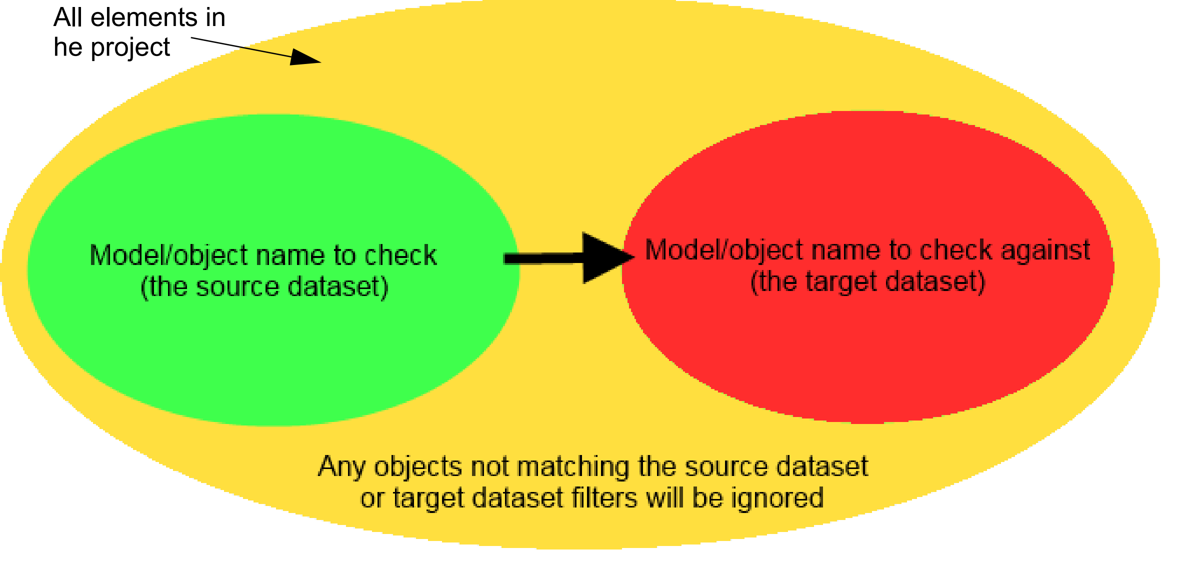
The **Model to check against** and **Object name to check against** defines which of the remaining elements (where remaining = all elements minus source data) are in the **Target dataset**. Both fields can contain wild cards and wild characters.

Elements in the *Source dataset* will **only be checked** against elements in the T*arget dataset.* Any other objects not in the *Source dataset* or *Target dataset* are ignored

So you should be specific for the **Source dataset** and cannot be too generic, since being too generic will mean that there are few elements left to be in the **Target dataset** leaving little or nothing to check against

Hence you should be fairly specific in your **Source dataset** filters, but can be totally generic in the **Target dataset** filters.

To see this in a diagram, if the yellow region represents all the elements in the project and the green region the elements in the *Source dataset*, then the Target dataset (red region) can only be totally outside the green region. So if the green region is very large, then there are not many elements left to be in the red region. The elements in the yellow region that aren't in the red or green regions are the objects in the project that are totally ignored by that rule.



Recommendations for Using the Service Clash Detection:

(a) Model each type of utility in its own model, *e.g.* GAS, WATER, ELEC, TELECOM.

(b) As a minimum create a rule for each service type.

(c) If there are different clearances for different target services being checked, create a rule for each case. *e.g.* Gas vs Water, Gas vs Elec, Gas vs Other.

(d) If you need to check for clashes between utilities of the same type, place these in different models or name them differently so that they can be selected by name, *e.g.* WATER TRUNK and WATER CONNECTIONS or ELEC LEFT and ELEC RIGHT.

(e) Be as narrow and specific with the Source filters as you can be. There is a trade-off, however, between being specific and needing to create multiple rules. Find a balance.

(f) Use standard naming for models and strings and develop standard clash detection rule sets.

(g) You can use map files to help filter out or map strings to certain models to match existing rule sets.

Write Button

When the **Write** *button is selected, a* **Write Setup File** *panel comes up to specify where the* ***services_clash_rules.xml*** *file is to be written out to.*

For the choices on the panel, see 39.2.6 Writing Out Setup Files

A project restart is required for the new file to take effect

28.9.9.2 Check Polygon

Position of option on menu: **Utilities =>A-G =>Check/clash =>Check polygon**

Check polygon checks to see if a polygon passes the polygon checks performed by a polygon box.

The checks are to try and ensure that the polygon is suitable for use in some ***12d*** options.

For example, a polygon that crosses over itself, or has duplicate vertices, or has edges partially on top of other edges, or in parts consists of a single line, are not usable in most options requiring a polygon (fence) for calculations.

The ***Exact Volumes*** options in particular are very sensitive to having a well formed polygon whereas other options can use polygons that are unsuitable for *Exact Volumes*.

Some of the things that make a polygon unsuitable (and will produce the message "bad polygon" or "bad poly") are:

(a) self intersects in the polygon

(b) multiple vertices at the same (x,y) location

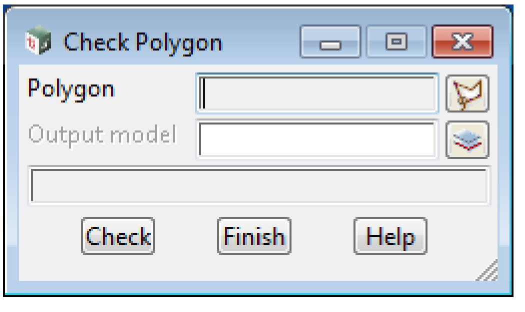
(c) sides being partially on top of other sides

(d) corners just touching other sides or vertices

(e) parts of the polygon that contain no area. For example, a loop at one end and then a line going out from the loop. The line does not enclose any area. This may be created by contouring a surface that contains has a ridge line of constant height.

Errors in the polygon are reported in the ***Output Window*** with intelligent log lines to help find the section of the polygon with the error.

Selecting **Check polygons** brings up the **Check Polygon** panel



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Polygon	polygon box		

select a polygon to check

Output model

*if **non blank**, the resolved polygon is added to this model*

Check button

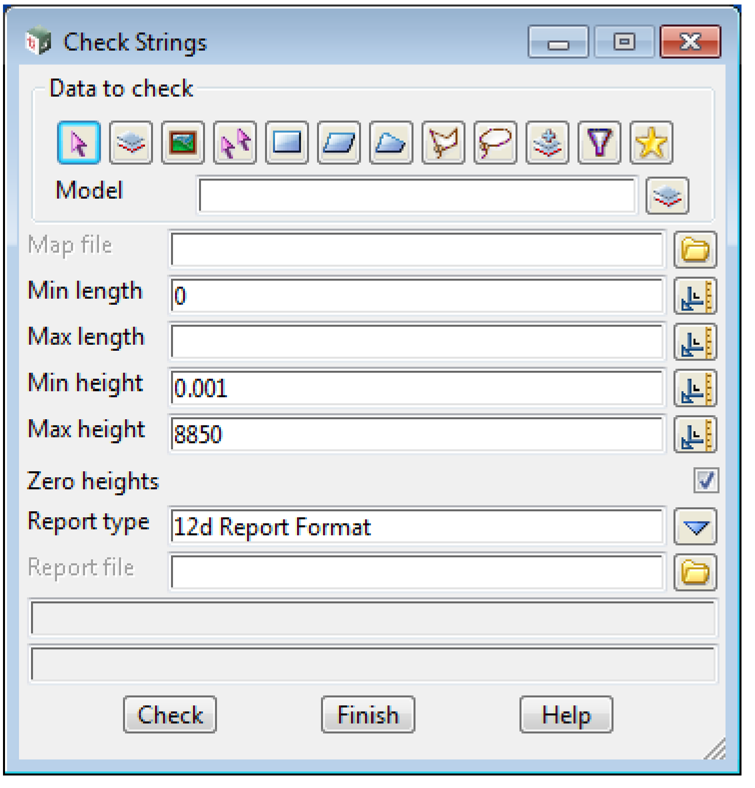
perform the polygon checks. Error messages are written to the Output Window as Intelligent Log Lines to help find the problems.

28.9.9.3 Check Strings

Position of option on menu: **Utilities =>A-G =>Check/clash =>Check strings**

Check strings compares selected strings against a ***Map File*** and also checks distances between vertices on strings.

Selecting **Check strings** brings up the **Check Strings** panel.



The fields and buttons used in the panel have the following functions.

Field Description   Type   Defaults   Pop-Up

Data source type   Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source   input

source of data to be processed.

Map file   map file box

if a map file is picked then each selected string is compared against the map file keys and if any matches occur, the string attributes must agree with the map file fields of the matched key. Any differences will be reported to the Output window and the Report file.

Min length   input

report if any distance between adjacent vertices in a string is less than Min length.

Max length   input

report if any distance between adjacent vertices in a string is greater than Max length.

Min height   input

report if any vertex height is less than Min height.

Max height   input

report if any vertex height is greater than Max height.

Zero heights tick box

if ticked, any vertex heights equal to 0.0 will be reported. It is vary rare that any height is exactly 0.0

Report file

*if **non blank**, any failures are reported in this file.*

Check button

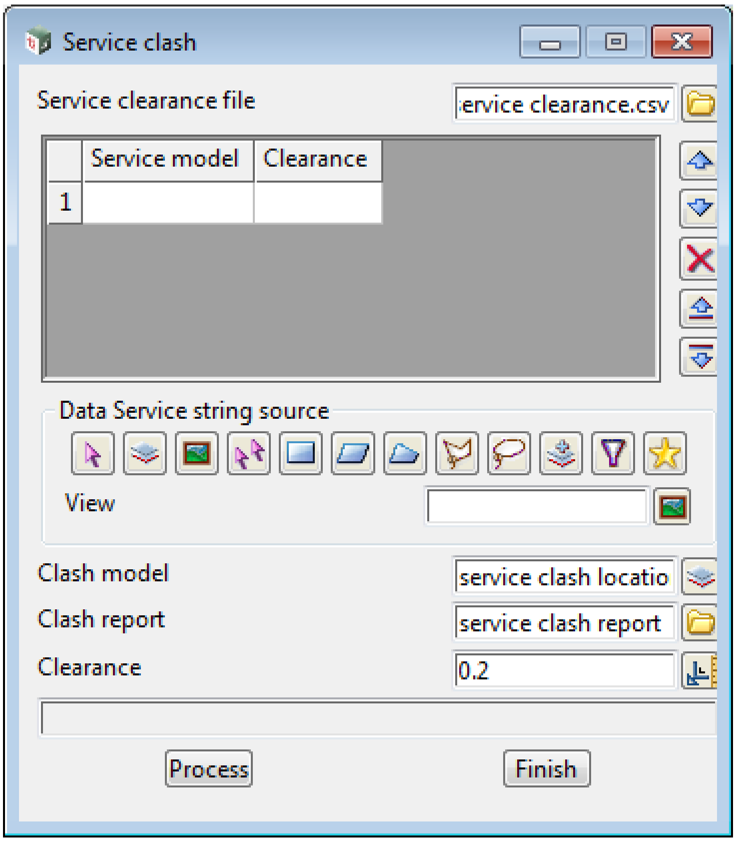
process the selected strings

28.9.9.4 Strings Clash in 3d

Position of option on menu: **Utilities =>A-G =>Check/clash =>3d service clash**

3d service clash compares selected models of strings and checks to see if they intersect each other.

Selecting **3d service clash** brings up the **Service Clash** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Service clearance file	file box		*.csv files

csv file containing a list of model names and clearances. This file is read in as soon as the option starts and fills out the Service and Clearance grid.

Grid - Service model and Clearance

For a row in the grid:

*any string in the model of name **Service model** must have the clearance given in the **Clearance** column. That is, any other string must be at least the **Clearance** distance from the string from the **Service** model.*

When the option starts, the grid is loaded from the **Service clearance file**. *The grid can be modified and whenever the* **Process** *button is selected, the contents of the grid is written to the file name given by* **Service clearance file.**

Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Each string in the data source is processed against all other strings selected by the Data source.

If a string is from a model listed in the ***Service model and Clearance*** *grid, then the corresponding clearance is used for the string, otherwise the default clearance given in the* **Clearance** *panel field is used.*

Clash model model box available models

the lines of clash between any two strings is placed in the **Clash model**.

Clash report

a report is generated for any clashes

Clearance input

the default clearance to use for a string that is ***not*** *in any of the Service models given in the* ***Service model and Clearance*** *grid*

Process button

process the selected strings and check for clashes

28.9.10 Classify Conduits

Position of option on menu: **Utilities =>A-G =>Classify conduits**

This option sets attributes on “conduit strings”, *i.e.* strings of the following type only: *Super* (with conduit dimensions), *Drainage*, *Pipeline*, *Pipe*.

String attributes set are:

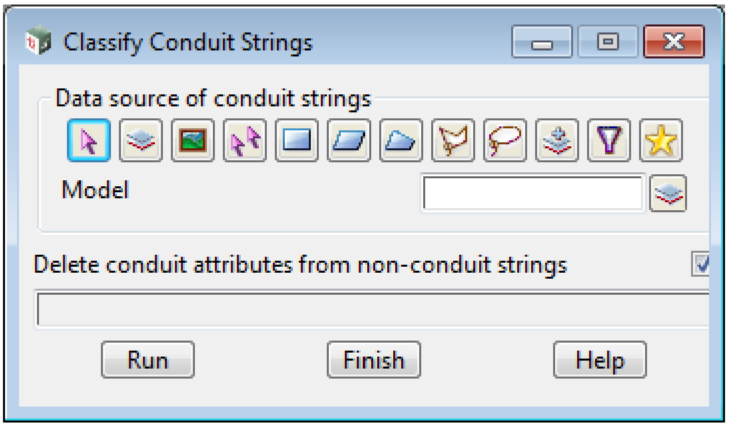
"justification" (text) on all strings - values set to "invert", "obvert" or "centre".
"pipe size" (text) on constant-size Super string conduits, Pipeline and Pipe strings.
"diameter" (real) on constant-size Super string conduits, Pipeline and Pipe strings.
"width" (real) on constant-size Super string box conduits.

Segment attributes set are:

"pipe size" (text) on all Super string conduit segments.
"diameter" (real) on all Super string conduit segments.
"width" (real) on all Super string box conduit segments.

Notes:
1) *Drainage* and *Pipeline* strings are always invert justified.
2) *Pipeline* and *Pipe* strings are always circular with a constant diameter.
3) *Super* string conduits may be circular or box. *Drainage* strings may be circular, box, vee or trapezoid.
4) For non-circular conduit shapes, attribute "diameter" represents height of conduit.
5) Attribute "pipe size" is in mm (base units x 1000) and supports shapes: circular, box, vee, trapezoid - eg: "600", "1200x600", "V2000x600", "T2000B1200x600".
6) *Drainage* strings already have Pipe attributes "diameter" and "pipe size" (and potentially "width" and/or "top width") set via the *Drainage Network Editor*.

On selecting the **Classify conduits** option, the **Classify Conduit Strings** panel is displayed.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source of conduit strings input

source of data to be processed

Delete conduit attributes from non-conduit strings tick box ticked *whether to delete the above mentioned string and segment attributes (if present) from non-conduit string types*

Run button

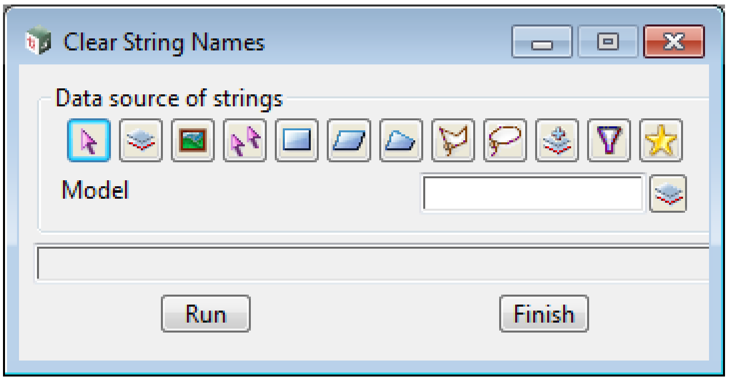
runs the option

28.9.11 Clear String Names

Position of option on menu: **Utilities =>A-G =>Clear string names**

Clear string names removes the names for all the selected strings.

Selecting **Clear string names** brings up the **Clear String Names** panel.



The fields and buttons used in the panel have the following functions.

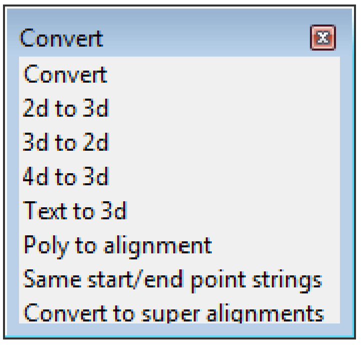
Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source.			
Data source	input		
source of data to be processed.			
Run	button		
remove/delete the string names from the selected strings			

28.9.12 Convert

Position of menu: **Utilities =>A-G =>Convert**

The **convert** options are designed to convert large numbers of strings between string types. There is also a **global convert** option which will convert even more string types.

The **convert** walk-right menu is



convert bulk strings
convert 2d strings to 3d strings
convert 3d strings to 2d strings
convert 4d strings to 3d strings
convert text to 3d points
convert polylines to alignments
convert closed strings to closed super strings
convert strings to super alignments

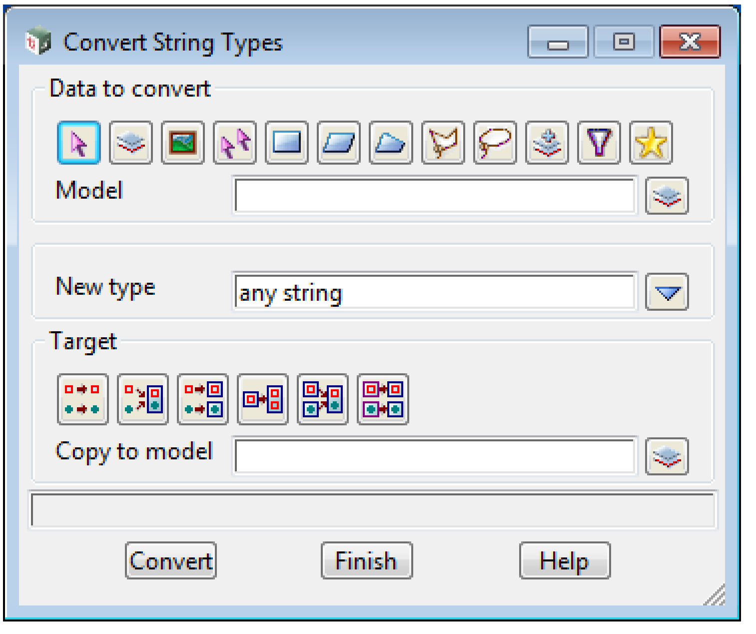
For the option *Convert*, go to the section 28.9.12.1 Convert
2d to 3d 28.9.12.2 2d to 3d
3d to 2d 28.9.12.3 3d to 2d
4d to 3d 28.9.12.4 4d to 3d
Text to 3d 28.9.12.5 Text to 3d
Poly to alignment 28.9.12.6 Poly to Alignment
Same start/end point strings 28.9.12.7 Same Start/End Point Strings
Convert to super alignments 28.9.12.8 Convert to Super Alignment

28.9.12.1 Convert

Position of option on menu: **Utilities =>A-G =>Convert =>Convert**

The **Convert** option converts strings to a selected string type.

On selecting the **Convert** option, the **Convert String Types** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up

Data source type | | Model |

data selection type - for a full description go to 4.19.3 Data Source.

Data source | input

source of data to be processed.

New type | string type box | | all string types

the type of string to try and convert the data to.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info | input

extra information required for the target.

Convert | button

convert all the selected strings to the type given in the **New type** *field.*

28.9.12.2 2d to 3d

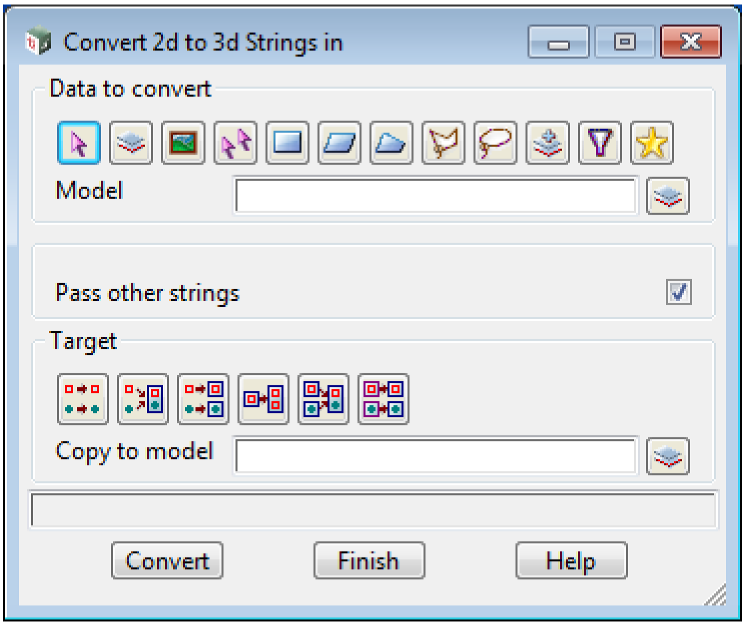
Position of option on menu: **Utilities =>A-G =>Convert =>2d to 3d**

The main difference between a 2d and a 3d string is that all the points in a 2d string have the same height. Hence to modify the z-values at individual points, a string must be 3d.

The **2d to 3d** option is used to turn 2d (contour) strings into 3d strings.

This option is especially useful when a large number of strings have been read in with constant z-values (for example, cadastre) and the user then wants to modify the heights at each point on the string.

On selecting **2d to 3d** and then the appropriate **Data Source** in the panel, the **Convert 2d to 3d Strings in** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Pass other strings	tick box	tick	

*if **ticked**, copies of all other strings are passed through to the model for converted strings*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Convert	button		

convert all the 2d string in the Data source to 3d strings.

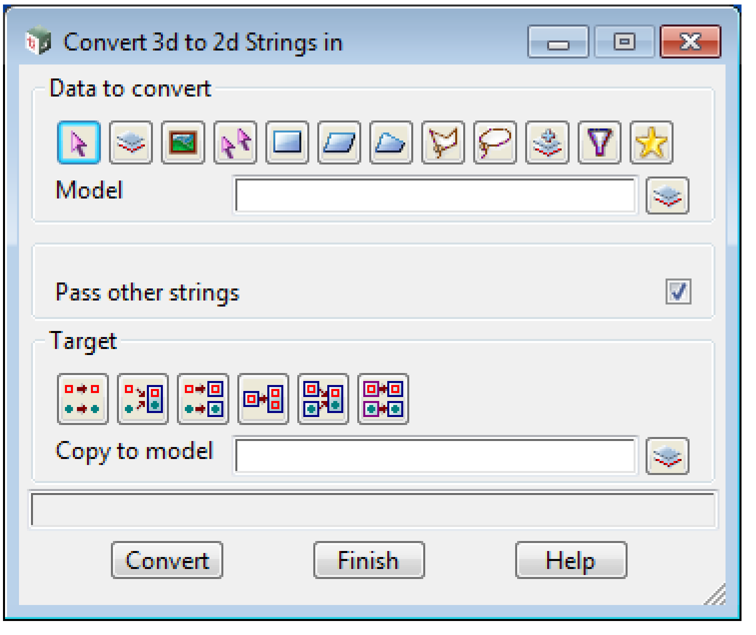
28.9.12.3 3d to 2d

Position of option on menu: **Utilities =>A-G =>Convert =>3d to 2d**

The difference between a 3d and a 2d string is that all the points in a 2d string have the same height. The **3d to 2d** option turns 3d string with a constant height into 2d strings. That is, it only converts 3d strings that have the **same** height at each point.

This option is useful when contours strings have come from another system as 3d strings, not 2d strings.

On selecting **3d to 2d** and then the appropriate **Data Source** in the panel, the **Convert 3d to 2d Strings in** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Pass other strings	tick box	tick	

*if **ticked**, copies of all other strings are passed through to the model for 2d strings*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Convert	button		

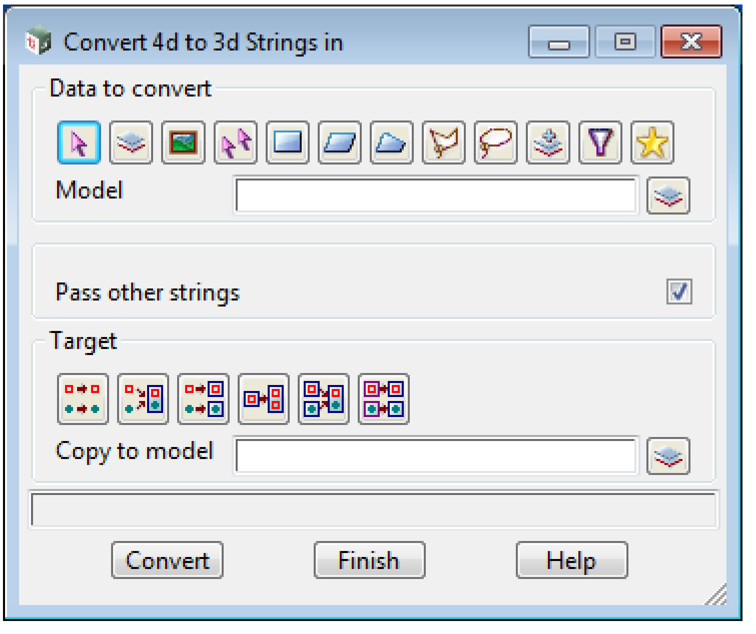
*convert all the 3d strings with **constant** height in the Data source to 2d strings.*

28.9.12.4 4d to 3d

Position of option on menu: **Utilities =>A-G =>Convert =>4d to 3d**

The difference between a 4d and a 3d string is that a 4d string can have a text label at each point on the string. The **4d to 3d** option turns 4d string into 3d strings by stripping off the text labels at each point of the 4d string.

On selecting **4d to 3d** and then the appropriate **Data Source** in the panel, the **Convert 4d to 3d Strings in** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.

Pass other strings tick box tick

*if **ticked**, copy all other strings and pass them through to the model for 3d strings*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Convert button

convert all the 4d strings in the Data source to 3d strings.

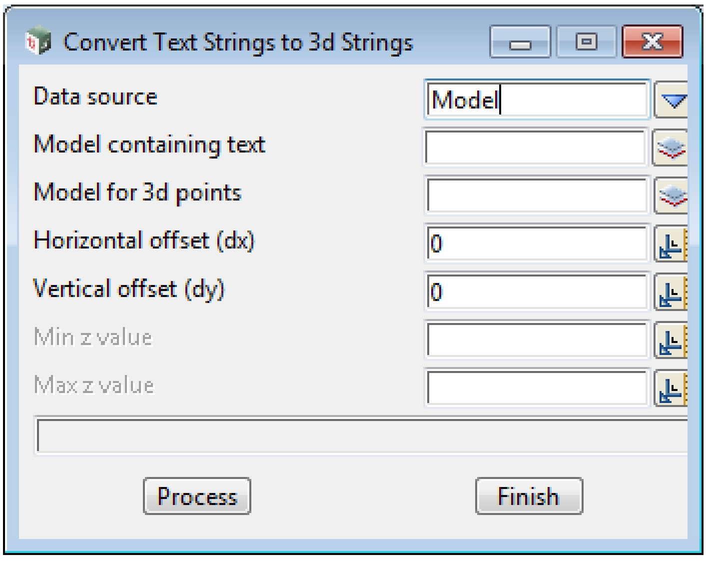
28.9.12.5 Text to 3d

Position of option on menu: **Utilities =>A-G =>Convert =>Text to 3d**

Sometimes when data for points is received from a CAD systems, all that is received is the text of the z-value of the point and no actual point.

The *Text to 3d* option will find text representing a z-value and create a new point using the justification point of the text as the (x,y) position and the value of the text as the z-value.

On selecting **Text to 3d**, the **Convert Text Strings to 3d Strings** panel is displayed.



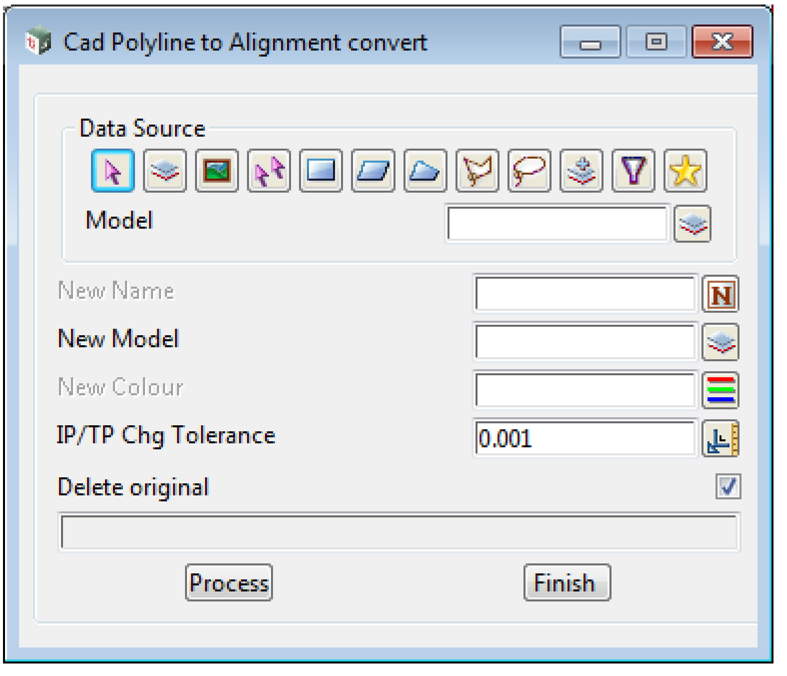
The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source.			
Data source	input		
source of data of the text to be processed.			
Model for 3d points	model box		available models
model to place the 3d points in.			
Horizontal offset (dx)	input	0	
the x-value for created point is the text justification point less the horizontal offset.			
Vertical offset (dy)	input	0	
the y-value for created point is the text justification point less the vertical offset.			
Min z value	input		
if non-blank, only convert text with z-value greater than **Min z value**.			
Max z value	input		
if non-blank, only convert text with z-value less than **Max z value**.			
Process	button		
convert all the selected text strings to 3d strings.			

28.9.12.6 Poly to Alignment

Position of option on menu: **Utilities =>A-G =>Convert =>Poly to alignment**

Selecting **Poly to alignment** brings up the **CAD Polyline to Alignment Convert** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source.			
Data source	input		
source of data of the text to be processed.			
New name	name box		available names
*if **non blank**, new name for the converted strings*			
New model	model box		available models
new model for the converted strings			
New colour	colour box		available colours
*if **non blank**, new colour for the converted strings*			
IP/TP chg tolerance	input		0.001
Delete original	tick box		tick
*if **ticked**, the original strings are deleted.*			
Process	button		
convert all the selected alignments.			

28.9.12.7 Same Start/End Point Strings

Position of option on menu: **Strings =>Properties =>Same start/end point strings**

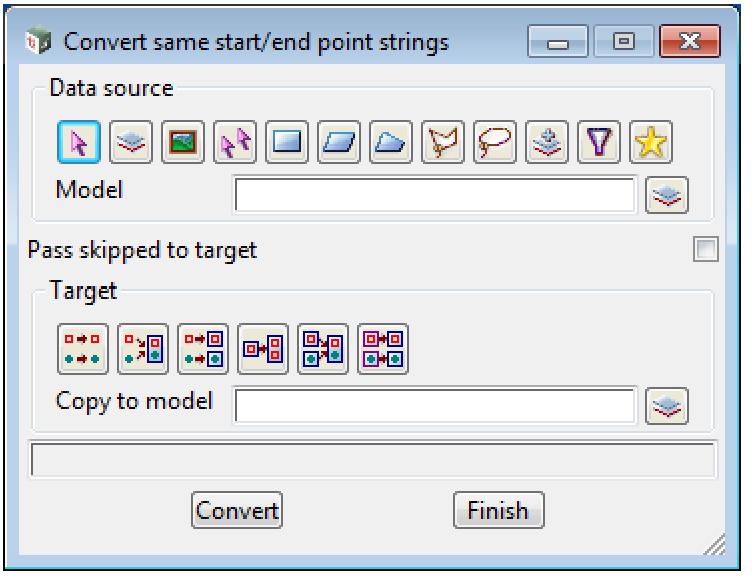
Position of option on menu: **Utilities =>A-G =>Convert =>Same start/end point strings**

Position of option on menu: **Utilities =>Super strings =>Same start/end point strings**

When non super string strings are closed, an extra vertex identical to the first vertex is added to the end of the string. For super strings, there is a ***closed string*** flag and no duplication of the first and last vertices is required.

This options converts closed non super strings to closed super strings and deletes the duplicated vertex.

Selecting **Same string/end point strings** brings up the **Convert Same Start/End Point Strings** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Pass other strings	tick	tick	

*if **ticked**, copy all other strings and pass them through to the target model*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Convert	button		

convert all the closed strings to closed super strings with duplicated end point.

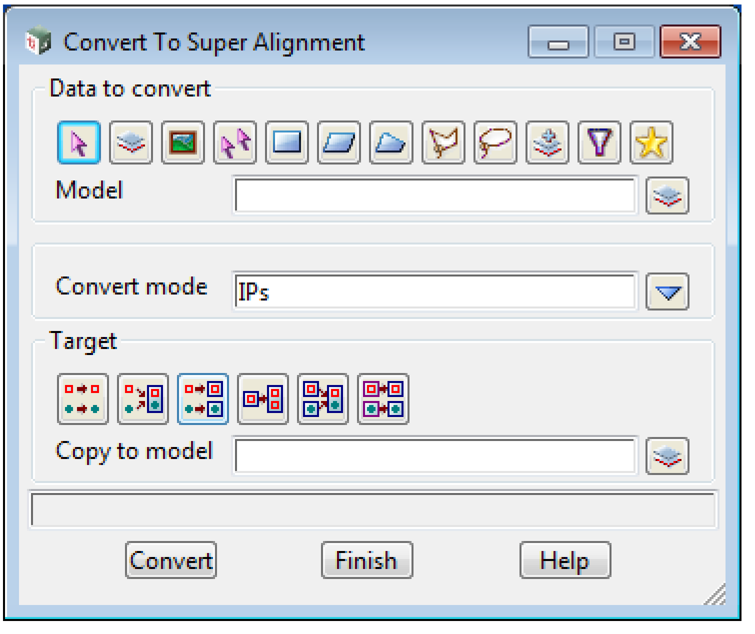
28.9.12.8 Convert to Super Alignment

Position of option on menu: **Utilities =>A-G =>Convert =>Convert to super alignments**

The **Convert** option converts strings to super alignments, either with just IPs or using Elements.

Note - conversion to *Elements* is only possible if you have the ***Alignment*** module.

Selecting **Convert to super alignments** brings up the **Convert to Super Alignment** panel.



The fields and buttons used in this panel have the following functions.

Field Description Type Defaults Pop-Up

Data source type Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.

Convert mode choice box IPs, Elements

*if **IPs**, the strings are converted to super alignments with IPs.*

*If **Elements**, the strings are converted to super alignments using Elements.*

Note - if the user does not have the Alignment module, then the **Convert mode** *is automatically set to IPs.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Convert button

convert all the selected strings to either super alignments with IPs or super alignments with Elements.

28.9.13 Cuts

Position of menu: **Utilities =>A-G =>Cuts**

Cuts is used to create intersections through string data rather than tins.

That is, it calculates the cuts that a plan string makes with each of the strings in a model or view, at creates cut points with the z-value from the cut strings.

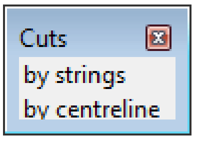
The cut points that the plan string creates are connected as a 4d string - the x-section of cuts through a model or view - with the z value coming from the cut string, and the text at the point being the name of string that was cut.

There are two methods for generating the cuts x-sections

(a) by taking sections along selected strings or all the strings in a model or view

(b) by taking sections at regular intervals and perpendicular to a selected centre line string.

The **Cuts** walk-right menu contains these two methods



For the option *by strings*, go to the section 28.9.13.1 Cuts by Strings.
by centreline 28.9.13.2 Cuts by Centreline.

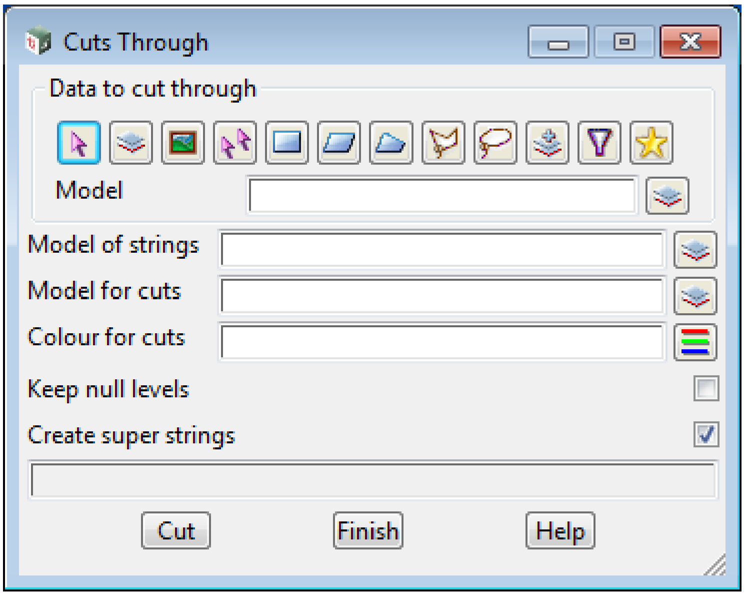
28.9.13.1 Cuts by Strings

Position of option on menu: **Utilities =>A-G =>Cuts =>by strings**

by strings generates cuts through a Data source of strings, for all the strings in a user specified model.

For each string in the **Model of strings**, the plan representation of the string is cut through the all the string in ***Data to cut through***, to generate cut x-sections.

Selecting **by strings** displays the **Cuts Through** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be cut through.

Model of strings input available models

each string in this model will be processed against all the strings in the Data source ***Data to cut through.***

Model for cuts input available models

model to place the cut x-sections into.

Colour for cuts input available colours

colour for the cut x- section strings

Cut button

each string in the **Model of strings** *is processed against all the strings in the Data source* ***Data to cut through****. The 4d strings of cuts are placed in the* **Model for cuts**.

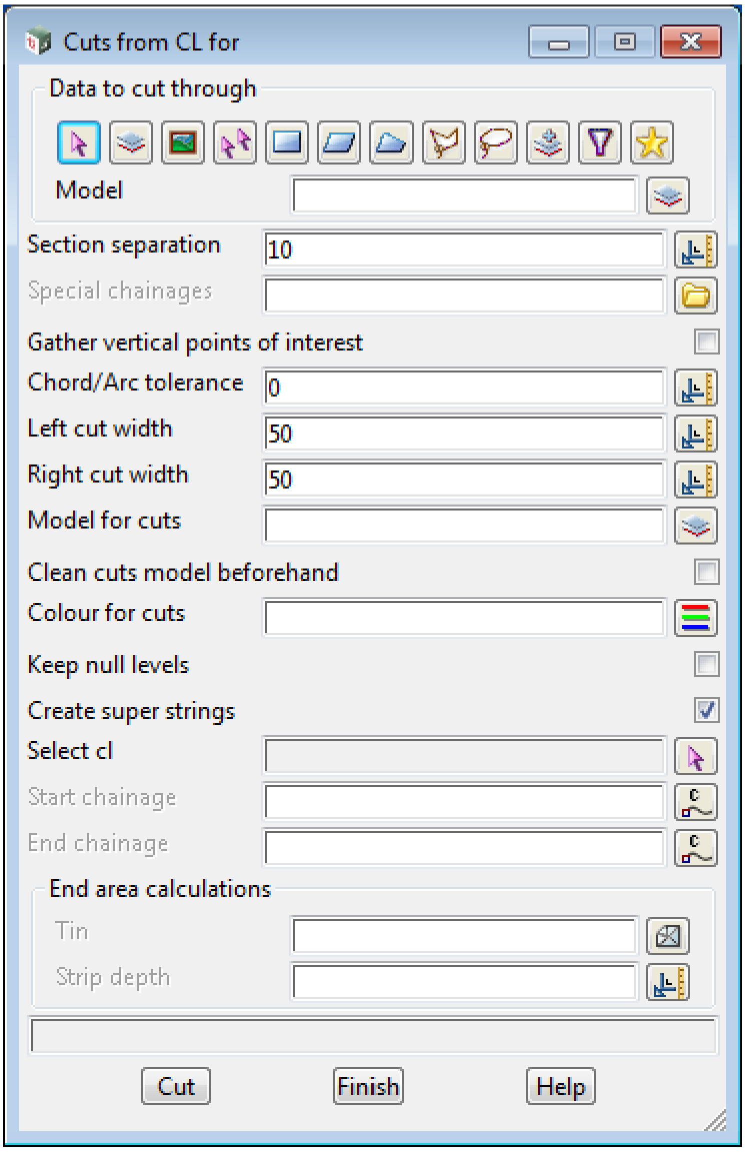
28.9.13.2 Cuts by Centreline

Position of option on menu: **Utilities =>A-G =>Cuts =>by centreline**

For **by centreline**, a centre line string is selected by the user and temporary plan lines are created at regular intervals perpendicular to the selected string.

Cut x-sections are then generated for the temporary plan section lines by taking cuts through the Data source **Data to cut through**.

Selecting **by centreline** displays the **Cuts from CL for** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Section separation	input	10.0	

the distance along the selected centre line to generate plan section lines to be used to cut through the *data source.*

Special chainages input *.spf files

a file containing chainages, one per line, that are also used as chainages to create cross sections at.

Gather vertical points of interest tick box

whether or not to create cuts at vertical points of interests (sags, crests, vertical tangent points etc)

Chord/arc tolerance input default chord/arc tolerance

the chord to arc tolerance to use on the selected string for determining how many plan sections are created around horizontal curves.

Left/Right cut width input 50

the left/right distance to go out from the centre line for creating a section to cut through the strings.

Model for cuts input available models

model to place the cut x-section strings into.

Clean cuts model beforehand tick box

*if **ticked**, the model is cleaned of all data before new sections are created.*

Colour for cuts colour box available colours

colour for the cut section strings

Keep null levels tick box

*if **ticked**, then if a null level exists on the string being cut, then a null level point is created.*

Select cl string-select

the selected cl string is used to create plan section lines at regular intervals and perpendicular to the centre line string. These strings are cut though the model/view of strings.

Start/End chainage input

if non-blank then sections for the cuts are restricted to between the given start and end chainage of the selected cl string.

End Area Calculations

Tin tin box available tins

*if **non-blank**, the cut and fill areas for the section against the tin are calculated and added as attributes to the section.*

Strip depth input

*if **non-zero**, then a strip depth is removed from the tin before the cut and fill areas for the section against the tin are calculated.*

Cut button

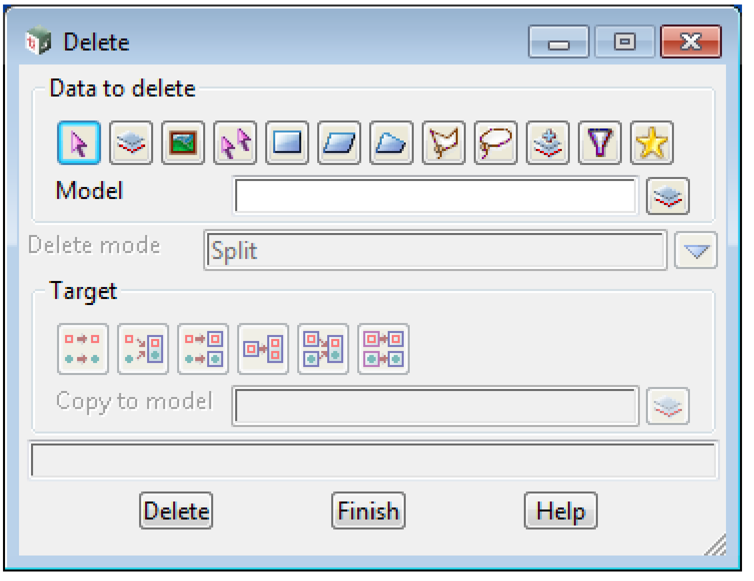
each plan section line generated down the selected centre line string is processed against all the strings in the Data source. The 4d strings of cuts are placed in the **Model for cuts**.

28.9.14 Delete

Position of option on menu: **Utilities =>A-G =>Delete**

The **Delete** option deletes all the selected strings.

On selecting the **Delete** option, the **Delete** panel is displayed.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source	input		

source of data to be processed.

Delete	button		

delete the selected strings.

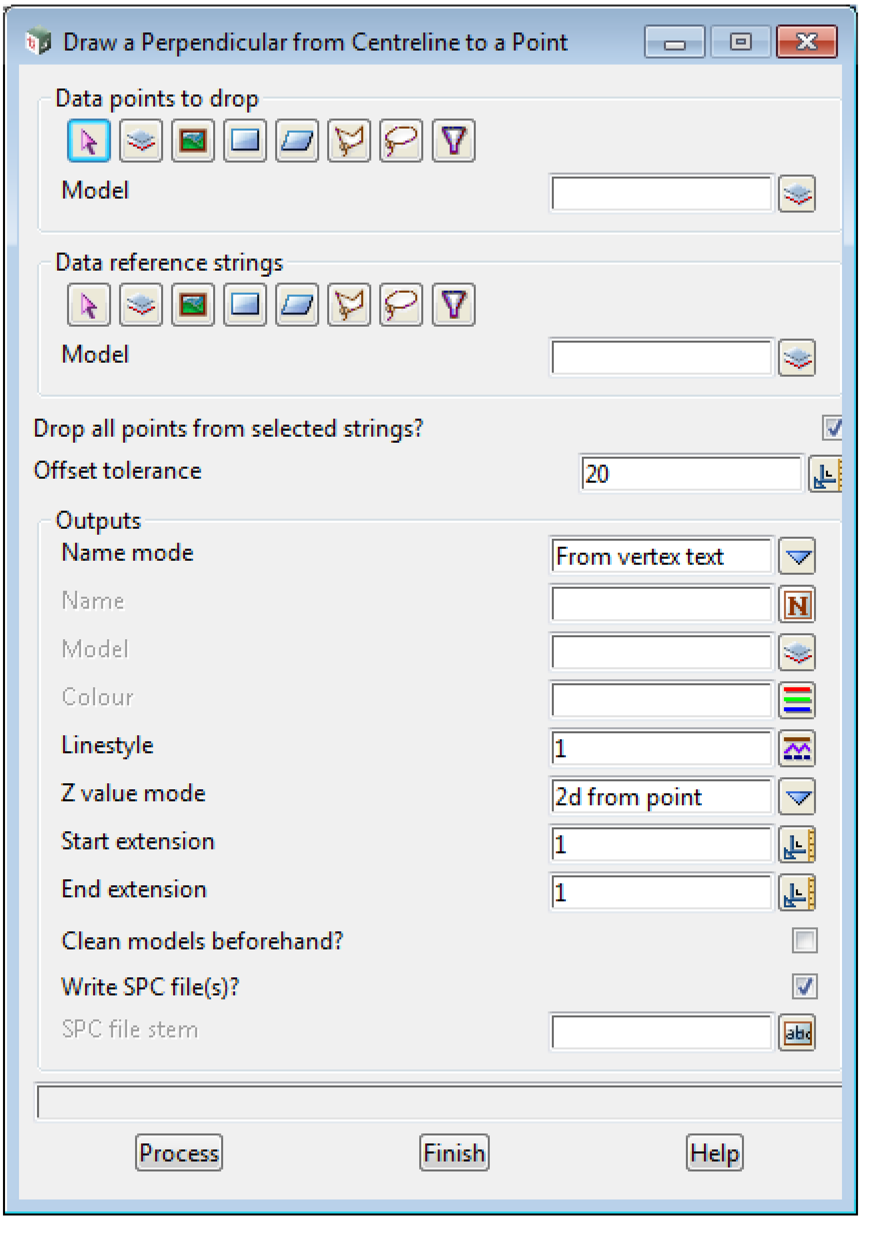
28.9.15 Draw a Perpendicular from Centreline to a Point

Position of option on menu: **Utilities =>A-G =>Draw perpendicular cl to points**

This option creates strings drawn perpendicular from reference alignments to selected points, and output a Special Chainage (SPC) file of the reference chainages that the points are perpendicular to. The user has the choice of either output, or both.

Typical uses are to create a model of cut strings which can be used to for cut labelling on long section plots where features such as property access locations occur along the road corridor, or to write SPC files that can be used to create cross sections through the dropped points when running **Apply MTF** functions.

Selecting **Draw perpendicular cl to points** displays the **Draw a Perpendicular from Centreline to a Point** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up

Data Points To Drop

Gathers a list of all the points on the selected strings.

For a full description of data source go to 4.19.3 Data Source

Data Reference Strings

Selects the reference strings that the above points will be dropped onto. Reference strings must be of type Alignment or Super Alignment.

For a full description of data source go to 4.19.3 Data Source

Drop all points from chosen strings? tick box ticked

The default is to calculate chainages and/or strings from every point in the selected strings.

*Turning this tick box off will restrict the calculation to the end points only. e.g. It can be used to create cut strings for use with the **paired cuts** functionality in long section plotting.*

Offset Tolerance input

Will restrict the search to points that fall within the specified width from the reference string.

Outputs

Name mode	choice box	From point text	From point text, From string names, Typed

*For the **From point text** mode, the name of the new string is set by the text attached to the points.*

*For the **From string names** mode, the name of the new string is set by the selected strings.*

*For the **Typed** mode, the name is given in the* **Name** *field.*

Name	name box		names.4d file

*This only needs to be filled in when using the **Typed** name mode. This field is not required for the other* **Name mode** *choices.*

Model	model box		available models

The model to store the new strings on. This field is optional and no strings will be created if left blank. e.g. if you only want Special Chainage Files.

Colour	colour box		available colours

The colour to draw the new strings with.

Linestyle	linestyle box	1	available linestyles

The linestyle to draw the new strings with.

Z value mode	choice box	2d from point	2d from point, 2d from reference, 3d reference to point

The method by which z values are assigned to the points on the new string.

*For the **2d from point** mode, all points have the same z value as the point being dropped.*

*For the **2d from reference** mode, all points have the same z value as the reference string.*

*For the **3d reference to point** mode, the new string is drawn from the z value at the reference to the z value of the dropped point.*

Start extension	measure box	1	At point, Point to Point, String from Point, String to Point

End extension	measure box	1	At point, Point to Point, String from Point, String to Point
Write SPC Files(s)?	tick box	ticked	

The writing of Special Chainage Files is optional.

If ticked, the names of the files are automatically derived from the combination of Model name and Reference string name and a user defined file stem (given in the **SPC file stem** *field) may be added to the name.*

SPC File Stem text box

An optional user entered text value that is added to the automatically derived file name.

Process button

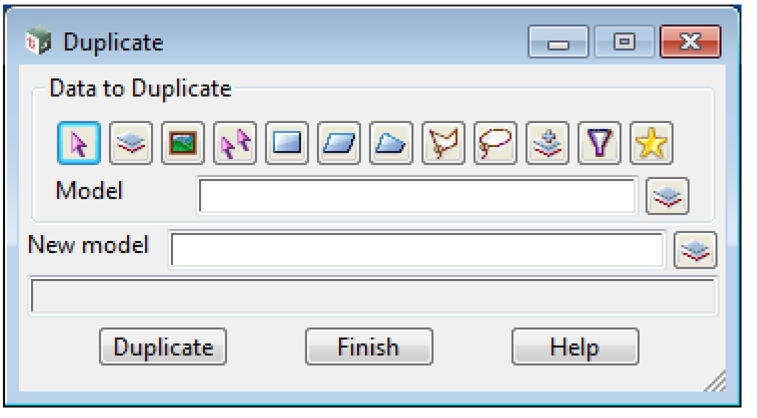
run the option.

28.9.16 Duplicate

Position of option on menu: **Utilities =>A-G =>Duplicate**

Duplicate makes duplicates of strings.

Selecting **Duplicate** displays the **Duplicate** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

New model	input		available models

name of the model to place the duplicated strings into.

Duplicate	button		

duplicate all the strings in the data source.

<esc> can be used to abort the duplicate option.

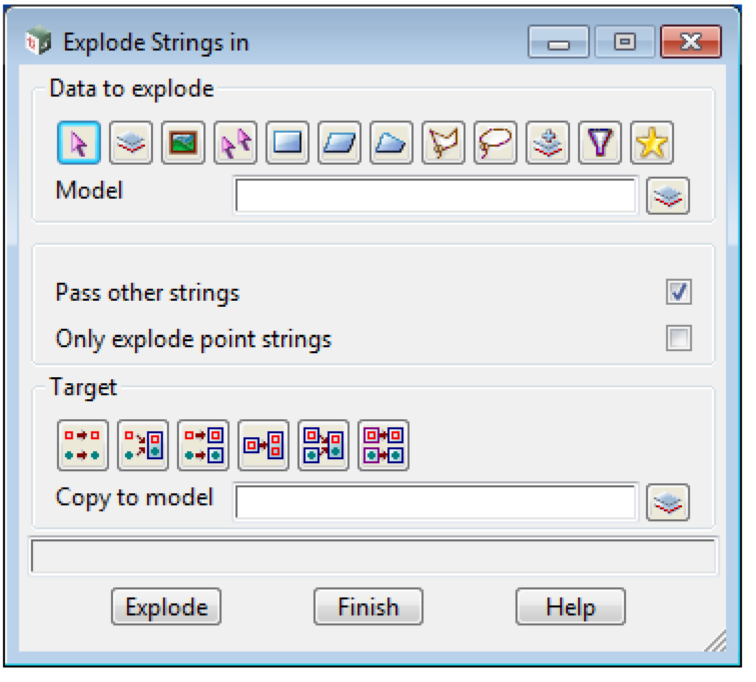
28.9.17 Explode

Position of option on menu: **Utilities =>A-G =>Explode**

The **Explode** option explodes point strings into individual one vertex strings and line strings into individual segments.

Super alignment, Alignment, pipeline, sewer and drainage strings are not exploded.

On selecting **Explode** and then the appropriate **Data Source** in the panel, the **Explode Strings in** panel is displayed.



The fields and buttons used in the panel have the following functions.

Field Description Type Defaults Pop-Up

Data source type Model

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

Pass other strings tick box tick

if ***ticked****, copies of all other strings and passed through to the exploded model.*

Only explode point strings tick box

if ***ticked****, only point strings are exploded. Line strings are left unexploded.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Explode button

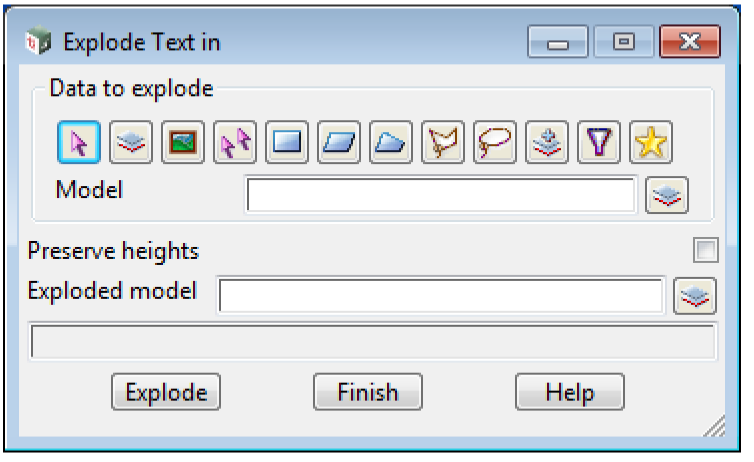
explode all the strings in the data source into one vertex strings and segments.

28.9.18 Explode Text

Position of option on menu: **Utilities =>A-G =>Explode (text)**

Explode (text) explodes text in text strings and the text from 4d strings, into its component arcs and lines. The exploded arcs and lines are placed in one new model.

Selecting **Explode (text)** displays the **Explode Text in** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Exploded model	input		available models

name of the model to place the exploded text strings and text of 4d strings into.

Explode	button		

explode all the selected text and add them to the model given in the **Exploded model** *field.*

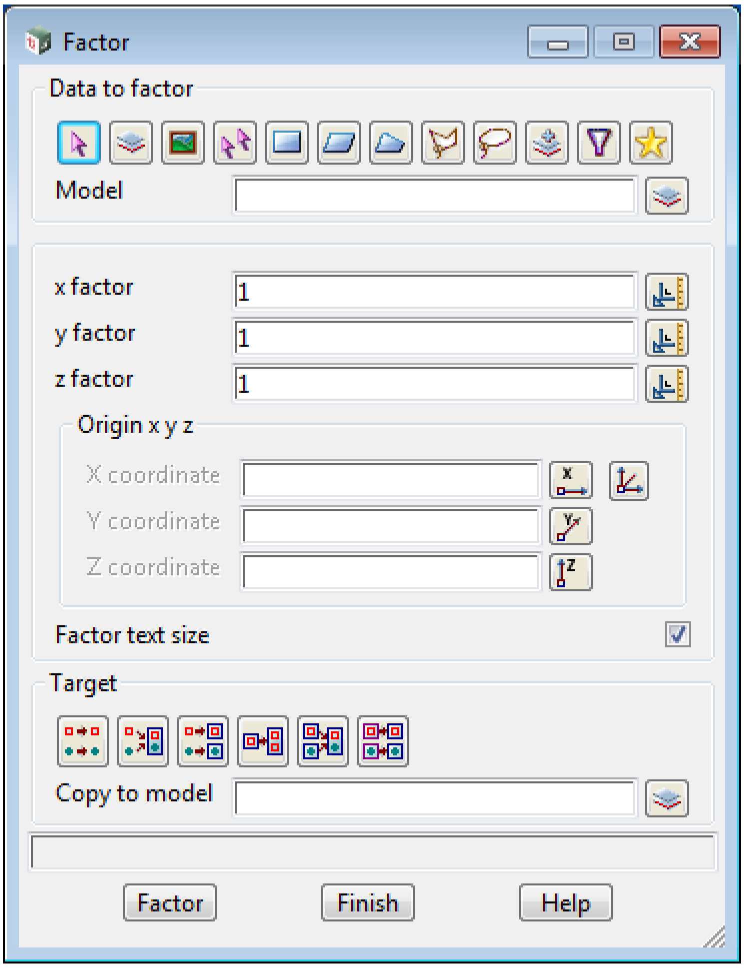
28.9.19 Factor

Position of option on menu: **Utilities =>A-G =>Factor**

Factor multiplies the x,y and z values of selected strings by user supplied factors.

The option is useful for changing the units of any data in a model (*e.g.* Imperial to metric).

Selecting **Factor** displays the **Factor** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

x/y/z factor	input	1.0	

factor to multiply the x/y/z-values of a string by.

Origin x y z	input		**xyz ops** menu

field with x y z value to be used as (x,y,z) origin for the factor.
*if **blank**, an origin of (0,0,0) is used.*

Factor text size tick box tick

*if **ticked**, the size of text is factored.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Factor button

multiply the (x,y,z) values of the selected strings by the x,y and z factors given in the appropriate panel fields.

WARNING - if the x factor and y factor are not equal, then arcs in arcs, circles, alignment and polyline strings can not be factored. For these cases, the y factor will be set the x-factor and then applied to the arcs.

28.9.20 Filter

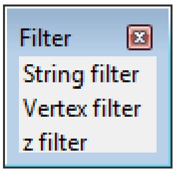
Position of menu: **Utilities =>A-G =>Filter**

The **Filter** options are used to remove surplus points from strings.

Three types of filters are currently supported in 12d Model:

- a string filter, which removes points from 2d and/or 3d line strings that do not deviate by more than a specified offset tolerance from straight lines joining successive string points (in three dimensions for 3d strings)
- a vertex-filter which removes adjacent vertices closer than a given user defined (x,y) and z distance
- a z-filter which eliminates points not contained within a specified z-range

The **Filter** walk-right menu is



filter 2d and 3d strings
removes close adjacent vertices
filter z values

For the option *String filter*, go to 28.9.20.1 String Filter
Vertex filter 28.9.20.2 Vertex Filter
z filter 28.9.20.3 Z Filter

28.9.20.1 String Filter

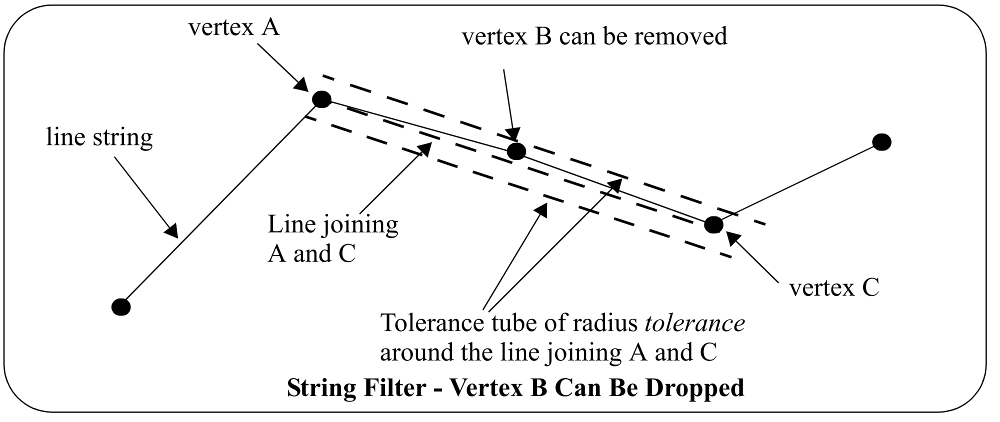
Position of option on menu: **Utilities =>A-G =>Filter =>String filter**

The **String filter** option is used to remove surplus vertices from 2d strings (contours) and 3d strings.

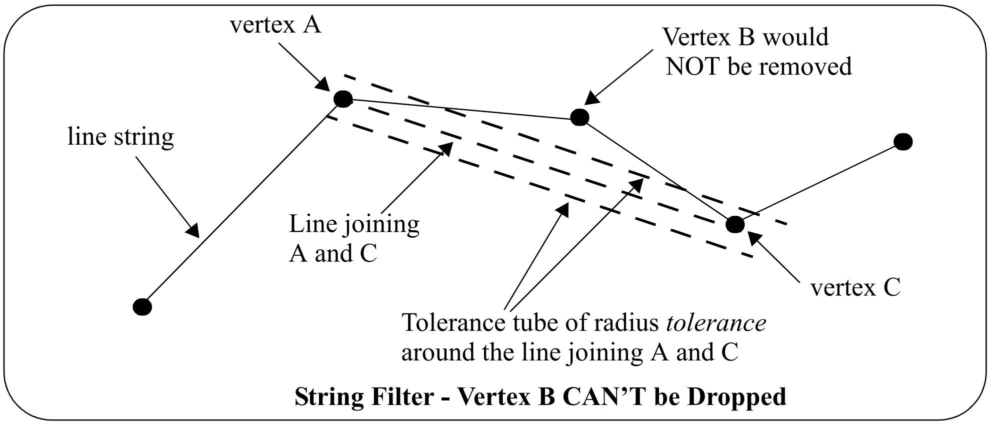
The string filter option tries to drop out vertices that if left out, don't make "too much difference".

So for a user defined tolerance:

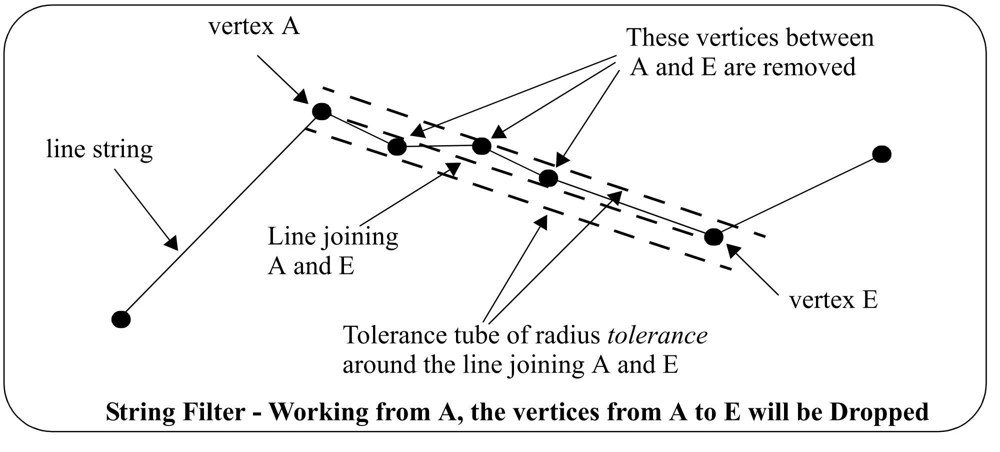
> if you have successive vertices A, B and C, and by leaving out vertex B, then the lines AB and BC don't go outside a tube of radius tolerance around the lines AC, then vertex B is dropped.



String Filter - Vertex B Can Be Dropped



String Filter - Vertex B CAN'T be Dropped



String Filter - Working from A, the vertices from A to E will be Dropped

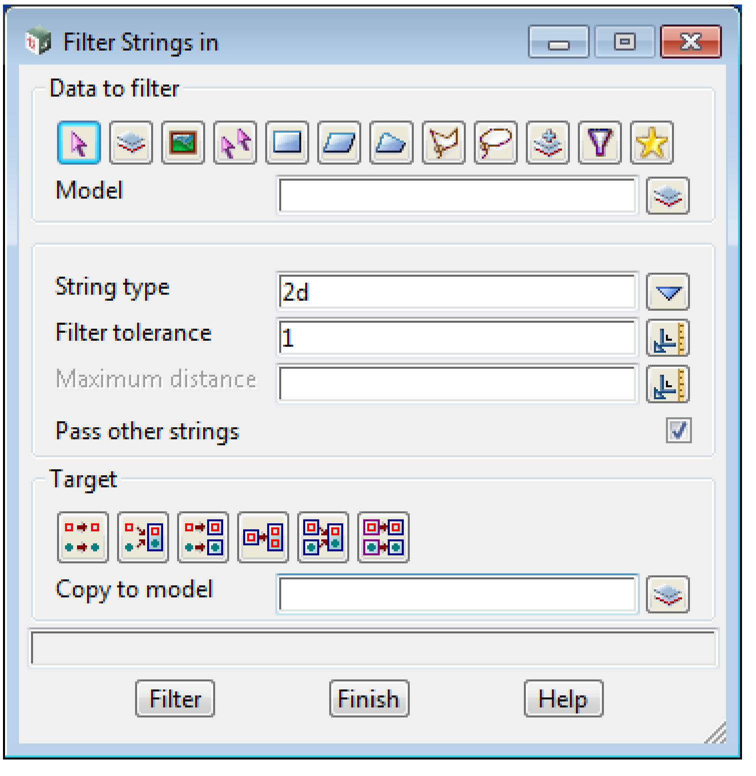
The filter starts at the first vertex of the string and looks ahead, dropping out vertices until it finds one that can't be removed. That vertex then become the new second vertex and the process is repeated but starting at the new second vertex. This process is repeated for the new third vertex and so on until the end of the string.

The *tolerance* value used normally depends on the data set and the job that the data is being used for.

So the string filter removes vertices from 2d and/or 3d line strings that do not deviate by more than a specified offset tolerance from straight lines joining successive string vertices (in three dimensions for 3d strings).

NOTE - string filer does not apply to point strings.

Selecting **String filter** displays the **Filter Strings in** panel.



The fields and buttons used in this panel have the following function

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source			
Data source	input		
source of data to be processed.			
String type	input	2d	2d, 2d & 3d
string types to be filtered			
Filter tolerance	input	1	
tolerance to be used in filtering			
Pass other strings	tick box	tick	
*if **ticked**, pass all other strings through to the model for filtered strings*			
Target type			
Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target			

Target info input

extra information required for the target.

Filter button

filter all the selected strings.

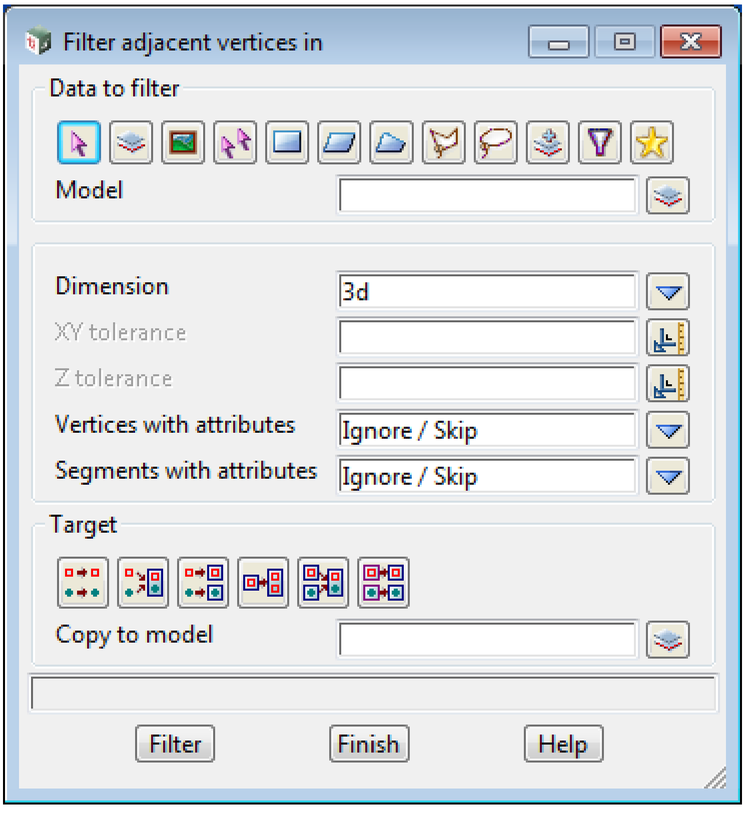
28.9.20.2 Vertex Filter

Position of option on menu: **Utilities =>A-G =>Filter =>Vertex filter**

The **Vertex filter** option is used to remove close adjacent vertices from selected strings. The strings can be *point* or *line* strings.

The option can remove adjacent string vertices that are equal to a given tolerance either in plan position only (*i.e.* have similar x and y co-ordinates) or equal to a given tolerance for x, y and z co-ordinates.

Selecting **Vertex filter** displays the **Filter adjacent vertices in** panel.



The fields and buttons used in this panel have the following function

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Dimension	input	2d	2d,3d

*if **2d**, adjacent string vertices with equal x and y co-ordinates are filtered.*
*If **3d**, adjacent string vertices with equal x, y and z co-ordinates are filtered.*

xy tolerance	input		

the distance to use for checking if adjacent vertices are too close in (x,y)

z tolerance	input		

the delta-z to use for checking if adjacent vertices are too close in z

Vertices with attributes	choice box	Ignore/skip	Ignore/skip, Merge attributes

Lose attributes

*if **Ignore/skip**, don't drop any vertices with attributes.*

*If **Merge attributes**, merge the attributes from a dropped vertex with the kept vertex.*

*If **Lose attributes**, drop the attributes from a dropped vertex.*

Segments with attributes choice box Ignore/skip Ignore/skip, Merge attributes Lose attributes

*if **Ignore/skip**, don't drop any vertices of segments with attributes.*

*If **Merge attributes**, merge the attributes from a dropped segment with the kept segment.*

*If **Lose attributes**, drop the attributes from a dropped segment.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Filter button

filter the selected strings.

28.9.20.3 Z Filter

Position of option on menu: **Utilities =>A-G =>Filter =>Z filter**

It is often necessary to remove data which is not within a certain z range. For example, all points with z-values below 0.0. The **z filter** option allows the user to define a z-range by specifying a minimum and maximum z value.

Strings of type 2d, 3d and 4d can then be processed against the z-range and new strings created containing only those points that are

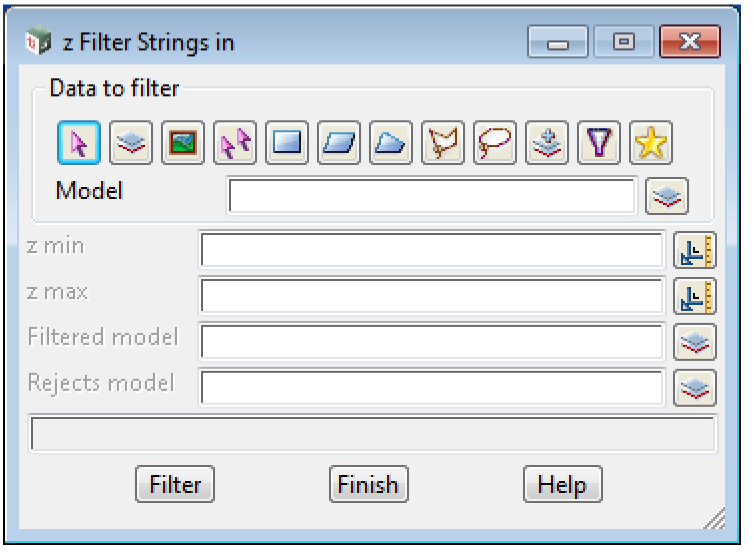
(a) within the z-range - accepted points

or

(b) outside the z-range - rejected points

For all other string types, the entire string is accepted if any part of the string is within the z-range, otherwise it is rejected.

Selecting **Z filter** displays the **Z Filter Strings in** panel:



The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up

Data source type | | Model |

data selection type - for a full description go to 4.19.3 Data Source

Data source | input

source of data to be processed.

z min | input

minimum z value to be accepted, If this field is blank, all string z-values pass the minimum test.

z max | input

maximum z value to be accepted, If this field is blank, all string z-values pass the maximum test.

Filtered model | input | | available models

if non-blank, the name of the model to place the accepted string points in. The string has the same name as the original string. If blank, the accepted point strings are not saved.

Rejects model | input | | available models

if non-blank, then strings containing the rejected points are placed in this model. The strings of rejected points have the same name as the original strings. If blank, the rejected point strings are not saved.

Filter button

z filter the selected strings by the z minimum and z maximum values.

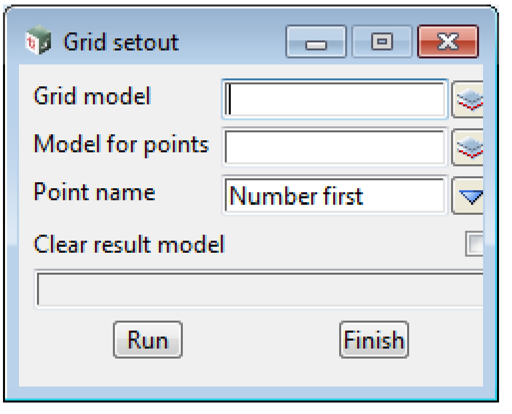
28.9.21 Grid setout

Position of option on menu: **Utilities =>A-G =>Grid setout**

Grid setout creates a set of points from the intersections of lines and/or arc strings. The strings to intersect normally form a grid.

It is assumed that the strings to intersect are named with letters along one axis of the grid and numbers in the other so that a point may be named in the following manner: 1a or a1.

Selecting **Grid setout** displays the **Grid Setout** panel.



The fields and buttons used in this panel have the following function

Field Description	Type	Defaults	Pop-Up
Grid model	model box		Select Model

The model of strings to intersect with each other

Field Description	Type	Defaults	Pop-Up
Model for points	model box		Select Model

the model to contain the points of intersection for the strings in **Grid model**.

Field Description	Type	Defaults	Pop-Up
Point name	choice box	Number first	Number first, Letter first, Any order

Method used to determine how to name the created points based on names of the strings being intersected:

Number first: use the numbered string first

Letter first: use the alphabetical string first

Any order: use the order in which the strings are processed

Field Description	Type	Defaults	Pop-Up
Clear result model	tick box		

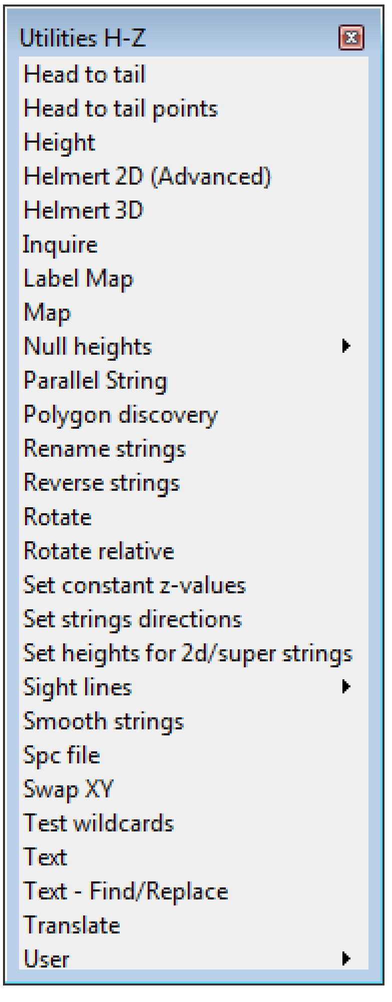
if tick, clean out the **Model for points** *before finding the intersections.*

Field Description	Type	Defaults	Pop-Up
Run	**button**		

run the option.

28.10 Utilities H-Z

Position of menu: **Utilities =>H-Z**



join strings with common ends
join one point strings into multi-point strings
give strings new height
2D Helmert, also allowing fixed scale
3D Helmert transformation
highlight selected strings
apply a Label Map File on strings
apply a Map File on strings
set heights to null value
parallel a string
find enclosing polygon from strings surrounding selected point
rename strings
reverse string directions
rotate strings about one point
various methods of rotating strings
give strings a constant z value
give strings same direction as selected string
set heights for 2d/3d super strings
options using sight lines
smooth strings
create special chainage points file
swap X and Y coordinates of strings
testing pattern and expression matching
modify text parameters
find and replace text
translate strings in model/view

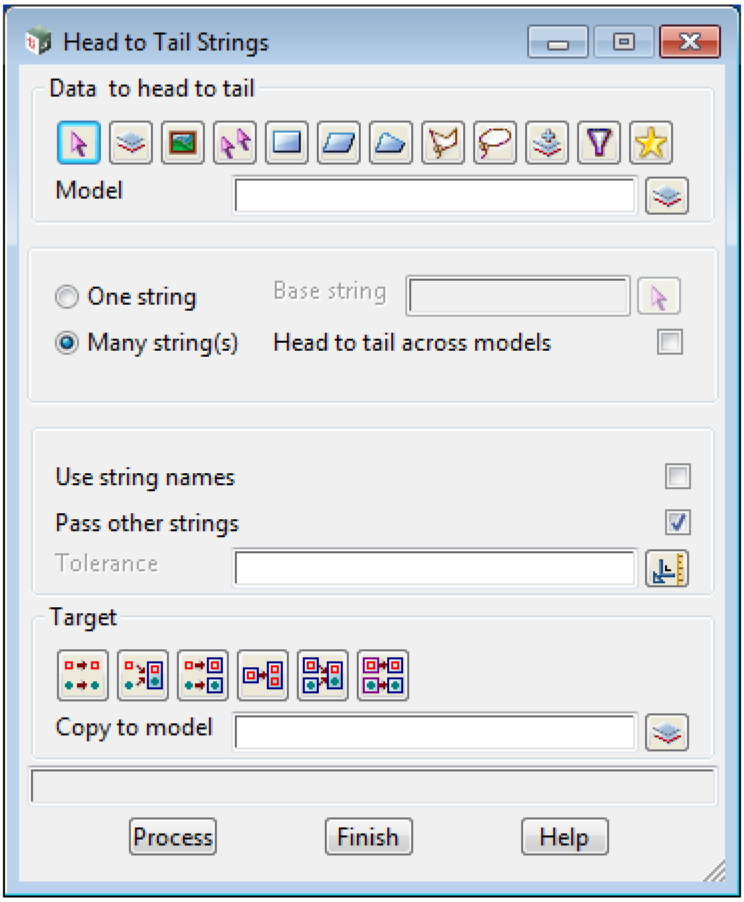
28.10.1 Head to Tail

Position of option on menu: **Utilities =>H-Z =>Head to tail**

Head to tail is used to join strings with common end points together.

If requested, strings are only joined if they have matching names as well as matching end points.

Selecting **Head to tail,** displays the **Head to Tail Strings** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

One string or **Many strings** radio button

*if **One String** is selected, then a Base string is selected and only the head-to-tailed string containing the Base string is created.*

*If **Many strings** is selected, then head to tailing occurs for all the strings in the Data source.*

Head to tail across models tick box

*if **ticked**, then strings can be created from head to tailing strings from any of the selected models.*

*If **not ticked**, then strings will only be head to tailed with strings from the same model.*

Use string names tick box

*if **ticked**, the string names must also match for the strings to be joined.*

Pass other strings tick box tick

*if **ticked**, any string not joined will also copied to the joined model.*

Tolerance input 0.0005

If the distance between two end points is less than **tolerance***, then the points are considered the same and the strings may be joined.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Process button

process all the selected strings

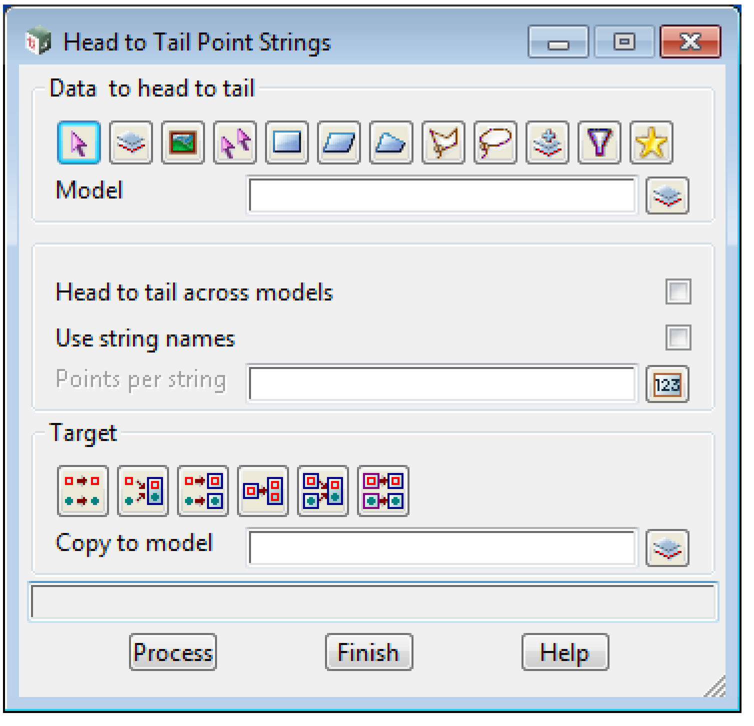
28.10.2 Head to Tail Point Strings

Position of option on menu: **Utilities =>H-Z =>Head to tail point strings**

Head to tail point string is used to joins point strings into larger point strings. This can speed up drawing and processing when there are large numbers of single point strings.

If requested, strings are only joined if they have matching names as well as being point strings.

Selecting **Head to tail points** displays the **Head to Tail Point Strings** panel.



The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

Head to tail across models tick box

*if **ticked**, then strings can be created from joining point strings from any of the selected models.*

*If **not ticked**, then strings will only joined with strings from the same model.*

Use string names tick box

*if **ticked**, the string names must also match for the strings to be joined.*

Points per string integer box

the maximum number of vertices to have in the joined strings.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Process button

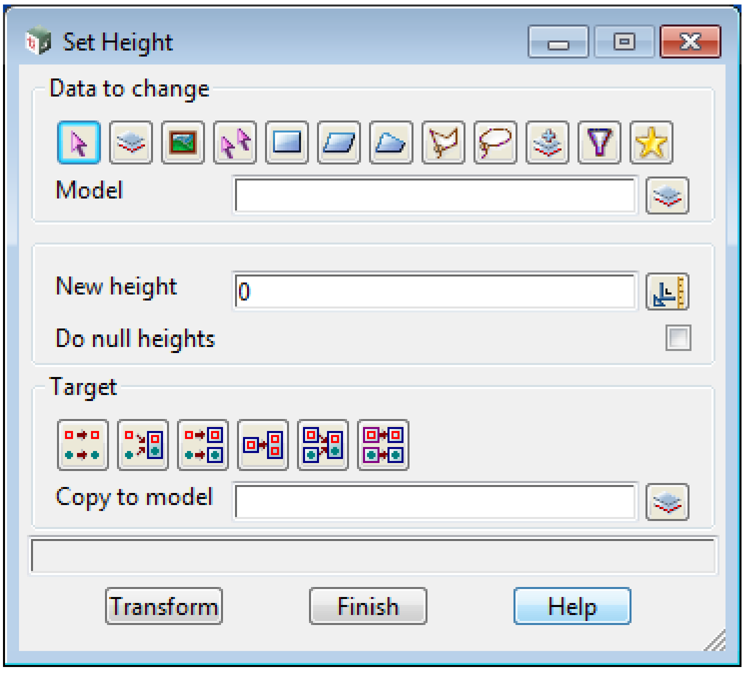
process all the selected point strings

28.10.3 Set Height

Position of option on menu: **Utilities =>H-Z =>Height**

For the selected strings, **Height** will set all the z-values to the given height.

Selecting **Height** displays the **Set Height** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

New height	input	0	

the new height to set all the z-values in the selected strings to.

Do null heights	tick box		

*if **ticked**, null heights are set to the new height.*
*If **not ticked**, null heights are not modified.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Set	button		

process the selected string

28.10.4 Helmert Transformations

See 28.10.4.1 2D Helmert (Advanced)
28.10.4.2 3D Helmert

28.10.4.1 2D Helmert (Advanced)

Position of option on menu: **Utilities =>H-Z =>Helmert 2D (Advanced)**

A ***2D Helmert*** transformation is a two dimensional linear transformation consisting of a scaling, rotation and a 2D- translation (shift) of data. That is, there are **four** parameters to be specified.

Hence the 2D Helmert parameters are

(a) the one scale factor for both the x and y axes

(b) the same rotation of the x-axis and y-axis of the existing coordinates to align it with the control x and coordinate axis

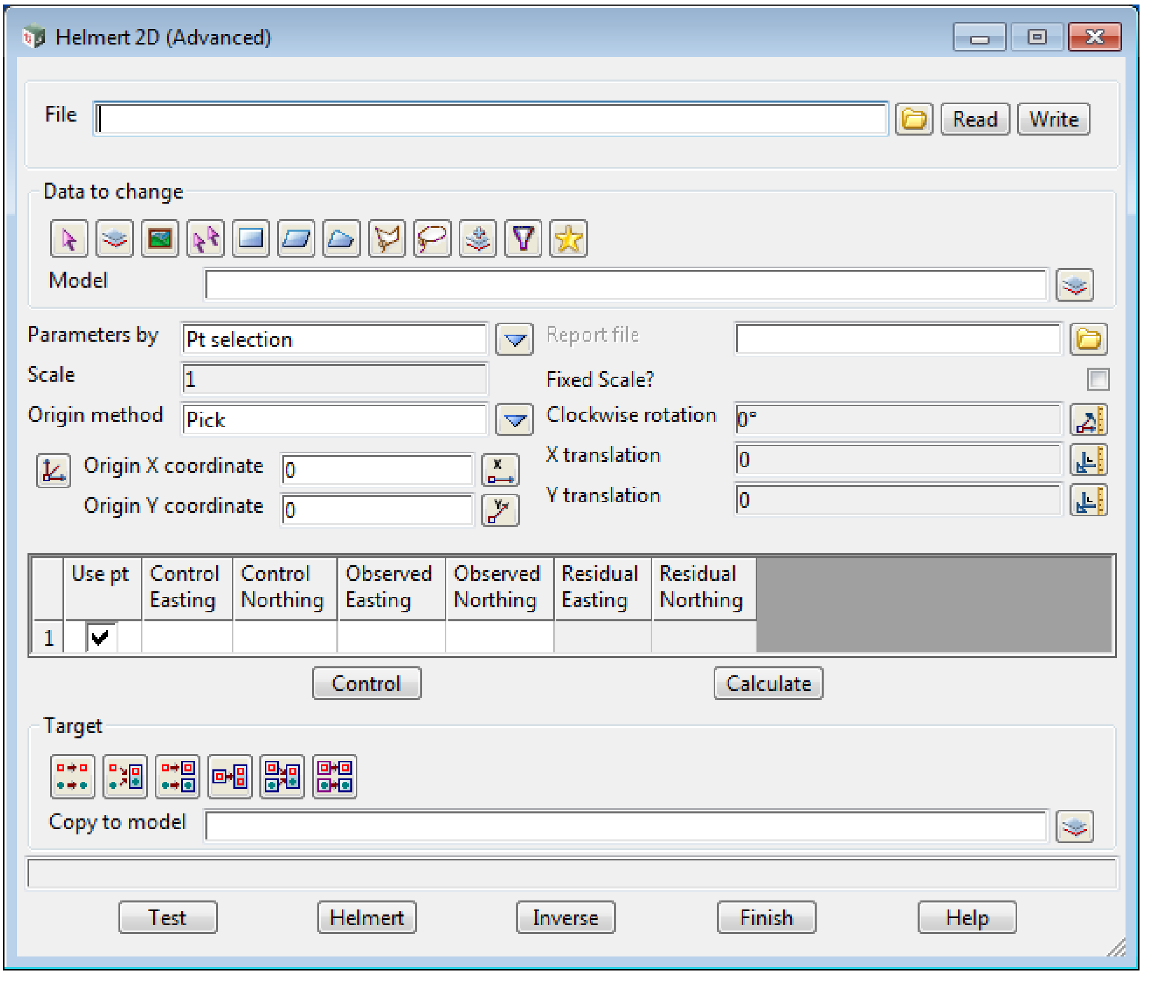
(c) the x and y translation of the observed coordinates after the scalings and rotations have been applied

The **2D Helmert (Advanced)** option calculated and applied a Helmert transformation, and also allows the user to ***fix the scale*** for the transformation. That is, the scale is user defined and not determined by the least squared calculations.

For information on the 2D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the **Affine Transformation works with Rasters,** go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

Selecting **2D Helmert (Advanced)** brings up the **Helmert 2D (Advanced)** panel.



If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
File	file box		*.hel_adv, *.hel files

the name of a 2d Helmert parameter file to read in/write out

Read button

read the contents of the .hel_adv (or .hel) file given in **File** *and load the parameters saved in the file into the panel fields.*

Note*: the *.hel file format is from an earlier Helmert panel that no longer exists in* ***12d Model****.*

Write button

write the parameters and data in the panel fields to the file given in **File**.

Data source type Model

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Parameters by	choice	Pt selection	Pt selection Direct entry

the parameter entry method.

Report file			*.rpt files

if not blank, write a report on the Helmert transformation.

Scale input/output

the scale factor for the existing coordinates with respect to the transformed coordinates

Fixed scale? tick box

*if ticked, the scale is entered into the **Scale** field and it is held fixed when the Helmert parameters are calculated from the selected control-observed point pairs.*

Clockwise rotation input/output

the rotation of the axes of the existing points with respect to the transformed axes.

Origin method	choice box	Pick	Pick, Obs'd centroid Ctrl centroid

the translation can be reported against another origin than the default (0,0).

Origin X/Y coordinate input

the translation parameters are written out with respect to this origin.

X Translation input/output

the x translation of the existing coordinates with respect to the transformed x coordinates

Y Translation input/output

the y translation of the existing coordinates with respect to the transformed y coordinates

Control button

restarts the selection process for choosing more control points.

Calculate button

calculate the helmert parameters from the selected points shown in the grid.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target.

Target info input

extra information required for the target.

Helmert button

apply the helmert transformation to the data specified in the source box, and put it into the appropriate target area.

Inverse button

applies the inverse transformation to the one defined in the panel.

Finish button

end the option, remove the panel from the screen.

28.10.4.2 3D Helmert

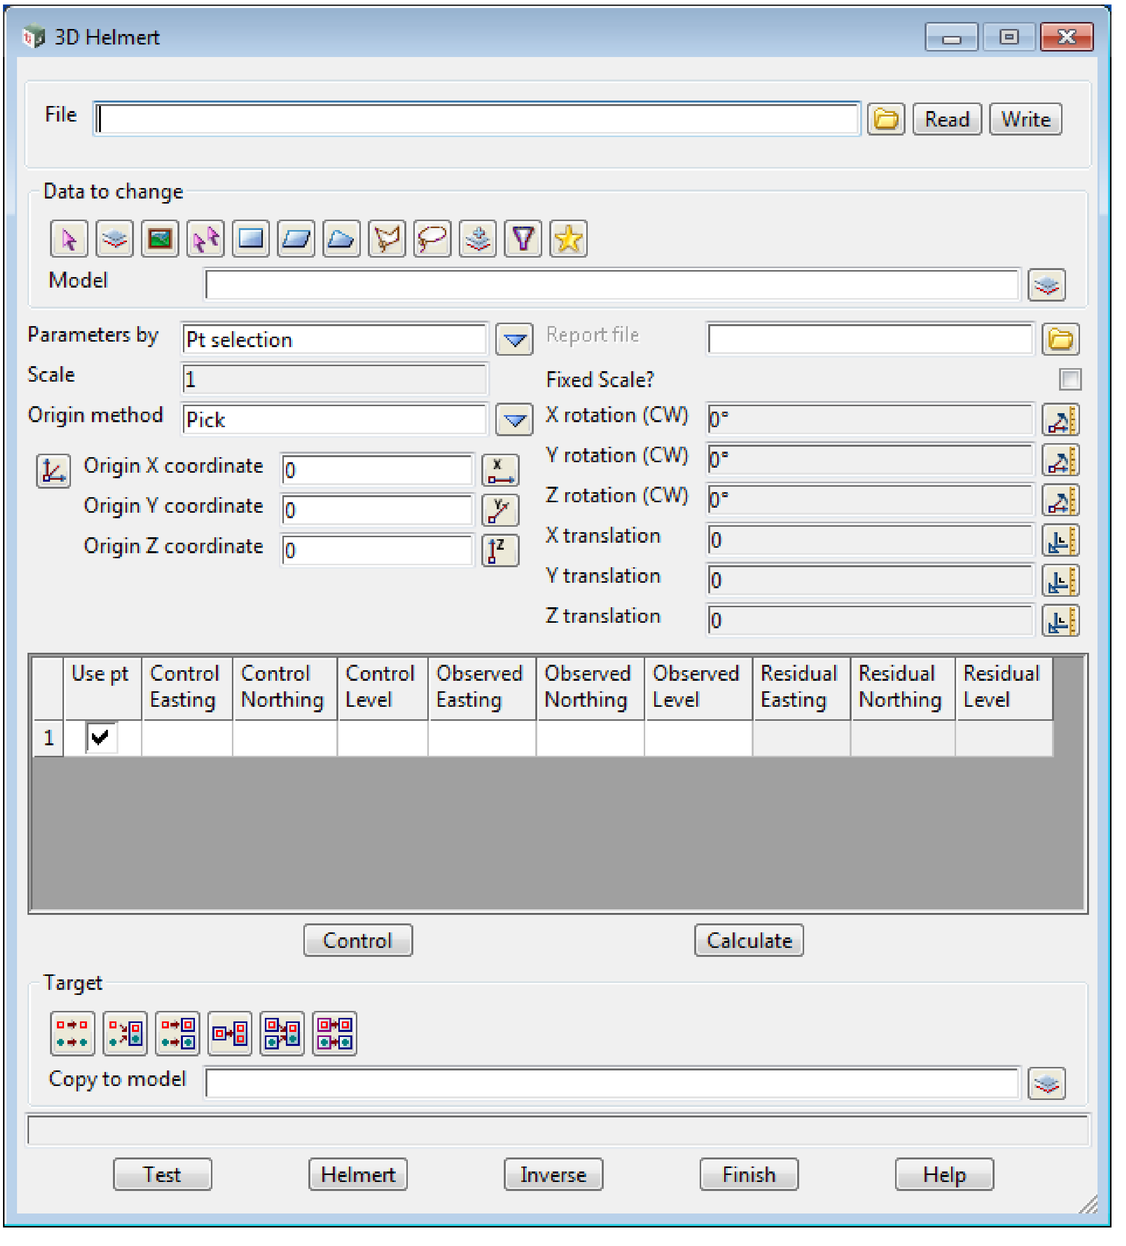
Position of option on menu: **Utilities =>H-Z =>Helmert 3D**

A ***3D Helmert*** transformation is a three dimensional linear transformation consisting of a scaling, three rotations, and a 3D-translation (shift) of data. Hence there are 7 parameters to be specified.

For information on the 3D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the **Affine Transformation works with Rasters,** go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

Selecting **Helmert 3D** brings up the **3D Helmert** panel.



If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons in the panel have the following functions

Field Description	Type	Defaults	Pop-Up
File	file box		*.hel_3d

the name of a 3d Helmert parameter file to read in/write out

Read button

read the contents of the .hel_3d file given in **File** *and load the parameters saved in the file into the panel fields.*

Write button

write the parameters and data in the panel fields to the file given in **File**.

Data source type — Default: Model

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

Field Description	Type	Defaults	Pop-Up
Parameters by	choice	Pt selection	Pt selection Direct entry

the parameter entry method.

Report file — Pop-Up: *.rpt files

if not blank, write a report on the 3D Helmert transformation.

Scale input/output

the scale factor for the existing coordinates with respect to the transformed coordinates

Fixed scale? tick box

if ticked, the scale is entered into the ***Scale*** *field and it is held fixed when the Helmert parameters are calculated from the selected control-observed point pairs.*

Field Description	Type	Defaults	Pop-Up
Origin method	choice box	Pick	Pick, Obs'd centroid Ctrl centroid

the translation can be reported against another origin than the default (0,0,0).

Origin X/Y/Z coordinate input

the translation parameters are written out with respect to this origin.

X rotation (Clockwise rotation

the rotation in the (y,z) plan about the x-axis of the axes of the existing points with respect to the transformed axes.

Y rotation (Clockwise rotation

the rotation in the (z,x) plane of the axes of the existing points with respect to the transformed axes.

Z rotation (Clockwise rotation

the rotation in the (x,y) plane of the axes of the existing points with respect to the transformed axes.

X/Y/Z Translation input/output

the x/y/z translation of the existing co-ordinate with respect to the transformed x/y/z coordinates

Control button

restarts the selection process for choosing more control points.

Calculate button

calculate the helmert parameters from the selected points shown in the grid.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Helmert button

apply the Helmert transformation to the data specified in the source box, and put it into the appropriate target area.

Inverse button

applies the inverse transformation to the one defined in the panel.

Finish button

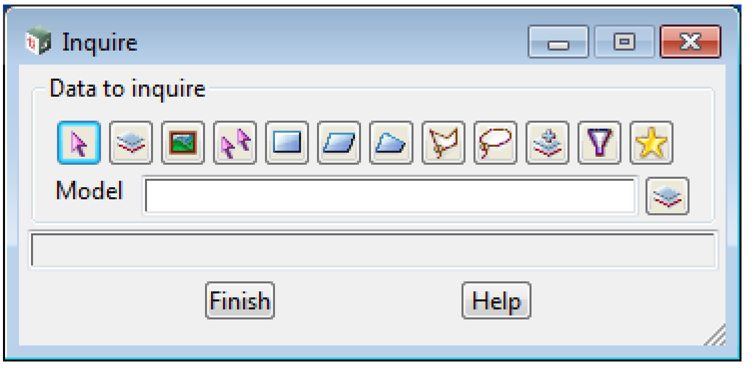
end the option, remove the panel from the screen.

28.10.5 Inquire

Position of option on menu: **Utilities =>H-Z =>Inquire**

Inquire highlights all the selected strings.

On selecting the **Inquire** option, the **Inquire** panel is displayed.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

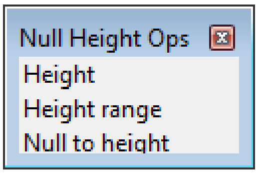
source of data to be highlighted.

28.10.6 Null Heights

Position of option on menu: **Utilities =>H-Z =>Null heights**

A null value is used as a z-value (height) when no actual z-value exists at a vertex. That is, the vertex has valid x and y coordinates but no valid z-value.

The **null heights** walk-right menu is



For the option *Height*, go to 28.10.6.1 Heights

Height range 28.10.6.2 Height Range

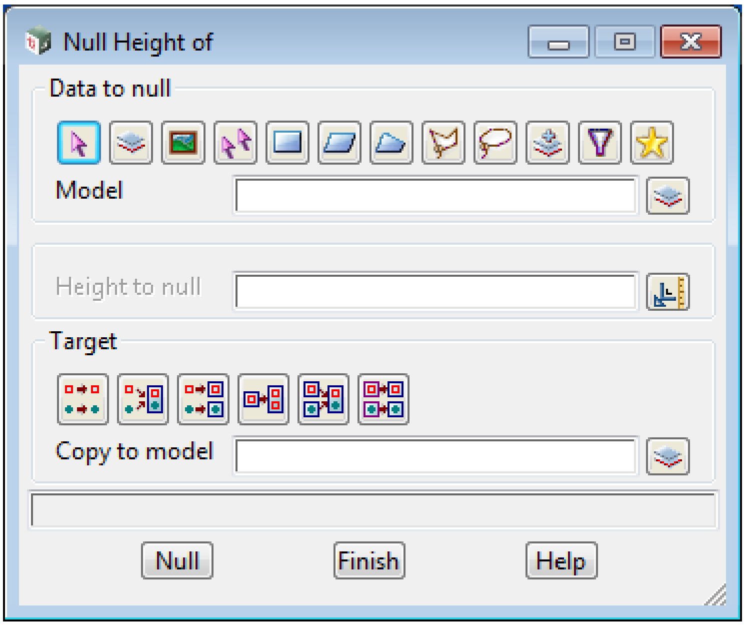
Null to height 28.10.6.3 Null to Height

28.10.6.1 Heights

Position of option on menu: **Utilities =>H-Z =>Null heights =>Height**

Null heights is used to set vertices with a given z-value to ***12d Model***'s null value.

Selecting **Heights** displays **Null Height of** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Height to null	input		

height value to set to the null value.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Null	button		

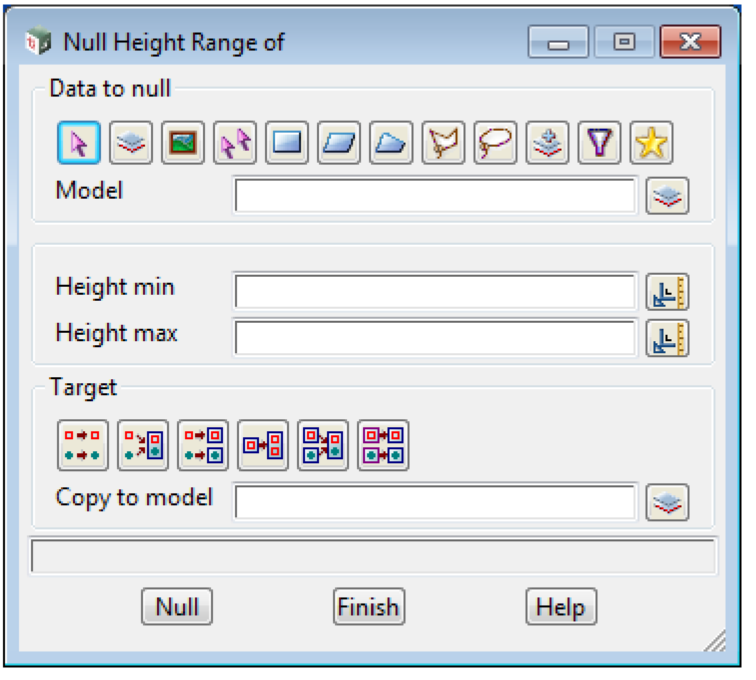
test all the z-values in the selected strings and if the value is equal to the **Height to null** *value, set the z-value to null.*

28.10.6.2 Height Range

Position of option on menu: **Utilities =>H-Z =>Null heights =>Null range**

Null height range sets the vertices with z-values between a given height minimum and height maximum, to ***12d Model***'s null value.

Selecting **Height range** displays the **Null Height Range of** panel.



The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up

Data source type | | Model |

data selection type - for a full description go to 4.19.3 Data Source

Data source | input

source of data to be processed.

Height min | input

minimum value of the heights to be set as null values.

Height max | input

maximum value of the heights to be set as null values.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info | input

extra information required for the target.

Null | button

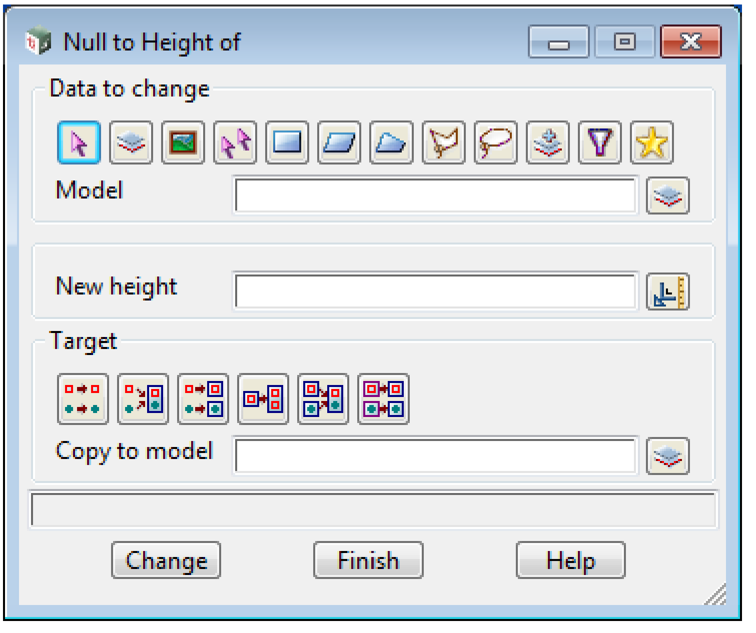
test all the z-values in the selected strings and if the value is between the **Height min** *and* **Height max** *value, set the z-value to null.*

28.10.6.3 Null to Height

Position of option on menu: **Utilities =>H-Z =>Null heights =>Null to height**

Null to height is used to set vertices with a null z-value to a user given value.

Selecting **Null to height range** displays the **Null to Height of** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

New height input

height value to change null values to.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Change button

Change all the null z-values in the selected strings to the value in the **New height** *field.*

28.10.7 Parallel String

Position of option on menu: **Utilities =>H-Z =>Parallel string**

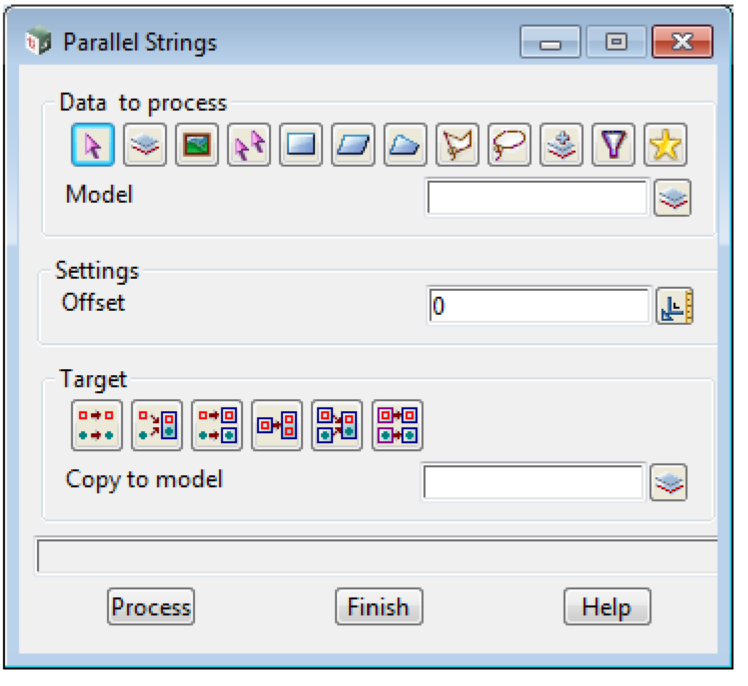
This option parallels horizontally one or more strings (the option **Strings => Strings edit => Parallel** only parallels one string at a time).

It is a macro and runs in two ways*:*

1. from the menu or
2. via a command line interface that does not require user interaction.

Note: the command line interface is available so that the option can be run in a chain if the macro can not be recorded in a chain. If the macro is called without any command line arguments, then it will assume it is being run in the graphical, interactive manner and will display a panel to the user. Otherwise, the macro will parse the relevant command line arguments and run without user interaction.

Selecting **Parallel** brings up the **Parallel Strings** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
data selection type - for a full description go to 4.19.3 Data Source			
Data source	input		
source of data to be processed.			
Offset	measure box	0	available measures
the distance to parallel the source element.			
The direction of the source string is used to determine the left and right side of the string in the parallel operation. A positive offset parallels the string to the right with respect to the string direction. A negative offset parallels to the left with respect to the string direction.			
Target type			

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Process button

processes the selected data.

Note When Using the Option With Command Line Arguments:

When calling the macro using the command line interface, it must be called according to the following format:

parallel_strings_panel.4do “SOURCE MODEL” offset “TARGET MODEL”

The first argument passed must be the name of a model containing the data to process. The source model of data to process must be the first argument provided to the macro.

The second argument must be the offset distance to parallel the source strings. This can be negative or positive, but it must be a valid real number (*e.g.* 1.234, -567.00, 0).

The third and final argument must be the name of the model in which to place the resultant paralleled strings.

If any of the fields contain spaces, they must be enclosed in quotes
For example: “SOURCE DATA”

When using the command line interface, there must be 3 and only 3 arguments. Any fewer or more will be considered an error and will stop the macro from progressing any further.

Refer to the description of the fields in the Graphical User Interface section for further details, including restrictions on fields and expected behaviour

The macro uses the **Parallel()** function made available through the macro language. As such, the string types supported and behaviour of the macro is dependent on the implementation of that function.

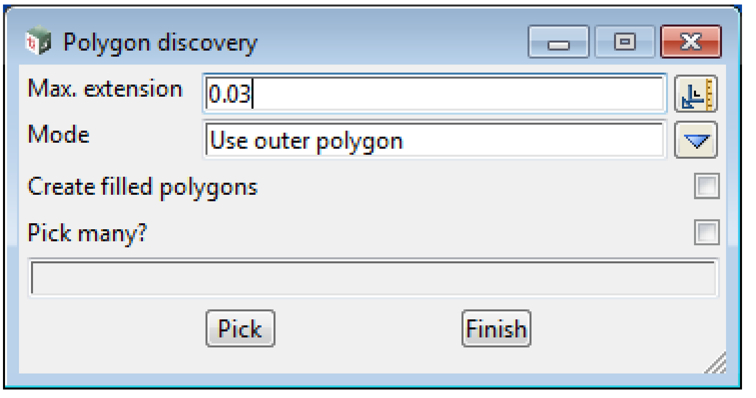
28.10.8 Polygon Discovery

Position of option on menu: **Utilities =>H-Z =>Polygon discovery**

Polygon discovery takes a selected position/point on a plan view and from the data displayed on the view, finds the polygon enclosing the selected position/point from the line and arc segments in strings around the position/point.

The name, colour and model for the created polygon are taken from the *CAD* Tool bar.

Selecting **Polygon discovery** brings up the **Polygon Discovery** panel.

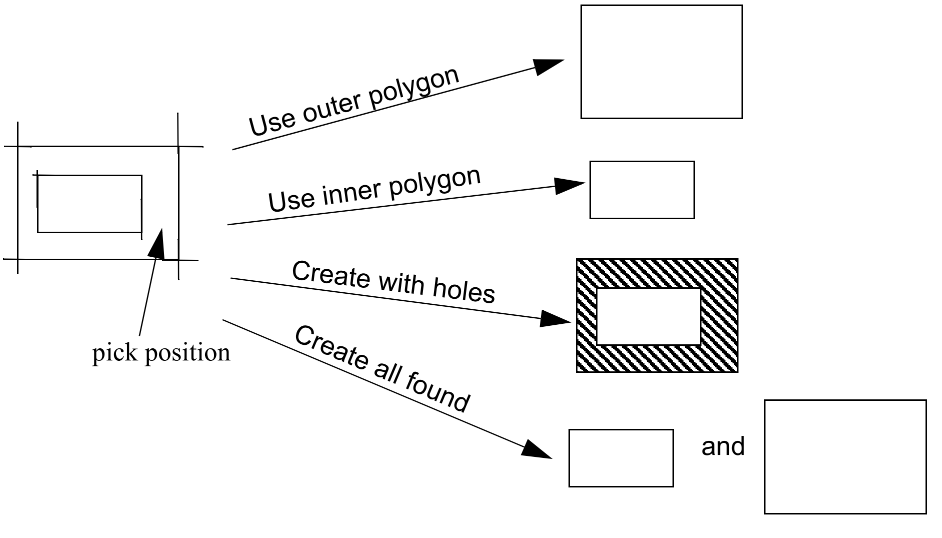


The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Max. extension	real value box	0.03	measures

maximum distance to extend segments to get an intersection to help define the surrounding polygon.

Field Description	Type	Defaults	Pop-Up
Mode ,	choice box	Use outer polygon	Use outer polygon User inner polygon Create with holes Create all found



Field Description	Type	Defaults	Pop-Up
Create filled polygons	tick box		

if ticked, the created polygons are given a fill colour.

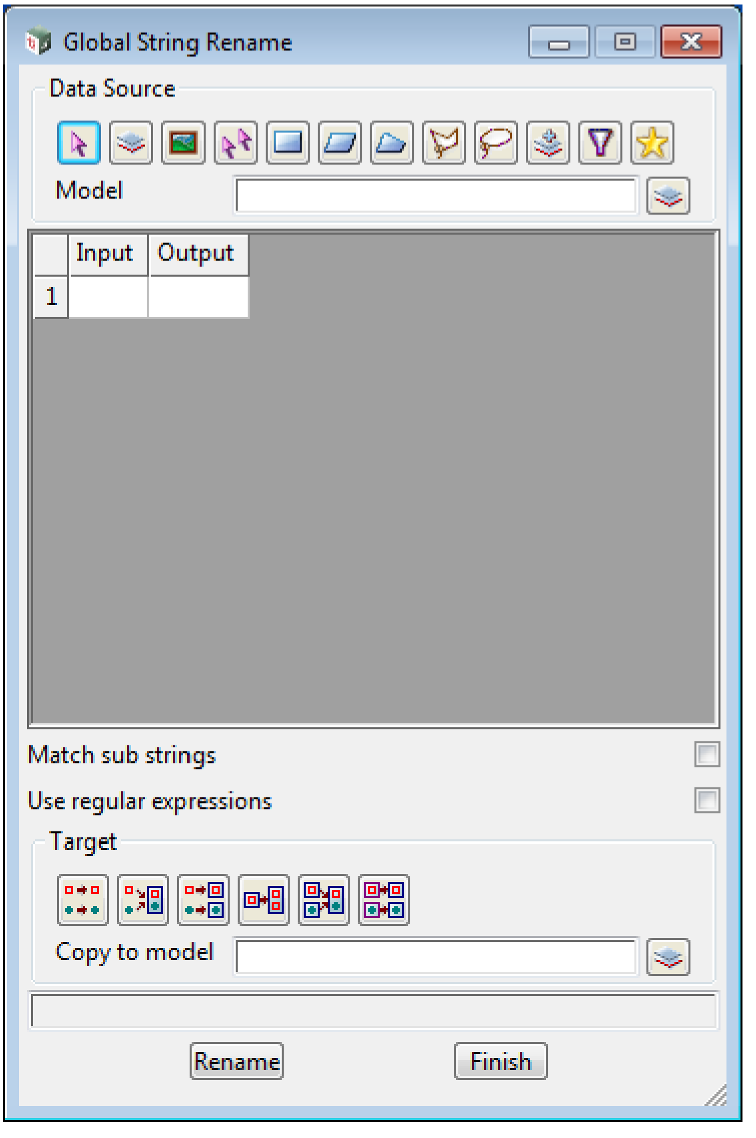
Pick button

pick the position/point that will be used to find an enclosing polygon for.

28.10.9 Rename Strings

Position of option on menu: **Utilities =>H-Z =>Rename strings**

Selecting **Rename strings** brings up the **Global String Rename** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

Input

expression to match the selected string names against.

If a match occurs then the string name is modified as per the **Output** *field.*

Output

expression for renaming the strings that matched **Input**.

Match sub strings tick box not ticked

if ticked, only a part of the string name needs to match the expression in **Input**.

Use regular expressions tick box not ticked

if ticked, **Input** *is a regular expression.*

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Rename button

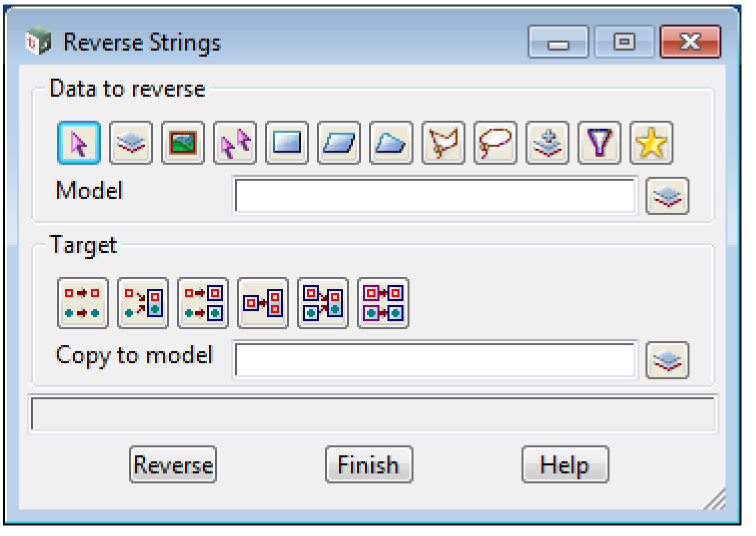
rename the selected data.

28.10.10 Reverse Strings

Position of option on menu: **Utilities =>H-Z =>Reverse strings**

Reverses the direction of the selected strings.

Selecting **Reverse strings** brings up the **Reverse Strings** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Reverse	button		

reverse the direction of the selected strings.

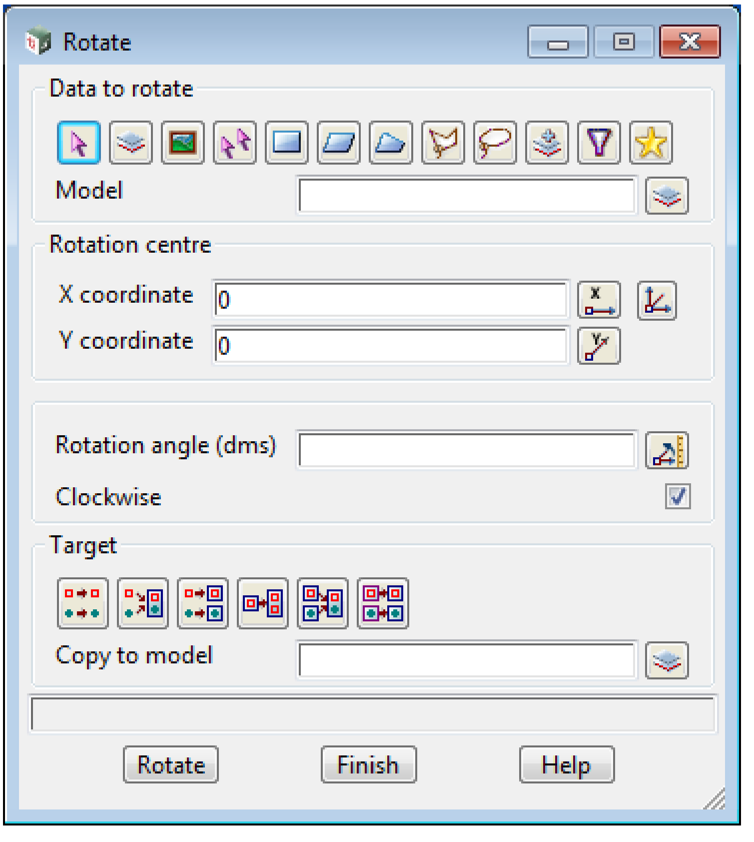
28.10.11 Rotate

Position of option on menu: **Utilities =>H-Z =>Rotate**

Rotate rotates all the selected strings about a central point (the rotation centre). The strings are rotated through a user supplied angle and can be moved or copied to their new rotated position.

The difference between a copy and a move is that if a string is **copied**, a copy of the string is rotated and the original string left untouched, whereas for a **move**, the actual string is moved from its original position to the new rotated position.

Selecting **Rotate** displays the **Rotate** panel.



The centre of the rotation is defined by selecting the **Centre** button and picking a point as the new centre. The centre can be changed at any time by using the **Centre** button to select another centre.

The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Rotation centre			xyz ops

select the centre of the rotation. The centre can be changed at any time.

Rotation angle (dms)	angle box		

the angle in degrees to rotate the string through. The angle is measured about the rotation centre point in either a clockwise or anticlockwise direction.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Rotate button

rotate the selected data.

28.10.12 Rotate Relative

Position of option on menu: **Utilities =>H-Z =>Rotate relative**

Rotate Relative allows multiple strings to be rotated in the XY plane by a user given angle and about various base points (rotation centres).

The simpler Rotate option (**Utilities =>H-Z =>Rotate**) only rotates the selected strings about a **single** point.

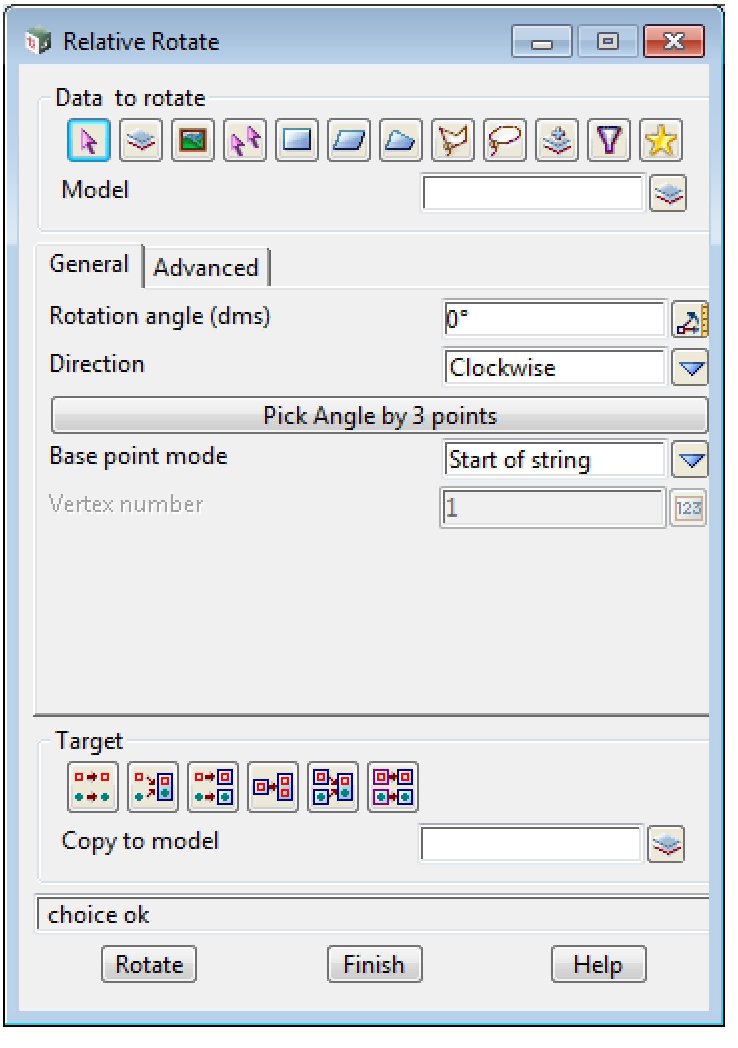
Rotate Relative is more flexible and has many methods for defining the base points (rotation centres), even allowing individual strings to have their own base point. In this case, the base point for rotation is calculated for each string in the Data Source and the rotation applied to each string individually. For example, Relative Rotate can rotate strings where the base point for each string is the start vertex of each string.

Allowing various base point modes allows greater flexibility in rotating many strings at once.

Rotate Relative performs a 2d rotation of strings. That is, the rotation is only in the XY plane.

The strings can be **moved** or **copied** to their new rotated position. The difference between a copy and a move is that if a string is copied, a copy of the string is rotated and the original string left untouched, whereas for a move, the actual string is moved from its original position to the new rotated position.

Selecting **Rotate Relative** displays the **Relative Rotate** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type	source box	Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data is to be processed.

Rotation angle (dms)	angle box	0°	

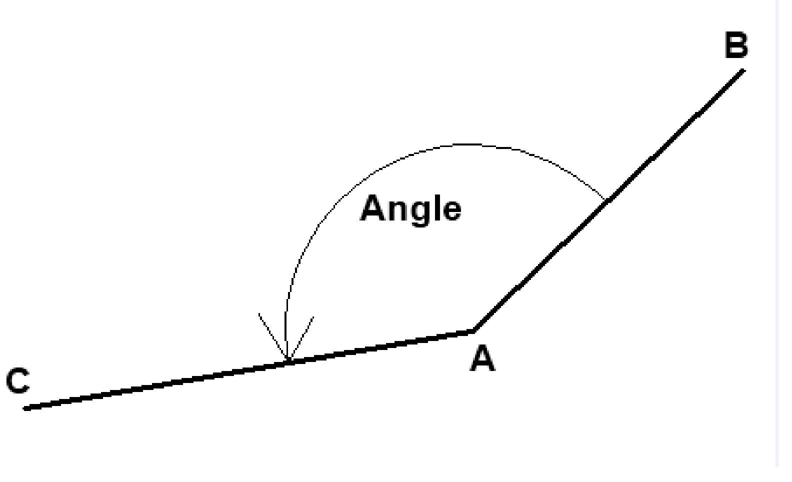
the angle in degrees to rotate the string through. The angle is measured about the rotation centre point in either a clockwise or anticlockwise direction.

Direction	choice box	Clockwise	Clockwise, Counter-clockwise

the direction in which to apply the angle, either clockwise or counter-clockwise.

Pick Angle by 3 points	button		

allows the user to measure the angle for rotation by picking 3 points on the screen.



Upon clicking the button, the user will be asked to pick the:

1. *Base point about which the angle is measured (A);*
2. *Reference point (B); and*
3. *New point (C).*

The Rotation angle and Direction will be calculated based on the 3 picked points.

Base point mode	choice box	Start of string	Start of string, End of string, Middle of string, Middle Vertex, Vertex Number, Chainage, Chainage & Offset, Coordinates, Angle by 3 pts Vertex, Justification point (Text only!)

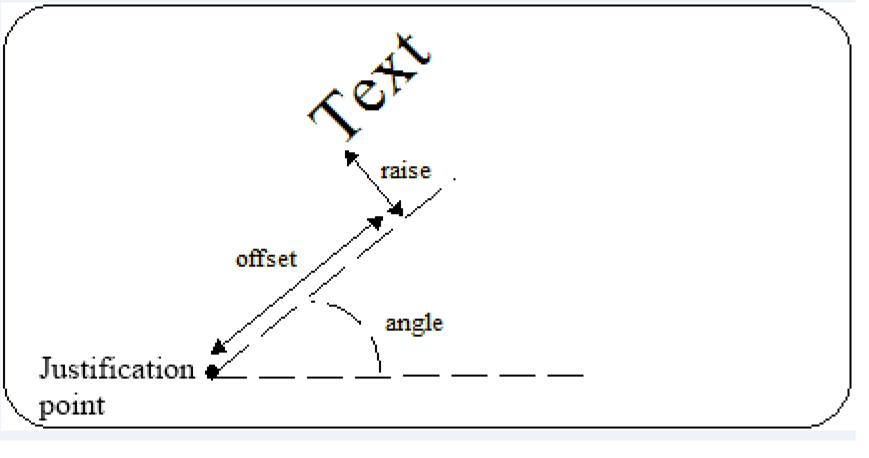
allows the user to define how the base point for the rotation is determined for the data. Valid options include:

• *Start of string – the base point is the start of each string*

• *End of string – the base point is the end of each string*

• *Middle of string – the base point is the middle (based on chainage) of each string*

- *Middle Vertex – the base point is the middle vertex of each string. In the case of a string with an even number of vertices, the behaviour of this routine can be varied. Refer to the Middle Vertex Mode in the Advanced tab.*
- *Vertex Number – the base point is a specific vertex of each string, specified by the vertex number. The start vertex is 1, the next vertex 2 and so on for a string with n vertices. The vertex number may also be specified as a negative number to count vertices from the end of the string back towards the start. In this case, for a string with n vertices, a vertex number of -1 is the last vertex (nth vertex), -2 the 2nd last vertex (n-1), and so on until the first vertex number is –n. If the specified vertex number exceeds the string extents, then an error will be produced and the string skipped.*
- *Chainage – the base point is calculated at a specific chainage along each string. Where the chainage is beyond either end of a string, the behaviour of this routine can be varied. Refer to the Base point chainage extend mode in the Advanced tab.*
- *Chainage & Offset – the base point is calculated at a specific chainage along and offset from each string. The standard convention of a negative offset to the left of the string and positive offset to the right of the string applies.*
- *Coordinates – the base point is specified by a set of coordinates. In this mode, the routine behaves in the same way as the normal Rotate routine- the same base point is used for all strings. The Z coordinate is not optional and must be entered, even if it is zero. The Z coordinate, however, does not affect the rotation.*
- *Angle by 3pts Vertex – the base point is the set of coordinates selected when the Angle by 3 pts was picked. This is the coordinates of point A in the diagram above.*
- *Justification point (Text only!) – the base point is the justification point of a Text object. Note that this only applies to Text objects- all other objects will be skipped in this mode.*



The fields displayed on the panel will change depending on the base point mode chosen.

Vertex number integer box 1

the vertex number to be used as a base point. Enabled for Vertex Number mode only.

Chainage real box 0

the chainage to be used for calculating the base point. Enabled for Chainage and Chainage & Offset modes only.

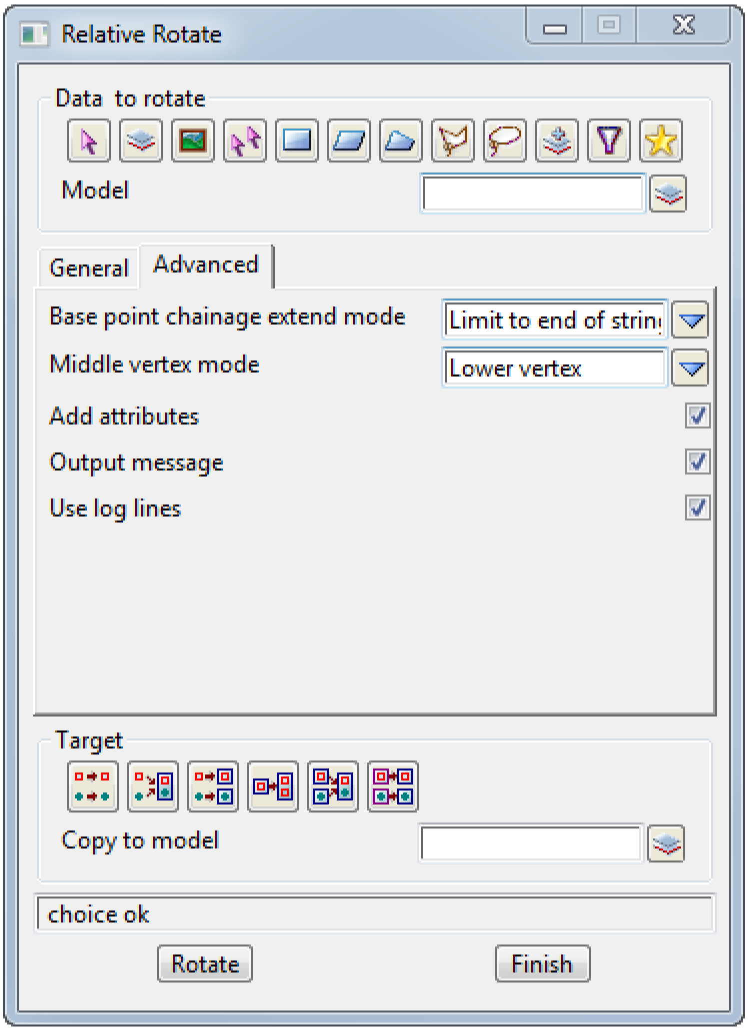
Offset real box 0

the offset to be used for calculating the base point. Enabled for Chainage & Offset mode only.

Base Point xyz box 0,0,0

the coordinates (X, Y, Z) to be used as the base point. Enabled for Coordinates mode only.

Advanced Tab

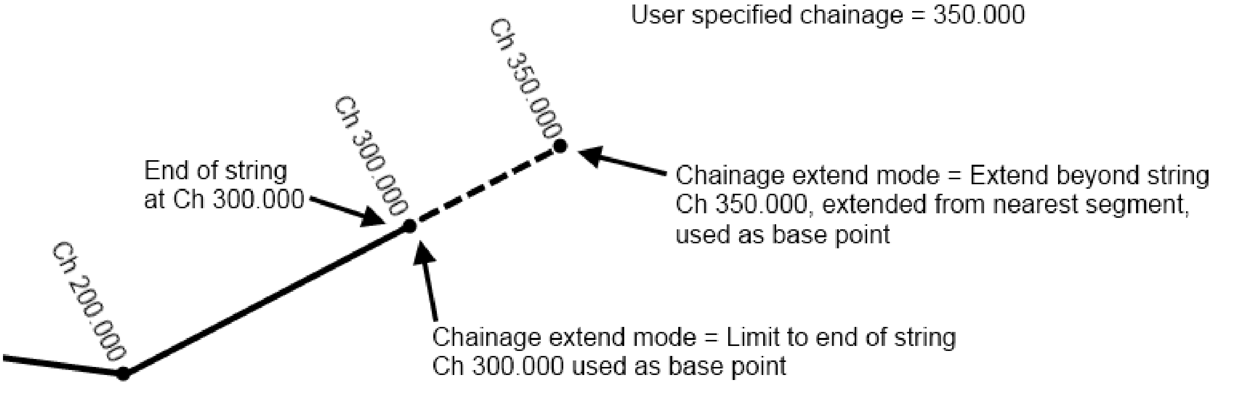


The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Base point chainage extend mode	choice box	Limit to end of string	Skip with error, Limit to end of string, Extend beyond string

controls the behaviour of the routine when the base point mode is Chainage and the specified chainage is beyond the string extents.

- *Skip with error – the string will be skipped, with an error written to the output window*
- *Limit to end of string – the base point will use the chainage of the nearest end point*
- *Extend beyond string – the base point will be calculated based on a projection beyond the string to the specified chainage and based on the bearing of the nearest end.*



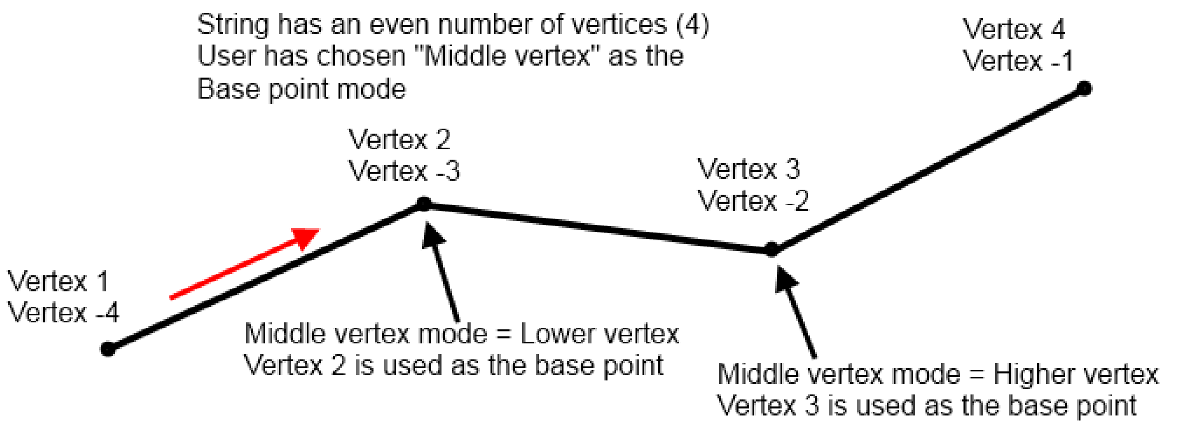
Middle vertex mode	choice box	Lower vertex	Skip with error, Lower vertex< Higher vertex

controls the behaviour of the routine when the base point mode is Middle Vertex and the string has an even number of vertices. Where the string has an even number of vertices, the middle vertex can be one of two possibilities.

Skip with error – the string will be skipped, with an error written to the output window

Lower vertex – the lower-numbered vertex will be used as the middle vertex

Higher vertex – the higher-numbered vertex will be used as the middle vertex



Add attributes	tick box	ticked

writes the various relative rotate settings to the rotated string as string attributes.

Output messages	tick box	ticked

writes various output messages when run. If not ticked, no output messages will be produced by the routine, including critical warning and error messages.

Use log lines	tick box	ticked

use intelligent log lines for the certain output messages. If not ticked and output messages are enabled, the messages will be normal messages.

Target type

data selection type - for a full description go to 4.19.3 Data Source

Target info input

extra information required for the target.

Rotate button

rotate the selected data.

28.10.13 Set Constant Z-Values

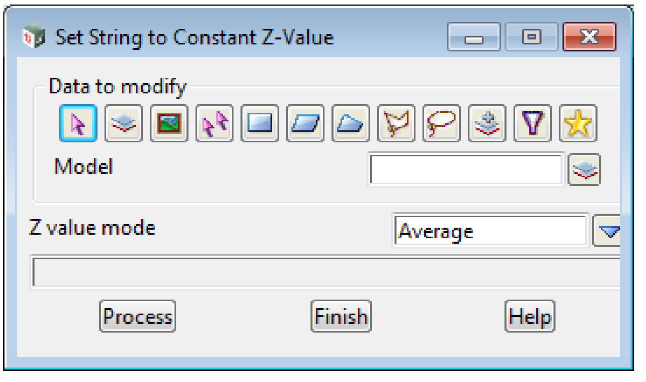
Position of option on menu: **Utilities =>H-Z =>Set constant z-values**

This option sets all the points on a string to the same elevation - the average, highest, or lowest z-value of each selected string's z-values.

For example, the option can be used to set a starting value for building pads.

The user can drape a string then average the z-values to get close to a volumes balance. Alternatively, the user can opt for the highest z-value calculated by the drape, *i.e.* the entire platform is in fill, or select the lowest z-value so the entire platform is in cut.

Selecting **Set constant z-values** brings up the **Set Constant Z-Value** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Z value mode	choice box	Average	Average, Highest, Lowest

if Average, the string is given the Z value that is the average of all the vertex Z values.

If Highest, the string is given the Z value that is the highest of all the vertex Z values.

If Lowest, the string is given the Z value that is the lowest of all the vertex Z values.

Process	button		

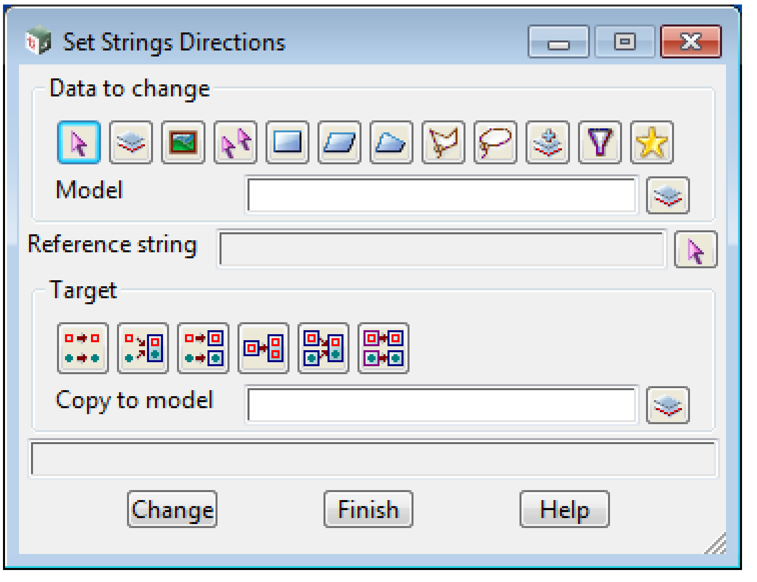
sets the constant z-value for the selected strings.

28.10.14 Set Strings Directions

Position of option on menu: **Utilities =>H-Z =>Set strings directions**

Set strings directions attempts to set the direction of select strings to be the same as the direction of a selected reference string.

On selecting **Set strings directions**, the **Set Strings Directions** panel is displayed.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

data source to be select strings to change direction.

Reference string	string select		

the string that is used as the reference direction. This is the direction that, if possible, the selected strings are given.

Target type

where to put the processed string - for a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Change	button		

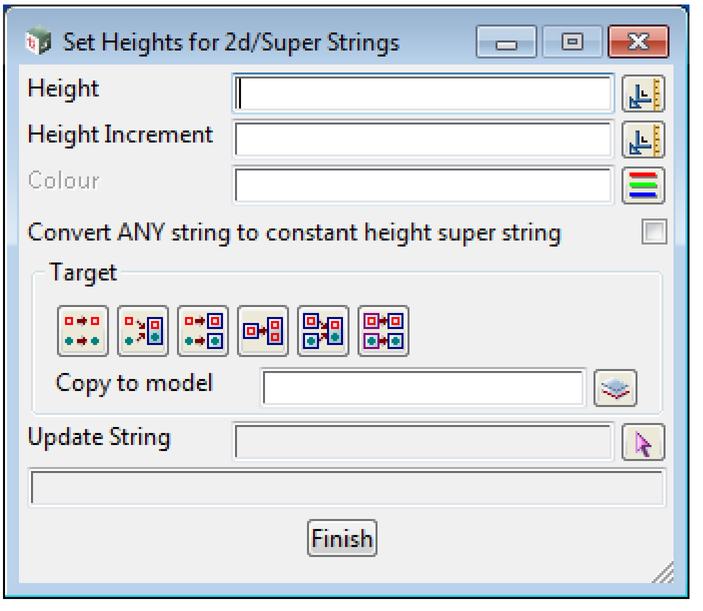
change the direction of the selected strings.

28.10.15 Set Heights for 2d/Super Strings

Position of option on menu: **Utilities =>H-Z =>Set heights for 2d/super strings**

Set heights for 2d/super strings is used to quickly change the height of selected 2d strings or 2d super strings (super strings with a constant z value). Is is especially useful when you have a lot of contours without z-values and you wish to give them z-values.

An initial height and increment is given and as each string is selected, it is given the current height and the height then incremented for use when picking the next string.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Height	input		

Height *to used as the height for the next selected string. This is incremented by the* **Height increment** *after each string is accepted.*

Height increment	input		

As each string is accepted and given the **Height**, **Height** *is incremented by this value.*

Colour	input		available colours

if not blank, the selected strings are given this colour when their z-value is changed.

If blank, the selected strings keep their original colour.

Target type

where to put the processed string - for a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Update string	string select		

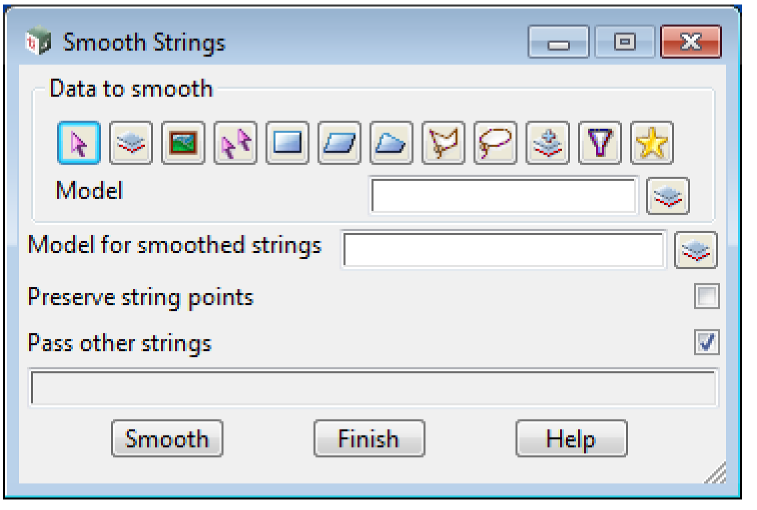
After clicking on the **Update string** *arrow icon, 2d strings are selected and when accepted, have their z-value changed to the value in* **Height**. *The height value is then automatically incremented by* **Height increment**. *The next string is then selected and accepted (without needing to click on* **Pick** *again). This continues until* ***Cancel*** *is selected from the* **Pick Ops** *menu.*

28.10.16 Smooth Strings

Position of option on menu: **Utilities =>H-Z =>Smooth strings**

The **Smooth** options are used to add extra points into 2d or 3d strings to make a smoother string.

Selecting **Smooth strings** displays the **Smooth Strings** panel.



The fields and buttons used in this panel have the following function

Field Description	Type	Defaults	Pop-Up
Data source type		Model	
Data source	input		
Model for smoothed strings	input		available models
Preserve string points	tick box		
Pass other strings	tick box	tick	
Smooth	button		

Data source type — Model

data selection type - for a full description go to 4.19.3 Data Source.

Data source — input

data source to be smoothed.

Model for smoothed strings — input — available models

model for the smoothed strings to go to

Preserve string points — tick box

*if **ticked**, the smoothed strings will still contain all the original points.*
*if **not ticked**, the smoothed strings may deviate from the original string points*

Pass other strings — tick box — tick

*if **ticked**, any strings that can't be smoothed are copied and added to the* **smoothed strings** *model.*

Smooth — button

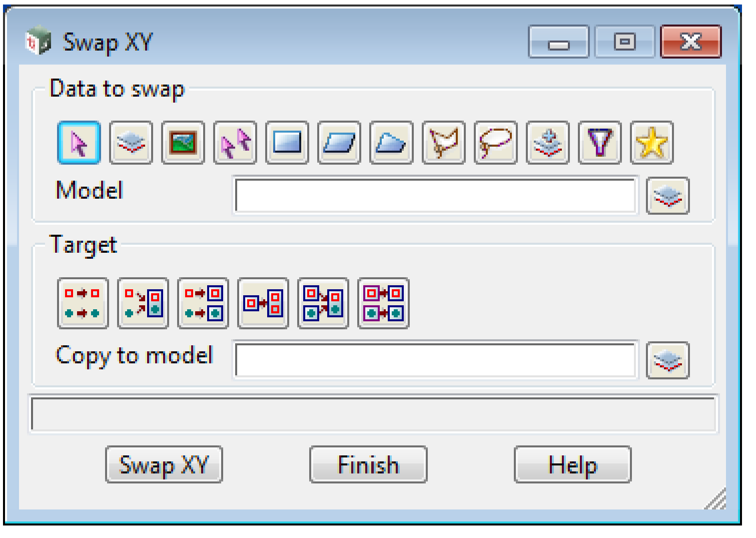
smooth the selected strings.

28.10.17 Swap XY

Position of option on menu: **Utilities =>H-Z =>Swap XY**

The **Swap xy** option is used to swap the (x,y) coordinates of selected strings.

Selecting **Swap XY** displays the **Swap XY String/Model/View** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be have the XY coordinates swapped.

Target type

Data target - where to put the processed string. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Swap XY button

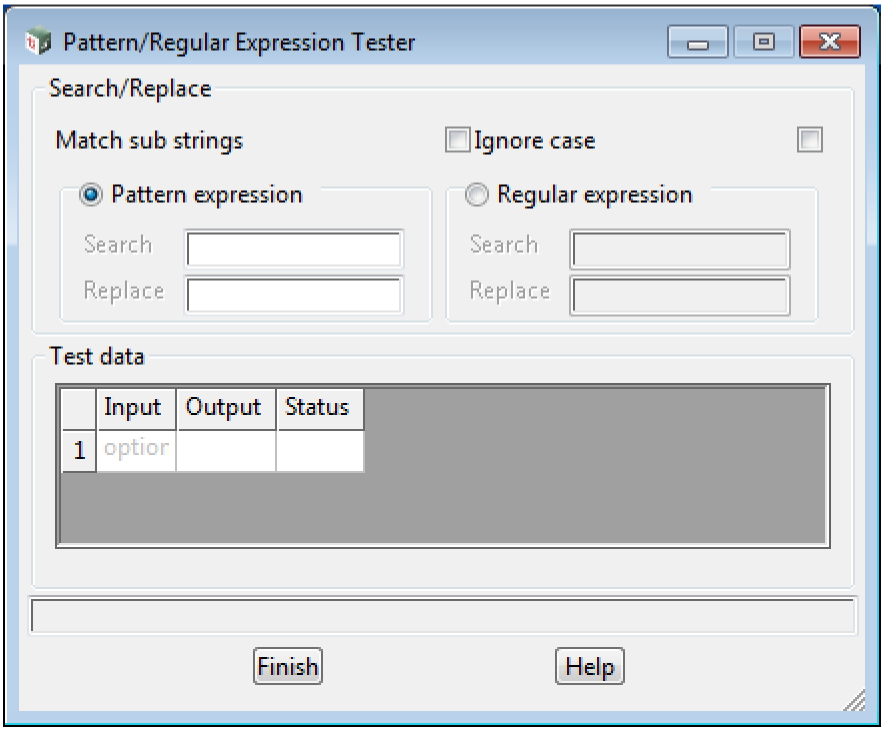
swap the selected strings and add them to the target.

28.10.18 Test Wildcards

Position of option on menu: **Utilities =>H-Z =>Test wildcards**

Test wildcards is used to test the effect of pattern expressions and regular expressions on text.

Selecting **Test wildcards** displays the **Pattern/Regular Expression Tester** panel



The **Search/Replace** criteria and the **Pattern expression** or **Regular expression** are applied to the data in the **Input** column and the results are placed in the **Output** column.

28.10.19 Text

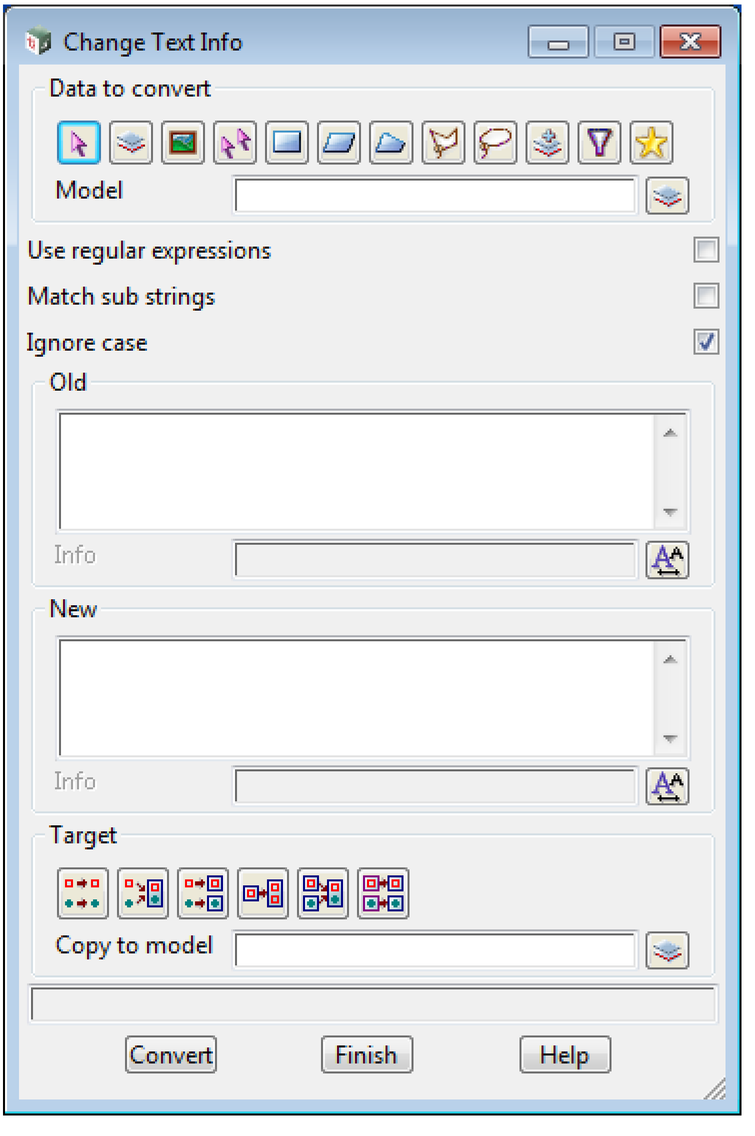
Position of option on menu: Utilities =>H-Z =>Text

The Text option is used to change the text style, units, height, offset, justification, angle and text for text, 4d strings and super strings.

For this option the selection process is extended from the standard Data Source.

After the data is selected as defined by the Data Source, the two extra parameters, **Old text** and the Textdata parameters in **Info**, are used to further specify which text is to be selected and modified.

Selecting Text displays the **Change Text Info** panel.



The fields and buttons used in the panel have the following functions.

Field Description	Type	Default
Data source type	Model	

data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.

Use regular expressions tick box not ticked

if ticked, then ***Regular*** *expressions given in the* **Old** *and* **New** *fields are used to modify the text.*

Ignore case tick box ticked

if ticked, the search for **Old** *text will make a match independent of upper or lower case.*

If not ticked, the search for **Old** *text will treat upper or lower case as being different.*

Any matched text is replaced by new text.

Old text input

if the **Old text** *field is non-blank, then any text in 4d or text strings will be checked for a match against this value. Wild cards and characters can be used.*

Info input

if non-blank, then only strings which match these Textdata parameters will be selected.

New text input

if non-blank, then any selected text the selected strings will be modified to this value. Wild cards and characters can be used.

Info input

if non-blank, then the select text on the selected strings will be given these Textdata parameters.

Target type

Data target - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Convert button

run the option and change the selected text.

28.10.20 Translate

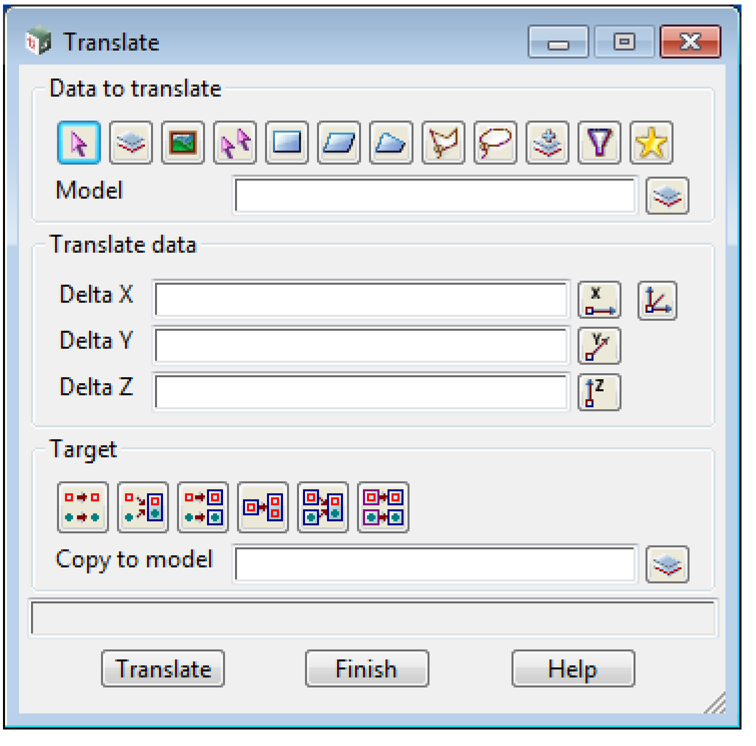
Position of option on menu: **Utilities =>H-Z =>Translate**

Translate is used to translate the selected strings through a user supplied translation vector (dx,dy,dz).

The strings can be translated in the x,y and z directions and be moved or copied to their new translated positions.

The difference between a **copy** and a **move** is that if a string is copied, a **copy** of the string is translated and the original string left untouched, whereas for a **move**, the actual string is moved from its original position to the new translated position.

Selecting **Translate** displays the **Translate** panel.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source input

source of data to be processed.

dx dy dz input

the translation vector (dx,dy,dz). This vector is added to all points in the strings.

The translation (dx dy dx) can be typing into the **dx dy dz** *field or by picking the* **dx dy dx** *button and then selecting two points with the cursor. When two points are selected, the difference vector of the two selected points is taken as the translation vector (dx,dy,dz). The (dx,dy,dz) value is piped into the* **dx dy dz** *field.*

Target type

Data target - where to put the processed string. For a full description go to 4.19.4 Data Target

Target info input

extra information required for the target.

Translate button

translate the selected strings.

How to Use the Panel

(a) Enter the **Data source** for the strings are to translated.

(b) Define the translation vector (dx dy dz) by either typing the value into the **dx dy dz** field or by selecting the **dx dy dz** button and picking two points to define the translation vector. The resulting (dx dy dz) values are piped into the **dx dy dz** field.

(c) Select the **target** mode.

(d) Selecting the **Translate** button then does the required translations (moves or copies).

28.11 Old

Position of option on menu: **Utilities =>Old**

The **Old Utilities** contains superseded options. They should no longer be used.

For *Check breaklines*, go to 28.11.1 Check Breaklines
Check breaklines (advanced) 28.11.2 Check Breaklines (Advanced)
Helmert 2D 28.11.3 2D Helmert

28.11.1 Check Breaklines

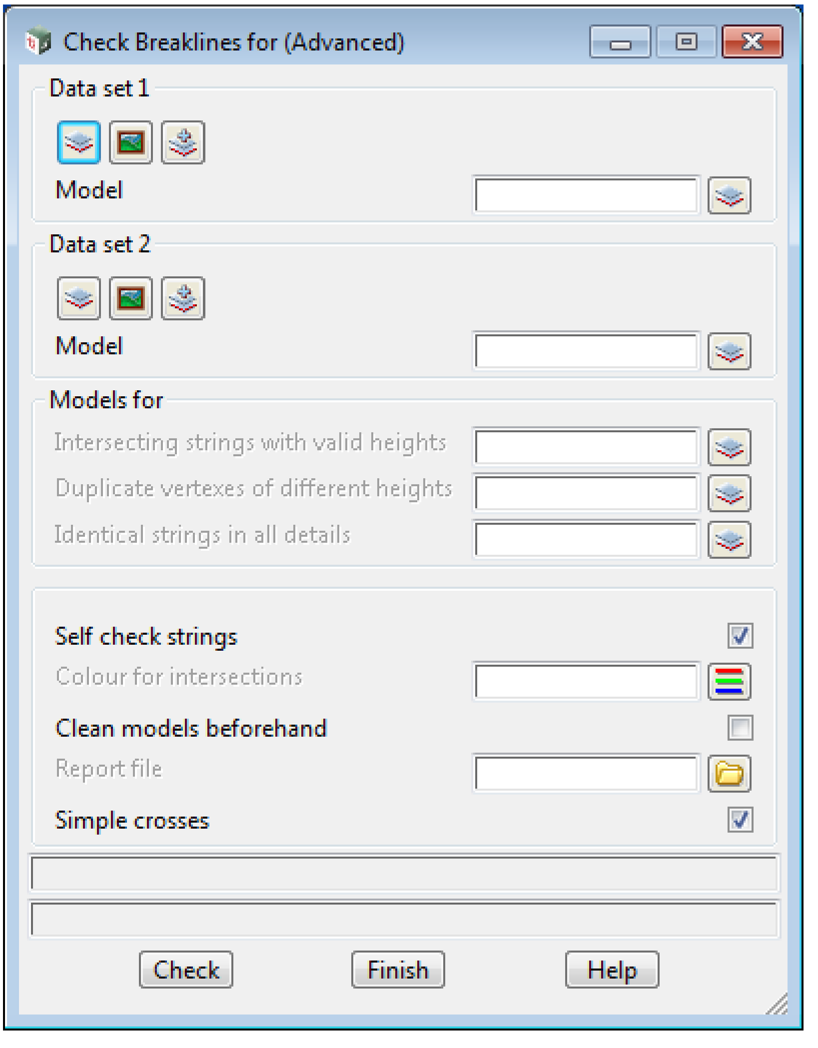
Position of option on menu: **Utilities =>Old=> Check breaklines**

For information on this option please go to the section 16.4 Check Breaklines - Old

28.11.2 Check Breaklines (Advanced)

Position of option on menu: **Utilities =>Old=> Check breaklines (advanced)**

This section of documentation is a work in progress and will be updated in subsequent releases.



The fields and buttons in the panel have the following functions.

Field Description	Type	Defaults	Pop-Up

Data set 1

*if **Data set 2** is ticked **off**, then all the selected strings in Data set 1 are checked against all the other selected strings from Data set 1.*

*If **Data set 2** is ticked **on**, then all the selected strings in Data set 1 are checked against all the selected strings in Data set 2, BUT the strings in Data set 1 are not checked against each other and the strings in Data set 2 are not checked against each other.*

Data set 1 source type Model

data selection type - for a full description go to 4.19.3 Data Source.

Data set 1 source input

data to be processed.

Data set 2

Data set 2 source type Model

data selection type - for a full description go to 4.19.3 Data Source.

Data set 2 source input

data to be processed.

Intersecting strings with valid heights model box available models

if non-blank, check for any crossing line segments and place either a copy of the crossing segments into the model given in this field or a diamond depending on the state of Simple crosses.

Duplicate vertices of different heights model box available models

if non-blank, ***copies*** *of any strings that are completely duplicated are placed in the model given in this field and circles are placed in this model at any duplicate points that aren't from an entire string.*

Identical strings in all details model box available models

if non-blank, the duplicates of any strings are ***moved*** *to model given in this field. That is, if any strings are identical in all ways, then the second and subsequent identical strings are moved to the this model. This is especially for the case when a second copy of some data has been supplied.*

Self check strings tick box tick

if ticked, a string is not check against itself for crossing breaklines etc.
If not ticked, a string is not checked against itself for crossing breaklines. This speeds up processing.

Colour for intersections colour box available colours

colour for the copies of the crossing segments.

Clean models beforehand tick box tick

if ***ticked****, the models for intersecting string, duplicate points, identicals are cleaned before the option is run.*

Report file file box

if non-blank, a report file of this name is created giving details of all the crossing breaklines and duplicate plan points with different z-values.

Simple crosses tick box tick

if ***ticked****, create diamonds at the position where strings cross, otherwise create a string in the shape of a cross with parts of the crossing strings.*

Check button

after selecting the **check** *button, all the strings in the model/view are tested for any crossing line segments or duplicate points. If requested, a report is generated.*

<esc> can be used to abort the checking option.

28.11.3 2D Helmert

Position of option on menu: **Utilities =>Old=> 2D Helmert**

NOTE - this option has been superseded and should not be used. It is for upward computability only.

A ***2D Helmert*** transformation is a two dimensional linear transformation consisting of a scaling, rotation and a 2D- translation (shift) of data. Hence there are flour parameters to be specified.

Hence the 2D Helmert parameters are

(a) the one scale factor for both the x and y axes

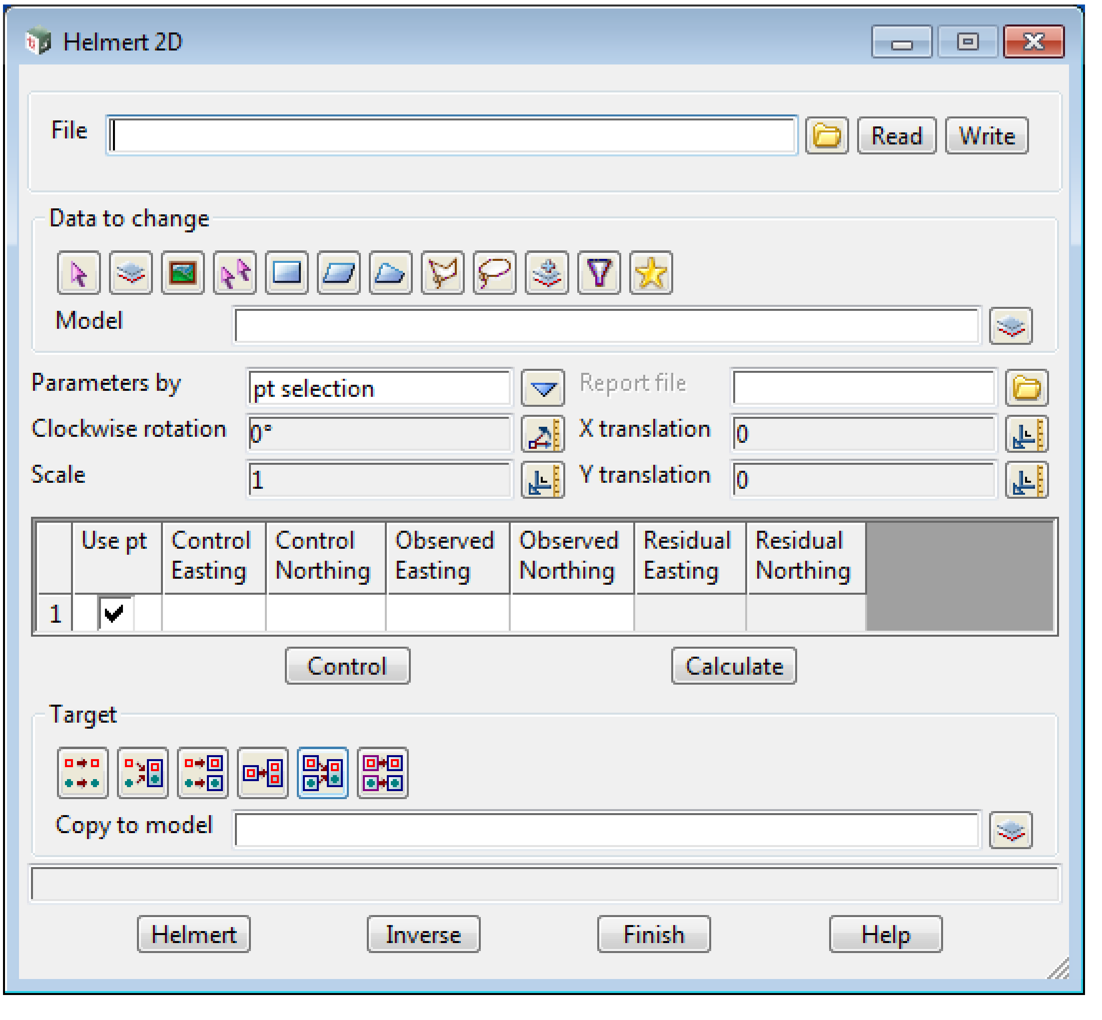
(b) the same rotation of the x-axis and y-axis of the existing coordinates to align it with the control x and coordinate axis

(c) the x and y translation of the observed coordinates after the scalings and rotations have been applied

For information on the 2D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

This case of a fixed scale is not allowed in this option but is in the 28.10.4.1 2D Helmert (Advanced) option.

Selecting **Helmert** brings up the **Helmert 2D** panel.



If the **Parameters by** choice box is set to ***Pt Selection*** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions

Field Description	Type	Defaults	Pop-Up
File	file box		*.hel files

a file name can be specified for reading or writing a file.

Read	button		

if a valid file exists, the file contents can be loaded into the panel.

Write	button		

if a valid name is specified, the user can write the input data to a file.

Data source type		Model	

data selection type - for a full description go to 4.19.3 Data Source

Data source	input		

source of data to be processed.

Helmert parameters by	choice	Pt selection	Pt selection Direct entry

the parameter entry method.

Report file			*.rpt files

if not blank, write a report on the Helmert transformation.

Rotation	input/output		

the rotation of the axes of the existing points with respect to the transformed axes.

Scale	input/output		

the scale factor for the existing coordinates with respect to the transformed coordinates

X Translation	input/output		

the x translation of the existing coordinates with respect to the transformed x coordinates

Y Translation	input/output		

the y translation of the existing coordinates with respect to the transformed y coordinates

Control	button		

restarts the selection process for choosing more control points.

Calculate	button		

calculate the helmert parameters from the selected points shown in the grid.

Target type

Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info	input		

extra information required for the target.

Helmert	button		

apply the helmert transformation to the data specified in the source box, and put it into the appropriate *target area.*

Inverse button

applies the inverse transformation to the one defined in the panel.

Finish button

end the option, remove this panel and the **Helmert control points table** *from the screen.*

29 User

12d Model allows options to be placed on User menus.

Go to

29.1 User Defined Menus

To help customise ***12d Model***, there is a pull down menu **User** on the Main menu and **User** menus on each of the pull down menus on the Main menu.

The **User** menus can run 12d Model macros, external programs, chains, and bring up ***12d Model*** screen layout files, panels and menus.

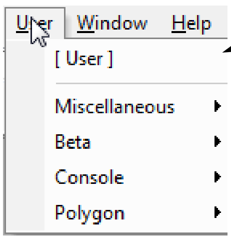
For the full definition and format for user defined menus, see 41.2 User Defined Menus in the Appendix 41 Functions Keys, Menus, Toolbars.

29.2 User on the Main Menu

All the options under **User** and **User menus** are either customers own macros or unsupported macros from ***12d Solutions*** which may not be documented. For more information on defining *User* menus, go to 29.1 User Defined Menus

The **User** walk-right menu on the Main menu is

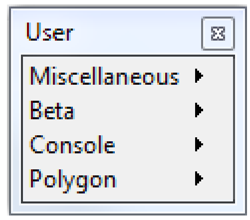
on Main menu



create floating
User menu

create floating User menu
miscellaneous macros
beta macros
console macros
polygon macros

on 12d Model menu and floating User menu

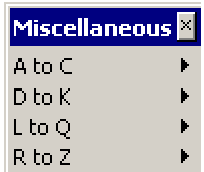


For the option Miscellaneous, go to 29.3 Miscellaneous
Beta 29.4 Beta
Console 29.5 Console
Polygon 29.6 Polygon

29.3 Miscellaneous

All the options under **User** and **User menus** are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on *User* menus, go to 29.1 User Defined Menus

The walk rights **User =>Miscellaneous** menu is:



and the walk rights on the **Miscellaneous** menus are:

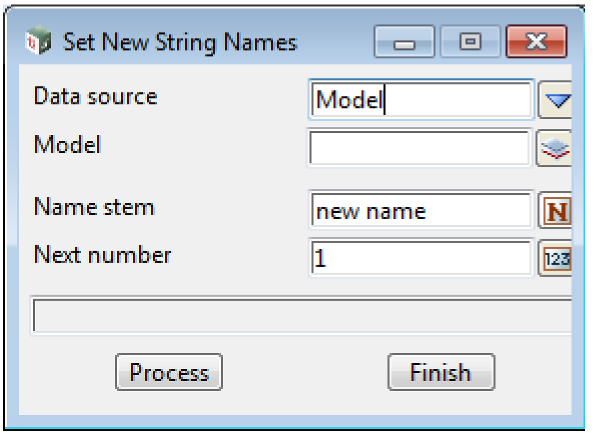
29.3.1 XXX New Name

Position of option on menu: **User =>Miscellaneous =>A to C =>Change name of strings**

Note - This is an unsupported option which may not be fully documented.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source		Model	string, model, view
Model/View/String of circles			

type of source of the data to process.

Model for centres	model box		available models

source of data to process.

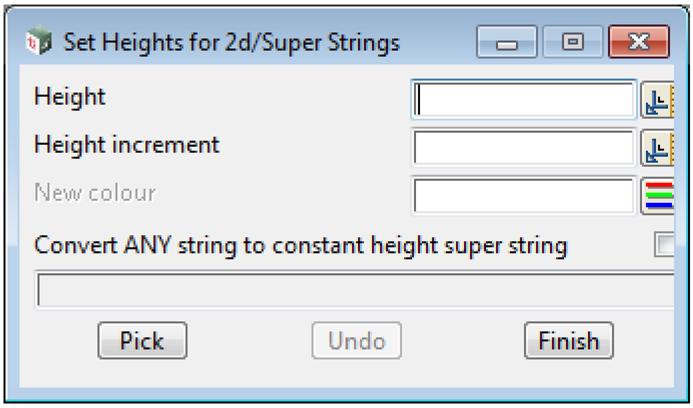
Name stem	input		
Process	button		

29.3.2 Set Heights for 2d (contour) Strings

Position of option on menu: **User =>Miscellaneous =>A to C =>Contour levels**

Note - This is an unsupported option which may not be fully documented.

This panel is used to quickly change the height of contour strings. An initial height and increment is given. As each string is accepted, it is given the height and the height then incremented.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Height	input		

Height to use for the next selected string. This is incremented by the "Height increment" after each string is accepted.

Height increment	input		

As each string is accepted, the "Height" value is incremented by this value.

New colour	input		available colours

If non-blank, the selected strings are given this colour when their z-value is changed.

Pick	input		

After clicking on Pick, 2d strings are selected and when accepted, have their z-value changed to the value in the Height field. The height value is then automatically incremented. The next string is then selected and accepted (without needing to click on Pick again). This continues until Cancel is selected from the "Pick Ops" menu.

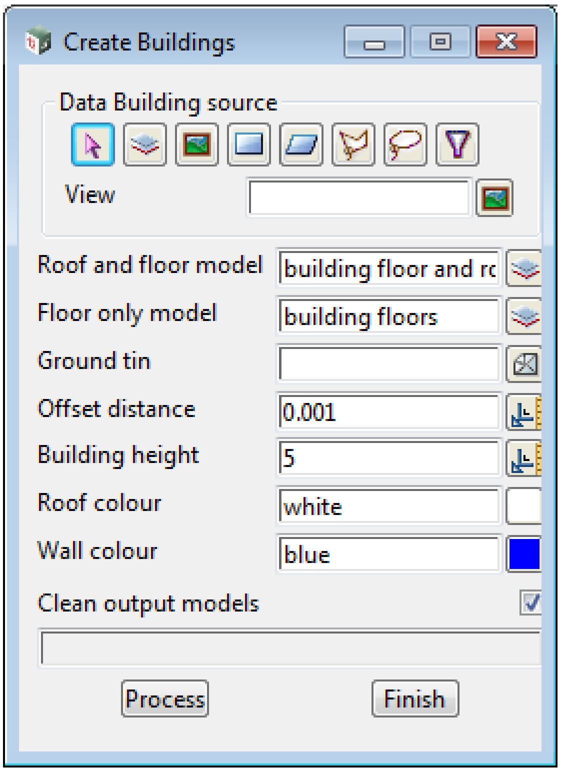
Undo	button		

Undo the last height change. This can be selected up to 200 times.

29.3.3 XXX Create Building for a Tin

Position of option on menu: **User =>Miscellaneous =>A to C =>Create buildings for tin**

Note - This is an unsupported option which may not be fully documented.

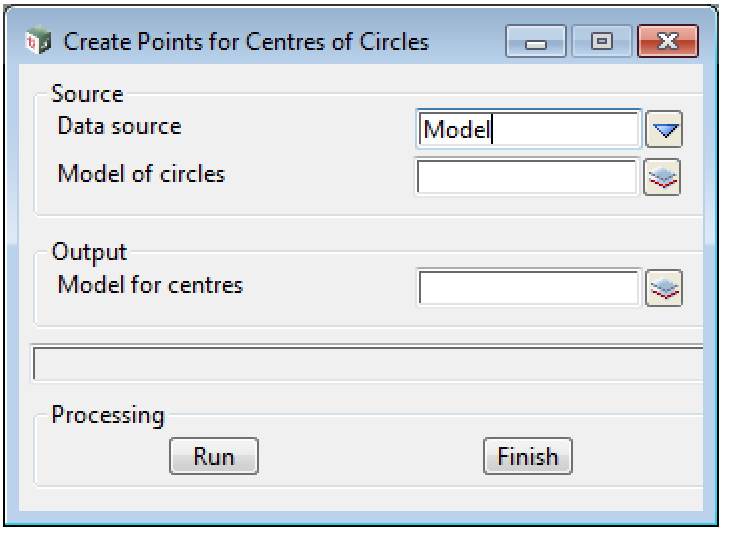


29.3.4 Create Points for Centre of Circles

Position of option on menu: **User =>Miscellaneous =>A to C =>Convert circles to points**

Note - This is an unsupported option which may not be fully documented.

This options creates points at the centres of circles.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source		Model	string, model, view
Model/View/string of circles			

source of the circles to create centre points for.

Model for centres	model box		available models

model to place the created centre points in.

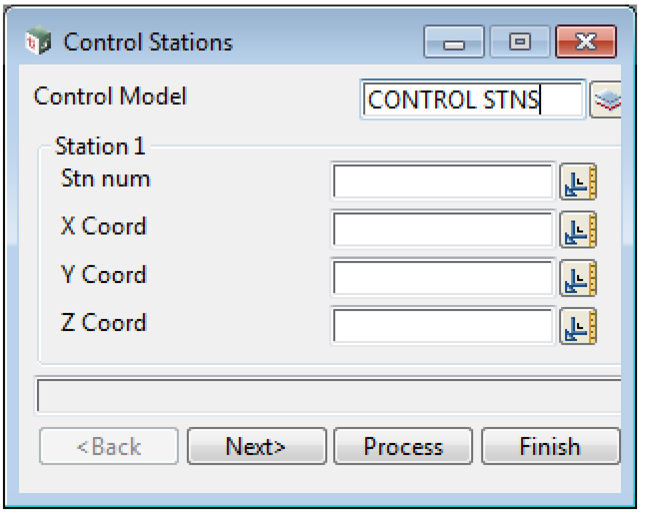
Run	button		

run the option.

29.3.5 XXX Create Control Stations

Position of option on menu: **User =>Miscellaneous =>A to C =>Create control stations**

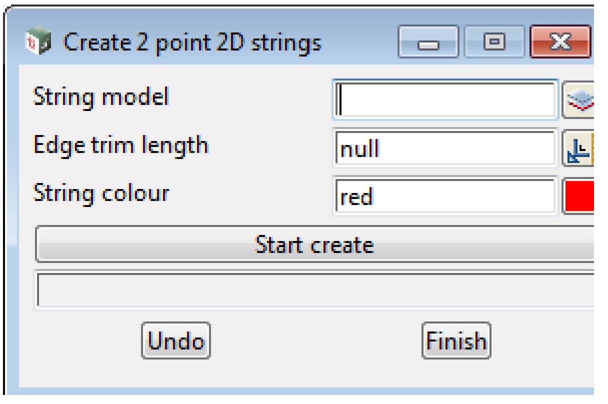
Note - This is an unsupported option which may not be fully documented.



29.3.6 XXX Create 2d String from Two Points

Position of option on menu: **User =>Miscellaneous =>A to C =>Create 2 point - 2d strings**

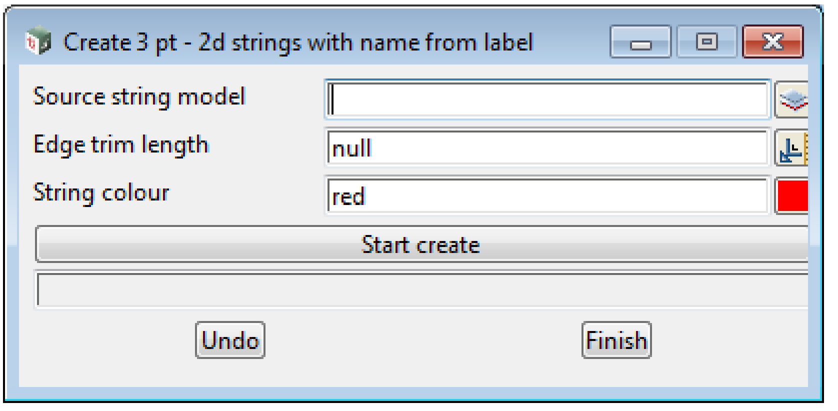
Note - This is an unsupported option which may not be fully documented.



29.3.7 XXX Create 3 Point 2d Strings

Position of option on menu: **User =>Miscellaneous =>A to C =>Create 3 point - 2d strings**

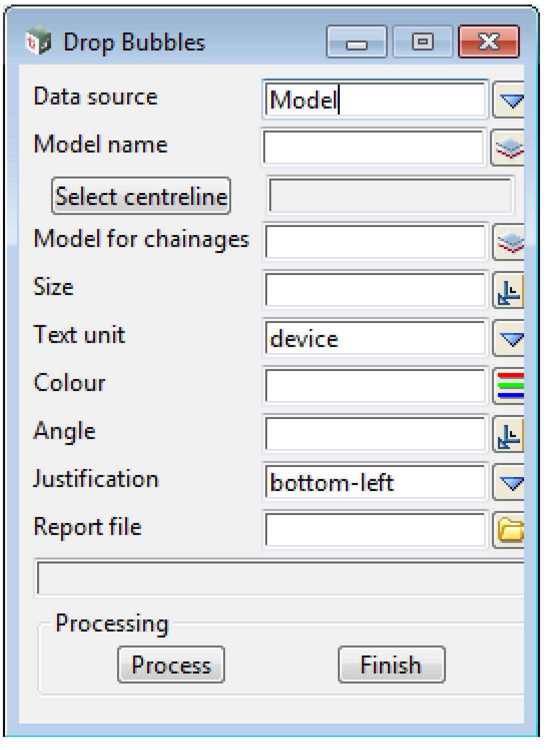
Note - This is an unsupported option which may not be fully documented.



29.3.8 XXX Drop Bubbles

Position of option on menu: **User =>Miscellaneous =>D to K =>Drop bubbles**

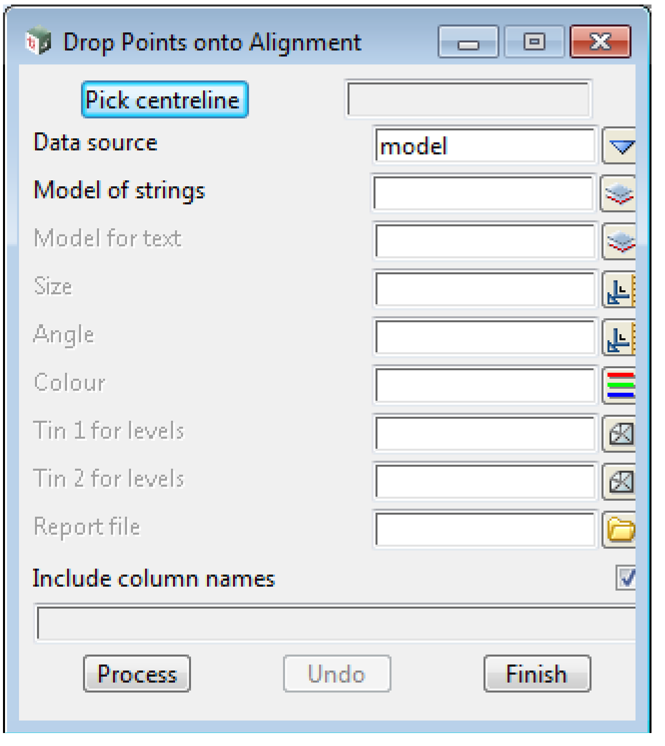
Note - This is an unsupported option which may not be fully documented.



29.3.9 XXX Drop Points onto Alignment

Position of option on menu: **User =>Miscellaneous =>D to K =>Drop points onto alignment**

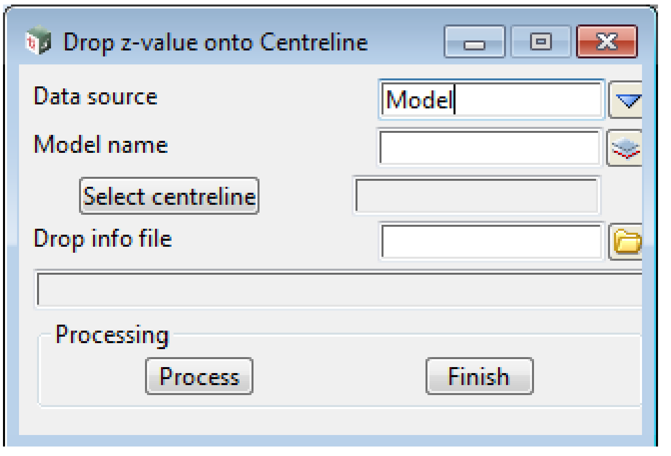
Note - This is an unsupported option which may not be fully documented.



29.3.10 XXX Drop z-value onto Centreline

Position of option on menu: **User =>Miscellaneous =>D to K =>Drop points on centreline**

Note - This is an unsupported option which may not be fully documented.

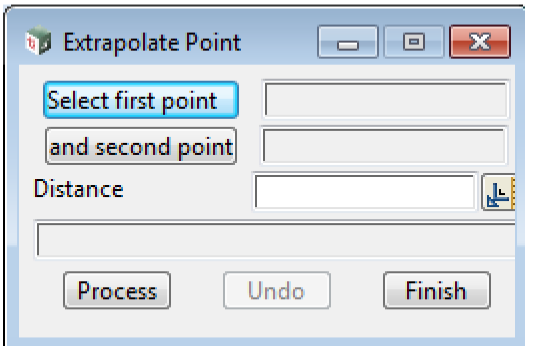


29.3.11 Extrapolate Point

Position of option on menu: **User =>Miscellaneous =>D to K =>Extrapolate**

Note - This is an unsupported option which may not be fully documented.

This option is used to select two point and then creates a new point a given distance from the second point along the line from the first point to the second point. The z-value for the point is the extrapolated z-value from the two selected points.



The fields and buttons used in this panel have the following functions:

Field Description Type Defaults Pop-Up

Select first point string select

select the first point to use in the extrapolation.

and second point string select

select the second point to use in the extrapolation.

Distance output box

distance to project from the second point along the line from the first to the second point.

Process button

run the option.

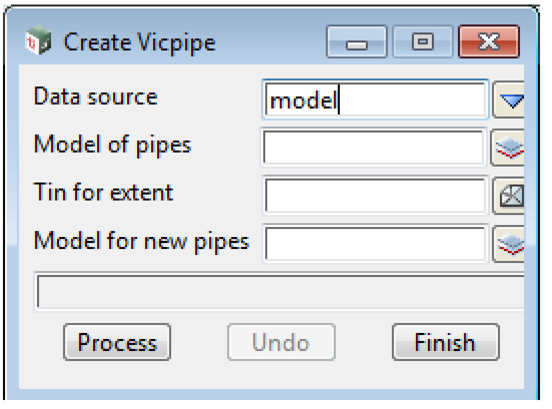
Undo button

undo the last extrapolated point created since the panel has been up.

29.3.12 XXX Create VicRoad Pipe

Position of option on menu: **User =>Miscellaneous =>D to K =>Extend pipe**

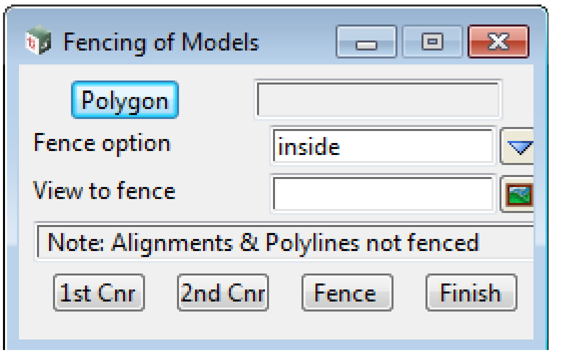
Note - This is an unsupported option which may not be fully documented.



29.3.13 XXX Fencing Models

Position of option on menu: **User =>Miscellaneous =>D to K =>Fencing models**

Note - This is an unsupported option which may not be fully documented.

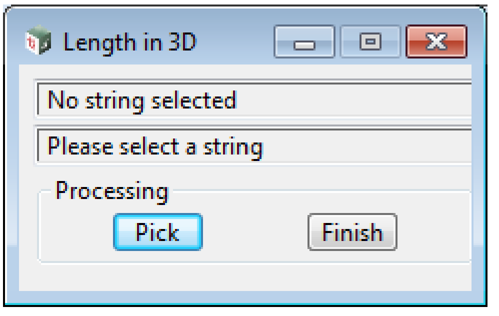


29.3.14 Length in 3d

Position of option on menu: **User =>Miscellaneous =>D to K =>Get length in 3d**

Note - This is an unsupported option.

This panel is used to calculate the 3d length of a selected string.



The fields and buttons used in this panel have the following functions:

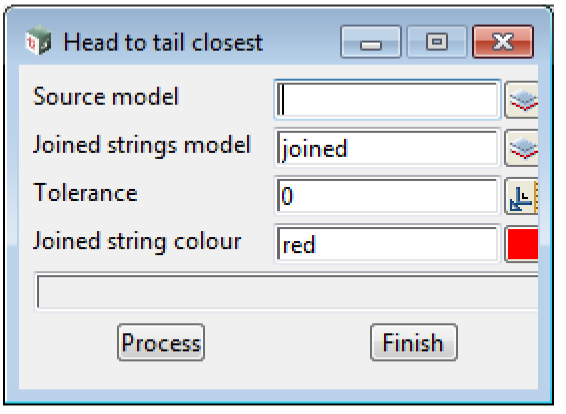
Field Description	Type	Defaults	Pop-Up
Pick	button		

select the string to calculated the 3d length for.

29.3.15 XXX Head to Tail Closest Points

Position of option on menu: **User =>Miscellaneous =>D to K =>Head to tail closest points**

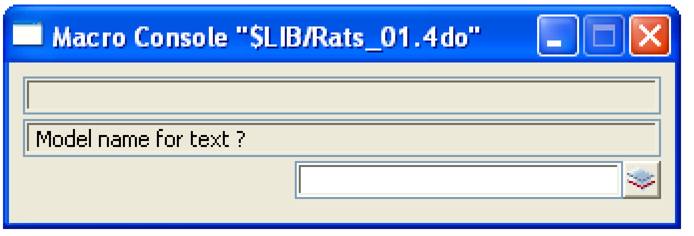
Note - This is an unsupported option which may not be fully documented.



29.3.16 XXX Label Alignment

Position of option on menu: **User =>Miscellaneous =>L to Q =>Label alignment**

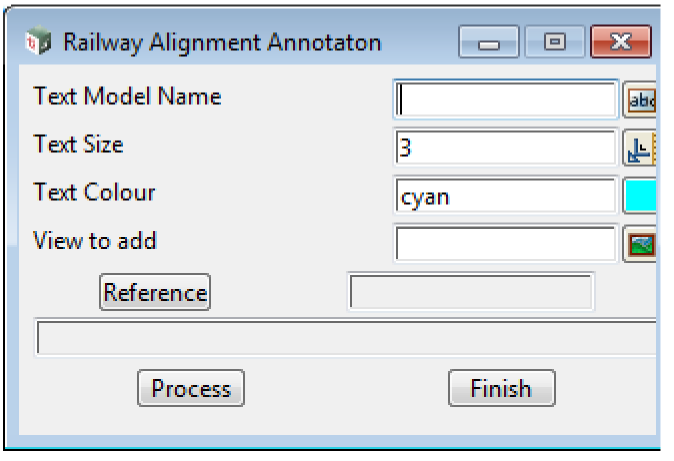
Note - This is an unsupported option which may not be fully documented.



29.3.17 XXX Label Alignment Radius

Position of option on menu: **User =>Miscellaneous =>L to Q =>Label alignment radius/ip (rail)**

Note - This is an unsupported option which may not be fully documented.

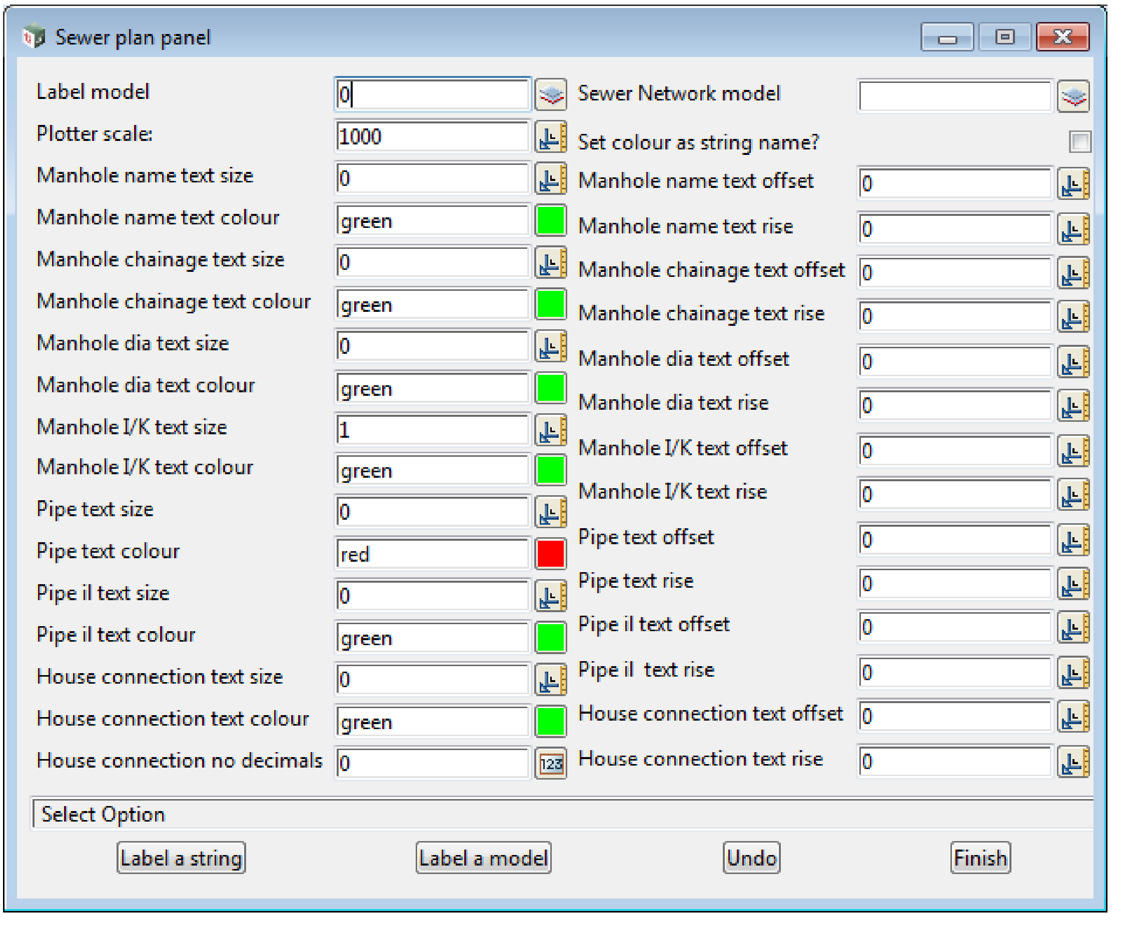


29.3.18 XXX Label Sewer Plan (old)

Position of option on menu: **User =>Miscellaneous =>L to Q =>Label sewer plan**

Note - This is an unsupported option which may not be fully documented.

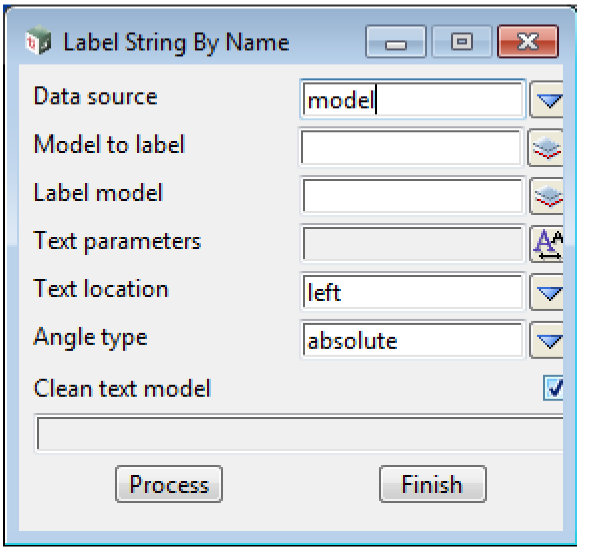
This option has been superseded.



29.3.19 XXX Name Strings by Nearby Text

Position of option on menu: **User =>Miscellaneous =>L to Q =>Label strings with name**

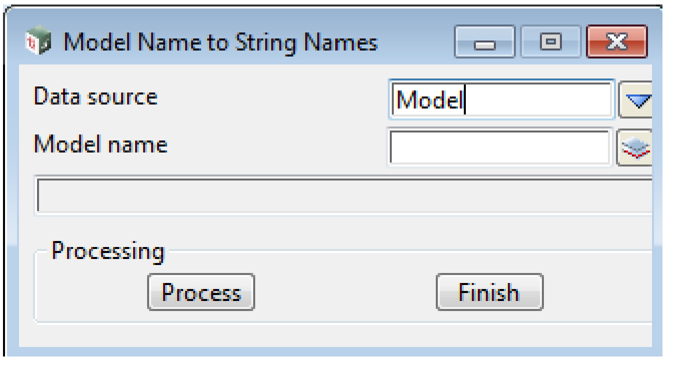
Note - This is an unsupported option which may not be fully documented.



29.3.20 XXX Name Strings by Model Name

Position of option on menu: **User =>Miscellaneous =>L to Q =>Model to name**

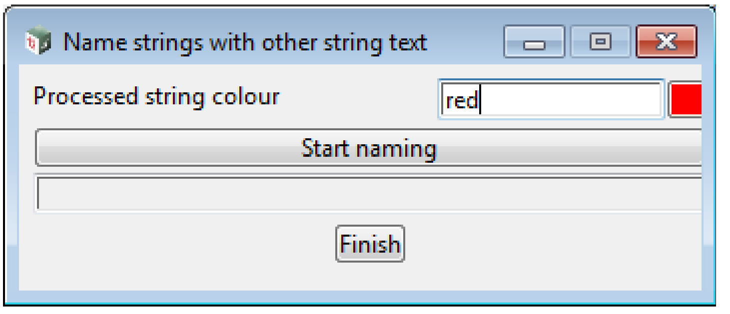
Note - This is an unsupported option which may not be fully documented.



29.3.21 XXX Name Section Strings by Picking Text

Position of option on menu: **User =>Miscellaneous =>L to Q =>Name strings using text strings**

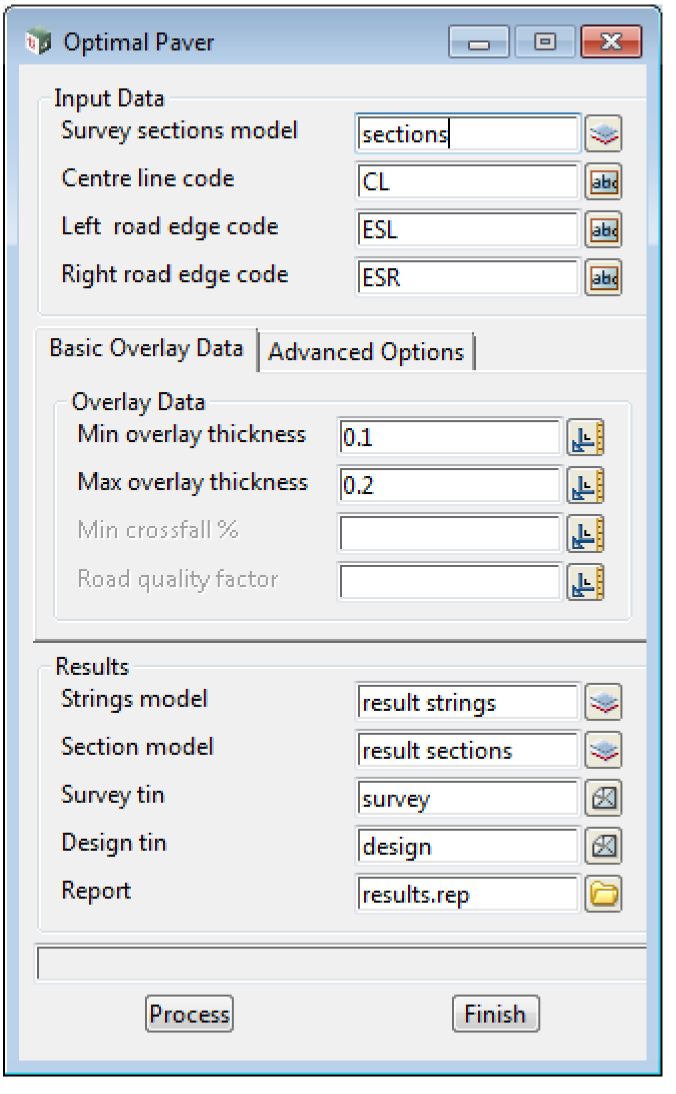
Note - This is an unsupported option which may not be fully documented.



29.3.22 XXX Overlay Optimiser

Position of option on menu: **User =>Miscellaneous =>L to Q =>Overlay optimiser**

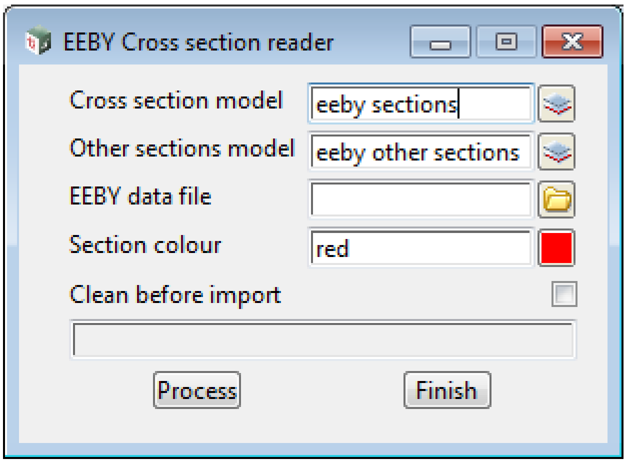
Note - This is an unsupported option which may not be fully documented.



29.3.23 XXX Read EEBY Sections

Position of option on menu: **User =>Miscellaneous =>R to Z =>Read EEBY sections**

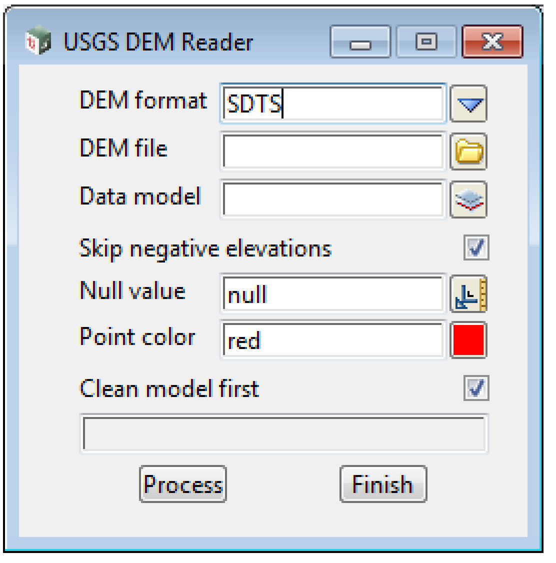
Note - This is an unsupported option which may not be fully documented.



29.3.24 XXX Read USGS DEM Data

Position of option on menu: **User =>Miscellaneous =>R to Z =>Read USGS DEM data**

Note - This is an unsupported option which may not be fully documented.

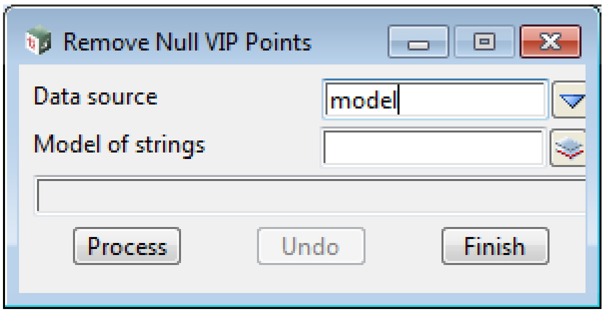


29.3.25 Remove Null VIP Points

Position of option on menu: **User =>Miscellaneous =>R to Z =>Remove null VIP’s**

Note - This is an unsupported option which may not be fully documented.

This option is used to remove any null vertical intersection points from alignment strings.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source	data source	Model	String, Model, View

Type of data to remove null vips for.

Model/View/String	data source

Data source for all the alignment strings to remove all null vips from.

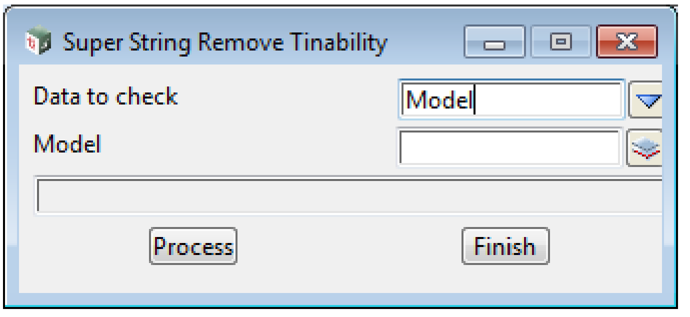
Process	button

Run the option.

29.3.26 XXX Remove Tinability

Position of option on menu: **User =>Miscellaneous =>R to Z =>Remove tinability**

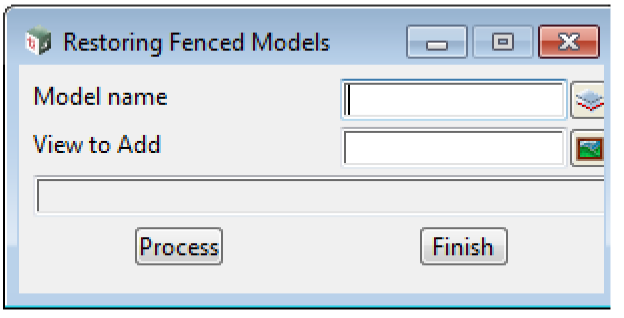
Note - This is an unsupported option which may not be fully documented.



29.3.27 XXX Restore Fenced Model

Position of option on menu: **User =>Miscellaneous =>R to Z =>Restore fenced model**

Note - This is an unsupported option which may not be fully documented.



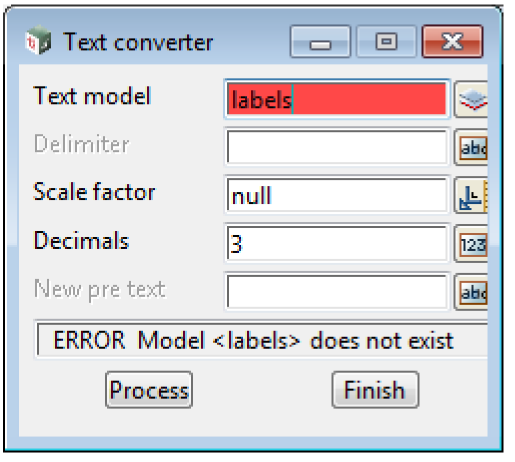
The fields and buttons used in this panel have the following functions:

Field Description Type Defaults Pop-Up

29.3.28 XXX Scale Text Values

Position of option on menu: **User =>Miscellaneous =>R to Z=>Scale text values**

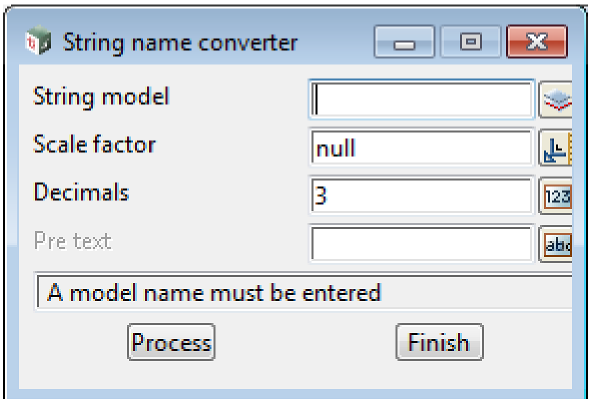
Note - This is an unsupported option which may not be fully documented.



29.3.29 XXX Scale String Names

Position of option on menu: **User =>Miscellaneous =>R to Z=>Scale string names**

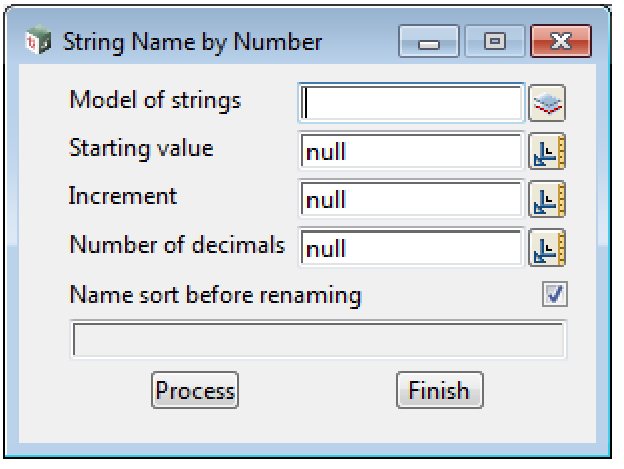
Note - This is an unsupported option which may not be fully documented.



29.3.30 XXX Set String Names by Number

Position of option on menu: **User =>Miscellaneous =>R to Z=>Set string names by number**

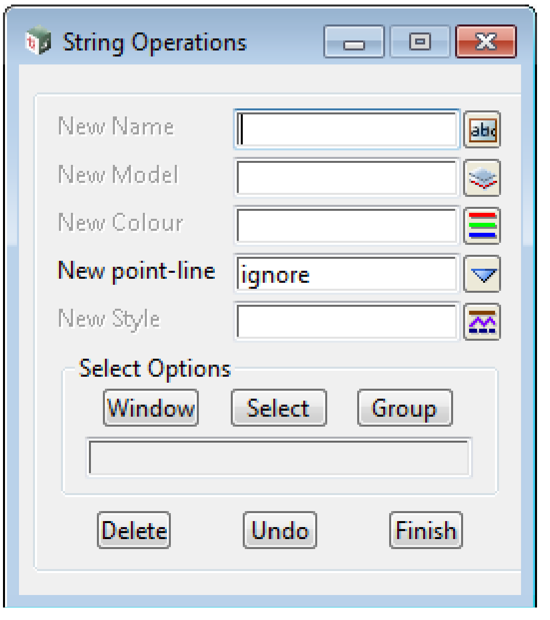
Note - This is an unsupported option which may not be fully documented.



29.3.31 XXX String Operations

Position of option on menu: **User =>Miscellaneous =>R to Z=>Set string properties**

Note - This is an unsupported option which may not be fully documented.

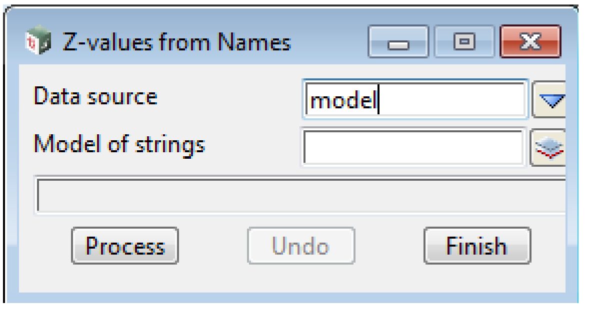


29.3.32 Set Contour Levels from String Names

Position of option on menu: **User =>Miscellaneous =>R to Z=>Set contour level from contour name**

Note - This is an unsupported option which may not be fully documented.

This operates on contour strings and sets the contour z-value to be the value of the name of the contour string. The z-values may need to be factored to bring them into the correct units.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source	data source	Model	Model, View

Type of data to set contour z-values for.

Model/View	data source		

Data source to of contours to set z-values for.

Process	button		

Run the option

Undo	button		

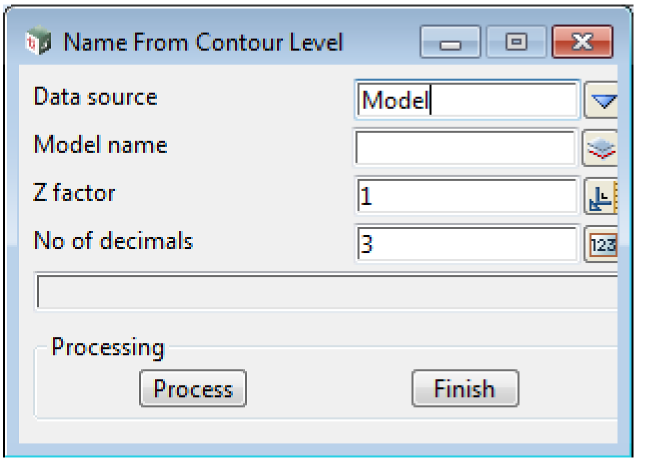
Undo the last set of contours labelled since the panel was up.

29.3.33 Set Contour Names From Contour Levels

Position of option on menu: **User =>Miscellaneous =>R to Z=>Set contour names from contour levels**

Note - This is an unsupported option which may not be fully documented.

This option operates on contours only and sets the string name to be the contour z value multiplied by the given factor.



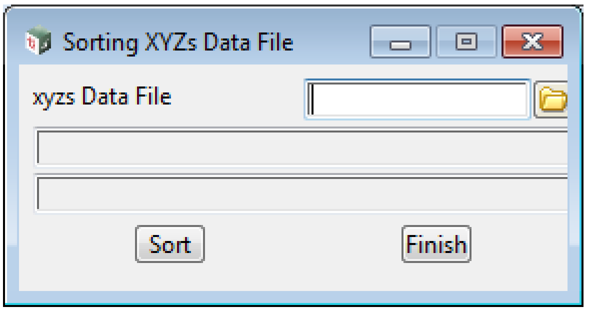
The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source	data source	Model	String, Model, View
Type of data to label contours strings for.			
Model/View/String	data source		
Data source to calculate label the contours for.			
Z factor	input	1	
Value to multiply the z values by before creating the string name.			
No of decimals	input	3	
Number of decimals places to use in the string name.			
Process	button		
Run the option.			

29.3.34 XXX Sort XYZs Data File

Position of option on menu: **User =>Miscellaneous =>R to Z=>Sort xyz data file**

Note - This is an unsupported option which may not be fully documented.



29.3.35 String Clipboard

Position of option on menu: **User =>Miscellaneous =>R to Z=>String attributes-properties to-from clipboard**

Position of option on menu: **File I/O=>User =>String attributes-properties to-from clipboard**

Note - This is an unsupported option which may not be fully documented.

On selecting the **String attributes-properties to-from clipboard** option, the **String clipboard** panel is displayed.

This panel can be used to export string properties and attributes to the windows clipboard and import the properties to update the same strings.

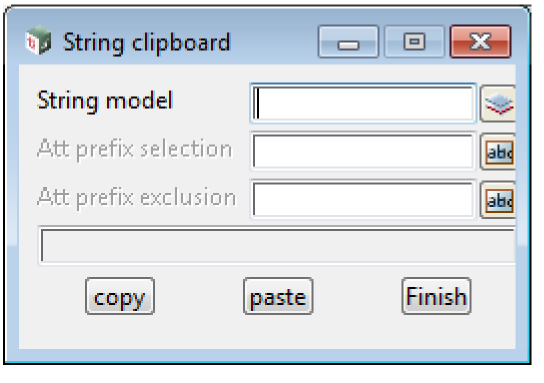
The following properties are always exported when **copy** is selected:

String id	Name	Type	Breakline	Style	Colour	Length
1	3	3	1	3	1	3
3322187D1		Drainage	1	1	1004	238.358

String id, **Type** and **Length** are for export only and cannot be changed on an import. **Name, Breakline, Style** and **Colour** may be changed to update the string when **paste** is selected. **Style** (linestyle order number from linestyl.4d) and **Colour** (colours.4d) numbers are used.

Starting in the 8th column, all of the string attributes are exported unless the **Att prefix selection** and/or the **Att prefix exclusion** filters are used. The first row is the string attribute name and the second row contains a number indicating the type of attribute. Attribute type numbers are

1	integer numbers (no decimals)
2	real numbers (decimals allowed)
3	text (characters allowed)



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
String model	model box		

name of the model to select strings from.

Att prefix selection	input	last data used	

(copy only) if blank all attributes will be selected prior to the exclusion. If text is entered then only attributes with this exact text (case sensitive) will be selected prior to the exclusion.

Att prefix exclusion	input	last data used	

(copy only) if blank all attributes matching the selection above will be exported. If text is entered then attributes with this exact text (case sensitive) will be excluded from the export.

Copy button

copies the data from the string to the windows clipboard

Paste button

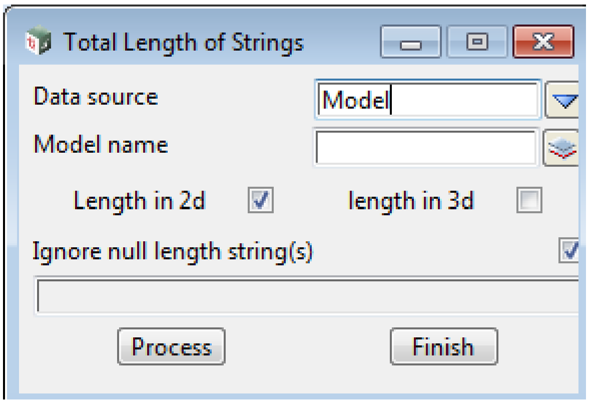
pastes the data from the windows clipboard. The string id is used to locate the string in the given model and then the properties/attributes are created and/or updated. If the attribute name is prefixed by DELETE followed by a space this string attribute will be deleted from all strings listed in the import.

29.3.36 Total Length of Strings

Position of option on menu: **User =>Miscellaneous =>R to Z=>Sum length of all strings**

Note - This is an unsupported option which may not be fully documented.

This panel is used to calculate the total length of the strings in a selected model or view.



The fields and buttons used in this panel have the following functions:

Field Description	Type	Defaults	Pop-Up
Data source			model, view, string

data source type

Data source

data source to calculate lengths for.

Length in 2d/3d	radio button	2d

if 2d, the lengths are only calculated in 2d.

If 3d, the lengths are calculated in 3d.

Ignore null length string(s)	tick box	ticked

if ticked, strings of null length are ignored in the string count and hence don't affect the average length.

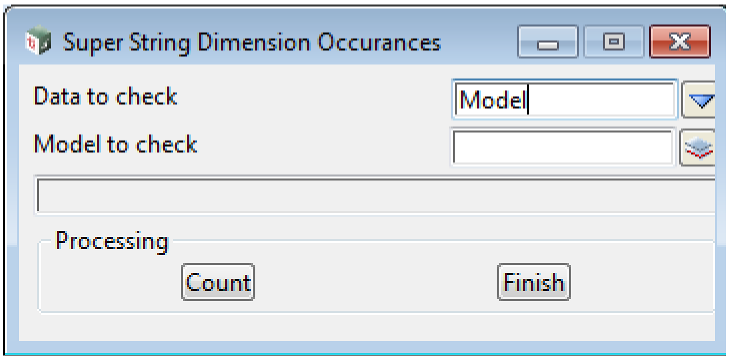
Process	button

run the option

29.3.37 XXX Super String Dimension Occurrences

Position of option on menu: **User =>Miscellaneous =>R to Z=>Super string dimension occurrences**

Note - This is an unsupported option which may not be fully documented.

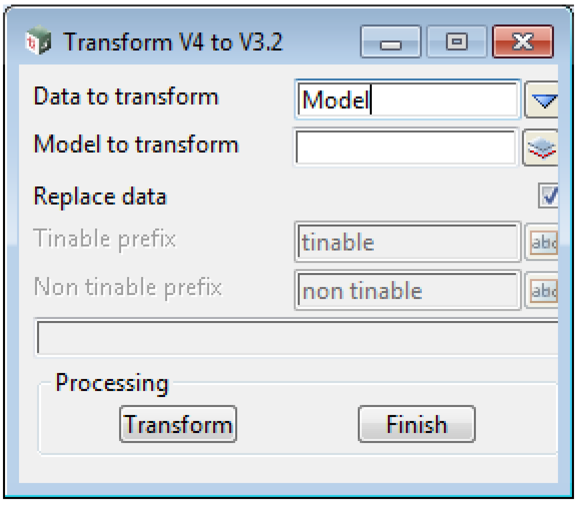


29.3.38 XXX Transform V4 to V3.2

Position of option on menu: **User =>Miscellaneous =>R to Z=>Super string to V3.2 strings**

Note - This is an unsupported option which may not be fully documented.

This panel convert a super string from ***12d Model*** V4.0 format to V3.2 strings.

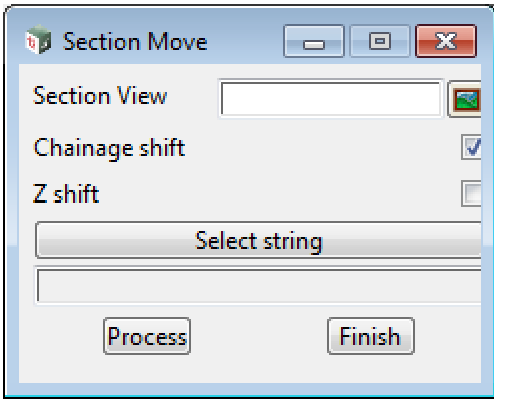


29.3.39 XXX Section Move

Position of option on menu: **User =>Miscellaneous =>R to Z=>Translate string in section view**

Note - This is an unsupported option which may not be fully documented.

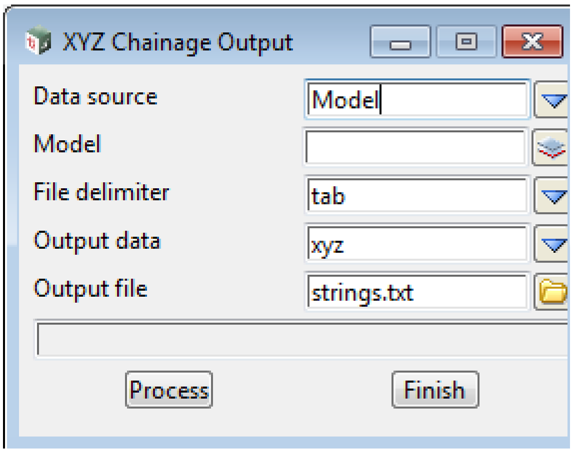
This panel is used to translate a string on a section view.



29.3.40 XXX Output XYZ and Chainage

Position of option on menu: **User =>Miscellaneous =>R to Z=>XYZ chainage**

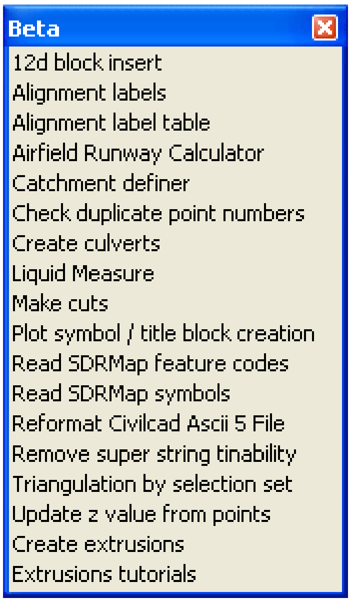
Note - This is an unsupported option which may not be fully documented.



29.4 Beta

All the options under **User** and **User menus** are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on *User* menus, go to 29.1 User Defined Menus

The walk rights **Beta** menu is:

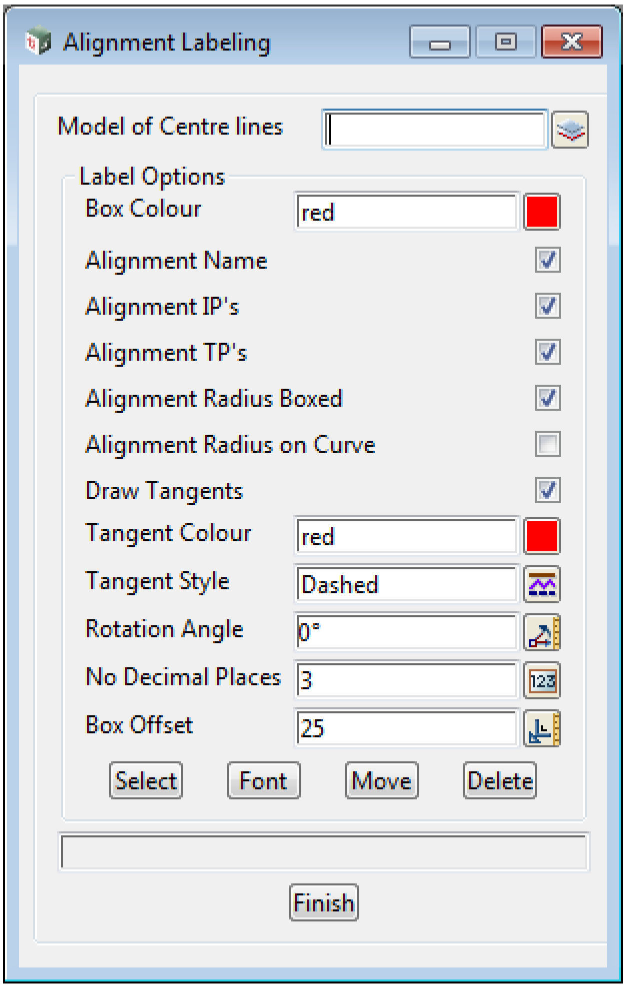


For the option *Alignment labels*, go to	29.4.1 XXX Alignment Labels
Alignment label table	29.4.2 XXX Table of Alignment Labels
Airfield Runway Calculator	29.4.3 Airfield Runway Calculator
Catchment definer	29.4.4 XXX Catchment Definer
Check duplicate point numbers	29.4.5 XXX Check Duplicate Point Numbers
Create culverts	29.4.6 XXX Create Culvert
Liquid measure	29.4.7 XXX Liquid Measure
Make cuts	29.4.8 XXX Make Cuts Through Strings
Plot symbol/title block	29.4.9 XXX Plot Symbol and Title Block Creation (old)
Read SDRMap feature codes	29.4.10 XXX Read SDRMap Feature Code
Read SDRMap symbols	29.4.11 XXX Read SDRMap Symbols
Reformat CivilCAD Ascii 5 file	29.4.12 XXX Reformat CivilCAD Ascii 5 file
Remove super string tinability	29.4.13 XXX Remove Super String Tinability
Triangulate by selection set	29.4.14 XXX Triangulate by Selection Set
Update z values from points	29.4.15 XXX Update Z Values from Points

29.4.1 XXX Alignment Labels

Position of option on menu: **User =>Beta =>Alignment labels**

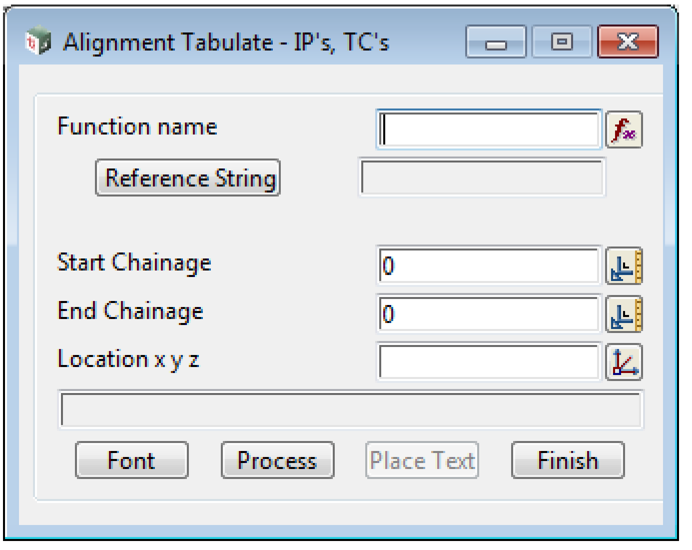
Note - This is an unsupported option which may not be fully documented.



29.4.2 XXX Table of Alignment Labels

Position of option on menu: **User =>Beta =>Alignment label table**

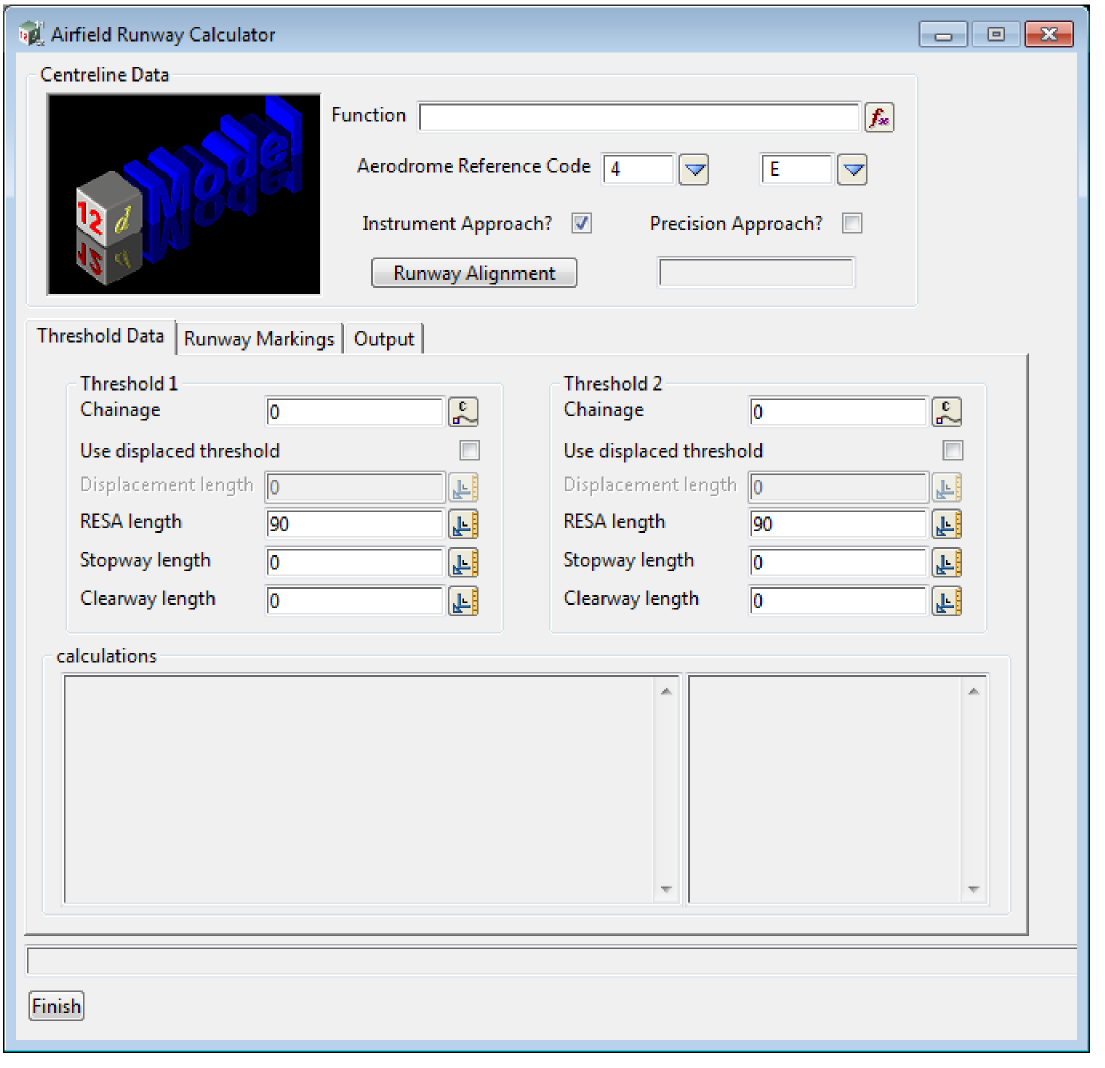
Note - This is an unsupported option which may not be fully documented.



29.4.3 Airfield Runway Calculator

Position of option on menu: **User =>Beta =>Airfield Runway Calculator**

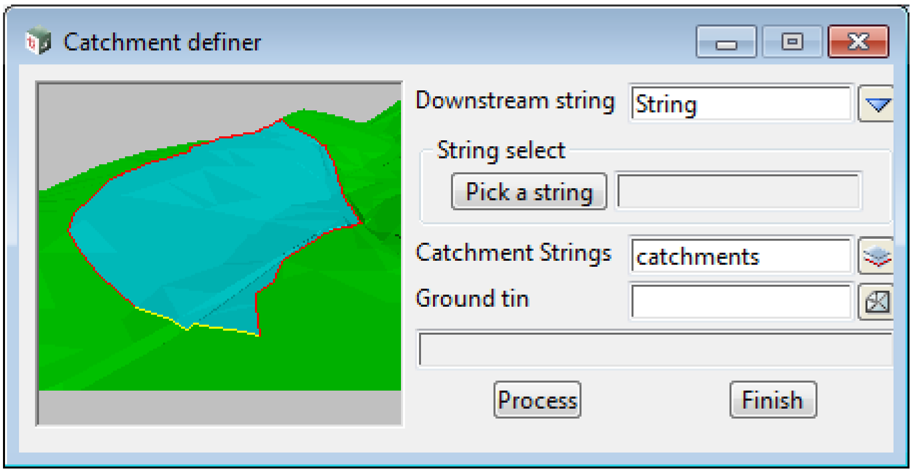
This option is under development



29.4.4 XXX Catchment Definer

Position of option on menu: **User =>Beta =>Catchment definer**

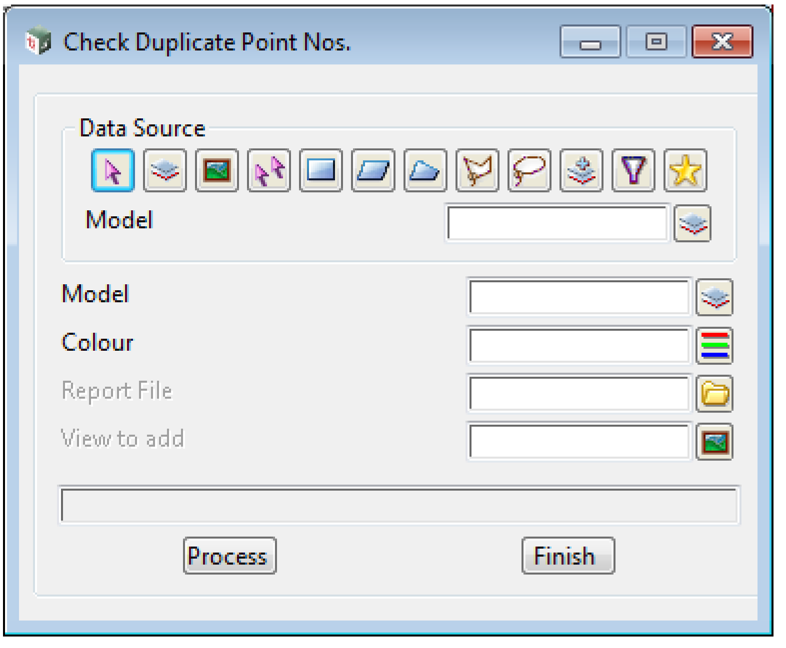
Note - This is an unsupported option which may not be fully documented.



29.4.5 XXX Check Duplicate Point Numbers

Position of option on menu: **User =>Beta =>Check duplicate point numbers**

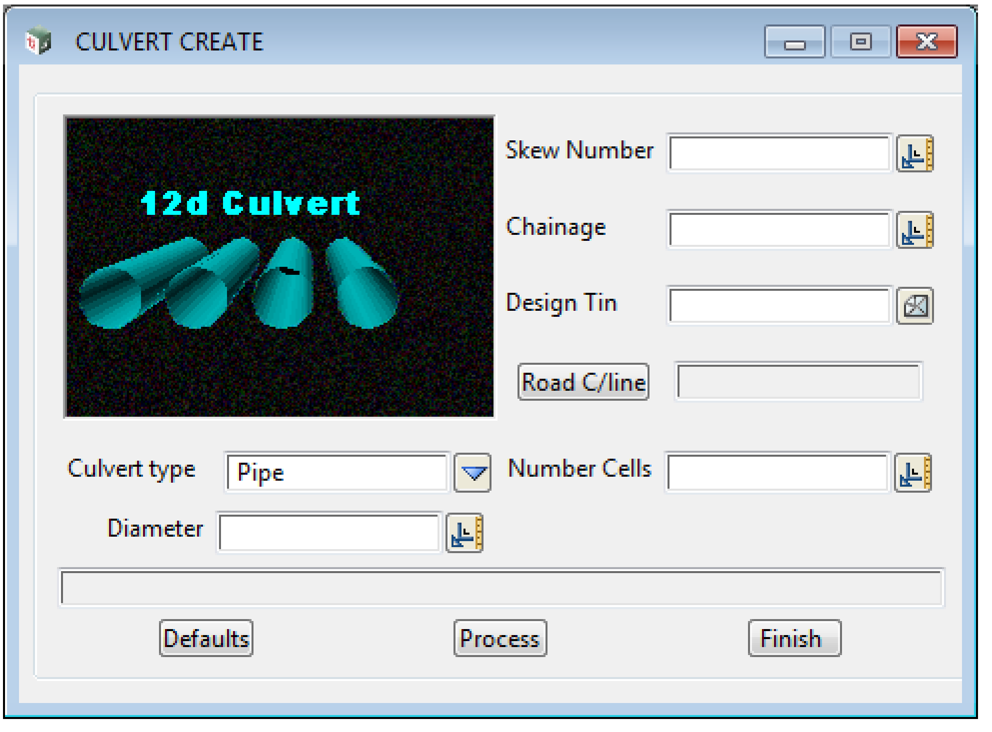
Note - This is an unsupported option which may not be fully documented.



29.4.6 XXX Create Culvert

Position of option on menu: **User =>Beta =>Create culvert**

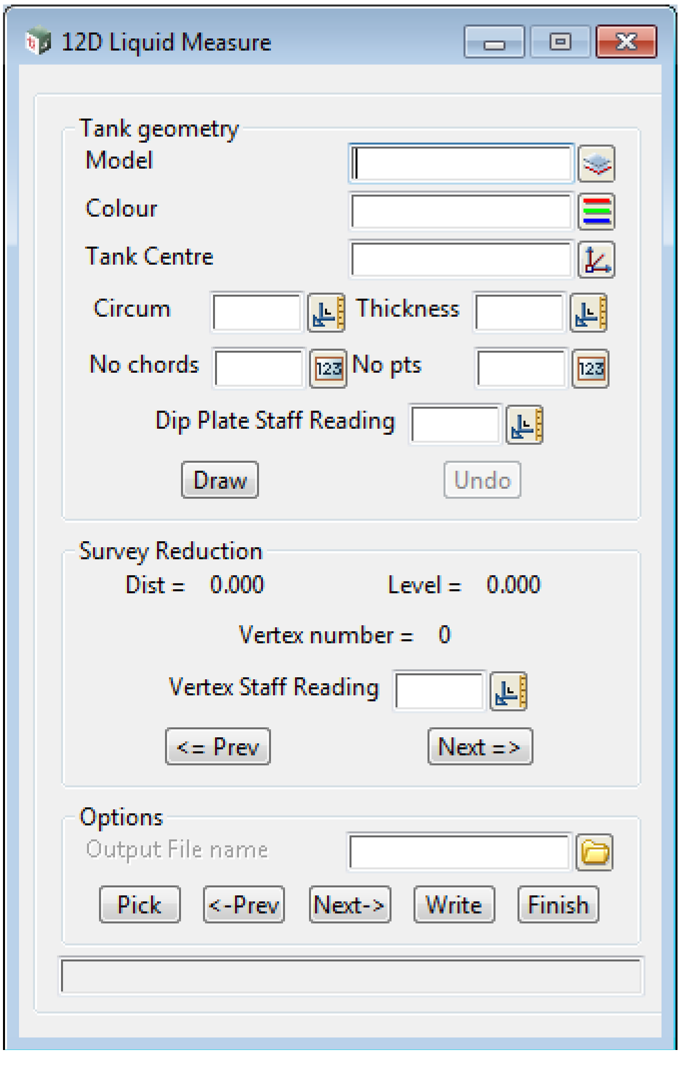
Note - This is an unsupported option which may not be fully documented.



29.4.7 XXX Liquid Measure

Position of option on menu: **User =>Beta =>Liquid measure**

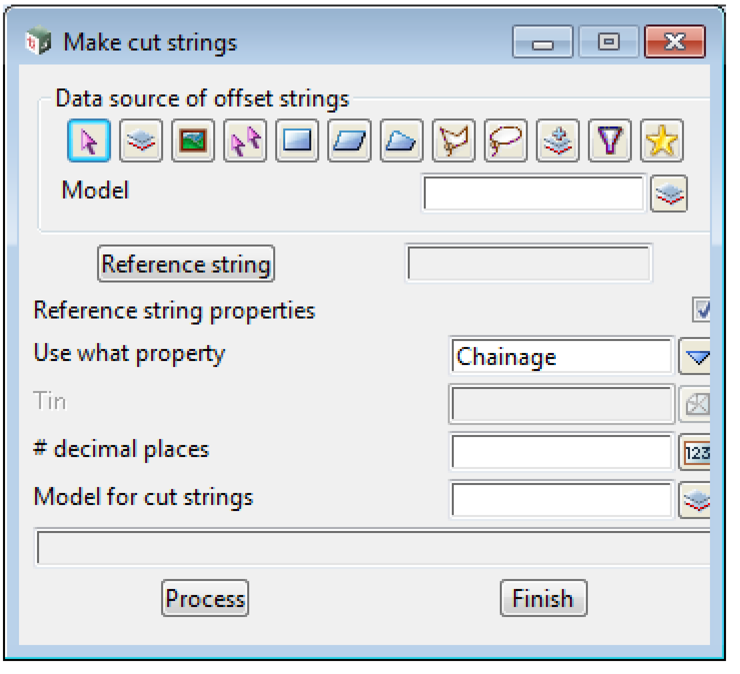
Note - This is an unsupported option which may not be fully documented.



29.4.8 XXX Make Cuts Through Strings

Position of option on menu: **User =>Beta =>Make cuts**

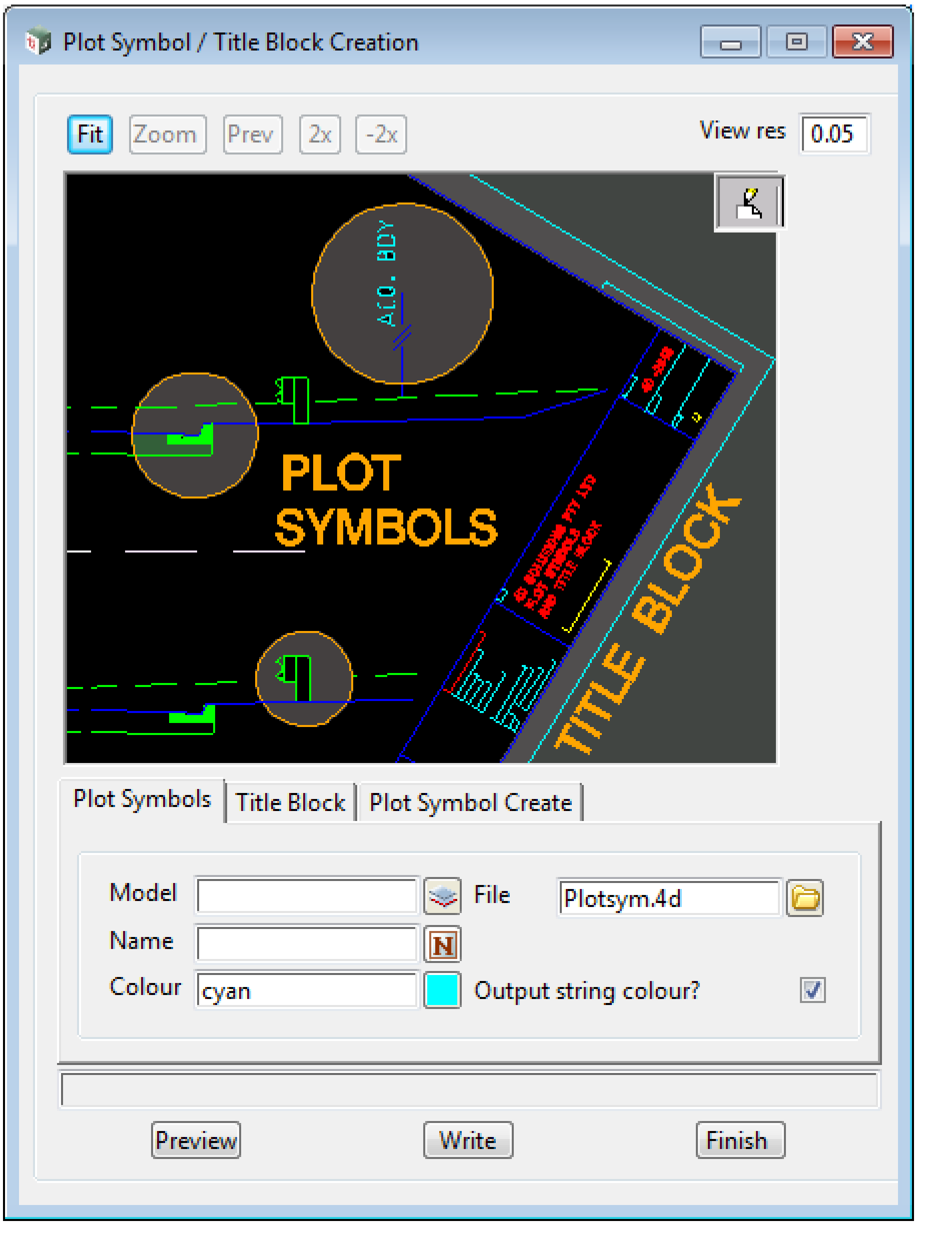
Note - This is an unsupported option which may not be fully documented.



29.4.9 XXX Plot Symbol and Title Block Creation (old)

Position of option on menu: **User =>Beta =>Plot symbol/title block creation**

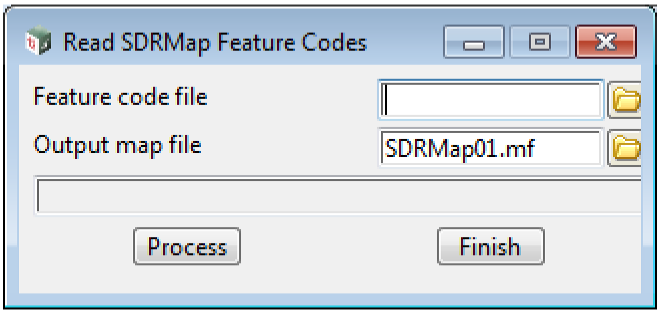
Note - This is an unsupported option which may not be fully documented.



29.4.10 XXX Read SDRMap Feature Code

Position of option on menu: **User =>Beta =>Read SDRMap feature codes**

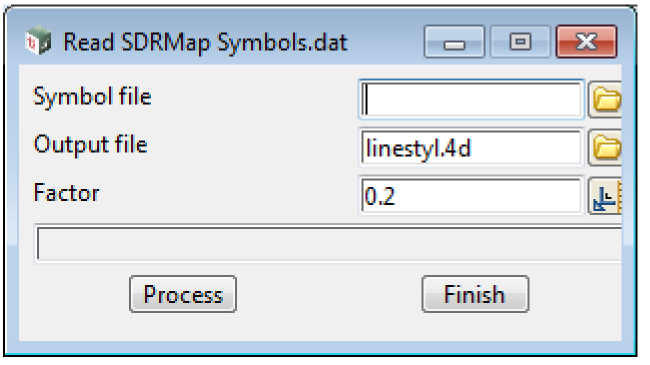
Note - This is an unsupported option which may not be fully documented.



29.4.11 XXX Read SDRMap Symbols

Position of option on menu: **User =>Beta =>Read SDRMap symbols**

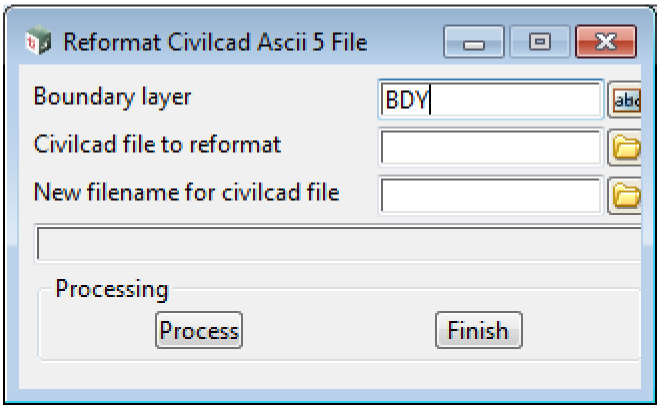
Note - This is an unsupported option which may not be fully documented.



29.4.12 XXX Reformat CivilCAD Ascii 5 file

Position of option on menu: **User =>Beta =>Reformat CivilCAD Ascii 5 file**

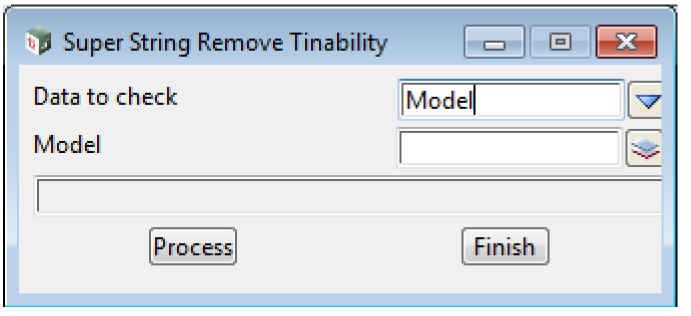
Note - This is an unsupported option which may not be fully documented.



29.4.13 XXX Remove Super String Tinability

Position of option on menu: **User =>Beta =>Remove super string tinability**

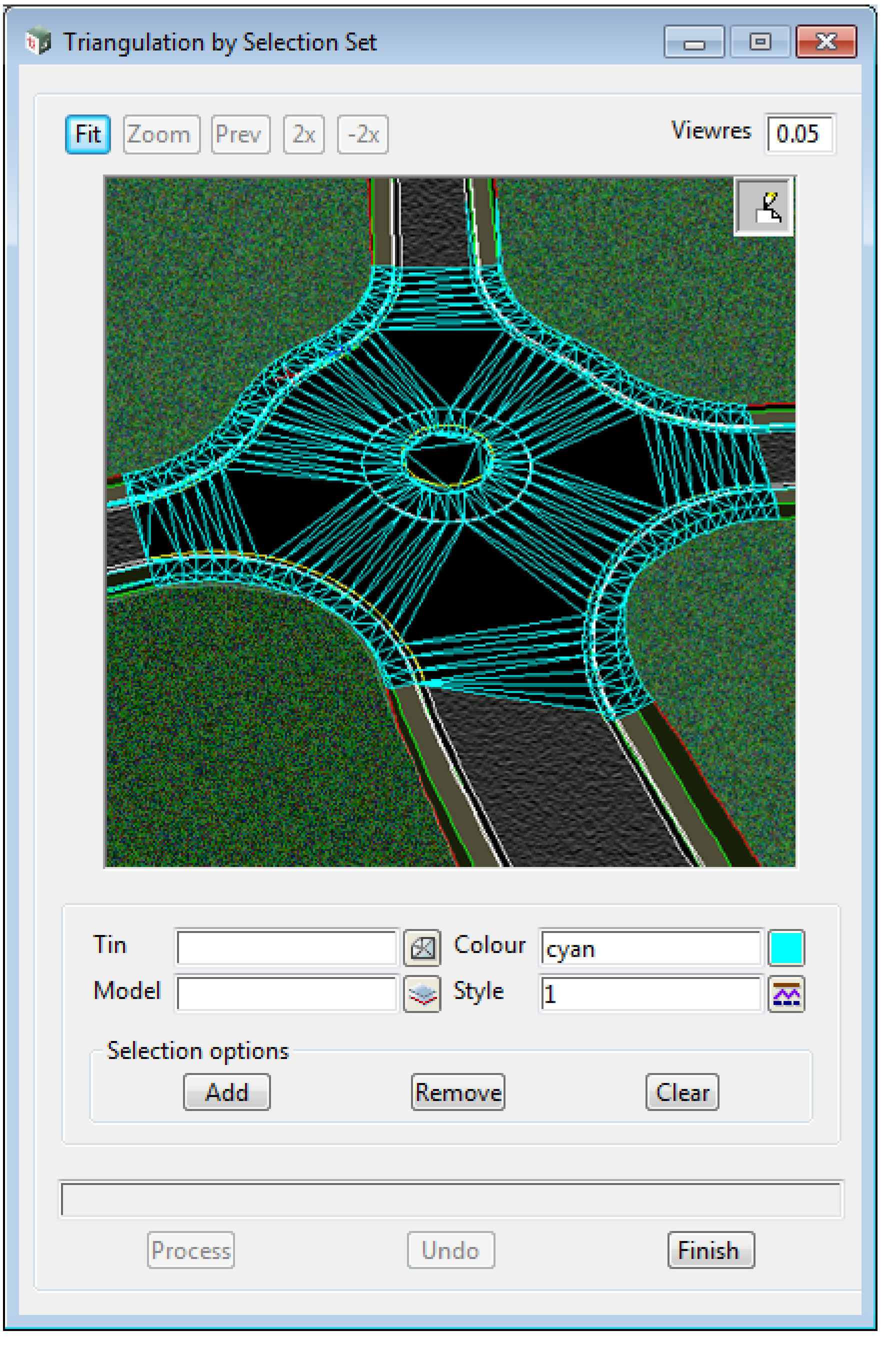
Note - This is an unsupported option which may not be fully documented.



29.4.14 XXX Triangulate by Selection Set

Position of option on menu: User =>Beta =>Triangulation by selection set

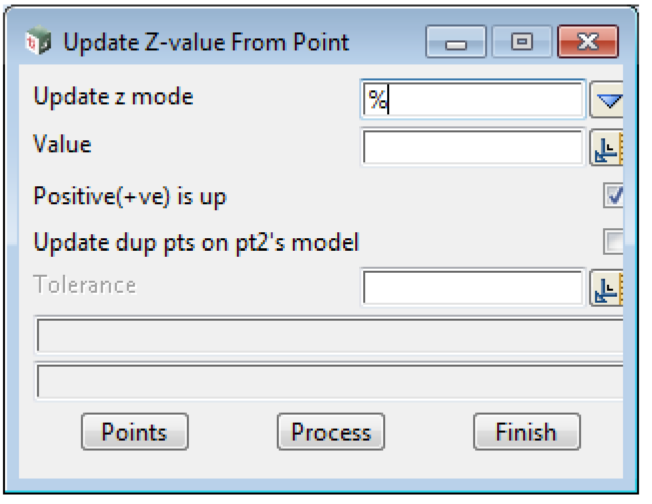
Note - This is an unsupported option which may not be fully documented.



29.4.15 XXX Update Z Values from Points

Position of option on menu: **User =>Beta =>Update z value from points**

Note - This is an unsupported option which may not be fully documented.



29.5 Console

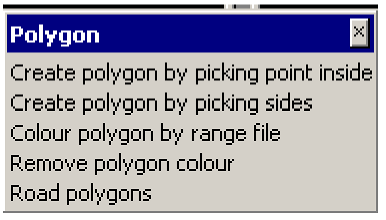
All the options under **User** and **User menus** are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on *User* menus, go to 29.1 User Defined Menus

All the macros on the **Console** menu only use the console panel and so do not support a F1 key for help.

The **User =>Console** rights menu is:

29.6 Polygon

The **Polygon** walk-right menu is



create polygon by picking point inside
create polygon by picking sides
colour polygon by range file
remove polygon colour

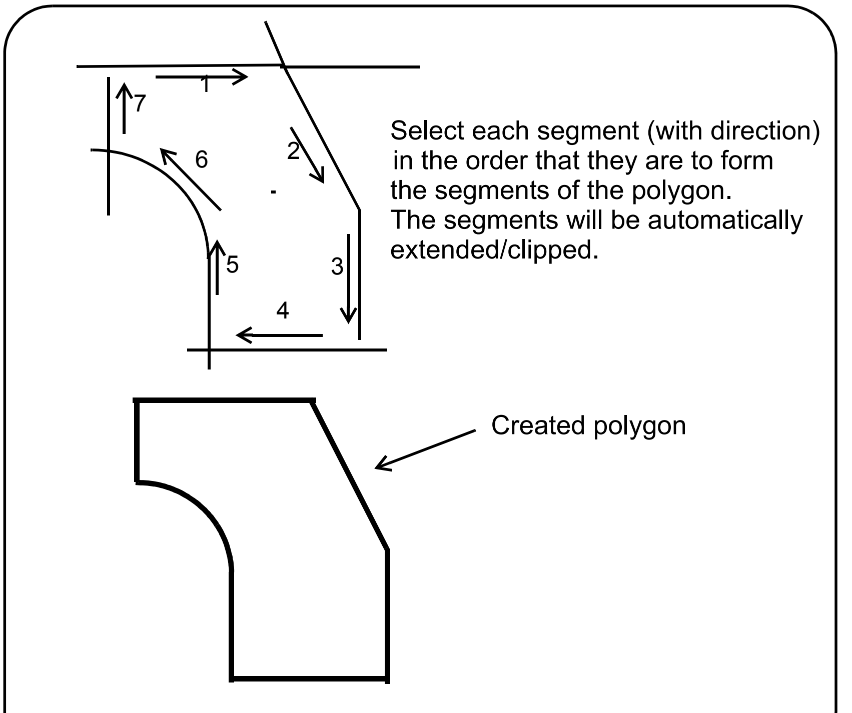
and each option in this menu will now be discussed.

For *Create polygon by picking point inside area*, go to 14.6.18 Surrounding Polygon
Create polygon by picking sides 29.6.1 Create Polygon by Picking Sides
Colour polygons from range file 29.6.2 Colour Polygons by Range File
Remove polygon colour 29.6.3 Remove Polygon Colour
Road polygons 20.8.12.3 Road Polygons

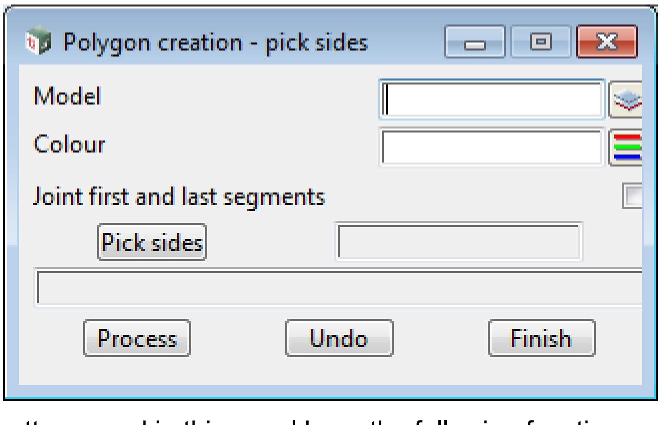
29.6.1 Create Polygon by Picking Sides

Position of option on menu: **User =>Polygon =>Create polygon by picking sides**

This option creates a polygon by a picking each segment in its order (and with direction) around the polygon. Segments will be automatically extended or clipped to form the polygon.



Creating a Polygon by Picking String Segments



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Model for polygon	model box		available models
model for the created polygon			
Lot colour	colour box		available colours
colour for the created polygon			
Join first and last segment	tick box		

if tick, join the end of the last selected segment to the start of the first selected segment to form the final *side of the polygon. The segments may be automatically trimmed/extended.*

Pick sides string select

pick, with direction, the segments to be joined together to form the sides of the polygon.

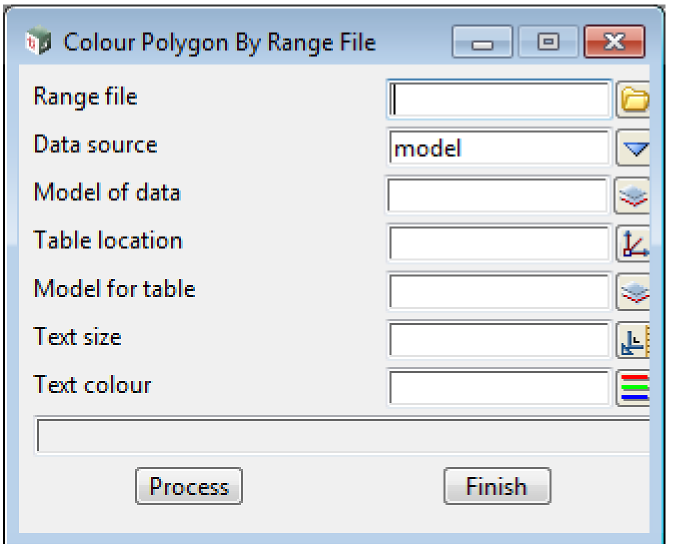
Process button

create the polygon from the selected segments.

29.6.2 Colour Polygons by Range File

Position of option on menu: **User =>Polygon =>Colour polygons by range file**

This option creates a polygon by a picking each segment in its order (and with direction) around the polygon. Segments will be automatically extended or clipped to form the polygon.



The fields and buttons used in this panel have the following functions.

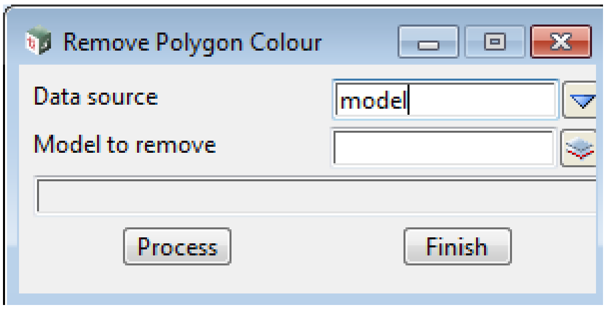
Field Description	Type	Defaults	Pop-Up
Range file	file box		*.lrf
range file for colouring polygons.			
Data source type		model	model, view
data source type.			
Data source			
data source for polygons to be coloured.			
Table location	position select box		
position of the table.			
Model for table	model box		available models
model for the table of statistics on the polygon areas.			
Text colour	colour box		available colours
colour of the text.			
Text size (w)	double box		
size of the text for the table.			
Process	button		
select all the polygons given by the Data source *and colour them according to the lot range file.*			

29.6.3 Remove Polygon Colour

Position of option on menu: **Design =>Estate/Lots =>Lot utilities =>Remove polygon colour**

Note - This is an unsupported option which may not be fully documented.

This option removes the colour of all the selected polygons.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Data source type		model	model, view

data source type.

Data source

data source for polygons to have their colour removed.

Process button

select all the polygons given by the Data source *and remove the polygon colour.*

29.7 Undocumented User Menus

The options on a **User** menu are either customer's macros or unsupported macros from 12D Solutions and may not be documented.

To return to the start of the documentation on the **User** menu, click on 29 User.

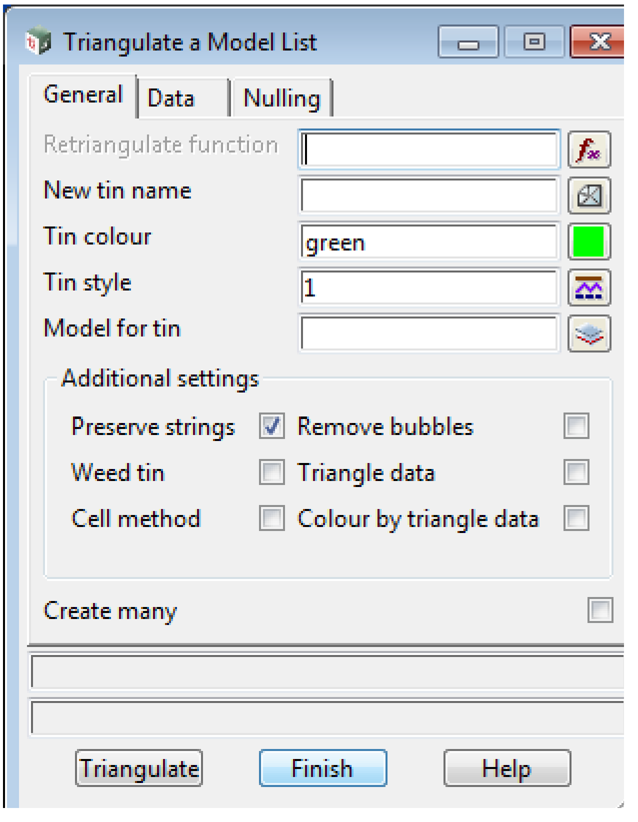
29.8 Obsolete Options

These options are now obsolete and may not be documented.

To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.1 Triangulate a Model List

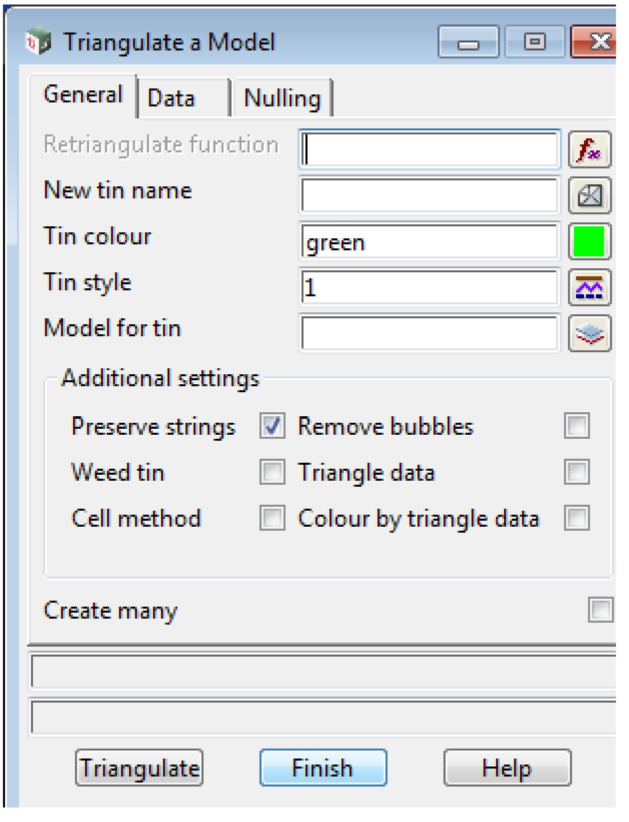
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.2 Triangulate a Model

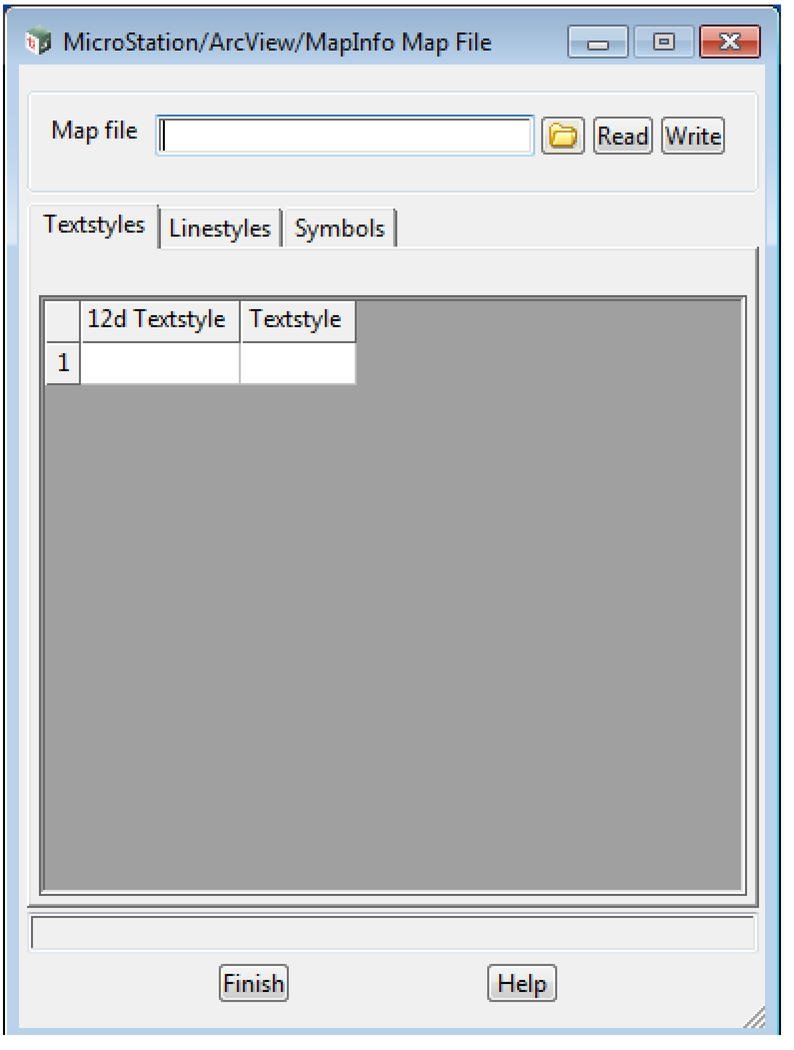
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.3 MicroStation/ArcView/MapInfo Map File

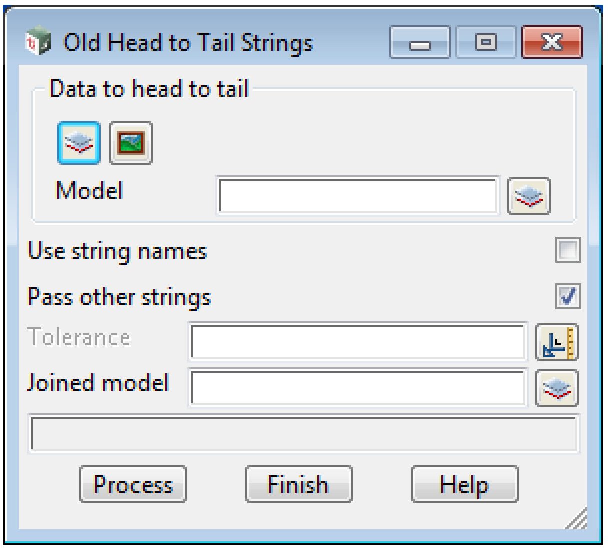
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.4 Old Head to Tail Strings

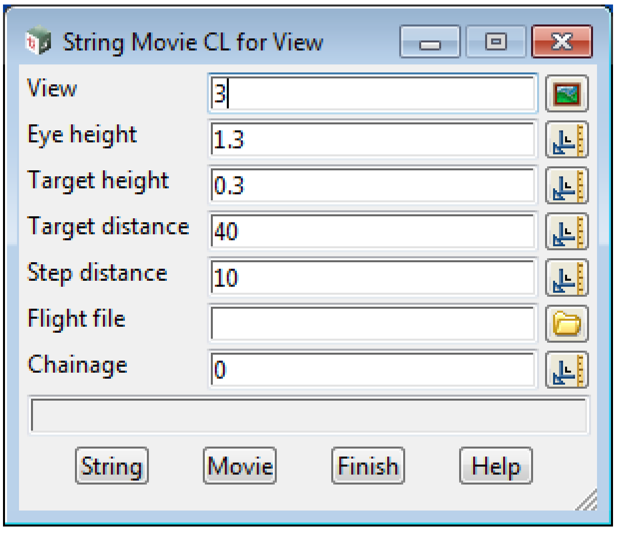
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.5 String Movie CL for View

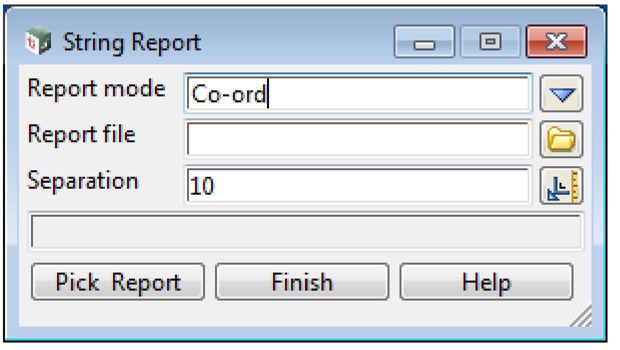
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.6 String Report

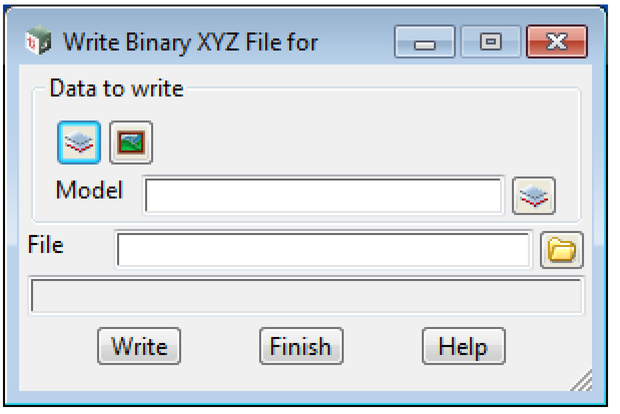
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.7 Write Binary XYZ File For

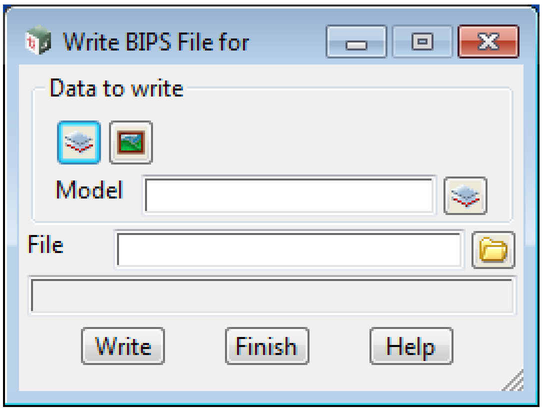
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.8 Write BIPS File For

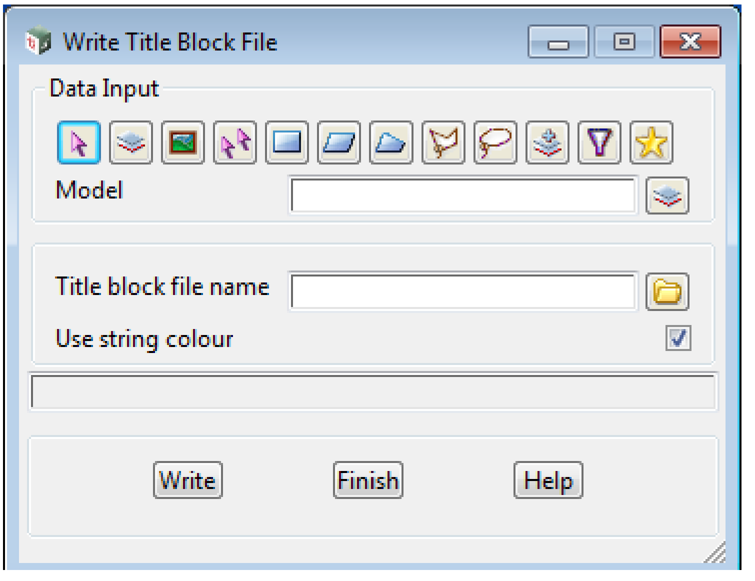
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.9 Write Title Block File

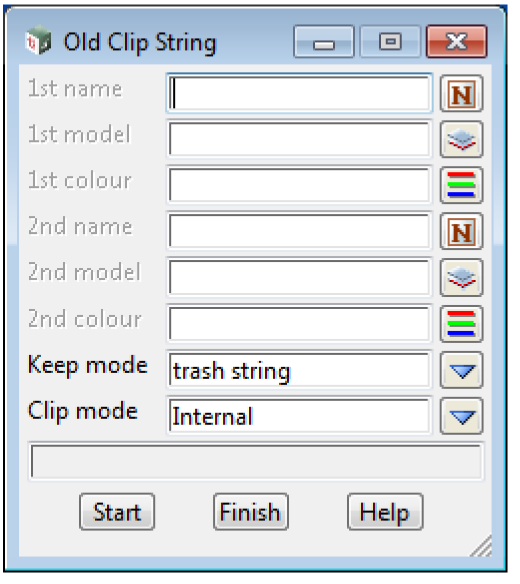
This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.8.10 Old Clip String

This is an obsolete option which is not documented.



To return to the start of the documentation on the **User** menu, click on 29 User.

29.9 Drainage Options

These options are part of the Drainage-Sewer menu.

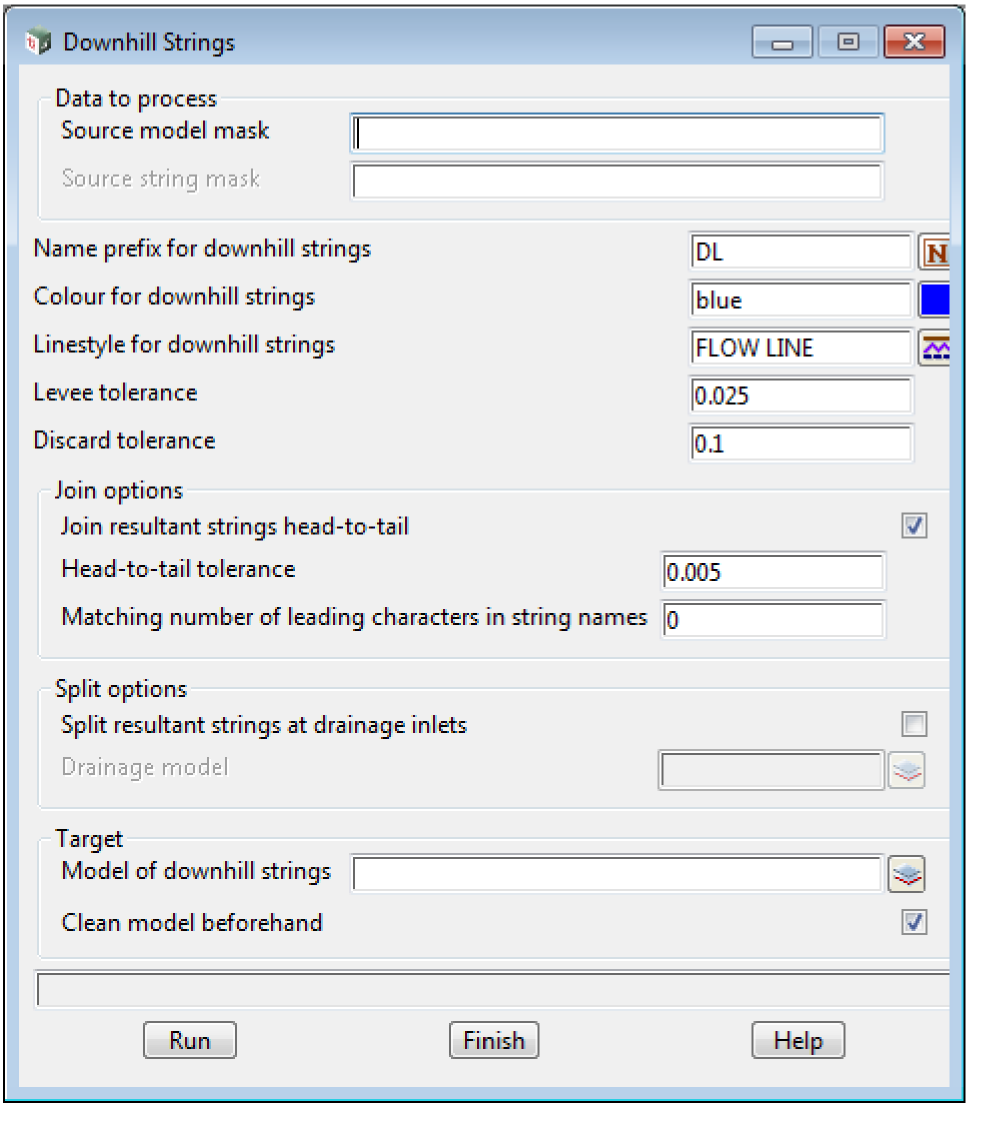
For the option	*Downhill strings, go to*	29.9.1 Downhill Strings
	Raindrop	29.9.2 Raindrop/Teardrop
	Aquaplaning risk	29.9.3 Aquaplaning Risk Assessment
	Extract sewer controls	29.9.4 Extract Sewer Controls
	Convert to pts and lines	29.9.5 Convert to Points and Lines

29.9.1 Downhill Strings

Position of option on menu: **Design=>Drainage-Sewer=>Downhill strings**

This option copies selected Super strings to a target model, where the strings are split at their crests and sags, and set in the downhill direction.

On selecting the **Downhill strings** option, the **Downhill Strings** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Source model mask	input text		

Specifies the model(s) from which to select Super strings to process. Use '' and '?' wildcards to specify multiple models. Note: the target model cannot be specified.*

Source string mask input text

Specifies the string name(s) to process from within the selected model(s). Use '' and '?' wildcards to specify multiple string names. Note: if blank, the option will match all string names in the selected model(s).*

Colour for downhill strings colour box available colours

Colour to apply to all strings in the target model (optional).

Linestyle for downhill strings linestyle box "FLOW LINE" available linestyles

Linestyle to apply to all strings in the target model (optional).

Levee tolerance input real 0.025

Localised uphill portions will be allowed to rise up within this vertical tolerance.

Discard tolerance input real 0.1

Resultant strings shorter than this tolerance will be discarded from the target model.

Join resultant strings head-to-tail tick box ticked

Whether to join strings in the target model in a head-to-tail fashion.

Head-to-tail tolerance input real 0.005

If joining strings head-to-tail, the head must be within this tolerance of the tail.

Matching number of leading characters in string names input integer0

If joining strings head-to-tail, this number of leading characters in both string names must match.

Split resultant strings at drainage inlets tick not ticked

Whether to split strings in the target model at nearby drainage inlets.

Drainage model model box available models

If splitting strings at drainage inlets, strings will be split at all nearby drainage inlet pits found in this model. Drainage inlets (i.e. on-grade and sag pits only) must be within one pit diameter of the string, and may not be closer than the Discard tolerance from either end of the string.

Model of downhill strings model box available models

Target model. All matching source strings are copied to and processed in this model.

Clean model beforehand tick box ticked

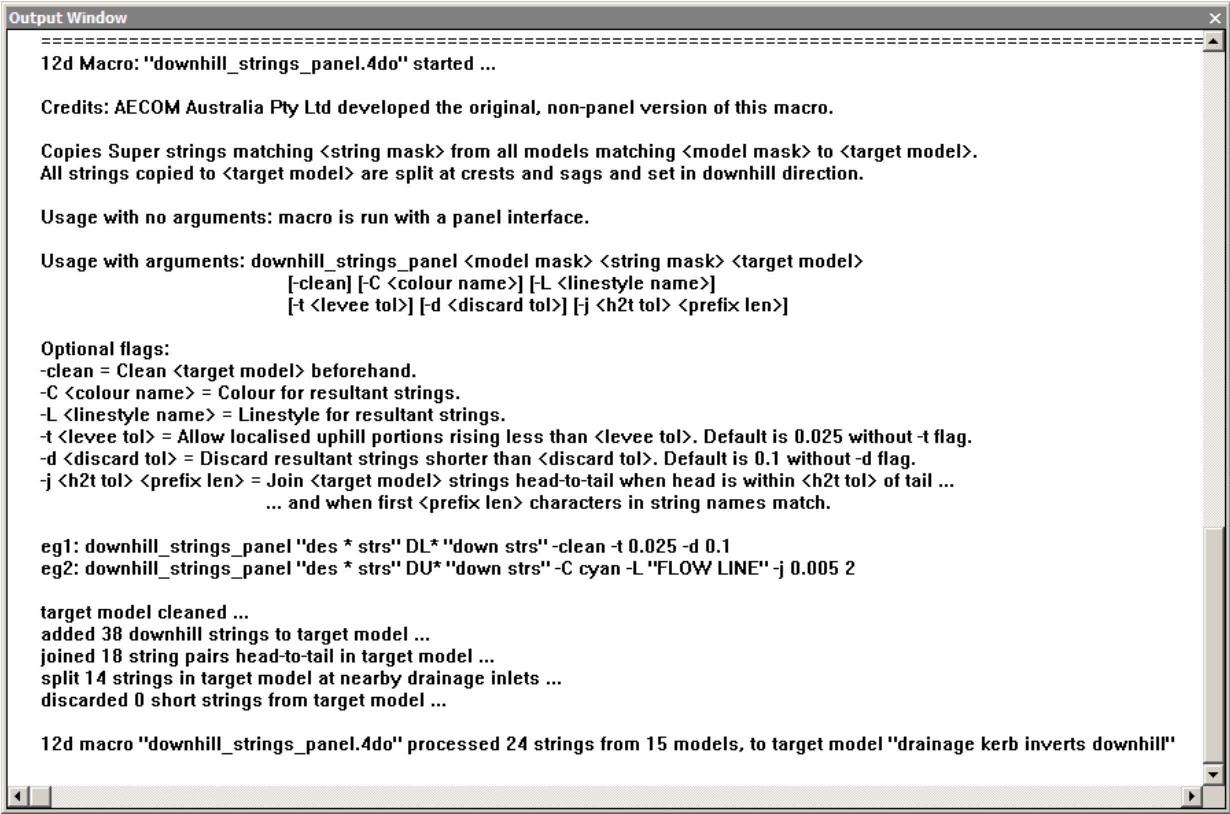
Whether to clean the target model beforehand.

Run button

Runs the option.

Special Note:

The **Downhill Strings** option is a macro, that may optionally be run from a chain via arguments, rather than via a panel. The details of the argument syntax are written to the Output Window, whenever the macro is run without valid arguments, viz:



```
Output Window
===========================================================================================================
12d Macro: "downhill_strings_panel.4do" started ...

Credits: AECOM Australia Pty Ltd developed the original, non-panel version of this macro.

Copies Super strings matching <string mask> from all models matching <model mask> to <target model>.
All strings copied to <target model> are split at crests and sags and set in downhill direction.

Usage with no arguments: macro is run with a panel interface.

Usage with arguments: downhill_strings_panel <model mask> <string mask> <target model>
                      [-clean] [-C <colour name>] [-L <linestyle name>]
                      [-t <levee tol>] [-d <discard tol>] [-j <h2t tol> <prefix len>]

Optional flags:
-clean = Clean <target model> beforehand.
-C <colour name> = Colour for resultant strings.
-L <linestyle name> = Linestyle for resultant strings.
-t <levee tol> = Allow localised uphill portions rising less than <levee tol>. Default is 0.025 without -t flag.
-d <discard tol> = Discard resultant strings shorter than <discard tol>. Default is 0.1 without -d flag.
-j <h2t tol> <prefix len> = Join <target model> strings head-to-tail when head is within <h2t tol> of tail ...
                    ... and when first <prefix len> characters in string names match.

eg1: downhill_strings_panel "des * strs" DL* "down strs" -clean -t 0.025 -d 0.1
eg2: downhill_strings_panel "des * strs" DU* "down strs" -C cyan -L "FLOW LINE" -j 0.005 2

target model cleaned ...
added 38 downhill strings to target model ...
joined 18 string pairs head-to-tail in target model ...
split 14 strings in target model at nearby drainage inlets ...
discarded 0 short strings from target model ...

12d macro "downhill_strings_panel.4do" processed 24 strings from 15 models, to target model "drainage kerb inverts downhill"
```

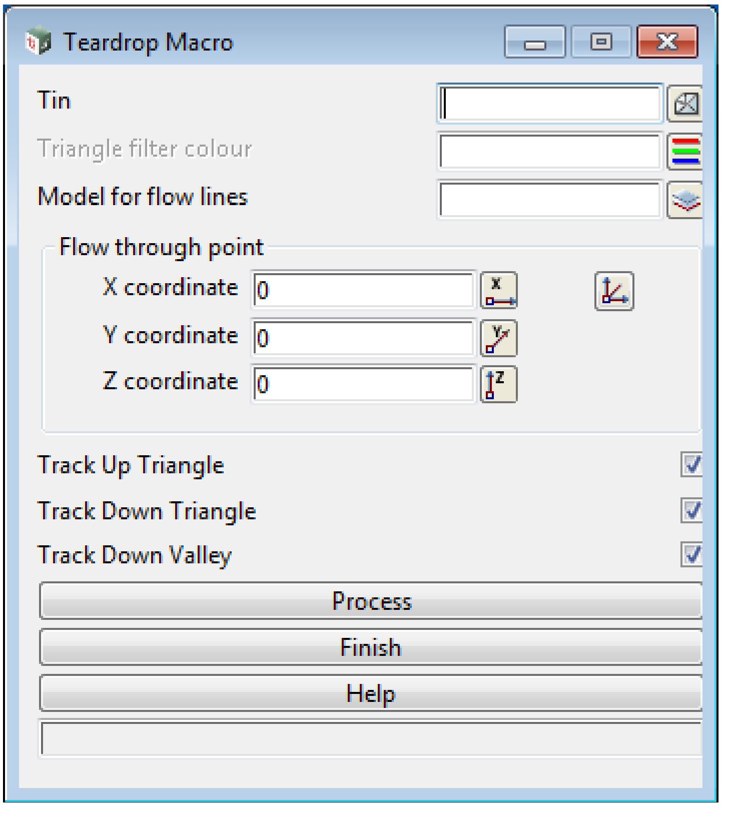
29.9.2 Raindrop/Teardrop

Position of option on menu: **Design=>Drainage-Sewer=>Raindrop**

Position of option on menu: **Tins=>Tin Analysis=>Rain drop**

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting the **Raindrop** option, the **Teardrop Macro** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Tin	tin box	GROUND	available tins
Triangle filter colour	colour box		available colours
Model for flow lines	model box	FLOWMODEL	available models

Flow through point

X coordinate	measure box	0	available measures
Y coordinate	measure box	0	available measures
Z coordinate	measure box	0	available measures
Track Up Triangle	tick box	ticked	
Track Down Triangle	tick box	ticked	
Track Down Valley	tick box	ticked	
Process	button		

29.9.3 Aquaplaning Risk Assessment

Position of option on menu: **Design=>Drainage-Sewer=>Aquaplaning risk**

This option performs an aquaplaning risk assessment using the *Gallaway Equation*. The user need only supply flow path strings as 2d Super strings in the areas of concern on the road pavement tin (typically at the transitions in the road cross-fall). The option then re-creates these flow path strings in 3d, with evenly spaced vertices, then applies the *Gallaway Equation* to determine a water film depth at each vertex (where all parameters considered are set as vertex attributes). It then assesses the risk of aquaplaning at each vertex by associating a risk level and segment colour with the water film depth calculated at each vertex. In addition, a report file is written to the *Windows* clipboard, and optionally to file.

The *Gallaway Equation* is defined as follows:

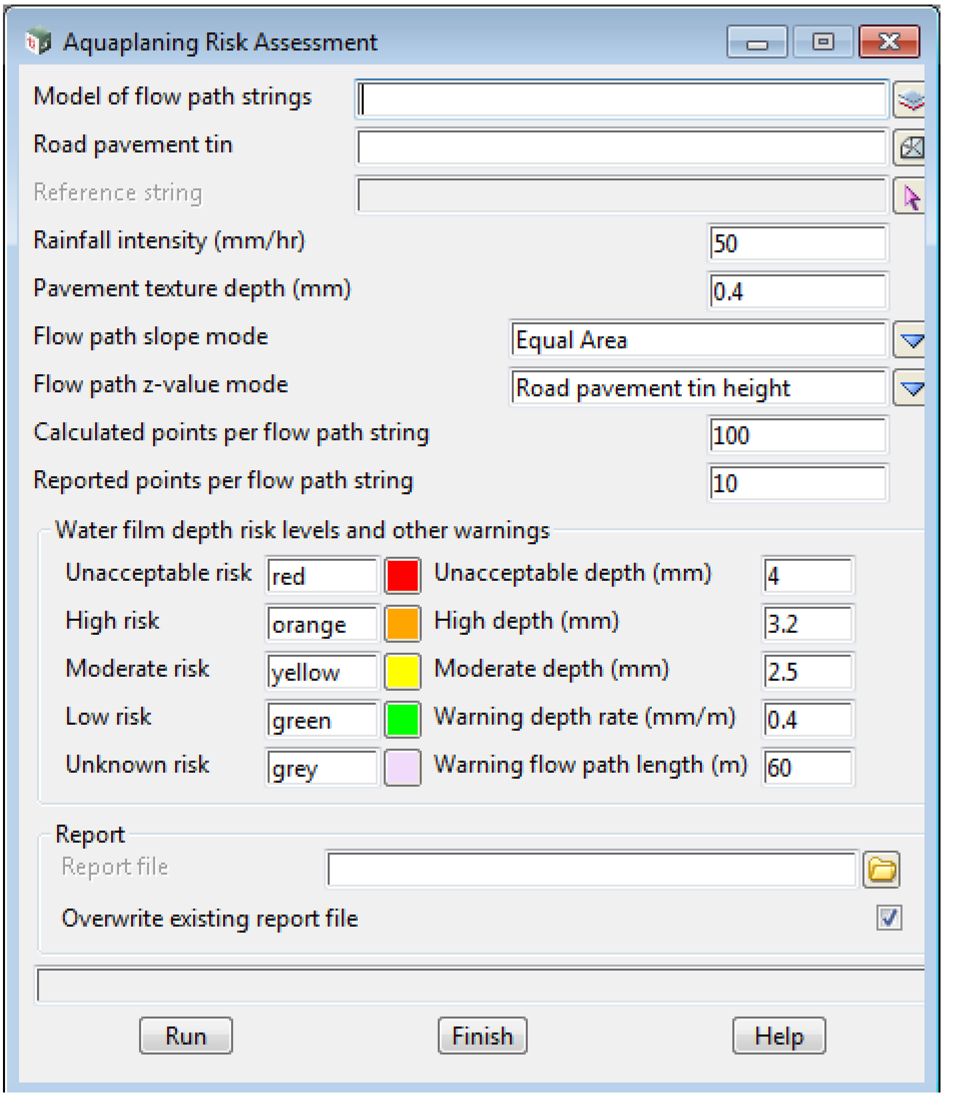
Gallaway Equation

$$d = \frac{0.103\, T^{0.11} L^{0.43} I^{0.59}}{S^{0.42}} - T$$

d = water film depth above top of pavement texture (mm)
L = length of flow path (m)
S = slope of the flow path (%)
T = average pavement texture depth (mm)
I = rainfall intensity (mm/hr)

Source:
Gallaway, B. M., et. al., *"Pavement and Geometric Design Criteria for Minimizing Hydroplaning", Federal Highway Administration, Report No. FHWARD-79-31, (1979).*

On selecting the **Aquaplaning risk** option, the **Aquaplaning Risk Assessment** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Model of flow path strings	model box		available models

All Super strings in this model will be analysed and updated with results.

Road pavement tin	tin box		available tins

Used to define the vertical profile of each flow path string.

Reference string	string select		

Used to locate, identify, rename and sort the flow path strings (optional).

Rainfall intensity (mm/hr)	input	50	

Typically 50 mm/hr for aquaplaning checks.

Pavement texture depth (mm)	input	0.4	

Average texture depths can range from about 0.2 to 4 mm for different pavement materials.

Flow path slope mode	choice box	Equal Area	Equal Area, Average

Determines how the slope of the flow path string is calculated at each vertex. Available modes are "Equal Area" and "Average" slope, from the start of the string to each vertex.

Flow path z-value mode choice box Road pavement tin height Road pavement tin height, Water film depth (mm)

Determines what the z-values of the flow path strings will represent. Available modes are "Road pavement tin height" and "Water film depth (mm)".

Calculated points per flow path string input 100

Number of evenly spaced points along each flow path string at which to calculate water film depths.

Reported points per flow path string input 10

Number of evenly spaced points along each flow path string at which to report water film depths.

Water film depth risk levels and other warnings

Unacceptable risk colour box red available colours

Colour to associate with an unacceptable risk.

Unacceptable depth (mm) input 4

The lowest water film depth associated with an unacceptable risk.

High risk colour box orange available colours

Colour to associate with a high (acceptable) risk.

High depth (mm) input 3.2

The lowest water film depth associated with a high (acceptable) risk.

Moderate risk colour box yellow available colours

Colour to associate with a moderate (acceptable) risk.

Moderate depth (mm) input 2.5

The lowest water film depth associated with a moderate (acceptable) risk.

Low risk colour box green available colours

Colour to associate with a low (acceptable) risk.

Unknown risk colour box grey available colours

Colour for strings that cannot be assessed for risk.

Warning depth rate (mm/m) input 0.4

Warn if <water film depth>/<flow path length> is excessive (optional).

Warning flow path length (m) input 60

Warn if flow path length is excessive (optional).

Report

Report file file box

Report will be written in tab-delimited format to the Windows clipboard, and optionally to this file.

Overwrite existing report file tick box ticked

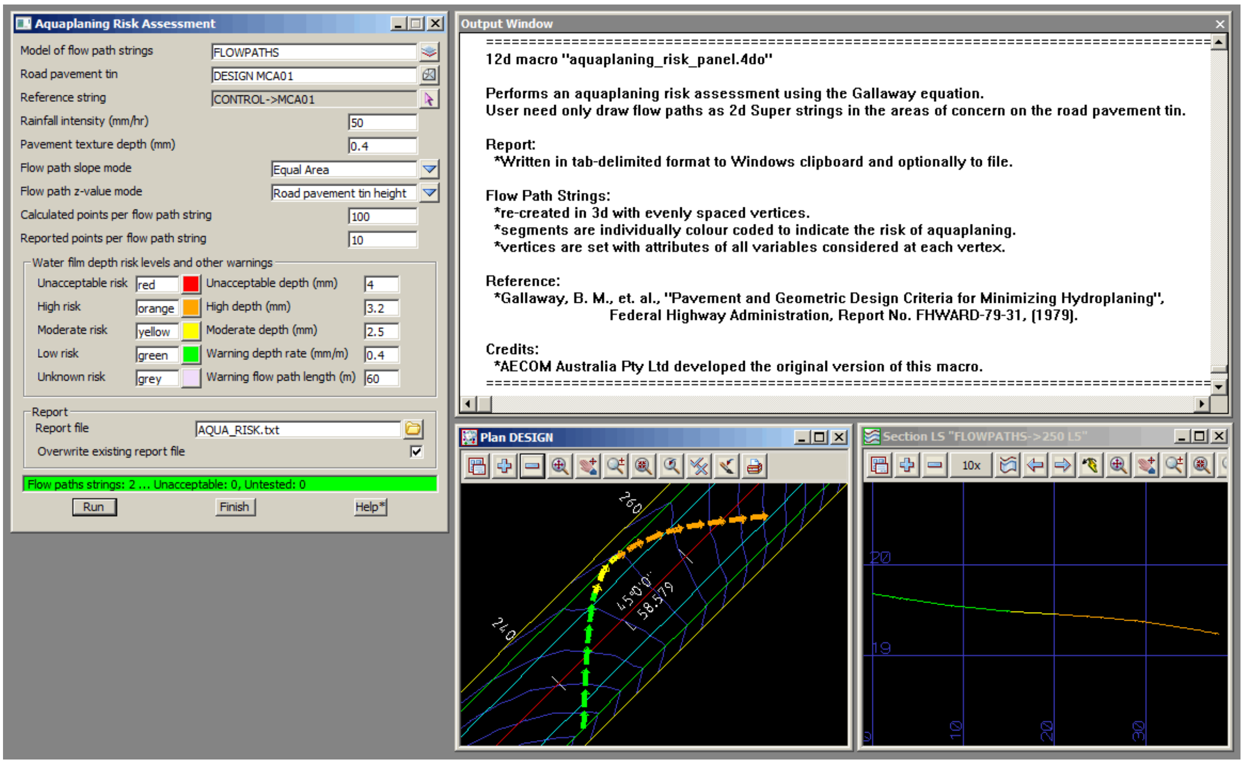
Whether to overwrite or append to an existing report file.

Run button

Runs the option.

Additional Notes:

1) The **Aquaplaning Risk Assessment** option writes auxiliary help information to the *Output Window* every time it is run, *viz*:



2) The tab-delimited report is always written to the *Windows* clipboard, even if a report file is not specified. A pre-formatted *Excel* report template is installed and available in the library – **$LIB\aquaplaning_report_template.xlsx** – and after running the aquaplaning option, the contents of the clipboard may be pasted directly into a copy of this template file, as shown here:

12D AQUAPLANING RISK ASSESSMENT

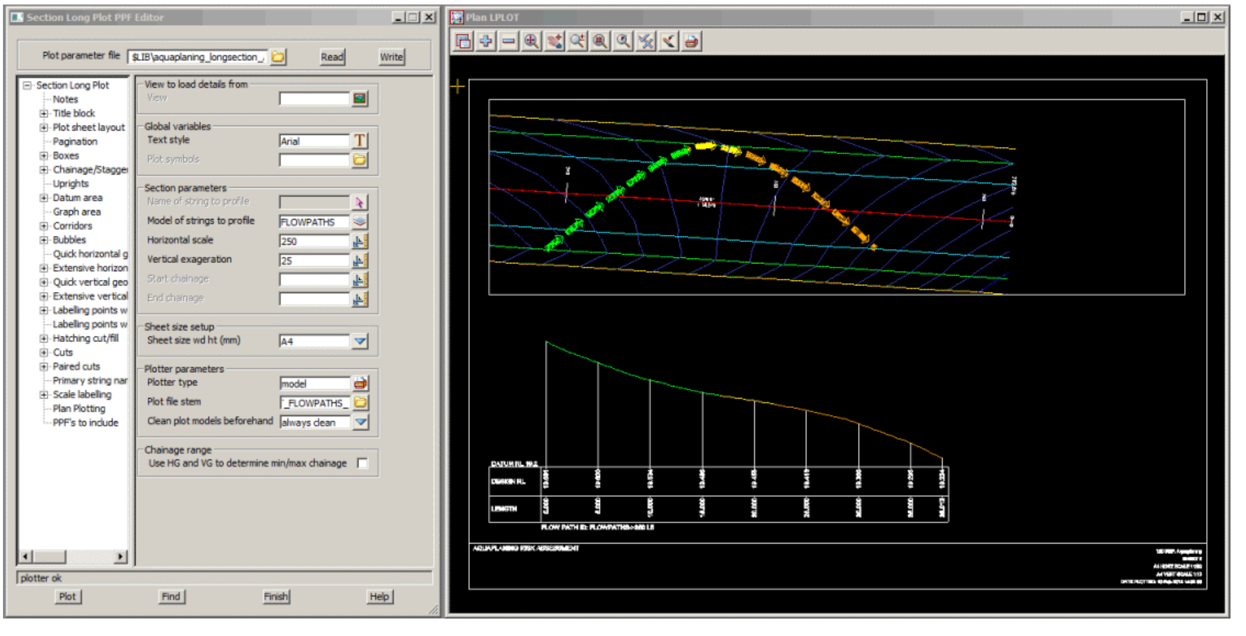
250 L5	10	38.012	19.234	1.19	3.76	HIGH	0.10	

3) Combined plan and profile plots of the analysed flow path strings, for inclusion in reports, may be generated from the **Section Long Plot PPF Editor**. A PPF file set specifically for this purpose is installed and available in the library – **$LIB\aquaplaning_longsection_A4.lplotppf** – as shown here:

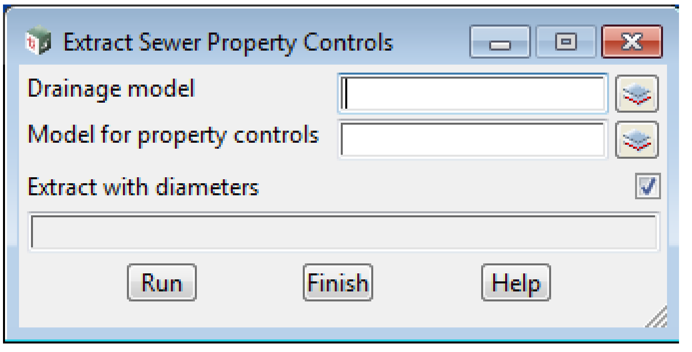


29.9.4 Extract Sewer Controls

Position of option on menu: **Design=>Drainage-Sewer=>Extract sewer controls**

The sewer property control strings are a sub string of the drainage string and therefore may only be profiled using a right mouse click of the profile button. To include these control strings on plots or export to other packages they need to be converted to super strings.

On selecting the **Extract Sewer Controls** option, the **Extract Sewer Property Controls** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Drainage model	model box		available models

All drainage strings in this model will have their property controls strings duplicated as super strings.

Field Description	Type	Defaults	Pop-Up
Model for property controls	model box		available models

The super strings for the property controls are placed in this model.

Field Description	Type	Defaults	Pop-Up
Extract with diameters	tick box	ticked	

The super strings will have the constant pipe dimension set to the control diameter.

Field Description	Type	Defaults	Pop-Up
Run	button		

Create the super strings representing the property controls.

29.9.5 Convert to Points and Lines

Position of option on menu: **Design=>Drainage-Sewer=>Convert to pts and lines**

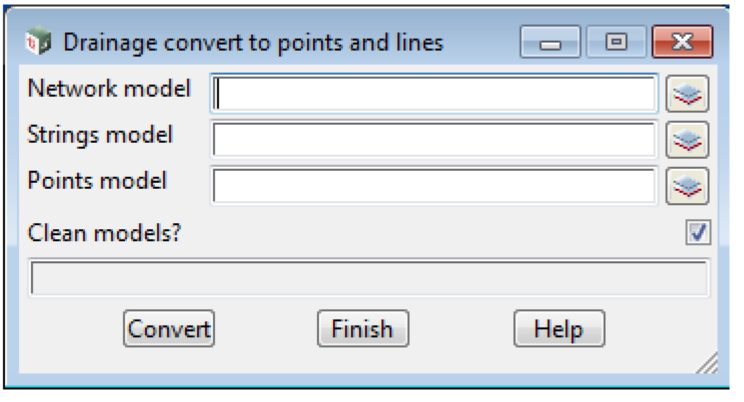
This option converts a drainage network into simple points and lines.

Pits will be created as single point super strings with the pit attributes set as string attributes.

Pipes will be created as single or multiple segment super strings with pipe attributes set as string attributes.

This may be useful for uploading to external GIS systems via the GIS module.

Selecting **Convert to pts and lines** brings up the **Drainage convert to points and lines** panel.



The fields and buttons used in this panel have the following functions.

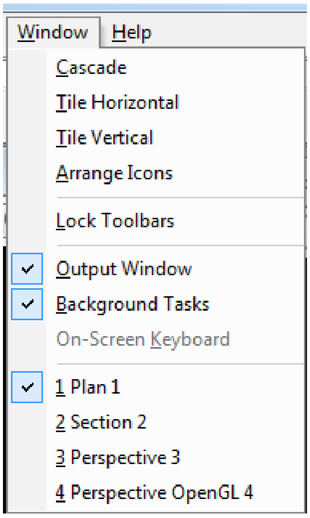
Field Description	Type	Defaults	Pop-Up
Network model	model box		available models
the source model of the drainage network			
Strings model	model box		available models
the model to output pipe strings to			
Points model	model box		available models
the model output pit point strings to			
Copy string attributes to pits and pipes?	tick box	not ticked	
if ticked, the string attributes for points are copied to to pit attributes and string attributes for lines are copied to the pipe attributes. *If not ticked, no attributes are copied.*			
Clean models	tick box	ticked	
whether or not to clean the models first			
Convert	button		
performs the conversion			

30 Window

The 12d Model **Window** menu contains options to cascade, tile horizontally and vertically. The ***Output window*** can also be toggled on and off.

The **Window** on main menu and walk-right menus are

on Main menu



cascade the non-minimized views
horizontally tile the non-minimized views
vertically tile the non-minimized views
place all minimized view icons at the bottom of the views area

lock toolbars so that they can't be moved

toggle the output window on/off
toggle the background tasks windo on/off
shows if on-screen keyboard is enabled

Continue to the next section 31.4 About 12d Model or return to 31 Help.

31.4 About 12d Model

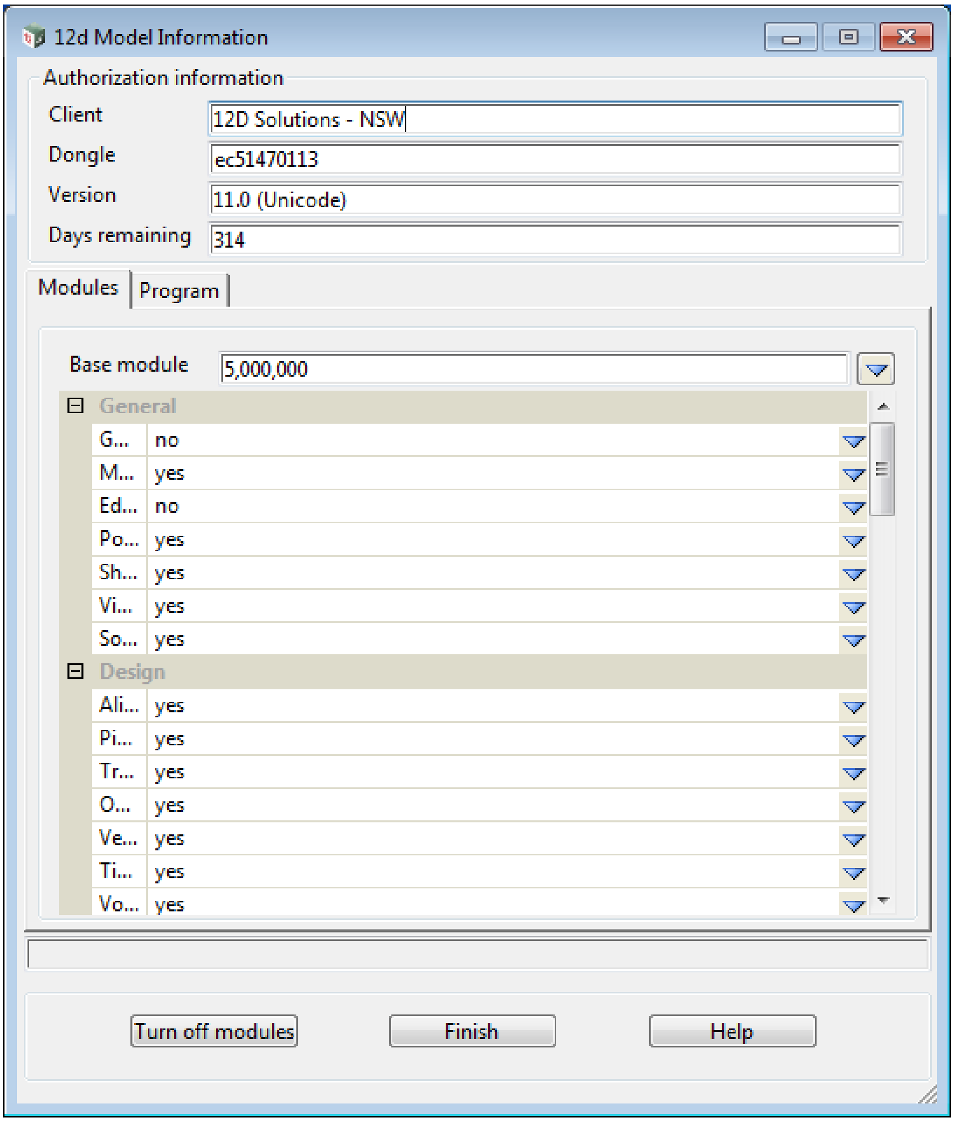
Position of option on menu: **Help =>About 12d Model**

The **About 12d Model** option displays information about the current ***12d Model*** authorization including such items as the Client name, dongle number and authorized modules.

The existing ***12d Model*** modules are shown on the **Modules** and **Extras** tabs with a tick indicating that the current licence has the module.

The **Program** tab has extra information about the current***12d Model*** executable and project.

On selecting the **About 12d Model** option, the **12d Model Information** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Client	output only		

name of the authorized client.

Dongle output only

number of the dongle for this licence.

Version output only

***12d Model** version number.*

Days remaining output only

number of days left for the authorisation.

Modules tab

Base module output only

number of allowed points in the Base module. If this number is exceeded then the project cannot be saved until enough points are deleted to bring the point count below the allowed number of points.

Alignment, Pipeline, Volumes, *etc.* choice boxes yes, no, maintenance.

*if **yes**, the module is authorised. If it is **yes** then it can be changed to **no** and when the* **Turn off modules** *button is pressed, the module will no longer be authorised until you exit the project and restart it.*

*If **no**, the module is not authorised.*

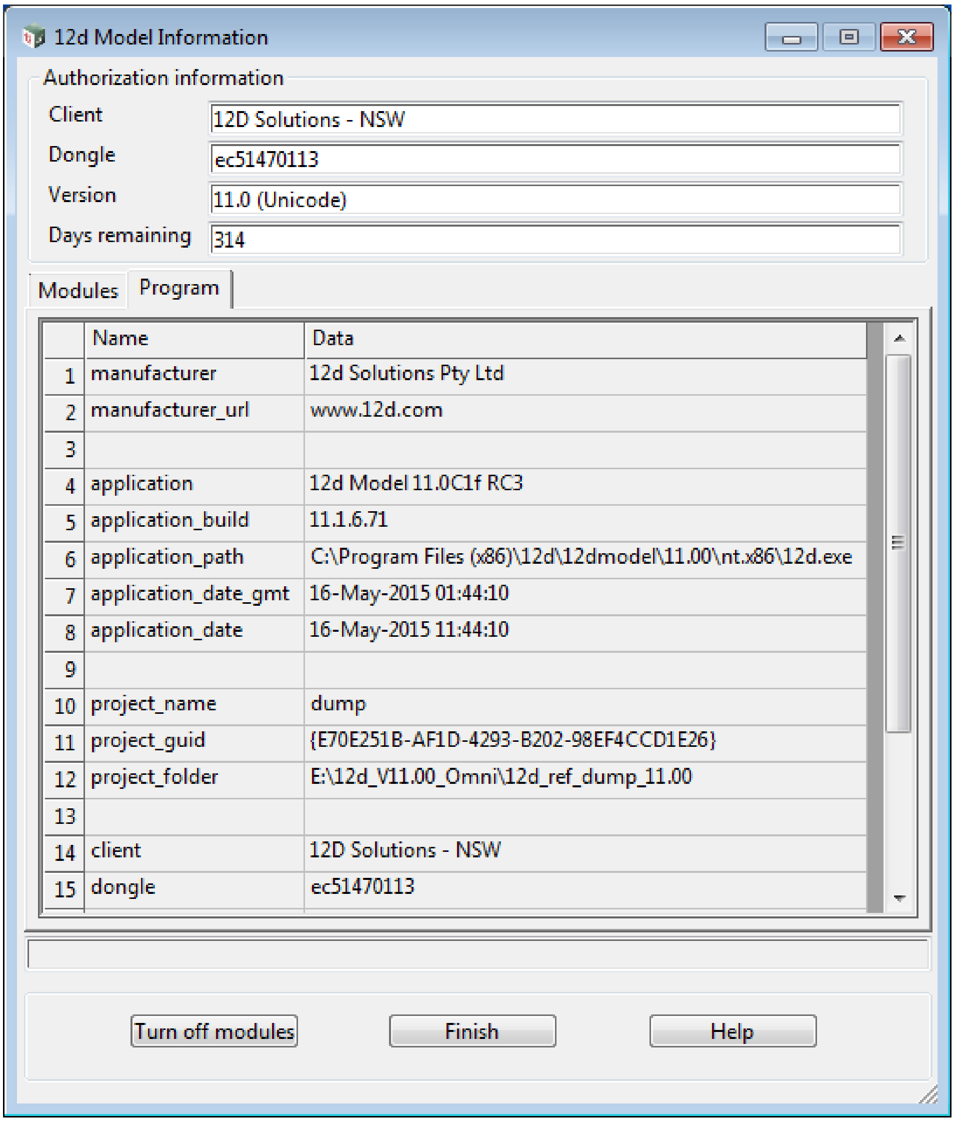
*If **Maintenance**, the module is included whilst you are on Maintenance.*

Turn off modules **button**

*for any modules with **yes**, you can **turn off** modules by setting the choice to **no** and then clicking this button.*

You can NOT turn modules back on. To get the module back you need to restart the project and then the modules that are authorised in the nodes.4d file will again have yes displayed, and hence be turned on.

Program tab



Name, Data grid

information about the 12d Model program and current project.

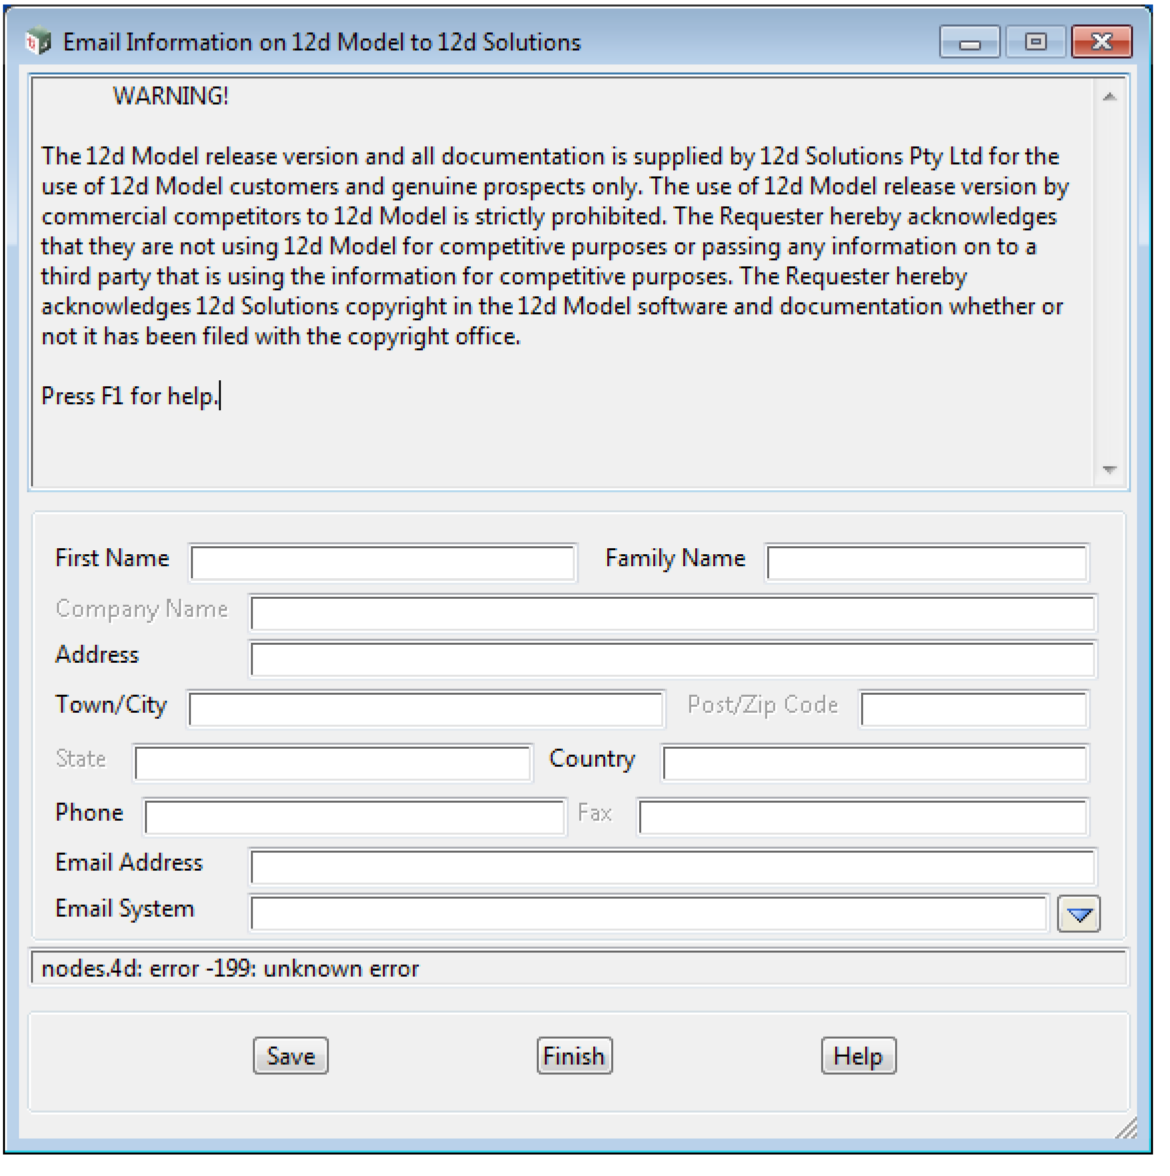
Continue to the next section 31.5 Email Info to 12d or return to 31 Help.

31.5 Email Info to 12d

Position of option on menu: **Help =>Email info to 12d**

The **Email info to 12d** option emails information about the current version of ***12d Model*** to 12d Solutions Pty Ltd. This is usually used for debugging authorization problems.

On selecting the **Email info to 12d** option, the ***12d Model*** **Information** panel is displayed.



The fields and buttons used in this panel have the following functions.

Field Description Type Defaults Pop-Up

First name/Last name/Company name ....

information about the user and the Company owning the license of ***12d Model****.*

Email button

try to send an email containing information about ***12d Model*** *and the user to 12d Solutions Pty Ltd.*

Save button

if the **Email** *button does not send an email, the* **Save** *button can be used to write the information out to a file called* ***12d_auth.txt****. This file can then be emailed to* ***support@12d.com****.*

Continue to the next section 31.6 Dongles Administration or return to 31 Help.

31.6 Dongles Administration

Position of option on menu: **Project =>Management =>Dongles =>Administration**
Position of option on menu: **Help =>Dongles**

This option is documented in 7.6.5.2 Dongles Administration.

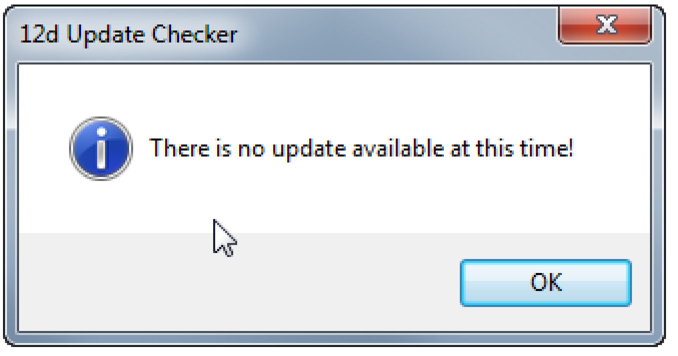
Continue to the next section 31.7 Check for Updates or return to 31 Help.

31.7 Check for Updates

Position of option on menu: **Help =>Check for updates**

Selecting **Check for updates** will check if there are any newer versions and/or builds of ***12d Model*** than the one currently being run.

The **12d Update Checker** panel will give a link to the new versions or display the message that there is no update available if the current version and build of ***12d Model*** is the latest one.



Continue to the next section 31.8 Microsoft 7 or return to 31 Help.

31.8 Microsoft 7

Position of option on menu: **Help =>Windows 7**

12d Model has a context sensitive reference help system which can be accessed directly from most menus and panels:

(a) For most menus in ***12d Model***, when the menu is on the screen and has the Windows focus, simply press F1 and the ***12d Help*** will open automatically at that menu

(b) For most panels in ***12d Model***, when the panel is on the screen and has the Windows focus, simply press F1 and the ***12d Help*** will open automatically at that panel

(c) Most panels in ***12d Model*** have a **Help** button on them and clicking on the **Help** button opens the ***12d Help*** at that panel

(d) By clicking on the option ***Help =>12d Model***

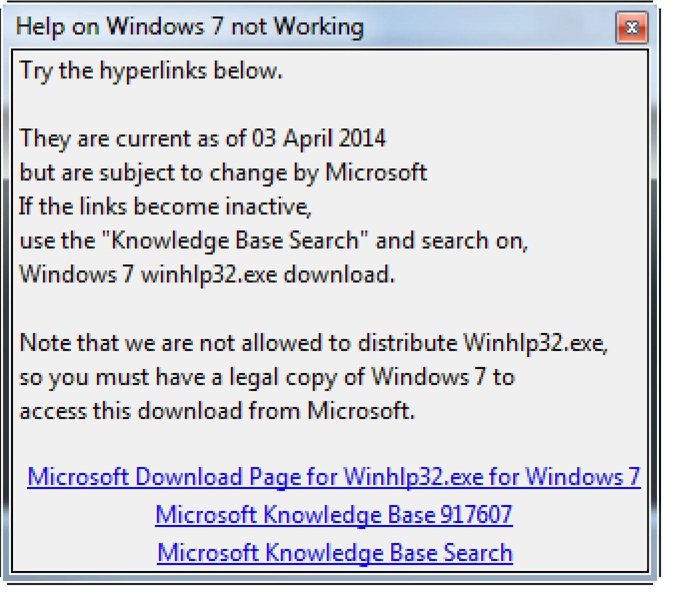
The ***12d Model*** context sensitive help uses Microsoft's ***WinHlp***.

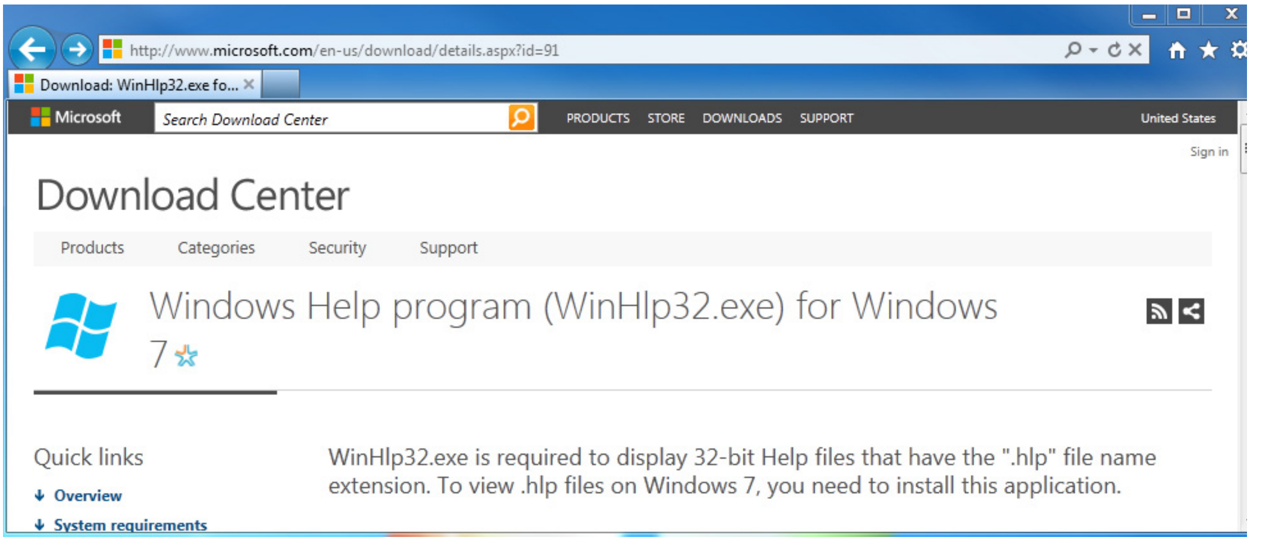
For *Win 7 and 8*, Microsoft no longer ships the WinHlp.exe executable and Microsoft will no longer allow it to be installed by the ***12d Model*** installation DVD.

So if you are running Win 7 or Win 8, you need to download and install WinHlp.exe from Microsoft's website to access the ***12d Model*** *Help* files.

The link to the area for the download is

Walking right on **Microsoft 7** displays the **Help on Windows 7 Not Working** panel which has a link to the Microsoft web site to download Winhel32.exe.





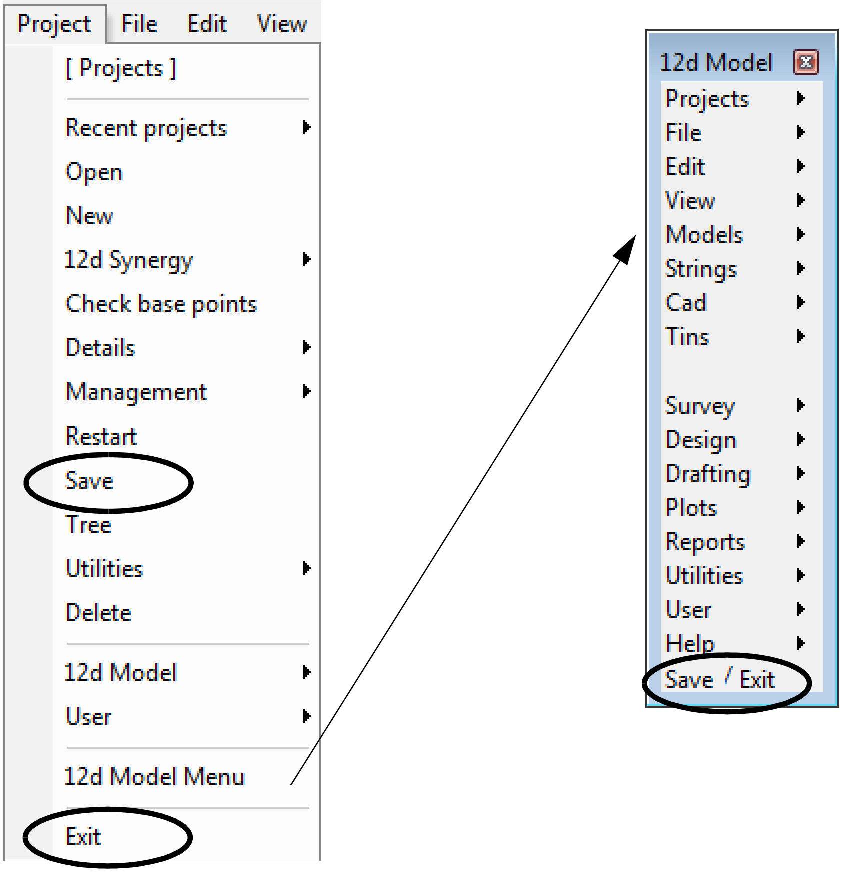
To return to the start of the documentation on the **Help** menu, click on 31 Help.

32 Save and Exit

Save and **Exit** are available from both the **Main Menu** under **Project** or on the floating ***12d Model*** menu.

on Main menu

floating **12d Model** menu

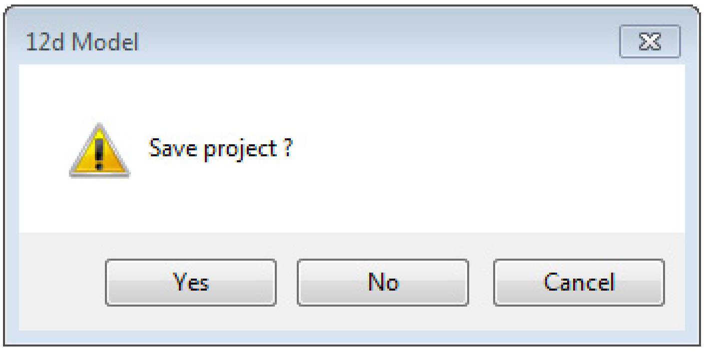


32.1 Save and Exit from Main Menu

Selecting **Save** from the **Main Menu=>Projects** menu simply saves all data in the project modified since the last save.

When **Exit** is selected from the bottom of the **Main Menu=>Projects** menu and a save is not needed, 12d Model exits the project.

If **Exit** is selected from the bottom of the **Main Menu=>Projects** menu and a save is needed, then the **Save Project ?** yes-no panel is placed on the screen.



If **Yes** is selected, then 12d Model saves the project and exits.

If **No** is selected, then 12d Model does not save the project and exits.

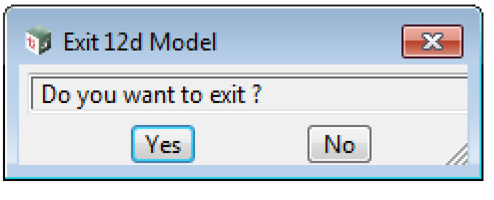
If **Cancel** is selected, then the Exit is aborted and 12d Model stays in the project.

Note: when exiting 12d Model, the user is reminded if any ***mtf*** files modified by the 12d Model *mtf editor* have not been saved, or any string editors are still running.

32.2 Save/Exit from Floating12d Model Menu

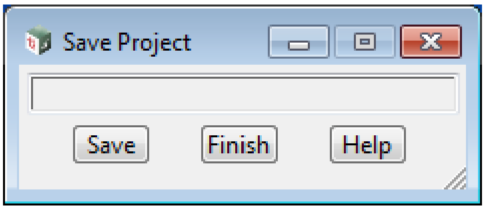
When **Save** is selected from the **left hand side** of the bottom of the ***12d Model*** menu (**Save / Exit** menu option), all the information modified since the last save is written to disk.

When **Exit** is selected from the **right hand side** of the bottom of the 12d Model menu (**Save / Exit** menu option), an **Exit12d Model** panel is fired up.



Selecting **No** removes the **yes-no** pop-up and leaves the user in ***12d Model***.

If **Yes** is selected and a modification to the project has been made since the last project save, a **Save Project** panel is fired up.



If **yes** is selected, the project is **saved** and 12d Model terminates.

If **no** is selected, the project is **not saved** and 12d Model terminates.

If **cancel** is selected, the **exit** option is **aborted** and the user is left in 12d Model.

Note: When exiting 12d Model, the user is reminded if any ***mtf*** files modified by the 12d Model *mtf editor* have not been saved, or any string editors are still running.

Selecting **No** removes the **yes-no** pop-up and leaves the user in ***12d Model***.

If **Yes** is selected and a modification to the project has been made since the last project save, a **Save Project** panel is fired up.

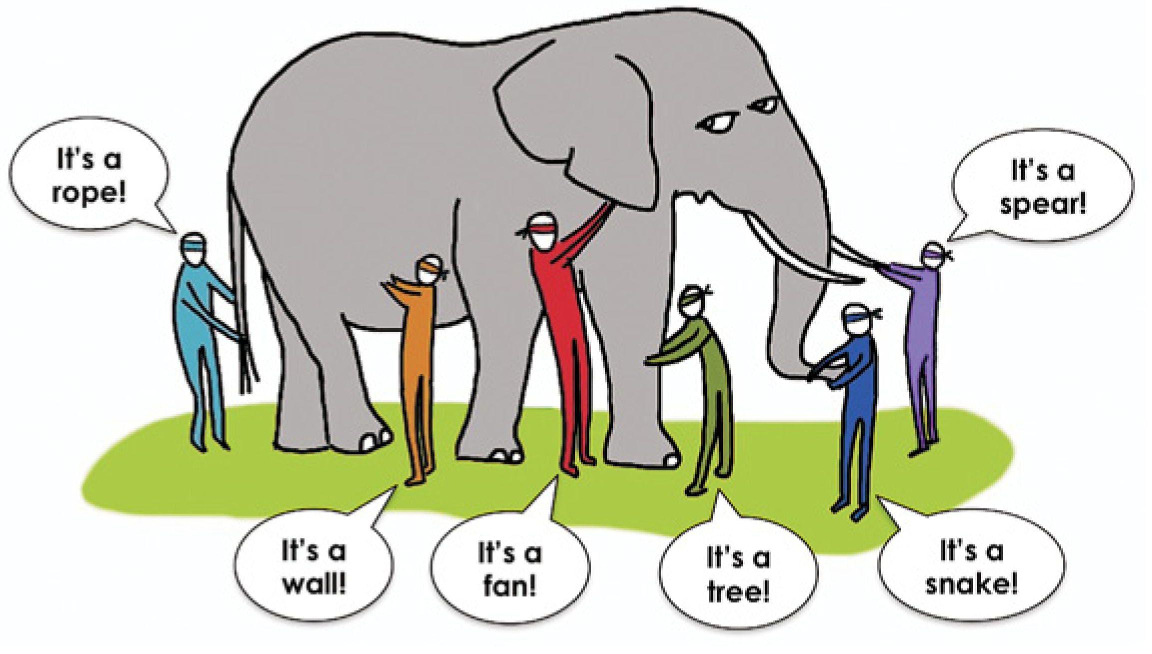
Appendices

33 BIM

See

33.1 What is BIM ?

What BIM is seems to depend on who you are talking to. And the various participants in the design, construction and management of the asset (building or infrastructure) also emphasise different aspects of BIM.



If a wide search of the literature for BIM and ISO Standards is made, and all the marketing fluff is ignored, one quickly sees that almost universally the **BI** in BIM is **Building Information** and although BIM is about the process, all the objects are for a Building on a site. The other constant is that the International Standard for transferring BIM data is the vendor independent format of IFCs. For more information on IFCs, see 8.2.19 IFC Output.

In 2011 the BIM movement received a major boost when the UK Government released the **Government Construction Strategy** which aimed to reduce he cost of government construction projects by 15-20% and BIM was identified as one of the strategies to achieve help the savings.

The **Strategy** contained an **Action Plan** that included the objective for BIM to *introduce a progressive programme of mandated use of fully collaborative Building Information Modelling for Government projects by 2016.*

One early outcome of the **Strategy** was for BuildingSMART *to develop a national BIM standard with the principles of interoperability. This will be key to future delivery of Level 3 "Open & Shared" BIM.*

buildingSMART is now the International group looking after the development of the **Industry Foundation Classes** (IFCs) which is the data model for the Open Standard for BIM. See http://www.buildingsmart-tech.org.

For more information, see 33.3 The UK Government and BIM and for some common BIM terms and the ***Levels of BIM*** outlined by the UK Government, see 33.4 Common Terms in BIM.

Under the umbrella of **buildingSMART** there are a number of International Committees currently grappling with the problem of extending IFCs from Buildings to Bridges, an Alignment for Roads, and for Roads and Railways in general, and to move IFCs from uncoordinated flat space with (0,0) in the corner, to a GIS and 12d environment with world coordinates and projections.

Beware that some groups talk BIM but then insist on data being supplied in an unpublished, encrypted proprietary format. In Australia this is often Revit, Navisworks, DWG or DGN.

This is diametrically opposed to the International Open BIM concept but apart from pointing that out to your client, you are caught between a rock and a hard place.

However for those users caught in the encrypted proprietary format trap, we are working to help solve your problems. For an overview of where we are currently at, please see the information in the next section 33.2 The 12d Approach to BIM.

Continue to 33.2 The 12d Approach to BIM or return to 33 BIM.

33.2 The 12d Approach to BIM

12d Solutions is actively involved in, and supporting, the International effort on IFCs.

12d Solutions is:

(a) a founding member of the **Open BIM Alliance** which supports the transferring of BIM data using the ISO Standard for IFCs.

(b) working with **buildingSMART** (the International Group looking after IFCs) on how non-Building data should be transferred using IFCs. See http://www.buildingsmart-tech.org.

(c) working with **buildingSMART** on how IFCs can be extended to Alignments, Roads and Railways.

(d) working on the **Precinct Information Model** project, part of the **CRC** for **Low Carbon Living**.

This project is looking at the problem of extending BIM from a few building on a site, to a larger area and including roads, drainage, sewerage etc.

For more information on ***12d Model*** and IFCs, see 8.2.19 IFC Output

For those users caught in the encrypted proprietary format trap, although we do not have access to the formats, **12d Solutions** will continue to look for ways to make that data accessible to our users.

To this end, the approaches we are pursuing with our users to write out BIM type data from ***12d Model*** are:

(a) Writing Out Fully Structured IFCs

Using IFCs correctly means that the data to be output must have a fully defined hierarchical structure (known as the Spatial Structure).

This is the approach of the ***12d Model* IFC Writer**. See 8.2.19 IFC Output.

(b) Writing Out Unstructured IFCs

The IFC format could also be used in an informal way as a method of transferring data where there is no concern for the spatial structure but just after the object shapes.

12d is currently working on an alternate IFC Writer to do this.

(c) Writing out OBJ and STL Files

Drainage and sewer strings, super strings with round or rectangular sections, extrusions and trimeshes can be written out as OBJ files (see 8.2.17 Export OBJ) or STL files (8.2.18 Export STL).

(d) Writing out Polyface Mesh in DWG

Drainage and sewer strings, super strings with round or rectangular sections, extrusions and trimeshes can be written out to DWG files as Polyface Meshes. See 8.2.7 Output DWG/DFX/DXB Files.

(e) Revit Routines to Read in 12d Model Data.

EXDS have developed routines that run from within Revit to read in ***12d Model*** data in 12d.XML format See www.EXDS.com.au.

The approaches we are using to bring data into ***12d Model*** are:

(a) Reading in OBJs

OBJ files can be read into to ***12d Model*** as trimeshes. See 8.1.18 Wavefront OBJ Input

(b) Reading in Polyface Mesh in DWG

Polyface mesh in a DWG file can be read into to ***12d Model*** as trimeshes. See 8.1.10 DWG/ DXF Input.

(c) Getting Revit Data into 12d Model

Although the Revit database itself is unreadable, Revit can write data out in the Autodesk fbx format and there is an option in ***12d Model*** to read in an fbx file trimeshes. See 8.1.11 FBX Input.

Also if data can be written out from Revit as Polyface Meshes to a DWG file then again that can be read in into ***12d Model*** as trimeshes. See 8.1.10 DWG/DXF Input.

Continue to 33.3 The UK Government and BIM or return to 33 BIM.

33.3 The UK Government and BIM

In 2011, the UK Government released the **Government Construction Strategy** which was the framework for a range of work streams, all of which have the ultimate aim of reducing the cost of government construction projects by 15-20% (https://www.gov.uk/government/publications/government-construction-strategy).

One problems was identified in Section 2.30:

2.30 *A lack of compatible systems, standards and protocols, and the differing requirements of clients and lead designers, have inhibited widespread adoption of a technology which has the capacity to ensure that all team members are working from the same data, and that:*

- *the implications of alternative design proposals can be evaluated with comparative ease;*
- *projects are modelled in three dimensions (eliminating coordination errors and subsequent expensive change);*
- *design data can be fed direct to machine tools, creating a link between design and manufacture and eliminating unnecessary intermediaries; and*
- *there is a proper basis for asset management subsequent to construction.*

and the remedy, BIM, was mandated in Section 2.31:

2.31 *The Cabinet Office will coordinate Government's drive to the development of standards enabling all members of the supply chain to work collaboratively through Building Information Modelling (BIM). This will be a phased process working closely with industry groups, in order to allow time for industry to prepare for the development of new standards and for training*

The **Strategy** also included an **Action Plan** with a timetable, and Section 7 was for Building Information Modelling (BIM):

*7(i)**Objective**: To introduce a progressive programme of mandated use of fully collaborative Building Information Modelling for Government projects by 2016.*

From the **Government Construction Strategy: One Year On and Action Plan Update** it reported for BIM:

A reciprocal Memorandum of Agreement has been reached with buildingSMART US to develop a national BIM standard with the principles of interoperability. This will be key to future delivery of Level 3 "Open & Shared" BIM.

Continue to 33.4 Common Terms in BIM or return to 33 BIM.

33.4 Common Terms in BIM

Here is a list of some need-to-know BIM terms and their definitions taken from the **NBS** website http://www.thenbs.com.

NBS is part of RIBA Enterprises Ltd, which is wholly owned by the Royal Institute of British Architects (RIBA) and was contracted by the UK Government to build the National BIM Library.

1. . 4D, 5D, 6D

First there was 2D CAD, then 3D CAD – now there are extra dimensions to refer to the linking of the BIM model with time-, cost- and schedule-related information (although the precise order hasn't to date been agreed across the whole industry).

2. . Asset Information Model (AIM), Building Information Model (BIM)

Not only is there the 'Building' information model, but the 'Asset' information model – which is the name given to the same model post-construction, i.e. supplemented with the data needed to assist in the running of the completed asset. Note that 'asset' can also refer to civil engineering and infrastructure work.

3. . Common Data Environment (CDE)

This is a central information repository that can be accessed by all stakeholders in a project. Whilst all the data within the CDE can be accessed freely, ownership is still retained by the originator.

The scope and requirements for a CDE are defined in PAS 1192-2 (see 8. . PAS 1192).

4. Level 0 BIM, Level 1 BIM, Level 2 BIM, Level 3 BIM

The move to 'full' collaborative working via distinct and recognisable milestones, in the form of 'levels'. These have been defined within a range from 0 to 3, and, whilst there is some debate about the exact meaning of each level, the broad concept is:

Level 0 – no collaboration.

2D CAD drafting only. Output and distribution is via paper or electronic prints, or a mixture of both.

Level 1 – a mixture of 3D CAD for concept work, and 2D for drafting of statutory approval documentation and Production Information.

CAD standards are managed to BS 1192:2007, and electronic sharing of data is carried out from a common data environment (CDE), often managed by the contractor.

There is no collaboration between different disciplines – each publishes and maintains its own data.

Level 2 – collaborative working – all parties use their own 3D CAD models.

Design information is shared through a common file format, which enables any organisation to be able to combine that data with their own in order to carry out interrogative checks on it.

Hence any CAD software that each party used must be capable of exporting to a common file format.

This is the method of working that has been set as a minimum target by the UK government for all public-sector work, by 2016.

Level 3 – integrated working between all disciplines by using a single, shared project model which is held in a common data environment.

All parties can access and modify that same model, removing the final layer of risk for conflicting information. This is known as ‘Open BIM’ (see 7. Open BIM), and the UK government’s target date for public-sector working is 2018, although the precise requirements have yet to be determined.

Note that the definition of BIM maturity Level 2 was originally developed as part of the UK Government strategy in 2011. It is also defined in PAS 1192-2, with reference to best practice and the adoption tools and standards.

It is also worth noting, though, PAS 1192-2 acknowledges that, given the early stages of adoption of managed methods of working in BIM at the time the PAS was drafted, it can be expected that Level 2 practices will continue to evolve, and that the scope of information sharing and exchange will vary from project to project.

Therefore, PAS 1192-2 anticipates that the definition of Level 2 BIM will continue to evolve around the core principles of the shared use of individually authored models in a CDE.

5. Construction Operations Building Information Exchange (COBie)

COBie is a data schema which is delivered in a spreadsheet data format, and contains a ‘subset’ of the information in the building model (all except graphical data, and hence a subset of IFC (see 6. Industry Foundation Class (IFC)), for FM handover. It was originally devised by the US Army Engineering Corps.

Over the course of a project, data can be added to it from a range of sources (besides CAD programs), relating to brief, design, construction, operation, refurbishment or demolition, as the case may be.

The UK Government’s Level 2 - mandated requirement is for COBie-compliant information exchange. BS 1192-4 documents best practice for the implementation of COBie.

6. Industry Foundation Class (IFC)

IFC is an object-based format, to enable exchange of information between different software. Developed by **buildingSMART**, a global alliance specialising in open standards for BIM, IFC is an official standard, BS ISO 16739, and contains geometric as well as other data.

7. Open BIM

An open-source approach to collaborative design, realisation and operation of buildings, based on open standards and work flows.

Open BIM is an initiative of several leading software vendors using the buildingSMART Data Model, which incorporates data to ISO 16739 (via the IFC file format), terms to ISO 12006-3 (using the International Framework for Dictionaries, which maps different technical terms that have the same meaning) and process to ISO 29481-1 (the Information Delivery Manual).

8. . PAS 1192

The PAS 1192 framework sets out the requirements for the level of model detail (the graphical content), model information (non-graphical content, such as specification data), model definition (its meaning) and model information exchanges:

(a) PAS 1192-2 deals with the construction (CAPEX) phase, and specifies the requirements for Level 2 maturity; sets out the framework, roles & responsibilities for collaborative BIM working; builds on the existing standard of BS 1192, and expands the scope of the Common Data Environment (see 3. . Common Data Environment (CDE)).

(b) PAS 1192-3 deals with the operational (OPEX) phase, focussing on use & maintenance of the Asset Information Model, for Facilities Management.

(c) BS 1192-4 documents best practice for the implementation of COBie.

(d) PAS 1192-5 is currently under development, and will cover security of data.

Continue to 33.5 What is Wrong with Local Coordinates ? or return to 33 BIM.

33.5 What is Wrong with Local Coordinates ?

What we mean by Local Coordinates is the placing of (0,0) somewhere on the site, with a direction for the x or y axis, NOT a cartographic projection with (0,0) defined on the site.

There is nothing wrong with using a Local Coordinate system as long as you are aware of the restrictions and consequences. As Einstein said for General Relativity "space is locally flat".

So as long as you are working on a small site (say under 5 kilometres long) and everyone is able to reliably measure back to your (0,0) and use your definition of angle of the coordinate axes, then there should be no major problems.

But if you are working on a large project, or trying to combine data from a variety of sources, or want to coordinate work with a GPS, then you need to know more about how and why there are problems with Local Coordinates.

One of the problems is that the earth is not flat.

See

33.5.1 An Exact Position for Everything on the Earth
33.5.2 Map (Cartographic) Projections - Eastings and Northings
33.5.3 Why Isn’t MGA Used on a Small Building Site ?

33.5.1 An Exact Position for Everything on the Earth

To give everything on earth a unique coordinates that fit in with GNSS systems (GPS, GLONASS, BeiDou and Galileo), a **reference ellipsoid** has been defined with:

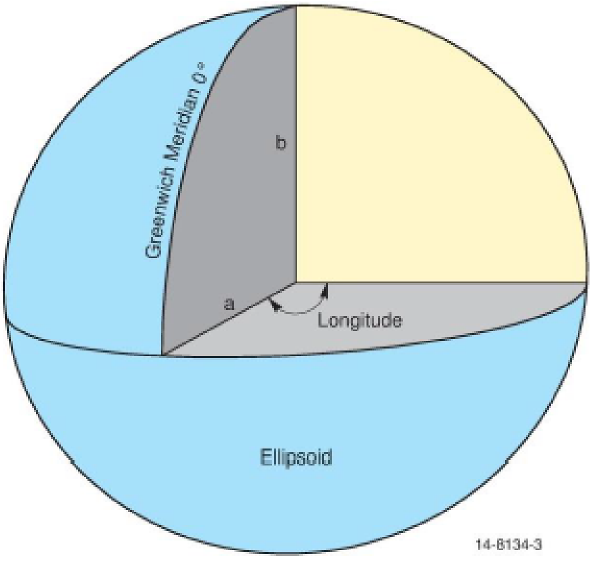
(a) (0,0,0) at the Mass centre of the earth (geocentre), a semi major axis of 6,378,137 m, and an inverse flattening of 298.257222101. This is known as **GRS80**.

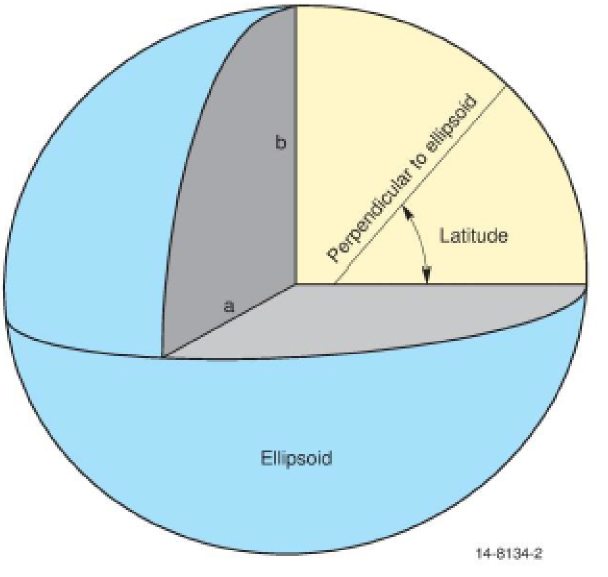
This is because satellites orbit around the mass centre of the earth.

(b) Longitude is an angular quantity measured from the Greenwich meridian.

(c) Latitude is an angular quantity measured from the equatorial plane, to the plane defined by the point position and the plumb line to the ellipsoid surface.

(d) Ellipsoid height is the height above the reference ellipsoid.





Using a GNSS system, the Geodetic coordinates of (Latitude, Longitude, Ellipsoid height) can be directly obtained for any position on earth that can see the satellites.

Note: Heights in Australia are not usually quoted as Ellipsoid heights h but instead in AHD (Australian Height Datum) H which is defined in terms of Means Sea Level. The difference between the ellipsoid height and the AHD is known as the **N (AHD Value**.

AHD (Geoid height) = Ellipsoid height - N (AHD) Value

Continue to 33.5.2 Map (Cartographic) Projections - Eastings and Northings or return to 33.5 What is Wrong with Local Coordinates ? or 33 BIM.

33.5.2 Map (Cartographic) Projections - Eastings and Northings

Although Geodetic coordinate of Latitude and Longitude give unique coordinates for a point, they are not very appropriate for drawing up civil engineering projects. They are usually represented on a map by mathematically "projecting" them on to a surface, which can be laid flat.

A Map or Cartographic Projection is a transformation of the latitudes and longitudes of locations on the surface of an ellipsoid into locations on a plane. The projection coordinates are usually referred to as Eastings (x) and Northings (y).

The important thing is that the Cartographic projection can be reversed. That is, has an inverse. So the Cartographic projection

(a) maps a (Latitude, Longitude) to a (Easting, Northing)

and

(b) the inverse projection maps an (Easting, Northing) to a (Latitude, Longitude).

Consequently if you have the (Easting, Northing) then can calculate the equivalent (Latitude, Longitude) and vice versa.

The most commonly used Cartographic projection for civil works is the **Transverse Mercator** projection.

In mathematical speak, **Transverse Mercator** projections are **conformal** projections and preserve angles locally, implying that they map infinitesimal circles of constant size anywhere on the Earth to infinitesimal circles of **varying sizes** on the map. In contrast, mappings that are not conformal distort most such small circles into ellipses of distortion. An important consequence of conformality is that relative angles at each point of the map are correct, and the local scale (although varying throughout the map) **in every direction around any one point is constant**.

Transverse Mercator projections are commonly used for road projects by the Road Authorities in each State of Australia. They are also used for the Meridional Circuits in New Zealand.

The Transverse Mercator projection is also used as the basis of the **UTM** (Universal Transverse Mercator). The UTM is not a single map projection but divides the Earth into sixty zones, each a six-degree band of longitude, and uses a Transverse Mercator projection.

In Australia, **MGA** coordinates (Map Grid of Australia) are based on the UTM using the ellipsoid GRS80 previously defined.

So an MGA coordinate (Easting, Northing) has a unique (Latitude, Longitude).

And a reading from a GNSS device (commonly known as GPS) uniquely converts to a MGA coordinate, and conversely a MGA coordinate converts to (Latitude, Longitude) for use in a GPS without knowing anything about a local coordinate system.

Continue to 33.5.3 Why Isn’t MGA Used on a Small Building Site ? or return to 33.5 What is Wrong with Local Coordinates ? or 33 BIM.

33.5.3 Why Isn't MGA Used on a Small Building Site ?

It is very easy to gloss over one very important point about Transverse Mercator projections as used in MGA.

Transverse Mercator projections are **conformal projections** and although they **preserve angles**, they do **not preserve distances**.

So a small circle will transform to a small circle but the radius will vary depending on where you are in an MGA zone.

The amount of the distortion is known as a **scale factor** and it varies from point to point. Over a small distance the scale factor is almost a constant but that constant value **is rarely 1**.

What that means in practise is if you draw everything up in MGA coordinates, the actual distance between two points in **NOT the standard square root distance between the two points**.

This means that on a plan in MGA coordinates, you can't simply use a ruler to measure he distance between two points. You need to allow for the scale factor. Over a small distance the scale factor will be a constant (for example 0.9996) but over a large distance you need to need to do the correct Geodetic calculations.

This also means that in a standard drafting system, the usual distance between two points that is used in conventional drafting dimensioning options, will not give the correct value.

For those working in a local coordinate project you may have noticed the scale factor effect when you have identified two points a good distance apart and you also have their MGA coordinates. If you measure between the points in your local coordinate system and then calculate the square root distance between the two MGA points using the actual MGA coordinates then you won't get the same number.

This is probably why most projects defined in local coordinates only give the MGA coordinates for o**ne point** and a **rotation of the axes**.

The result of all this is that if you only have a small building site then you can obtain fairly accurate MGA coordinates by applying a 2D Helmert transformation to the local coordinates. That is, a translation, a rotation or the axis and a **constant multiplication factor** (which could be the Point Scale Factor of the given MGA point).

However, as the size of the project increases, the larger errors will be in the MGA coordinates for points further away from the origin.

Similarly if you apply a translation, rotating and scale to convert data given in MGA coordinates (say from a GIS system or the State Road Authority) to local coordinates, then there will be errors the further away from the "best fitted" point.

Note

If you are not a surveyor you will probably not be aware that in ***12d Model***, you can specify the Cartographic projection that the coordinates are in and can then obtain the (Latitude, Longitude) for selected points, measure between points and get the square-root distance and also the **ellipsoid distance** between the points.

Return to 33.5 What is Wrong with Local Coordinates ? or 33 BIM.

34 12d Archive File Format

The ***12d Archive*** file format (called 12d ascii in Version 10 and earlier) is a text file definition from 12d Solutions which is used for reading and writing out string data from 12d Model. 12d Archive files normally end in '**.**12da' and are often referred to as 12da files.

Unlike the earlier 12d Ascii files in Version 9, from Version 10 onwards the 12d Archive file is a **Unicode** file.

This document is for the ***12d Archive file*** format used in ***12d Model*** *Version 11*.

For General Comments about 12da, see 34.1 General Comments about a 12da File

For the 12da definitions:

Attributes	34.2 Attributes
Commands	34.3 Commands
Each string type	34.4 12da Definition for each String Type
Tin	34.3.7 Tin
Super Tin	34.3.8 Super Tin

For documenation on the ***12d XML*** file format, see 35 12d XML File Format.

34.1 General Comments about a 12da File

Unicode - 12d Archive file is a Unicode file.

//

Anything written on a line after // is ignored. This is used to place comments in the file.

Blank lines

Unless they are part of a text string, blank lines are ignored.

Spaces

Unless enclosed in quotes ("), more than one consecutive space or tab is treated as one space. Except when it is the delimiter after a //, an end of line (<enter>) is also considered a space.

Spaces and special characters in text strings

Any text string that includes spaces and any characters other than a to z, A to Z or 0 to 9 (alphanumeric), must be enclosed in double quotes. In text strings, double quotes " and backslash \ must be preceded by a \. For example, \" and \\ define a " and a \ respectively in a text string.

Names of models, tins, styles, colours and attributes

Models, tins, styles (linestyles), colours and attributes can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters) and space. Leading and trailing spaces are ignored. The names can be up to 255 characters in length. If the name includes spaces, the name must be enclosed in double quotes (").

The names for models, tins, styles, colours or attributes can not be blank.

The names for models, tins, styles and colours can contain upper and lower alpha characters which are stored, but the set of model names, tin names, style names, colour names or attribute names for an object *must be unique when case is ignored*. For example, the model name "Fred" will be stored as "Fred" but "FRED" is considered to be the *same* model name as "Fred".

String names

String names can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters), space, decimal point (.), plus (+), minus (-), comma (,), open and closed round brackets and equals (=). Leading and trailing spaces are ignored. String names can be up to 255 characters in length. If the string name includes anything other than alphanumeric characters, then the name must be enclosed in double quotes (").

String names can contain upper and lower alpha characters which are retained but case is ignored when selecting by string name. That is, the string name **Fred** will be stored as **Fred** but **FRED** is not considered to be a different string name.

String names do not have to be unique and can be blank.

Continue to the next section 34.2 Attributes or return to 34 12d Archive File Format.

34.2 Attributes

Many *12d* ***Model*** objects (models and elements such as individual strings and tins) can have an unlimited number of named **attributes** of type integer (numbers), real and text.

The attributes for an object are given in an ***attributes block*** which consists of the keyword **attributes** followed by the definitions of the *individual attributes* enclosed in start and end curly braces { and }. That is, an ***attributes_block*** is

attributes {

attribute_1

attribute_2

...

attribute_n

}

where the attribute definitions for the individual attributes *attribute_i* consists of

attribute_type ***attribute_name*** ***attribute_value***

where

attribute_type	is integer, real or text
attribute_name	is the unique attribute name for the object.

If the attribute name includes spaces then the text of the name must be enclosed in double quote character (")

and

attribute_value	is the appropriate value of the integer, real or a text.

Within an object, the attribute names are case sensitive and must be unique. That is, for attribute names, upper and lower case alphabet characters are considered to be different characters.

If the *text* for a text attribute includes spaces then the text must be enclosed in double quote characters ("). It the text is blank, it is given as "".

An example of and ***attribute block*** defining four attributes named "pole id", "street", "pole height" and "pole wires" is:

```
attributes {
  text              "pole id"           "QMR-37"
  text               street             "477 Boundary St"
  real              "pole height"        5.25
  integer           "pole wires"         3
}
```

Continue to the next section 34.3 Commands or return to 34 12d Archive File Format.

34.3 Commands

Commands consist of a ***keyword*** followed by a space and then a ***value*** (a keyword and its value is often referred to as a ***keyword pair***). A *value* must always exist.

keyword *value* // a keyword pair

There can be more than on command keyword pair per line as long as each keyword pair is separated by a space. In fact, the *keyword* can be on one line and the *value* on the next line.

Although the names of commands are only shown in lower case in these notes, commands are case insensitive and all combinations of case are recognised as the same command. That is **model**, **MODEL** and **ModeL** are all recognised as the command **model**.

For the definition of the commands in the 12da file *see*:

34.3.1 Model
34.3.2 Colour
34.3.3 Style
34.3.4 Breakline
34.3.5 Null
34.3.6 String
34.3.7 Tin
34.3.8 Super Tin

Or return to 34 12d Archive File Format.

34.3.1 Model

There are two formats for the **model** command:

(a) model command when there are no attributes for the model

model *model_name*

All elements (strings, tins, plot frames etc) following until the next **model** keyword are placed in the model *model_name*. This can be overridden for an element by a **model** command inside the element definition.

The default model name used for elements when no model name has been specified is ***data***.

(b) model command when there are model attributes

If the model includes attributes, the following form of the *model* command must be used.

model {

name *model_name*

attributes_block

}

where the *attributes_block* is defined in 34.2 Attributes.

For example:

```
model {
  name        "telegraph poles"

  attributes {
    text          "pole id"          "QMR-37"
    text          "street"           "477 Boundary St"
    real          "pole height"       5.25
    integer       "pole wires"        3
  }
}
```

Continue to the next section 34.3.2 Colour or return to 34.3 Commands or 34 12d Archive File Format.

34.3.2 Colour

The format of the **colour** command is:

colour *colour_name*

When reading a 12da file, there is a ***current colour,*** which has the default value of ***red***, and when a **colour** command is read, the ***current colour*** is set to *colour_name.*

When strings are read in a 12da file, they are given the *current colour*.

This can be overridden for a string by a *string colour command* inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.3 Style or return to 34.3 Commands or 34 12d Archive File Format.

34.3.3 Style

The format of the **style** command is:

style *linestyle_name*

When reading a 12da file, there is a ***current linestyle,*** which has the default value of ***1***, and when a **style** command is read, the ***current linestyle*** is set to *linestyle_name.*

When strings are read in a 12da file, they are given the *current linestyle*.

This can be overridden for a string by a *string style command* inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.4 Breakline or return to 34.3 Commands or 34 12d Archive File Format.

34.3.4 Breakline

The format of the **breakline** command is:

breakline *breakline_type*

where *breakline_type* is *point* or *line*.

When reading a 12da file, there is a ***current breakline type,*** which has the default value of ***point***, and when a **breakline** command is read, the ***current breakline type*** is set to *breakline_type.*

When strings are read in a 12da file, they are given the *current breakline type*.

This can be overridden for a string by a *string breakline command* inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.5 Null or return to 34.3 Commands or 34 12d Archive File Format.

34.3.5 Null

The format of the **null** command is:

null *null_value*

When reading a 12da file, there is a ***current null value,*** which has the default value of ***-999***, and when a **null** command is read, the ***current null value*** is set to *null_value.*

When strings are read in a 12da file and the string has z-values equal to *null_value*, then the z-value is replaced by the ***12d Model*** null value.

This can be overridden for a string by a *null_value command* inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.6 String or return to 34.3 Commands or 34 12d Archive File Format.

34.3.6 String

The format of the **string** command is:

string *string_type* {

attributes_block

string_command_1

string_command_2

...

string_command_n

}

The ***string_type*** is compulsory and must be followed by all the string information enclosed in curly braces { and }.

So if a ***string type,*** or possibly information inside the string is not recognised, the 12da reader has a chance of being able to jump over the string by looking for the end curly brace }.

Inside the braces are **string commands** as keyword pairs defining information for the string.

There can be more than one *string command* keyword pair per line as long as each keyword pair is separated by a space. In fact, the *keyword* can be on one line and the *value* on the next line.

Any unrecognised *string commands* are ignored.

The *string command keyword pairs* include **model**, **colour**, **style** and **breakline,** which are all *optional* inside the string definition. However if any of them exist inside a string definition, then the *string command keyword* overrides the current value for **model**, **colour**, **style** or **breakline** *commands* but the override is only for that particular string.

Not all string types can have an *attributes_block*.

For some string types (e.g. super string) there is more data required than just the *string command* keyword pairs.

This extra data is contained is blocks consisting of a *keyword* followed by the required information enclosed in the curly braces **{** and **}**. For example attributes for all *string types* and (x,y,z) data for a super string.

For all string types, if there is not enough recognised information to define the string, the string is ignored.

For the definition for each *string type* and the allowed *string commands* and extra data that is required for that *string type, see* 34.4 12da Definition for each String Type.

Note: if the string does not have any attributes then the ***attributes_block*** can be left out entirely (see 34.2 Attributes for the definition of *attributes_block*).

Continue to the next section 34.3.7 Tin or return to 34.3 Commands or 34 12d Archive File Format.

34.3.7 Tin

Tins (***t****riangulated* ***i****rregular* ***n****etworks*) and *Super Tins* can be written out and read in from a 12da.

```
tin {
  name    tin_name        // MANDATORY name of the tin when created in 12d Model

  time_created text              // optional - time tin first created
  time_updated text              // optional - time tin last modified

// Attributes Block:

// The attributes style, faces, null_length, null_angle, null_combined_value
// and null_combined_angle are special attributes that has extra information used by
// 12d Model to create the tin. These special attributes should not be deleted.
//
// The attributes in this block and the Attributes block itself are optional.
// When a tin is read into 12d Model from a 12da file, the style is used
// as the Tin style.

  attributes {
    text "style"            text        // name of line style for the tin
    integer "faces          0/1          // 0 non triangle data, 1 triangle data
    real "null_length"      value         // values for null by angle/length
    real "null_angle"       value    // angle in radians
    real "null_combined_length"    value
    real "null_combined_angle"      value          // angle in radians

//                  any other attributes
  }                                                  // end of attributes block

// Points Block
//
// Co-ordinates of the points at the vertices of the triangles
// The points are implicitly numbered by the order in the list (starting at point 1).
//
// The Points Block is MANDATORY

  points {                         // x y z for each point in the tin
    x-value    y-value    -value           // point 1
        "         "         "              // point 2
       "          "           "
  }                                // end of points block

// Triangles Block
//
//    Each triangle is given as a triplet of the point numbers that make up
//      the triangle vertices (the point numbers are the implicit position of the points
//      given in the Points Block.
// The order of the triangles is unimportant
//
// The Triangles Block is MANDATORY
```

```
  triangles {                         // points making up each triangle
    T1-1      T1-2      T1-3          // point numbers of the 3 vertices of first triangle.
    T2-1      T2-2      T-33          // point numbers of the 3 vertices of second triangle.
       "         "
       "         "
  }                       // end of triangles block

// Base Colour
//    The tin has a base colour that is the default colour for all triangles

  colour tin_base_colour              // optional - base colour of the tin

// Colours Block
//
// Triangles can be given colours other than the base colour by including
// a colours block. The colour for each triangle in then individually given
// (-1 means base colour). The order is the same as the order of the triangles in
// the Triangles Block.
//
// If all the triangles are the base colour, then simply omit the Colours Block

  colours {
    C1     C2     C3                  // colour for each triangle given in triangle order
    C4   C5   C6   C7                 // colour "-1" means use the base tin colour.
       "    "    "
       "    "    "
  }                       // end of colours block

// Input Block
//
// More information about how the tin was created by 12d Model.
// None of this information is needed when reading a tin into 12d Model.
// This block can be omitted

  input {                                      // data for reconstructing tin from strings
    preserve_strings     true/false            // if true, preserve breaklines etc.
    remove_bubbles       true/false            //
    weed_tin             true/false
    triangle_data        true/false
    sort_tin             true/false
    cell_method          true/false

    models {
      "model_name_1"                  // name of the first model making up the tin
      "model_name_2"                  // name of the second model making up the tin
       "    "    "
       "    "    "
    }                                 // end of models block

  }                                   // end of input block
}                                     // end of tin 12a definition
```

Continue to the next section 34.3.8 Super Tin or return to 34.3 Commands or 34 12d Archive File Format.

34.3.8 Super Tin

Super Tins, which consists of a number of **tins** (***t***riangulated ***i***rregular ***n***etworks), can be written out and read in from a 12da.

```
super_tin {
  name   tin_name        // MANDATORY name of the super tin

  time_created text              // optional - time super tin first created
  time_updated text              // optional - time super tin last modified

// Attributes Block:

// This is mainly information used by 12d Model to create the super tin.
// The attributes in this block and the Attributes block itself are optional.
//   When a super tin is read into 12d Model from a 12da file, the style is used
//   as the Super Tin style.

  attributes {
        text "style"          text       // name of line style for the tin
//             any other attributes
  }                                            // end of attributes block

// Super Tin Colour
//      The super tin has a base colour

  colour tin_base_colour         // optional - base colour of the super tin

// Tins Block
//
// This is the list of tins that make up the super tin.
// This block is MANDATORY

  tins {                                   // list of tins for the super tin
    "tin_name_1"                 // name of the first tin making up the super tin
    "tin_name_2"                 // name of the second tin making up the super tin
    "    "    "
    "    "    "
  }                              // end of tins block

}                                // end of super tin 12a definition
```

Note that the tins that make up the super tin must exist in ***12d Model*** for the super tin to be fully defined.

Continue to the next section 34.4 12da Definition for each String Type or return to 34.3 Commands or 34 12d Archive File Format.

34.4 12da Definition for each String Type

For the 12da definition of each string type, see:

34.4.1 Arc String
34.4.2 Circle String
34.4.3 Drainage String
34.4.4 Face String
34.4.5 Feature String
34.4.6 Interface String
34.4.7 Plot Frame String
34.4.8 Super String
34.4.9 Super Alignment String
34.4.10 Text String

And for the superceded strings, see:

34.4.11 2d String
34.4.12 3d String
34.4.13 4d String
34.4.16 Alignment String
34.4.14 Pipe String
34.4.17 Pipeline String
34.4.15 Polyline String

Or return to 34 12d Archive File Format.

34.4.1 Arc String

```
string arc {
  model model_name  name string_name
  colour colour_name  style style_name
  chainage start_chainage  interval value  radius value
  xcentre value  ycentre value  zcentre value
  xstart value  ystart value  zstart value
  xend value  yend value  zend value
}
```

Continue to the next section 34.4.2 Circle String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.2 Circle String

```
string circle {
  model model_name  name string_name
  colour colour_name  style style_name
  chainage start_chainage  interval value  radius value
  zcentre value  xcentre value  ycentre value
}
```

Continue to the next section 34.4.3 Drainage String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.3 Drainage String

```
string drainage {
  chainage   start_chainage
  model  model_name   name  string_name
  colour  colour_name   style  style_name
  breakline  point or line
  attributes {
    text  Tin   finished_surface_tin
    text  NSTin   natural_surface_tin
    integer   "_floating"   1|0              // 1 for floating, 0 not floating
  }
  outfall     outfall_value                  // z-value at the outfall
  flow_direction    0|1                      // 0 drainage line is defined from downstream
                                             // to upstream

  data {                                     // key word - geometry of the drainage string
    x-value     y-value     z-value     radius   bulge
      "          "          "
      "          "          "
  }
  pit {                            // pit/manhole - one pit record for each pit/manhole
                                   // in the order along the string
      name            text                   // pit name
      type            text                   // pit type
      road_name       text                   // road name
      road_chainage        chainage          // road chainage
      diameter             value             // pit diameter
      floating        yes|no                 // is pit floating or not
      chainage        pit_chainage           // internal use only
     ip               value                  // internal use only
      ratio           value                  // internal use only
      x               x-value                // x-value of top of pit
      y               y-value                // y-value of top of pit
      z               z-value                // z-value of top of pit
  }
  pipe {                           // one pipe record for each pipe connecting pits/manholes
                                   // in the order they occur along the string
      name            text                   // pipe name
      type            text                   // pipe type
      diameter        value                  // pit diameter
      us_level        value                  //
      ds_level        value                  //
      us_hgl          value                  //
      ds_hgl          value                  //
      flow_velocity        value             //
      flow_volume          value             //
  }
  property_control {
    name              text                   // lot name
    colour            colour_name
    grade             value                  // grade of pipe in units of "1v in"

34.4.7 Plot Frame String

Plot frames can be written out and read in from a 12da file.

```
string plot_frame {
  name             frame_name
  title_file       filename
  border           0 or 1
  viewport         0 or 1
  user_title_file  0 or 1
  title_1          text
  title_2          text
  plot_file        filename
  text_size        mm
  sheet_code       text
  width            value
  height           value
  scale            value
  rotation         value
  xorigin          value
  yorigin          value
  left_margin      mm
  right_margin     mm
  top_margin       mm
  bottom_margin    mm
  plotter          text
  colour           colour
  textstyle        textstyle_name
}
```

Continue to the next section 34.4.8 Super String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.8 Super String

Because the super string is so versatile, its 12da format looks complicated but it is very logical and actually quite simple.

In its most primitive form, the super string is simply a set of (x,y) values as in a 2d string, or (x,y,z) values as in a 3d string, or (x,y,z,radius,bulge_flag) as for a polyline string or even lines, arcs and transitions (spirals and non-spiral transitions).

Additional blocks of information can extend the definition of the super string. For example, text, pipe diameters and visibility.

Some of the properties of the super string extend what were constant properties for the entire string in other string types. For example, *breakline* type for the string extends to *tinability* of *vertices* and *segments*. One colour for the string extends to individual colours for each segment.

Other properties such as vertex id's (point numbers), visibility and culvert data are entirely new.

For user attributes, the super string still has the standard user attributes defined for the entire string, but user attributes for each vertex and segment are also supported.

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a super string, being closed is a property of the string and no extra vertex is needed. That is, the first and the last vertices are not the same for a closed super string and the super string knows there is an additional segment from the last vertex back to the first vertex.

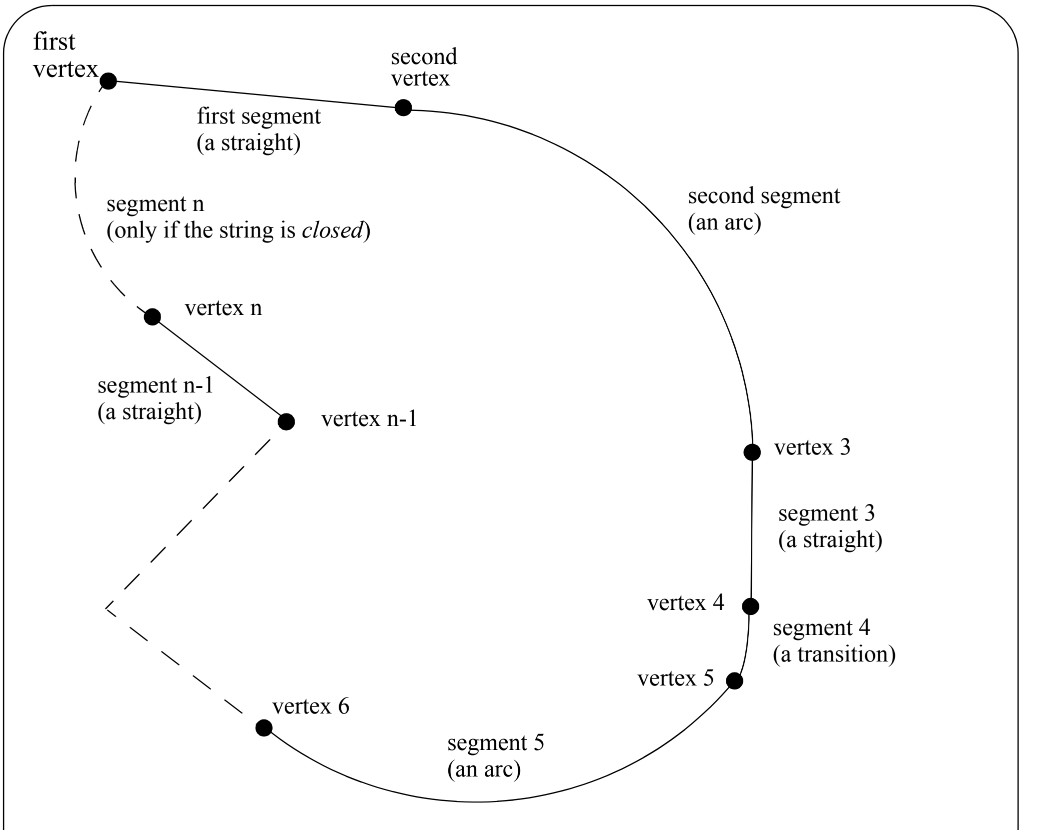
Hence in the 12da format, there is a *closed* flag for the super string:

closed *true* or *false*

where *true* can be 1 or T or t or Y or y (or words starting with T, t, Y or y))
and *false* is 0 or F or f or N or n (or words starting with F, f, N or n.

Thus if a string has *n* vertices, then an open string has *n-1* segments joining the vertices and a closed string has *n* segments since there is an additional segment from the last to the first vertex.

With the additional data for vertices and segments in the super string, the data is in vertex or segment order. So for a string with *n* vertices, there must be *n* bits of vertex data. For segments, if the string is open then there only needs to be *n-1* bits of segment data but for closed strings, there must be *n* bits of data. For an open string, *n* bits of segment data can be specified and the *nth* bit will be read in and stored. If the string is then closed, the *nth* bit of data will be used for the extra segment.



Vertices and Segments Forming the Super String

The full 12da definition of the super string is:

```
string super {
  chainage start_chainage
  model model_name  name string_name
  colour colour_name  style style_name
  breakline point or line
  closed true or false
  interval {
    chord_arc    value           // chord-to-arc tolerance for curves
    distance     value           // chainage interval to break the geometry up
  }

  block of info {
  }
  block of info {
  }
  block of info {
  }
}
```

The blocks of info can be broken up into four types.

(a) blocks defining the position of the vertices in z, y and z

data_2d **or** *data_3d*

(b) blocks defining the geometry of the segments

radius_data and *major_data* **or** *geometry_data*

(c) a superseded block defining vertices and segment geometry

data

(d) extra information for the vertices and/or segments

pipe diameters - *diameter_value or diameter_data*
culvert dimensions - *culvert_value or culvert_data*
pipe/culvert justification - *justify*
colour - *colour or colour_data*
vertex ids (point numbers) at each vertex- *point_data*
tinability - *breakline or vertex_tinability_data and segment_tinability_data*
visibility - *vertex_visible_data and segment_visible_data*
vertex text and annotation - *vertex_text_data and vertex_annotation_data*
segment text and annotation - *segment_text_data and segment_annotation_data*
symbols at vertices - *symbol_value or symbol_data*
vertex attributes - *vertex_attribute_data*
segment attributes - *segment_attribute_data*
extrudes
image data
holes

The definition for the blocks of each type now follows.

(a) Blocks Defining the Position of the Vertices

For (x, y) Values with a Constant z

If there is only (x,y) values at each vertex (like a 2d string):

```
data_2d {                                       // keyword
            x-value    y-value
               "          "
               "          "
}
```

and if there is a non-null constant z for the string

```
z    value
```

For (x,y,z) Values

If there is (x,y,z) values at each vertex (like a 3d string):

```
data_3d {                                       // keyword
   x-value    y-value    z-value
      "          "          "
      "          "          "
}
```

(b) Blocks Defining the Geometry of the Segments

Straights and Arcs Only for the Segments

If data_2d or data_3d was used, it is possible to add radius and bulge_flag data:

```
radius_data {                                   // keyword
                 radius for first segment
                 radius for second segment
```

```
                    . . .
              radius for last segment
}

major_data {                                     // keyword
              bulge flag for first segment
              bulge flag for second segment
                    . . .
              bulge flag for last segment
}
```

Straights, Arcs and Transitions (Spiral and non-Spiral Transitions) for the Segments

If data_2d or data_3d was used, it is possible to specify if the segments are straight, arcs or transitions using a *geometry_data* block.

```
geometry_data {
  segment_info_1 {
    information on the first segment
  }
  segment_info_2 {
    information on the second segment
  }
      "    "
      "    "
  segment_info_n-1 {        // the last segment if it is open
    information on the (n-1) segment
  }
  segment_info_n {          // the last segment if it is closed
    information on the n-th segment
  }
}
```

where the *segment_info* blocks are from the following:

(a) Straight

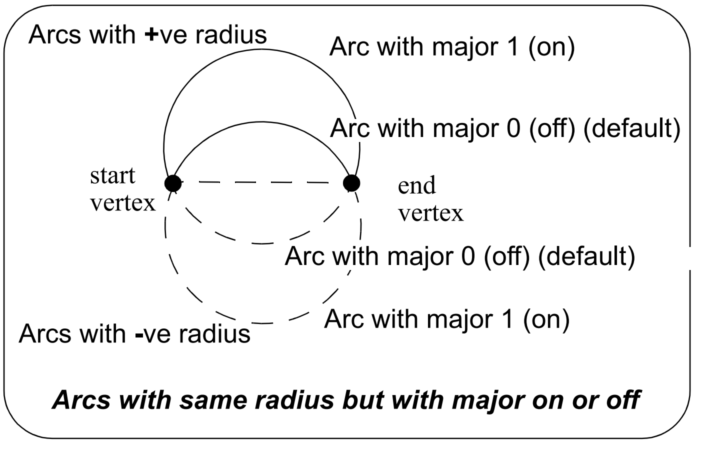
No parameters are needed for defining a straight segment. The *straight* block is simply:

```
straight {                  // no parameters are needed for a straight
}
```

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius, and a flag *major* which can be set to 1 (on) or off (0) to differentiate between the four possibilities.



So the *arc* block is:

```
arc {
  radius value     // radius of the arc (+ve is above the line connecting the vertices)
  major  0 or 1    // 0 is the smaller arc, 1 the larger arc).
}
```

(c) Spiral - this covers both spiral and non-spiral transitions

There can be a partial transition between adjacent vertices. The partial transition is defined by the parameters

l1 length of the full transition up to the start vertex
r1 radius of the transition at the start vertex
a1 angle in decimal degrees of the tangent to the transition at the start vertex
l2 length of the full transition up to the end vertex
r2 radius at the end vertex
a2 angle in decimal degrees of the tangent to the transition at the end vertex

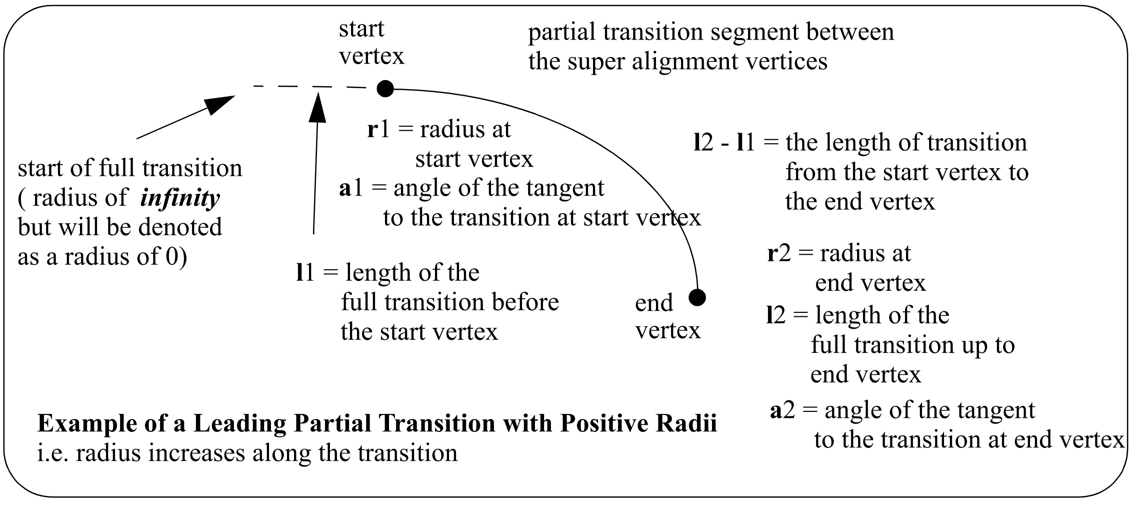
Since a radius can not be zero, a radius of infinity is denoted by *zero*.

The transition is said to be a *leading* transition if the absolute value of the radius is increasing along the direction of the transition (the transition will *tighten*). Otherwise it is a *trailing* transition.

If a leading transition is a full transition then **r**1 = 0 and **l**1 = 0. Similarly if a trailing transition is a full transition then **r**2 = 0 and **l**2 = 0.

For a partial transition, if the coordinates of the start of the full transition are needed then they can be calculated from l1,r1,a1, l2,r2,a2 and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii's are positive then a leading transition will curl to the right (and will be above the line joining the start and end vertices).



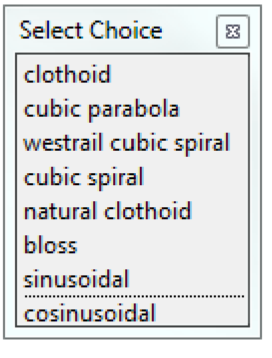
Example of a Leading Partial Transition with Positive Radii
i.e. radius increases along the transition

The parameters for the *spiral* block are:

```
spiral {
  type       value        // type can be clothoid, cubic parabola, westrail-cubic,
                          // cubic spiral, natural clothoid, bloss,
                          // bloss, sinusoidal, cosinusoidal
  leading    1 or 0       // 1 denotes a leading transition, 0 a trailing transition
  l1         value        // length of the full transition at start vertex
  r1         value        // radius at the start vertex
  a1         value        // angle in decimal degrees of the tangent to the transition
                          // at the start vertex
  l2         value        // length of the full transition at end vertex
  r2         value        // radius at end vertex
  a2         value        // angle in decimal degrees of the tangent to the transition
                          // at the end vertex
}
```

Notes

1. The ***spiral*** block covers both spiral and non-spiral transitions.
2. The transitions/spirals supported by ***12d Model*** are:



Clothoid - spiral approximation used by Australian road authorities and Queensland Rail.

Cubic parabola – special transition curve used by NSW railways. Not a spiral.

Westrail cubic – spiral approximating used by WA railways.

Cubic spiral – low level spiral approximation. Only ever used in surveying textbooks.

Natural Clothoid – the proper Euler spiral. Not used by any authority.

Bloss – special transition used by Deutsche Bahn. Not a spiral.

Sinusoidal - special transition. Not a spiral.

Cosinusoidal - special transition. Not a spiral.

(c) Block Defining the Vertices and Segments

For compatibility with the polyline, the *data* block gives the (x,y,z,radius,bulge) values at each vertex of the string and so defines both the vertices and the geometry of the segments in the one block.

```
data {                                                        // keyword
         x-value    y-value    z-value    radius   bulge
           "          "          "
           "          "          "
}
```

(d) Other Blocks

Pipe Diameters

There can be one pipe diameter value for the entire super string or the pipe diameter varies for each segment of the super string.

```
diameter_value value
```

or

```
diameter_data {                                               // keyword
         pipe diameter for first segment
         pipe diameter for second segment
                          . . .
         pipe diameter for last segment
}
```

Culvert Dimensions

There can be one culvert width and height for the entire super string or the culvert width and height vary for each segment of the super string.

```
culvert_value {
   width    value
   height    value
}
```

or

```
culvert_data { properties {width   value      // width and height for first segment
                           height  value
                          }
               properties {width   value      // width and height for second segment
                           height  value
                          }
                    . . .
               properties {width   value      // width and height for last segment
                           height  value
                          }
}
```

Justification for Pipe or Culverts

There can be only one justification for the pipe or culvert for the entire super string.

```
justify   justification            // bottom or invert
                                   // top or obvert
                                   // centre (default)
```

Colour

There can be one colour for the entire super string which is given by the `colour` command at the beginning of the string definitions (before the blocks of information) or the colour varies for each segment of the super string and is specified in a colour_data block.

```
colour_data {                                        // keyword
                colour for first segment
                colour for second segment
                    . . .
                colour for last segment
}
```

Vertex Id’s (Point Numbers)

Each vertex can have a vertex id (point number). This is not the order number of the vertex in the string but is a separate id which is usually different for every vertex in every string. The vertex id can be alphanumeric.

```
point_data {                                         // keyword
                vertex id or first vertex            // alphanumeric
                vertex id for second vertex
                    . . .
                vertex id for last vertex
}
```

Tinability

For a *super string*, the concept of breakline has been extended to a property called **tinable** which can be set independently for each vertex and each segment of the super string.

If a vertex is tinable, then the vertex is used in triangulations. If the vertex is not tinable, then the vertex is ignored when triangulating.

If a segment is tinable, then the segment is used as a side of a triangle during triangulation. This may not be possible if there are *crossing* tinable segments.

```
vertex_tinable_data {                                // keyword
                tinable flag for first vertex        // 1 for tinable
                tinable flag for second vertex       // 0 for not tinable
                    . . .
                tinable flag for last vertex

segment_tinable_data {                               // keyword
                tinable flag for first segment       // 1 for tinable
                tinable flag for second segment      // 0 for not tinable
                    . . .
                tinable flag for last segment
}
```

Note that even if a segment is set to tinable, is can only be used if both its end vertices are also tinable.

Visibility

For a *super string*, the concept of visibility and invisibility for vertices and segments has been introduced.

```
vertex_visible_data {                                  // keyword
                    visibility flag for first vertex   // 1 for visible
                    visibility flag for second vertex  // 0 for invisible
                          . . .
                    visibility flag for last vertex
}

segment_visible_data {                                  // keyword
                    visibility flag for first segment   // 1 for visible
                    visibility flag for second segment  // 0 for invisible
                          . . .
                    visibility flag for last segment
}
```

Vertex Text and Vertex Annotation

There can be the same piece of text for every vertex in the super string or a different text for each vertex of the super string. How the text is drawn is specified by vertex annotation values. Note that in vertex annotations, all vertices must be either worldsize or all vertices papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all vertices.

```
vertex_text_value       text
```

or

```
vertex_text_data {                                  // keyword
                  text for first vertex             // text string, enclose
                  text for second vertex            // by " " if there are any
                    . . .                           // spaces in the text string
                  text for last vertex
}

vertex_annotate_value {                             // keyword
                  angle value   offset value   raise value
                  textstyle textstyle_name   slant degrees   xfactor value
                  worldsize value or papersize value or screensize value
                  justify   "top|middle|bottom-left|centre|right"
                  colour colour_name
}
```

or

```
vertex_annotate_data {                              // keyword
          properties {  angle value   offset value   raise value
                        textstyle textstyle   slant degrees   xfactor value
                        worldsize value or papersize value or screensize value
                        justify   "top|middle|bottom-left|centre|right"
                        colour colour_name
          }
          properties {    text properties second vertex
          }
          properties {       ...
          }
          properties {    text properties for last vertex
          }
}
```

Segment Text and Segment Annotation

There can be the same piece of text for every segment in the super string or a different text for each segment of the super string. How the text is drawn is specified by segment annotation values. Note that in segment annotations, all segments must be either worldsize or all segments papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all segments. However, vertex text and segment text do not both have to be papersize or worldsize.

```
    segment_text_value          text
or
    segment_text_data {                              // keyword
                    text for first segment           // text string, enclose
                    text for second segment          // by " " if there are any
                      . . .                          // spaces in the text string
                   text for last segment
     }

    segment_annotate_value {                         // keyword
                    angle value  offset value  raise value
                    textstyle textstyle  slant degrees  xfactor value
                    worldsize value or papersize value or screensize value
                    justify  "top|middle|bottom-left|centre|right"
                    colour colour_name
     }
or
    segment_annotate_data {                          // keyword
                properties { angle value  offset value  raise value
                      textstyle textstyle  slant degrees  xfactor value
                    worldsize value or papersize value or screensize value
                      justify  "top|middle|bottom-left|centre|right"
                      colour colour_name
                }
                properties {  text properties second segment
                }
                properties {  ...
                }
                properties {   text properties for last segment
                }
     }
```

Symbols

There can be the same symbol (defined as a linestyle) for every vertex in the super string or a different symbol for each vertex of the super string. If a symbol does not have a colour, then it uses the string colour or the segment colour.

```
     symbol_value {                                  // keyword
                    style linestyle_name  colour colour_name  size value
                    rotation value                     // in dms
                    offset value  raise value
     }
or
    symbol_data {                                    // keyword
                properties { style linestyle_name  colour colour_name  size value
                    style linestyle  colour colour  size value
                    rotation value                     // in dms
                    offset value  raise value
                }
                properties {   symbol and properties for second vertex
```

```
            }
            properties  {   ...
            }
            properties  {   symbol and properties for last vertex
            }
}
```

Vertex Attributes

Each vertex can have one or more user defined named attributes.

```
vertex_attribute_data {                              // key word
            attributes  {   attribute_type   attribute_name   attribute_value
                            attribute_type   attribute_name   attribute_value
                                  . . .
                            attribute_type   attribute_name   attribute_value
            }
            attributes  {   named attributes for second vertex
            }
            attributes  {   ...
            }
            attributes  {   named attributes for last vertex
            }
}
```

Segment Attributes

Each segment can have one or more user defined named attributes.

```
segment_attribute_data {                             // keyword
            attributes  {   attribute_type   attribute_name   attribute_value
                            attribute_type   attribute_name   attribute_value
                                . . .
                            attribute_type   attribute_name   attribute_value
            }
            attributes  {   named attributes for second segment
            }
            attributes  {   ...
            }
            attributes  {   named attributes for last segment
            }
 }
```

Continue to the next section 34.4.9 Super Alignment String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.9 Super Alignment String

In an *alignment* string, only the intersection point method (IP's) could be used to construct the horizontal and vertical geometry. The IP definition is actually a *constructive* definition and the tangents points and segments between the tangent points (lines, arcs, transitions etc.) are calculated from the IP definition. For an alignment string, only the IP definitions are included in the 12da file.

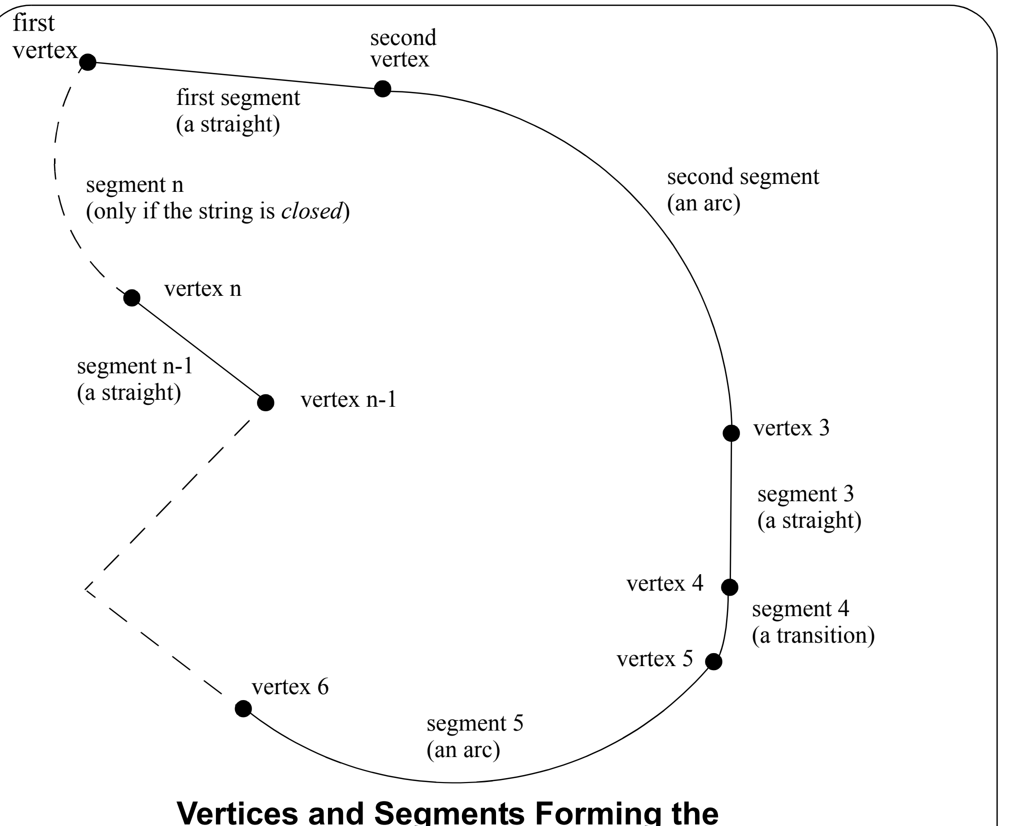
For a ***super alignment***, the horizontal and vertical geometry are also defined separately and with construction definitions but the construction definition can be much more complex than just IP's. For example, an arc could be defined as being tangential to two offset elements, or constrained to go through a given point.

If the horizontal construction methods are consistent then the horizontal geometry can be solved, and the horizontal geometry expressed in terms of consecutive segments (lines, arcs, transitions) that are easily understood and drawn.

Similarly if the vertical construction methods are consistent then the vertical geometry can be solved, and the vertical geometry expressed in terms of consecutive segments (lines, arcs, parabolas) that are easily understood and drawn.

Unlike the *alignment*, the *super alignment* stores ***both*** the ***construction methods*** (the ***parts***) and the resulting ***vertices*** and ***segments*** (lines, arcs, transitions etc.) that make up the horizontal and vertical geometry (the ***data***).

For many applications such as uploading to survey data collectors or machine control devices, only the ***horizontal data*** and the ***vertical data*** are required, not the *construction* methods (i.e. the ***horizontal*** and ***vertical parts***). When reading the 12da of a *super alignment*, only the ***horizontal*** and ***vertical data*** needs to be read in and the constructive methods (the ***horizontal*** and ***vertical parts***) can be skipped over.



Vertices and Segments Forming the Horizontal Data for a Super Alignment

Notes

1. Just using the horizontal and vertical data is valid ***as long as the super alignment geometry is consistent*** (and solves) and the horizontal and vertical parts can be created.

   There are flags in the 12da of the super alignment to say that the horizontal and vertical geometry is consistent and solves.

2. Segments meeting at a common vertex do not have to be tangential although for most road and rail applications, they should be.

The full 12da definition of the *super alignment* is:

```
string super_alignment {
//
  name              string_name
  chainage          start_chainage
  colour            colour_name
  style             style_name
  breakline         point or line
  closed            true or false
  spiral_type       transition_type          // the spiral_types are clothoid,
                                             // cubic parabola, westrail-cubic,
cubic spiral,
                                             // natural clothoid, bloss, sinusoidal
and
                                             // cosinusoidal. Note that some
spiral_type's
                                             // are non-spiral transitions

  valid_horizontal    true or false          // if true then the horizontal geometry
                                             // is consistent and solves
  valid_vertical      true or false          // if true then the horizontal geometry
                                             // is consistent and solves

  block of info {
             }
  block of info {
             }
  block of info {
             }

}                                            // end of super alignment
```

where the block of info can be one of more of:

attributes, horizontal_parts, horizontal_data, vertical_parts, vertical_data.

The *attributes* block has been described in the earlier section 34.2 Attributes.

The structure of the blocks *horizontal_parts*, *horizontal_data which define the horizontal geometry, and vertical_parts* and *vertical_data* which define the vertical geometry will now be described in more detail.

For information on *horizontal geometry,* go to Horizontal Geometry
vertical geometry Vertical Geometry

Horizontal Geometry

The horizontal geometry is described by two blocks - the *horizontal_parts* block and the *horizontal_data* block.

The ***horizontal_parts*** block contains the ***methods*** to construct the horizontal geometry such as float (fillet) an arc of a certain radius between two given lines or create a transition (spiral or non-spiral transition) between a line and an arc.

If the horizontal construction methods are consistent, then they can be solved to form a string made up of lines, arcs and transitions. The ***horizontal_data*** block is simply a list of the vertices and segments (lines, arcs etc.) that make up the ***solved*** geometry.

If the geometry in the *horizontal_parts* can be solved and produces a valid *horizontal_data* block, then the flag *valid_horizontal* in the super_alignment block is set to *true*.

```
valid_horizontal    true or false    //true if the horizontal geometry can be solved and
                                     // hence create a valid horizontal_data
horizontal_parts {/                  / methods for creating the horizontal geometry
    ....
}
horizontal_data {                    // the horizontal segments that make up the solved geometry
    ....
}
```

For information on *horizontal_parts,* go to the section Horizontal_parts
horizontal_data Horizontal_data

Horizontal_parts

The *horizontal_parts* block describes the methods used to construct the horizontal geometry of the super alignment. The parts that make up the horizontal geometry are defined in chainage order from the start to the end of the super alignment.

```
horizontal_parts {    // methods for creating the horizontal geometry
    blocks defining the sequential parts
    making up the horizontal geometry
}
```

Apart from the special case of parts defined by horizontal intersection points and their accompanying transitions and arcs, the other parts in the *horizontal_parts* block are not documented.

Horizontal_parts for defined by IP Method Only

For a horizontal intersection point (HIP) with no transitions or arc defined at that HIP, the part is defined by:

```
ip {
      id   value   // part id - a number that is unique for each horizontal and vertical part,
                   // and the value of part id is a multiple of 100
      x    value   // x co-ordinate of the horizontal intersection point
      y    value   // y co-ordinate of the horizontal intersection point
}
```

For a horizontal intersection point (HIP) with an arc but no transitions defined at that HIP, the part is defined by

```
    arc {
        id   value   // part id - a number that is unique for each horizontal and vertical part,
                     // and the value of part id is a multiple of 100
        r    value   // radius of the arc at the HIP
        x    value   // x co-ordinate of the HIP
        y    value   // y co-ordinate of the HIP
    }
```

For a horizontal intersection point (HIP) with an arc and transitions defined at that HIP, the part is defined by

```
    spiral {
        id   value   // part id - a number that is unique for each horizontal and vertical part,
                     // and the value of part id is a multiple of 100
        r    value   // radius of the arc at the HIP
        l1   value   // length of the leading transition at the HIP
        l2   value   // length of the trailing transition at the HIP
        x    value   // x co-ordinate of the HIP
        y    value   // y co-ordinate of the HIP
    }
```

Note that the *transition* used in the ***spiral*** block is given by *spiral_type* in the super_alignment block.

Hence a super alignment with horizontal geometry defined by IP methods only would consist of a horizontal_parts section with only the above ip, arc and spiral blocks in it.

```
horizontal_parts {

  ip_spiral_arc {
                 values          // values defining the ip_spiral_arc block
                 "
                 values
               }
      ....
  ip_spiral_arc {
                 values          // values defining the ip_spiral_arc block
                 "
                 values
}
```

For example,

```
horizontal_parts {
  ip {
      id 100
      x 42606.66161172
      y 37239.28824481
  }

  ip {
      id 200
      x 43134.36832349
      y 37330.26705997
  }

  spiral {
      id 300
      r 50
      l1 30
      l2 40
      x 43336.6595
      y 37469.2563
  }

  arc {
      id 400
      r 75
      x 43481.15324268
      y 37331.6431906
  }

  ip {
      id 500
      x 43627.02308964
      y 37544.94343852
  }
}
```

1st HIP
HIP only

Unique Part id
incrementing by 100

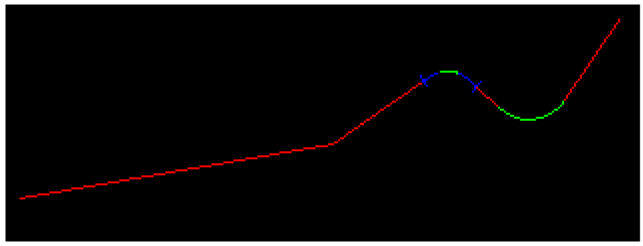
2nd HIP
HIP only

3rd HIP
HIP with arc and leading and trailing transitions

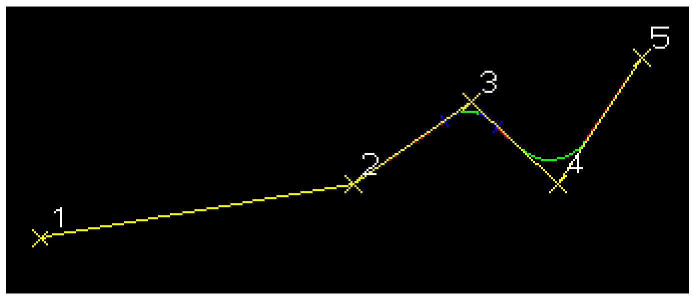
4th HIP
HIP with arc only

5th HIP
HIP only

Plan View of Super Alignment



Super Alignment Being Edited



Horizontal Parts with IP Methods Only

Horizontal_data

The *horizontal_data* block contains the ***solved*** horizontal geometry of the super alignment.

The *solved horizontal geometry* is made up of a series of (x,y) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, an arc, a transition (e.g. a spiral) or a partial transition.

If the horizontal geometry has n vertices, then there will be (n-1) segments for an *open* super alignment or n segments if the super alignment is *closed*.

The format of the *horizontal_data* block is:

```
horizontal_data {
  name        ""
  chainage    value
  breakline   line or point
  colour      colour
  style       linestyle
  closed      0 or 1               // 0 if the string is open, 1 if it is closed
```

```
interval {
  chord_arc     value          // chord-to-arc tolerance for curves
  distance      value          // chainage interval to break the geometry up
}

data_2d {
           x1-value   y1-value          // co-ordinates of the first vertex
           x2-value   y2-value          // co-ordinates of the second vertex
              "          "
              "          "
           xn-value   yn-value          // co-ordinates of the n-th vertex
}

geometry_data {
  segment_info_1 {
    information on the first segment
  }
  segment_info_2 {
    information on the second segment
  }
      "    "
      "    "
  segment_info_n-1 {           // the last segment if it is open
    information on the (n-1) segment
  }
  segment_info_n {             // the last segment if it is closed
    information on the n-th segment
  }
}
```

where the *segment_info* blocks are from the following:

(a) Straight

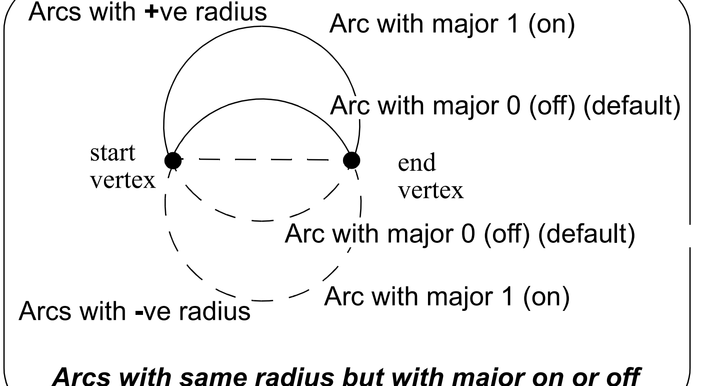
No parameters are needed for defining a straight segment. The *straight* block is simply:

```
straight {                     // no parameters are needed for a straight
}
```

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius, and a flag *major* which can be set to 1 (on) or off (0) to differentiate between the four possibilities.



Arcs with same radius but with major on or off

So the *arc* block is:

```
arc {
  radius value       // radius of the arc (+ve is above the line connecting the vertices)
  major  0 or 1      // 0 is the smaller arc, 1 the larger arc).
}
```

(c) Spiral - this covers both spiral and non-spiral transitions

There can be a partial transition between adjacent vertices. The partial transition is defined by the parameters

l1 length of the full transition up to the start vertex
r1 radius of the transition at the start vertex
a1 angle in decimal degrees of the tangent to the transition at the start vertex
l2 length of the full transition up to the end vertex
r2 radius at the end vertex
a2 angle in decimal degrees of the tangent to the transition at the end vertex

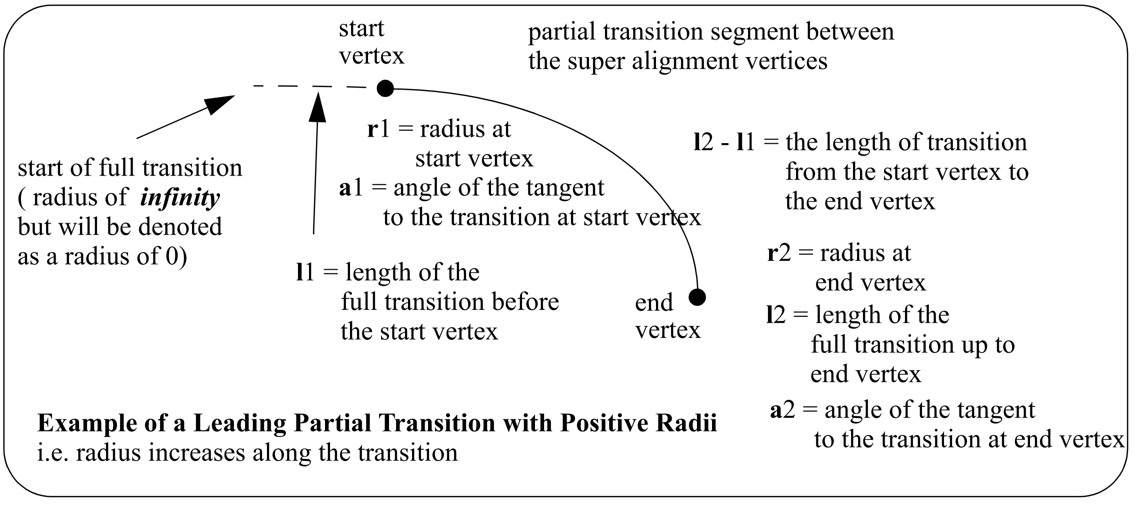
Since a radius can not be zero, a radius of infinity is denoted by *zero*.

The transition is said to be a *leading* transition if the absolute value of the radius is increasing along the direction of the transition (the transition will *tighten*). Otherwise it is a *trailing* transition.

If a leading transition is a full transition then **r**1 = 0 and **l**1 = 0. Similarly if a trailing transition is a full transition then **r**2 = 0 and **l**2 = 0.

For a partial transition, if the coordinates of the start of the full transition are needed then they can be calculated from l1,r1,a1, l2,r2,a2 and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii's are positive then a leading transition will curl to the right (and will be above the line joining the start and end vertices).



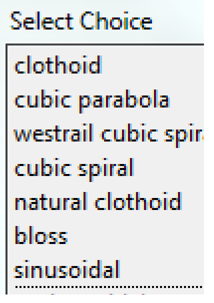
The parameters for the *spiral* block are:

```
spiral {
  type       transition_type    // any of the transitions supported in 12d
  leading    1 or 0             // 1 denotes a leading transition, 0 a trailing transition
  l1         value              // length of the full transition at start vertex
  r1         value              // radius at the start vertex
  a1         value              // angle in decimal degrees of the tangent to the transition
                                // at the start vertex
  l2         value              // length of the full transition at end vertex
```

```
    r2          value                    // radius at end vertex
    a2          value                    // angle in decimal degrees of the tangent to the transition
                                         // at the end vertex
}
```

Notes

1. The ***spiral*** block covers both spiral and non-spiral transitions.
2. The transitions/spirals supported by ***12d Model*** are:



Clothoid - spiral approximation used by Australian road authorities and Queensland Rail.

Cubic parabola – special transition curve used by NSW railways. Not a spiral.

Westrail cubic – spiral approximating used by WA railways.

Cubic spiral – low level spiral approximation. Only ever used in surveying textbooks.

Natural Clothoid – the proper Euler spiral. Not used by any authority.

Bloss – special transition used by Deutsche Bahn. Not a spiral.

Sinusoidal - special transition. Not a spiral.

Cosinusoidal - special transition. Not a spiral.

Vertical Geometry

The *vertical* geometry is described by two blocks - the *vertical_parts* block and the *vertical_data* block.

The ***vertical_parts*** block contains the ***methods*** to construct the vertical geometry such as float (fit) a parabola of a certain length between two given lines.

If the vertical construction methods are consistent, then they can be solved to form a string made up of lines, parabolas and arcs. The ***vertical_data*** block is simply a list of the vertices and segments (lines, parabolas and arcs) that make up the *solved* geometry.

If the geometry in the *vertical_parts* can be solved and produces a valid *vertical_data* block, then the flag *valid_vertical* in the super_alignment block is set to *true*.

```
valid_vertical   true or false///true if the vertical geometry can be solved and
                             // hence create a valid vertical_data
vertical_parts {             // methods for creating the vertical geometry
    ....
}
vertical_data {              // the vertical geometry
    ....
}
```

For information on *vertical_parts,* go to the section Vertical_parts
vertical_data Vertical_data

Vertical_parts

The *vertical_parts* block describes the methods used to construct the vertical geometry of the super alignment. The parts that make up the vertical geometry are defined in chainage order from the start to the end of the super alignment.

```
vertical_parts {             // methods for creating the vertical geometry
    blocks defining the sequential parts
    making up the vertical geometry
}
```

Apart from the special case of parts defined by vertical intersection points and their accompanying parabolas and arcs, the other parts in the *vertical_parts* block are undocumented.

Vertical_parts for defined by IP Method Only

For a vertical intersection point (VIP) with no parabola or arc defined at that VIP, the part is defined by:

```
ip {
        id   value    // part id - a number that is unique for each horizontal and vertical part,
                      // and the value of part id is a multiple of 100
        x    value    // chainage co-ordinate of the VIP
        y    value    // height co-ordinate of the VIP
}
```

For a vertical intersection point (VIP) with a parabola defined by a k value at that VIP, the part is defined by

```
kvalue {
        id   value    // part id - a number that is unique for each horizontal and ver-
```

```
tical part,
                          // and the value of part id is a multiple of 100
            k    value    // k-value of the parabola at the VIP
            x    value    // chainage co-ordinate of the VIP
            y    value    // height co-ordinate of the VIP
    }
```

For a vertical intersection point (VIP) with a parabola defined by length at that VIP, the part is defined by

```
    length {
            id   value    // part id - a number that is unique for each horizontal and ver-
tical part,
                          // and the value of part id is a multiple of 100
            l    value    // length of the parabola at the VIP
            x    value    // chainage co-ordinate of the VIP
            y    value    // height co-ordinate of the VIP
    }
```

For a vertical intersection point (VIP) with a parabola defined by an effective radius at that VIP, the part is defined by

```
    radius {
            id   value    // part id - a number that is unique for each horizontal and ver-
tical part,
                          // and the value of part id is a multiple of 100
            r    value    // effective radius of the parabola at the VIP
            x    value    // chainage co-ordinate of the VIP
            y    value    // height co-ordinate of the VIP
    }
```

For a vertical intersection point (VIP) with an asymmetric parabola defined by the start and end lengths at that VIP, the part is defined by

```
    length {
            id   value    // part id - a number that is unique for each horizontal and ver-
tical part,
                          // and the value of part id is a multiple of 100
            l1   value    // start length of the asymmetric parabola at the VIP
            l2   value    // end length of the asymmetric parabola at the VIP
            x    value    // chainage co-ordinate of the VIP
            y    value    // height co-ordinate of the VIP
    }
```

For a vertical intersection point (VIP) with an arc defined by a radius at that VIP, the part is defined by

```
    arc {
            id   value    // part id - a number that is unique for each horizontal and ver-
tical part,
                          // and the value of part id is a multiple of 100
            r    value    // radius of the arc at the VIP
            x    value    // chainage co-ordinate of the VIP
            y    value    // height co-ordinate of the VIP
    }
```

Hence a super alignment with vertical geometry defined by IP methods only would consist of a vertical_parts section with only the above ip, parabola and arc blocks in it.

```
vertical_parts {

  ip_parabola_arc {
                    values          // values defining the ip_parabola_arc block
                    "
                    values
  }
     ....
  ip_parabola_arc {
                    values          // values defining the ip_parabola_arc block
                    "
                    values
  }
}
```

For example,

```
vertical_parts {
  ip {
    id 600
    x -50.8459652
    y 159.79764161
  }
  kvalue {
    id 700
    k 1.25
    x 38.4627
    y 179.2126
  }
  length {
    id 800
    l 50
    x 172.61694837
    y 154.72967932
  }
  asymmetric {
    id 900
    l1 25
    l2 75
    x 270.0182
    y 208.1493
  }
  arc {
    id 1000
    r 1000
    x 424.2402
    y 196.5637
  }
  radius {
    id 1100
    r 200
    x 526.7263
    y 201.5302
  }
  ip {
    id 1200
    x 637.69216273
    y 198.71894484
  }
}
```

1st VIP
VIP only

Unique Part id
incrementing by 100

2nd VIP
Parabola defined
by k value

3rd VIP
Parabola defined
by length

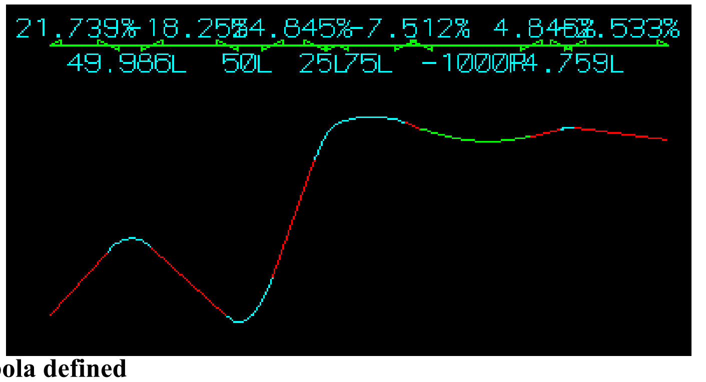
4th VIP
Asymmetric parabola defined
by two lengths

5th VIP
Arc with radius

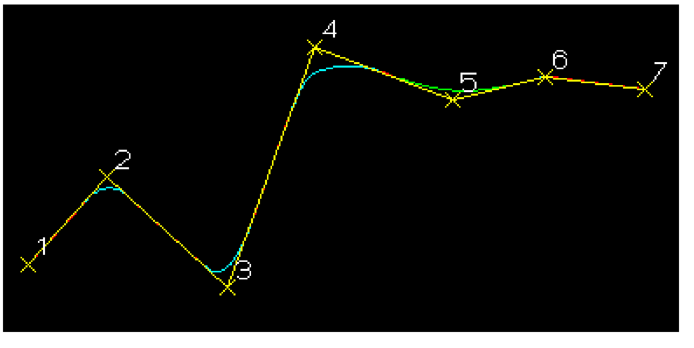
6th VIP
Parabola defined
by effective radius

7th VIP
VIP only

Section View of Super Alignment



Vertical Geometry Being Edited



Vertical Parts with IP Methods Only

Vertical_data

The *vertical_data* block contains the *solved* vertical geometry of the super alignment.

The *solved vertical geometry* is made up of a series of (chainage,height) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, a parabola or an arc.

If the vertical geometry has n vertices, then there will be (n-1) segments for an *open* super alignment or n segments if the super alignment is *closed*.

The format of the *vertical_data* block is:

```
vertical_data {
```

```
name       ""
chainage   value
breakline  line or point
colour     colour
style      linestyle
closed     0 or 1                 // 0 if the string is open, 1 if it is closed
interval {
  chord_arc    value              // chord-to-arc tolerance for curves
  distance     value              // chainage interval to break the geometry up
}

data_2d {
           ch1-value   ht1-value        // co-ordinates of the first vertex
           ch2-value   ht2-value        // co-ordinates of the second vertex
              "           "
              "           "
           chn-value   htn-value        // co-ordinates of the n-th vertex
}

geometry_data {
  segment_info_1 {
    information on the first segment
  }
  segment_info_2 {
    information on the second segment
  }
      "    "
      "    "
  segment_info_n-1 {              // the last segment if it is open
    information on the (n-1) segment
  }
  segment_info_n {                // the last segment if it is closed
    information on the n-th segment
  }
}
```

where the *segment_info* blocks are from the following:

(a) Straight

No parameters are needed for defining a straight segment. The *straight* block is simply:

```
straight {                        // no parameters are needed for a straight
}
```

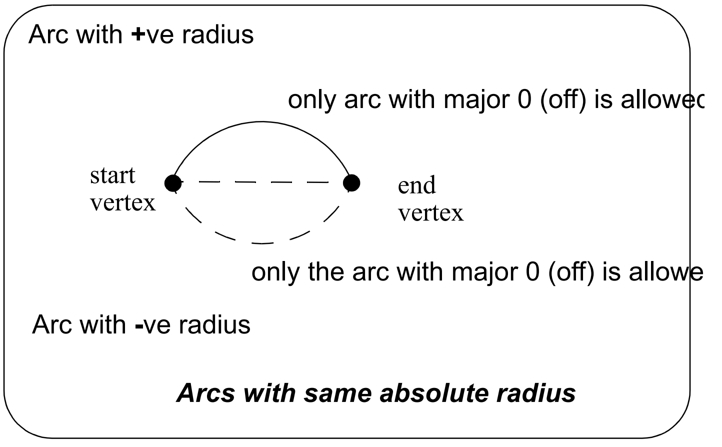
(b) Arc

Since vertical geometry can't go backwards in chainage value, the majors arcs can not be used and hence there are only possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius to differentiate between the four possibilities.

So the *arc* block is:

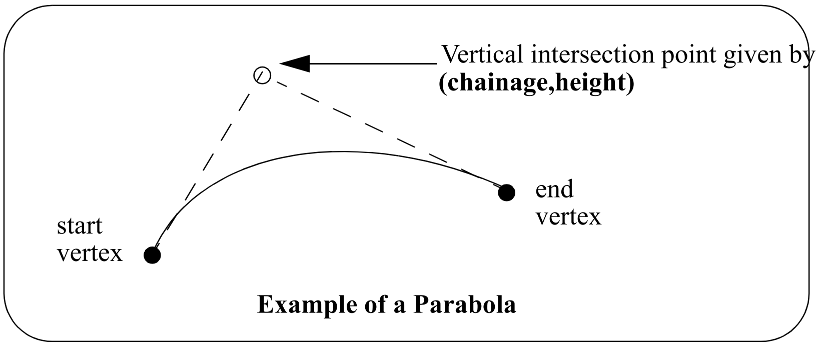
```
arc {
  radius value     // radius of the arc (+ve is above the line connecting vertices)
  major  value     // this is ignored since only minor arcs are used
}
```



(c) Parabola

There can be a parabola between adjacent vertices. The parabola is defined by giving the co-ordinates of the vertical intersection point for the parabola

chainage	chainage of the VIP of the parabola
height	height of the VIP of the parabola



The parameters for the *parabola* block are:

```
parabola {
  chainage      value        // chainage of the VIP of the parabola
  height        value        // height of the VIP of the parabola
}
```

Continue to the next section 34.4.10 Text String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.10 Text String

```
string  text {
  x value   y value   z value
  model model_name   name string_name   colour colour_name
  text text_value
  angle value   offset value   raise value
  textstyle textstyle_name   slant degrees   xfactor value
  worldsize value or papersize value or screensize value
  justify   "top|middle|bottom-left|centre|right"
}
```

The string types in the following sections have been superceded.

Continue to the next section 34.4.11 2d String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.11 2d String

The 2d string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```
string 2d {
  z   value    chainage   start_chainage
  model   model_name  name   string_name
  colour   colour_name    style   style_name
  breakline point or line
  data {                                        // keyword
    x-value    y-value
       "          "
       "          "
  }
}
```

Continue to the next section 34.4.12 3d String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.12 3d String

The 3d string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```
string 3d {
  chainage start_chainage
  model model_name   name   string_name
  colour colour_name   style style_name
  breakline point or line
  data {                                        // keyword
    x-value     y-value     z-value
       "           "           "
       "           "           "
  }
}
```

Continue to the next section 34.4.13 4d String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.13 4d String

The 4d string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```
string 4d {
  angle value   offset value   raise value
  worldsize value or papersize value or screensize value
  chainage start_chainage
  model model_name   name string_name
  colour colour_name   style style_name
  breakline point or line
  textstyle text   slant degrees   xfactor value
  justify    "top|middle|bottom-left|centre|right"
  data {                                          // keyword
    x-value   y-value    z-value    text          // text can not be blank
      "         "          "          "           // use "" for no text.
      "         "          "          "
  }
}
```

Continue to the next section 34.4.14 Pipe String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.14 Pipe String

The pipe string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```
string pipe {
  diameter value  chainage start_chainage
  model model_name  name string_name
  colour colour_name  style style_name
  breakline point or line
  data {                                        // keyword
    x-value  y-value  z-value
       "        "        "
       "        "        "
  }
}
```

Continue to the next section 34.4.15 Polyline String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.15 Polyline String

The polyline string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a polyline string, being closed is a property of the string and no extra vertex is needed - the first and the last vertices are not the same and the polyline string knows there is an additional segment from the last vertex back to the first vertex.

In the 12da format, there is a new *closed* flag for the polyline string:

closed *true* or *false*

where *true* can be 1 or T or t or Y or y (or words starting with T, t, Y or y))
and *false* is 0 or F or f or N or n (or words starting with F, f, N or n.

```
string polyline {
  chainage start_chainage
  model model_name   name string_name
  colour colour_name   style style_name
  breakline point or line
  closed true or false

  data {                                         // keyword
    x-value    y-value    z-value    radius  bulge_flag
       "          "          "
       "          "          "
  }
}
```

Continue to the next section 34.4.16 Alignment String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.16 Alignment String

The alignment string has been superceded and has been replaced by the super alignment (see 34.4.9 Super Alignment String).

In an alignment string the horizontal and vertical geometry are given separately and both can only be defined by the intersection point method (IP's).

For the horizontal geometry, the (x,y) position of the horizontal intersection points (HIPs) are given in the order that they appear in the string, plus the circular radius and left and right transition lengths on each HIP.

Hence a horizontal intersection point is given by either

```
x-value    y-value    radius        // circular curve, no transition
```

or

```
x-value  y-value  radius  spil1  left-transition-length   spil2  right-transition-length
```

radius, left-transition-length, right-transition-length can be zero (meaning they don't exist).

For the vertical geometry, the (chainage,height) position of the vertical intersection points (VIPs) are given in increasing chainage order, plus either the radius of the circular arc or the length of the parabolic curve on each VIP.

Hence for a vertical intersection point is given by either

```
ch_value    z-value    length   parabola
```

or

```
ch_value    z-value     radius    circle
```

where

the word *parabola* is optional. *length* and *radius* can be zero, meaning that the parabola or arc doesn't exist.

```
string alignment {
  model model_name   name string_name
  colour colour_name   style style_name
  chainage start_chainage   interval value
  draw_mode value              // 1 to draw crosses at HIPs and VIPs, 0 don't draw
  spiral_type text             // spiral_type covers both spiral and non-spiral transitions.
                               // For an alignment string, the supported transition types
                               // are clothoid, cubic parabola, westrail-cubic, cubic spiral
                               // More transition are supported in the super alignment
                               //
  hipdata {                    //  some hips must exist and precede the VIP data
    x-value y-value   radius                                   // or
    x-value y-value   radius   spil1  left-transition-length   spil2   right-transition-length
      "        "        "        "      "                       "         "
  }
  vipdata {                                                    // vips optional
    ch_value    z-value    parabolic-length                    // or
    ch_value    z-value    parabolic-length         parabola   // or
    ch_value    z-value    radius                   circle
       "           "          "           "
  }
}
```

Continue to the next section 34.4.17 Pipeline String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

34.4.17 Pipeline String

The pipeline string has been superceded and has been replaced by the super alignment (see 34.4.9 Super Alignment String).

This is the same as an alignment string except that it has the additional keywords

diameter, which gives the diameter of the pipeline in world units

and

length of the typical pipe making up the pipeline (used for deflections).

```
string pipeline {
  model model_name   name string_name
  colour colour_name   style style_name
  diameter diameter   length pipe-length
  chainage start_chainage   interval value
  spiral_type text            // spiral_type covers both spiral and non-spiral transitions
                              // supported by 12d. For an alignment string, the
                              // supported transition types are clothoid, cubic parabola,
                              // westrail-cubic, cubic spiral. Other transition types
                              // are supported in the super alignment
  hipdata {                   // some hips must exist and precede vips
   x-value y-value   radius                       // or
   x-value y-value   radius   spil1 left-transition-length   spil2   right-transition-length
      "       "        "        "    "                 "         "
  }
  vipdata {                                       // vips optional
    ch-value   z-value   parabolic-length         // or
    ch-value   z-value   parabolic-length   parabola // or
    ch-value   z-value   radius   circle
       "         "         "        "
  }
}
```

Return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.

35 12d XML File Format

Extensible Markup Language (***XML***) is a markup language that defines a set of rules for encoding documents in a format which is both human-readable and machine-readable. It is defined by the ***World Wide Web Consortium's*** (***W3C***) XML Specifications which are free open standards.[

The 1***2d XML*** file format is a text file definition from ***12d Solutions*** which is used for reading and writing out string data from ***12d Model***. 12d XML files normally end in **.12dxml**.

The ***12d XML*** file is a **Unicode** file.

This document is for the ***12d XML*** file format used in ***12d Model*** *Version 11*.

For general comments see:

For the 12d XML definitions see:

For documentation on the ***12d Archive*** (***12da***) file format, see 34 12d Archive File Format.

35.1 General Information about XML

(Unicode) Character

By definition, an XML document is a string of characters. Almost every legal Unicode character may appear in an XML document.

Markup and Content

The characters making up an XML document are divided into ***markup*** and ***content***, which may be distinguished by the application of simple syntactic rules.

Generally, strings that constitute markup either begin with the character **<** and end with a **>**, or they begin with the character **&** and end with a **;**.

Strings of characters that are not markup are content.

However, in a CDATA section, the delimiters <![CDATA[and]]> are classified as markup, while the text between them is classified as content. In addition, whitespace before and after the outermost element is classified as markup.

Characters "<", ">" and "&"

The characters "<", ">" and "&" are key syntax markers and may never appear in content outside a CDATA section. They need to be represented by special escape sequences:

&lt represents "<"

&gt represents ">"

&amp represents "&"

Tag

An XML tag is a markup construct that begins with **<** and ends with **>**.

Tags come in three flavours:

(a) start-tags - for example: <section>

(b) end-tags - for example: </section>

(c) empty-element tags - for example: <line-break />

XML Element

A logical document component which either begins with a start-tag and ends with a matching end-tag or consists only of an empty-element tag.

The characters between the start- and end-tags, if any, are the element's content, and may contain markup, including other elements, which are called child elements.

An example of an element is **<Greeting>**Hello, world.**</Greeting>**.

Another is **<**line-break **/>**.

Note: Because elements are ***12d Model*** items that are in a model, in the documentation of 12d XML we will refrain from using element for the element in XML. Instead we will use the words ***keyword block*** to refer to special XML Elements in 12d XML.

Empty XML Elements <keyword/>

When an XML element has no content it is called an **empty** element.

For example <name> </name>

There is special shorthand for empty elements:

<keyword/> is shorthand for **<keyword></keyword>**

XML Attribute

A markup construct consisting of a name/value pair that exists within a start-tag or empty-element tag. In the example (below) the element **img** has two attributes, **src** and **alt**:

<img src="madonna.jpg" alt='Foligno Madonna, by Raphael' **/>**

Another example would be

<step number="3">Connect A to B.**</step>**

where the name of the attribute is "number" and the value is "3".

An XML attribute can only have a single value and each attribute can appear at most once on each element.

Note: Because attributes are fundamental ***12d Model*** items, in the documentation of 12d XML the word attribute will refer to ***12d Model*** attributes.

The words **XML attribute** will always be used when there is need to refer to an XML attribute.

XML declaration

XML documents may begin by declaring some information about themselves, as in the following example:

<?xml version="1.0" encoding="UTF-8"?>

Escaping

XML provides escape facilities for including characters which are problematic to include directly. For example:

There are five predefined entities:

&lt represents "<"

&gt represents ">"

&amp represents "&"

&apos represents '

&quot represents "

**
** represents a new line.

XML Comments

Comments may appear anywhere in a document outside other markup. Comments cannot appear before the XML declaration.

Comments start with "**<!--**" and end with "**-->**".

For compatibility with SGML, the string "--" (double-hyphen) is not allowed inside comments; this means comments cannot be nested.

The ampersand has no special significance within comments, so entity and character references are not recognized as such, and there is no way to represent characters outside the character set of the document encoding.

An example of a valid comment: "<!--no need to escape <code> & such in comments-->"

Continue to the next section 35.2 General Information about a 12d XML File or return to 35 12d XML File Format.

35.2 General Information about a 12d XML File

Unicode

12d XML file is a Unicode file.

Blank lines

Unless they are part of a string of characters making up text, blank lines are ignored.

Names of models, tins, styles, colours and attributes

Models, tins, styles (linestyles), colours and attributes can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters) and space. Leading and trailing spaces are ignored. The names can be up to 255 characters in length.

The names for models, tins, styles, colours or attributes can not be blank.

The names for models, tins, styles and colours can contain upper and lower alpha characters which are stored, but the set of model names, tin names, style names, colour names or attribute names for an object *must be unique when case is ignored*. For example, the model name "Fred" will be stored as "Fred" but "FRED" is considered to be the *same* model name as "Fred".

String names

String names can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters), space, decimal point (.), plus (+), minus (-), comma (,), open and closed round brackets and equals (=).

Leading and trailing spaces are ignored.

String names do not have to be unique and can be blank.

String names can contain upper and lower alpha characters which are retained but case is ignored when selecting by string name. That is, the string name **Fred** will be stored as **Fred** but **FRED** is not considered to be a different string name.

Keywords Blocks

There are many regularly used blocks of information in 12d XML that are identified and documented by keywords.

The keyword and its block consist of a starting **<keyword>**, followed by the information in the keyword block, and ending in **</keyword>**

That is

<keyword> information in the keyword block **</keyword>**

Continue to the next section 35.3 Regularly Used Keyword Blocks or return to 35 12d XML File Format.

35.3 Regularly Used Keyword Blocks

In the documentation of ***12d XML*** the term ***keyword* block** refers to a ***<keyword>*** followed by various information then a ***</keyword>****.*

For the definition of some of the regularly used keyword blocks used in the 12d XML *see*:

Or return to 35 12d XML File Format.

35.3.1 Name

The format of the **name** keyword block is:

<name>*name_text*</name>

where ***name_text*** is a string of characters.

What characters can be in the name depends on where the name is used. See Names of models, tins, styles, colours and attributes and String names.

Continue to the next section 35.3.2 Colour or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.2 Colour

The format of the **colour** keyword block is:

<colour>*colour_name*</colour>

where ***colour_name*** is a string of characters that is to be the name of a colour or the colour number.

When reading a 12d XML file, there is a ***current colour,*** which has the default value of ***red***, and when a **colour** command is read, the ***current colour*** is set to *colour_name.*

When strings are read in a 12d XML file, they are given the *current colour*.

This can be overridden for a string by a *string colour command* inside the string command defining that string. For the definition of the string commands, see 35.6.3 String Header Block.

Continue to the next section 35.3.3 Line Style or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.3 Line Style

The format of the **line style** keyword block is:

<style>*line_style_name*</style>

where *line_style_name* is the name of a line style. It is a string of characters.

When reading a 12d XML file, there is a ***current linestyle,*** which has the default value of ***1***, and when a **style** command is read, the ***current linestyle*** is set to *linestyle_name.*

When strings are read in a 12d XML file, they are given the *current linestyle*.

This can be overridden for a string by a *string style command* inside the string command defining that string. For the definition of the string command, see 35.6.3 String Header Block.

Continue to the next section 35.3.4 Chainage or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.4 Chainage

The format of the **chainage** keyword block is:

<chainage> *chainage_real* </chainage>

where *chainage_real* is a real value.

Continue to the next section 35.3.5 Weight or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.5 Weight

The format of the **weight** keyword block is:

<weight> *weight_real* </weight>

where *weight_real* is a real value.

Continue to the next section 35.3.6 Interval or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.6 Interval

For all elements other than the super string, the format of the **interval** keyword block is:

<interval> *interval_real* </interval>

where *interval_real* is a real value.

For a super string, the format of the **interval** keyword block is:

<interval>

<chord_arc> chord_arc_real</chord_arc>

<distance> distance_real</chord_arc>

</interval>

where *chord_arc_real and distance_real* are real values.

Continue to the next section 35.3.7 Time Created or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.7 Time Created

The format of the **time_created** keyword block is:

<time_created>*time_text*</time_created>

where ***time_text*** is a string of characters in the W3C time format.

DD-*MMM*-*YYYY*T*hh*:*mm*:*ss*Z

and

dd in the day of the month

MMM in the first three letters of the month

YYYY in the year

hh in the hour in the 24-hour clock

mm in the number of minutes

ss in the number of seconds

For example, 28-Apr-2015T06:42:45Z

Continue to the next section 35.3.8 Time Updated or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.8 Time Updated

The format of the **time_updated** keyword block is:

<time_updated>*time_text*</time_updated>

where ***time_text*** is a string of characters in the W3C time format.

DD-*MMM*-*YYYY*T*hh*:*mm*:*ss*Z

and

dd in the day of the month

MMM in the first three letters of the month

YYYY in the year

hh in the hour in the 24-hour clock

mm in the number of minutes

ss in the number of seconds

For example, 28-Apr-2015T06:42:45Z

Continue to the next section 35.3.9 Breakline or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.9 Breakline

The format of the **breakline** keyword block is:

<breakline> *breakline_type_text* </breakline>

where ***breakline_type_text*** is text and can only have the values ***point*** or ***line***.

When reading a 12d XML file, there is a ***current breakline type,*** which has the default value of ***point***, and when a **breakline** command is read, the ***current breakline type*** is set to *breakline_type_text.*

When strings are read in a 12d XML file, they are given the *current breakline type*.

This can be overridden for a string by a *string breakline command* inside the string command defining that string. For the definition of the string command, see 35.6.3 String Header Block.

Continue to the next section 35.3.10 Null or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.10 Null

NOT CERTAIN ABOUT NULL ??

The format of the **null** command is:

null *null_value*

When reading a 12d XML file, there is a ***current null value,*** which has the default value of ***-999***, and when a **null** command is read, the ***current null value*** is set to *null_value.*

When strings are read in a 12d XML file and the string has z-values equal to *null_value*, then the z-value is replaced by the ***12d Model*** null value.

This can be overridden for a string by a *null_value command* inside the string command defining that string. For the definition of the string command, see 35.6.3 String Header Block.

Continue to the next section 35.3.11 Radius or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

Continue to the next section 35.4 Attributes or return to 35 12d XML File Format.

35.3.11 Radius

The format of the **radius** keyword block is:

<radius> *radius_real* </radius>

where *radius_real* is a real value.

Continue to the next section 35.3.12 data_2d or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.12 data_2d

For some strings, there is a constant z for the entire string, or even no z value at all. For such strings only the (x,y) coordinates are required for each vertex and no space is taken up by redundant z values. Vertex data with no z-values is written out in a ***data_2d*** block.

The definition of a ***data_2d*** block is:

<data_2d>

<p>*x_value_1 y_value_1***</p>**

<p>*x_value_2 y_value_2***</p>**

...

<p>*x_value_n y_value_n***</p>**

</data_2d>

where (x_value_i, y_value_i) are the 2D coordinates of the i'th vertex.

Continue to the next section 35.3.13 data_3d or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.13 data_3d

For most string, the z value can vary for each vertex along the string and so the (x,y,z) values are required for each vertex. This vertex data is written out as a ***data_3d*** block.

The definition of a ***data_3d*** block is:

```
<data_3d>
    <p>x_value_1    y_value_1    z_value_1</p>
    <p>x_value_2    y_value_2    z_value_2</p>
        ...
    <p>x_value_n   y_value_n    z_value_n</p>
</data_3d>
```

where (x_value_i, y_value_i, z_value_i) are the 3D coordinates of the i'th vertex.

For example, for a string of 5 vertices

```
<data_3d>
  <p>42578.27649249 37366.79821468 null</p>
  <p>42523.36402317 37252.26649295 null</p>
  <p>42575.1386371 37043.59910954 null</p>
  <p>42826.16706828 37026.34090489 null</p>
  <p>42766.49603263 37412.54781911 61.53707464</p>
</data_3d>
```

35.3.14 radius_data and major_data

If there are only straight and arc segments for the string, then for either **data_2d** or **data_3d**, it is possible to add a radius and major/minor arc flag for each segment of the string using the ***radius_data*** and **major_data** blocks respectively.

The order of the entries in the *radius_data* and *major_data* blocks must match the order of the segments in the string (which is also the order in the data_2d or data_3d block).

So there is exactly one entry for each segment.

Note: If there are n vertices in the super string, then there are (n-1) segments for a open string (not closed) and n segments for a closed string.

For each segment there are five possibilities for an arc going between the vertices and these are specified by using **positive**, **zero** or **negative** values for the **radius**, and **1** or **0** for the **major flag**.

1. Straight segment - radius = 0. Major flag can be 1 or 0.
2. Positive radius and major flag 0

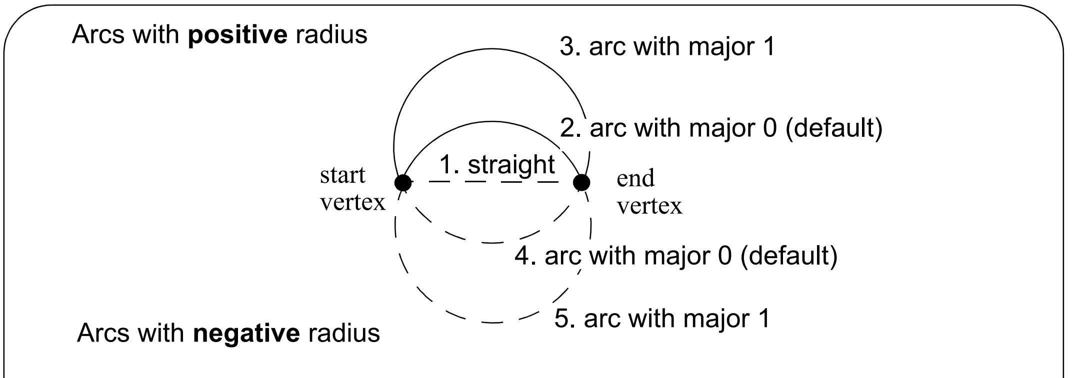
   The arc is above the straight line joining the two vertices but the arc is the smaller of the two possibilities (minor arc).
3. Positive radius and major flag1

   The arc is above the straight line joining the two vertices but the arc is the larger of the two possibilities (major arc).
4. Negative radius and major flag 0

   The arc is below the straight line joining the two vertices but the arc is the smaller of the two possibilities (minor arc).
5. Negative radius and major flag1

   The arc is below the straight line joining the two vertices but the arc is the larger of the two possibilities (major arc).

,



Arcs with same absolute radius but with major 1 or 0

The ***radius_data*** block is

<radius_data>

radius_for_segment_1

radius_for_segment_2

...

radius_for_segment_m

</radius_data>

where

radius_for_segment_i is the radius for the i'th segment and can be positive, zero or negative, and

m = n-1 for an open string or m = n for a closed string.

If the ***radius_block*** is missing then the radius is taken to be 0 and all the segments are straight lines.

The ***major_data*** block is

<major_data>

major_flag_for_segment_1

major_flag_for_segment_2

...

major_flag_for_segment_m

</major_data>

where

major_flag_for_segment_i for the i'th segment is 1 or t if the arc is a major arc, and 0 or f if it is a minor arc, and

m = n-1 for an open string or m = n for a closed string.

If the ***major_block*** is missing then the major flag is taken to be 0 and any segments with arcs are always the minor arcs.

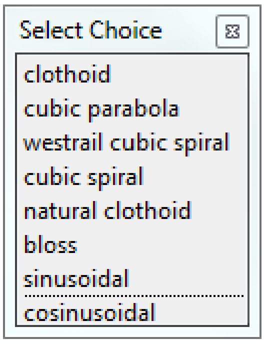
For example, for a closed string of five vertices

```
<radius_data>
    100 -300 0 0 0
</radius_data>
<major_data>
    f f f f f
```

```
</major_data>
```

35.3.15 Available Transition Types

The transition that are available are



where

clothoid, (or **spiral**) is the spiral approximation used by Australian road authorities and Queensland Rail

cubic parabola (or **state wide rail nsw**) is a special transition curve used by NSW Railways. It is not a spiral.

westrail cubic spiral (or **westrail-cubic)** is a spiral approximation used by WA railways.

cubic spiral (or **spiral**) is a low level spiral approximation. Mainly only used in surveying textbooks.

natural clothoid (or landxml spiral or clothoid landxml) is the full Euler spiral. Not used by any Authority in Australia or New Zealand.

bloss is a Bloss curve.

sinusoidal is a sinusoidal curve.

cosinusoidal is a cosinusoidal curve.

35.4 Attributes

Many *12d* ***Model*** objects (models and elements such as individual strings and tins) can have an unlimited number of named **attributes** of type integer (numbers), real and text. Super strings and drainage strings can also have attributes on each vertex and segment.

The attributes for an object are given in an ***attributes block*** which consists of the keyword **attributes** followed by the definitions of the *individual attributes* enclosed in start and end curly braces { and }. That is, an ***attributes_block*** is

<attributes>

attribute_1

attribute_2

...

attribute_n

</attributes>

where the attribute definitions for the individual attributes *attribute_i* consists of

<attribute_type>

<name> *attribute_name* ***</name>*** ***<value> attribute_value </value>***

</attribute_type>

where

attribute_type is **integer**, **real** or **text**

attribute_name is the unique attribute name for the object.

and

attribute_value is the appropriate value of the integer, real or a text.

OR

where *attribute_type* is **group**

<group>

<name> *group_name* ***</name>*** ***attributes_block***

</group>

where

group_name is the unique name of the group at this level

and

attributes_block is another attributes_block.

Note that the definition of **<group>** includes an attribute_block which can contain another **<group>** so the definition is recursive.

Hence you can have a hierarchy or tree of attributes going down to any level.

Within an object, the attribute names are case sensitive and must be unique. That is, for attribute names, upper and lower case alphabet characters are considered to be different characters.

An example of and ***attribute block*** defining four attributes named "pole id", "street", "pole height" and "pole wires" is:

```
<attributes>
  <text> <name>pole id</name> <value>QMR-37</value> </text>
  <text> <name>street</name> <value>477 Boundary St</value> </text>
```

```
  <real> <name>pole wires</name> <value>3</value> </text>
</attributes>
```

Continue to the next section 35.5 Model or return to 35 12d XML File Format.

35.5 Model

Within a ***12d Model*** project, information is collected in units called **MODELS**. The items that can be stored in a model are called elements and elements include strings, tins, super tins, grid tins, trimeshes and plot frames.

Each model has a unique user-defined text name, ***model_name***, of up to two hundred alphanumeric characters and spaces.

The format for the **model** keyword block is:

<model>

<name>*model_name*</name>

attribute_block

time_created_block

time_updated_block

<children>

element_data_1

...

element_data_n

</children>

</model>

where:

model_name is a string of characters for the model name. For the characters allowed, see

attribute_block is option. For *attributes_block* see 35.4 Attributes.

time_created_block is optional. See 35.3.7 Time Created.

time_updated_block is optional. See 35.3.8 Time Updated.

element_data_i is an element stored in the model. See35.6 Elements Contained in Models.

The ***children*** block is ***optional*** and is mainly there so that in an xml editor, the *element_data_i* items can be collapsed into the ***children*** section.

An example of a model with no elements and no *children* block:

```
<model>
  <name>telegraph poles,/name>

  <attributes>
    <text> <name>pole id</name> <value>QMR-37</value> </text>
    <text> <name>street</name><value>477 Boundary St</value></text>
    <real> <name>pole wires</name> <value>3</value> </text>
  </attributes>
</model>
```

Continue to the next section 35.6 Elements Contained in Models or return to 35 12d XML File Format.

35.6 Elements Contained in Models

See

35.6.1 Tin

A *tin* (***t****riangulated* ***i****rregular* ***n****etworks*) is an element that may, or may not, be in a model.

Each tin has text name, ***tin_name***, of up to two hundred alphanumeric characters and spaces and the names of each tin and super tin in the project must be unique.

The format for the **tin** element is:

<tin>

<name>*tin_name***</name>**

attribute_block

time_created_block

time_updated_block

colour_block

points_block

triangles_block

colours_block

input_block

</tin>

where

tin_name

is a string of characters for the tin name and can't be blank. This must be unique in a project.

For the characters that can make up a tin_name, see Names of models, tins, styles, colours and attributes.

time_created_block

is the time the tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

colour_block

this colour number is the primary (base) colour for all the triangles in the tin. A triangle in the tin will have this colour unless it is overridden by a *colours_block*. For the syntax of colour_block, see 35.3.2 Colour.

attribute_block is optional: For the syntax of an *attributes_block* see 35.4 Attributes.

The attributes in this block and the attributes_block itself are optional.

The attributes **Style**, **Weed, Faces**, **Boundary_String**, **null_length**, **null_angle**, **null_combined_length** and **null_combined_angle** are special attributes that have extra information used by ***12d Model*** to create the tin. These special attributes should not be deleted.

The format of the special attributes inside the **<attributes> ... </attributes>** is:

```
<text> <name>Style</name> <value>style_name</value> </text>
<integer> <name>Weed</name> <value>weed_value</value> </integer>
<integer> <name>Faces</name> <value>faces_value</value> </integer>
<text> <name>Boundary_String</name><value>full_string_name</value></text>
<real> <name>null_length</name> <value>null_len_val</value> </real>
<real> <name>null_angle</name> <value>null_angle_rad</value> </real>
<real> <name>null_combined_length</name> <value>null_com_ln/value> <real>
```

```
<real> <name>null_combined_angle</name><value>null_com_rad</value></real>
```

where

style_name is the style for the tin

weed_value is 0 or 1

faces_value is 0 if the data is not from triangles, 1 if the data is from triangles

full_string_name is the name of a polygon for nulling outside. This is optional.

null_len_val is value for nulling by angle

null_angle_rad is in radians value for nulling by angle

null_com_ln is for nulling by combined angle and length

null_com_rad is in radians for nulling by combined angle and length

points_block

This gives the coordinates of the points that will be vertices of the triangles in the tin. The points are implicitly numbered by the order in the list (starting at point 1). The Points Block is MANDATORY.

<points>

<p>x_value_1 y_value_1 z_value_1</p>

<p>x_value_2 y_value_2 z_value_2</p>

...

<p>x_value_m y_value_m z_value_m</p>

</points>

where (x_value_j, y_value_j, z_value_j) are the coordinates of the j'th point.

triangles_block

This gives the triangles that make up the tin.

Each triangle is given as a triplet of the point numbers in the Points block that are the triangle vertices. The order of the triangles is unimportant. The Triangles Block is MANDATORY

<triangles>

<t>t1_pt_1 t1_pt_2 t1_pt_3</t>

<t>t2_pt_1 t2_pt_2 t2_pt_3</t>

...

<t>tn_pt_1 tn_pt_2 tn_pt_3</t>

</triangles>

where *tk_pt_1 tk_pt_2 tk_pt_3* are point numbers from the points_block of the three vertices of the k'th triangle.

colours_block

Triangles can be given colours other than the base colour by including a Colours Block. The colour for each triangle in then individually given where -1 means use the base colour. The order of the entries in the colours block must match the order of the triangles in the Triangles Block. So there is exactly one entry for each triangle

If all the triangles are the base colour, then the *Colours Block* is omitted.

<colours>

c1 c2 **...** *c15 c16*

c17 c18 **...** *c31 c32*

...

cn-2 cn-1 cn

</colours>

where **ck** is the colour number of the k'th triangle in the *triangles_block*.

ck equals -1 when there is no special colour set and the triangle is drawn in the base colour.

input_block

The *input_block* gives more information about how the tin was created by 12d Model.

None of this information is needed when reading a tin into 12d Model and the *input_ block* can be omitted.

<input>

<**preserve_strings**> *pres_str_text_logical* **</preserve_strings>**

<**remove_bubbles**> *rem_bub_text_logical* **</remove_bubbles>**

<**weed_tin**> *weed_tin_text_logical* **</weed_tin>**

<**triangle_data**> *triangle_data_text_logical* **</triangle_data>**

<**sort_tin>** *sort_tin_text_logical* **</sort_tin>**

<**cell_method>** *cell_method_text_logical* **</cell_method>**

<models>

model_name_1

model_name_2

...

model_name_p

</models>

</input>

where

pres_str_text_logical, rem_bub_text_logical, weed_tin_text_logical, triangle_data_text_logical, sort_tin_text_logical and *cell_method_text_logical* are text and can only have the values **true** or **false**.

<models> ... </models> is the list of models in the tin where

model_name_i is the name of the i'th model making up the tin.

Continue to the next section 35.6.2 Super Tin or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.6.2 Super Tin

A *Super Tins* consists of a number of **tins** (***t***riangulated ***i***rregular ***n***etworks).

Each super tin has text name, ***tin_name***, of up to two hundred alphanumeric characters and spaces and the names of each tin and super tin in the project must be unique.

The format for the **super_tin** element is:

<super_tin>

<name>tin_name</name>

attribute_block

time_created_block

time_updated_block

colour_block

exact_block

tins_block

</super_tin>

where

tin_name

is a string of characters for the super tin name and can't be blank. This must be unique in a project.

For the characters that can make up a tin_name, see Names of models, tins, styles, colours and attributes.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

colour_block

this colour number is the primary (base) colour for the super tin. For the syntax of colour_block, see 35.3.2 Colour.

attribute_block is optional: For the syntax of an *attributes_block* see 35.4 Attributes.

The attributes in this block and the attributes_block itself are optional.

The attribute **Style** is a special attribute that is used by ***12d Model*** to create the super tin. This special attribute should not be deleted.

The format of the **Style** attribute inside the <attributes> **...** </attributes> is:

<text> <name>**Style**</name> <value>*style_name*</value> </text>

where

style_name is the style for the super tin

exact_block

<exact> *exact_text_logical* **</exact>**

where

exact_text_logical is text and can only have the value **true** or **false**.

tins_block

This gives the tins that make up the super tin within the keyword block **tins**.

<**tins**>

tin_info_1

tin_info_2

...

tin_info_p

</**tins**>

where

there are p tins in the super tin and *tin_info_i* is information about the i'th tin. The information about a tin is contained in a **tin** block.

<**tin**>

<name> tin_name_i</name>

<active> active_text_logical</active>

<mode> mode_text_logical</mode>

</**tin**>

where

tin_name_i is the name of the i'th tin making up the super tin.

active_text_logical and *mode_text_logical* are text and can only have the value **true** or **false**.

For example

```
<super_tin>
  <name>super tin</name>
  <colour>green</colour>
  <attributes>
    <text> <name>Style</name> <value>1</value> </text>
  </attributes>
  <time_created>28-Apr-2015 06:42:45</time_created>
  <time_updated>28-Apr-2015 06:42:45</time_updated>
  <exact>true</exact>
  <tins>
    <tin>
      <name>DESIGN ALL</name>
      <active>true</active>
      <mode>replace</mode>
    </tin>
    <tin>
      <name>HILL</name>
      <active>true</active>
      <mode>replace</mode>
    </tin>
  </tins>
</super_tin>
```

Note that the tins that make up the super tin must exist in ***12d Model*** for the super tin to be fully defined.

Continue to the next section 35.6.3 String Header Block or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.6.3 String Header Block

Strings are special types of elements that reside in a model.

Strings have common header information and this will be documented in this one spot as a ***string_header_block***.

The format for the string_header_block is:

string_name_block

chainage_block

colour_block

style_block

weight_block

interval_block

time_created_block

time_updated_block

attribute_block

where

string_name_block

The format of the **string_name_block** is:

<name> *string_name_text* </name>

where

string_name_text is a string of allowable characters that is the name of the string.

For the characters that can make up a string_name, see String names.

Any leading and trailing spaces will be removed in the string name.

string_name can be blank.

An example of a string name is:

```
<name> design 100.0 </name>
```

chainage_block

is the start chainage of the string. This is optional. For the syntax see 35.3.4 Chainage.

colour_block

the colour name is the primary colour for the string. For the syntax of colour_block, see 35.3.2 Colour.

style_block

is the line style of the string. This is optional. For the syntax of style_block see 35.3.3 Line Style.

weight_block

is the weight (thickness) of the string. This is optional. For the syntax of weight_block see 35.3.5 Weight.

interval_block

the chainage interval to temporarily introduce extra vertices into the string when the string is in a triangulation to form a tin. For the syntax of interval_block, see 35.3.6 Interval.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax of time_created_block see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax of time_updated_block see 35.3.8 Time Updated.

attribute_block

The string attributes are in this block. For the syntax of an *attributes_block* see 35.4 Attributes

The attributes_block is optional.

For example

string_header_block

```
<string_arc>
  <name>arc</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>yellow</colour>
  <style>1</style>
  <weight>2</weight>
  <time_created>28-Apr-2015 07:46:57</time_created>
  <time_updated>28-Apr-2015 07:46:57</time_updated>
  <interval>10</interval>
  <centre>1067.40263766 530.14953857 0</centre>
  <radius>226.6814323</radius>
  <chord_arc>0.1</chord_arc>
  <start>867.42825529 423.40349345 0</start>
  <end>1118.02452861 751.10631241 0</end>
</string_arc>
```

Continue to the next section 35.6.4 Text Information or return to 35.6 Elements Contained in Models or 35 12d XML File Format.

35.6.4 Text Information

See

35.6.4.1 Vertex Annotation Information
35.6.4.2 Segment Annotation Information

35.6.4.1 Vertex Annotation Information

The *vertex_annotation_information* is

<worldsize> *world_size_real* **</worldsize>**
<textstyle> *textstyle_name* **</textstyle>**
<angle> *angle_dec_deg_real* **</angle>**
<x_factor> *x_factor_real* **</x_factor>**
<slant> *slant_dec_deg_real* **</slant>**
<offset> *offset_real* **</offset>**
<raise> *raise_real* **</raise>**
<text_colour> text_colour_name **</text_colour>**
<justify> *text_justification_text* **</justify>**

where

world_size_real is the size of the text in world units.

textstyle_name is the name of the textstyle for the text.

angle_dec_deg_real is the angle of the text. The value is in decimal degrees and is measured in a counter clockwise direction from the positive x-axis.

x_factor_real is the factor to apply to the width of the text.

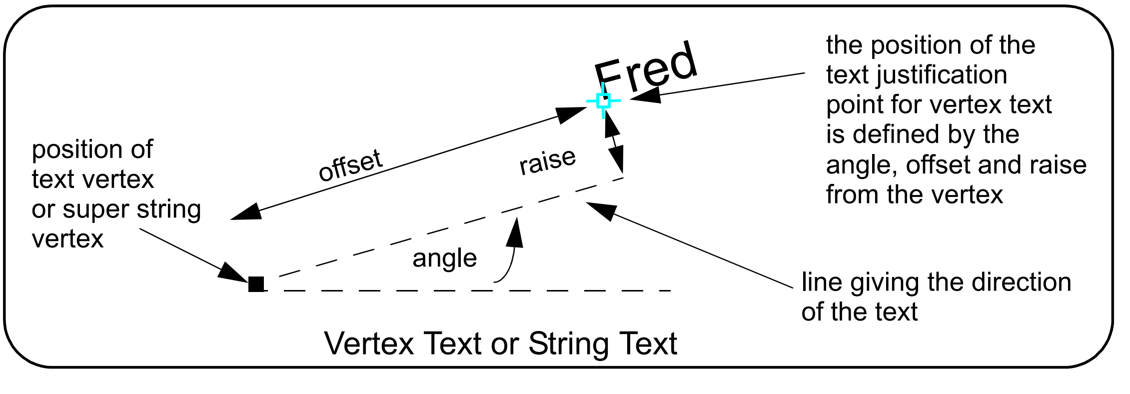
slant_dec_deg_real is the angle the text is slanted from the vertical. The value is in decimal degrees and is measured in a clockwise direction from the positive y-axis.

offset_real is distance to offset the text from the text vertex.

raise_real is the perpendicular distance the text is off the direction line of the text.

text_colour_name is the colour of the text. This should be the same as the colour in the *string_header_block*.For the syntax of colour_block, see 35.3.2 Colour.

text_justification_text is the text giving the justification point of the text.



35.6.4.2 Segment Annotation Information

The *segment_annotation_information* is

<worldsize> *world_size_real* **</worldsize>**

<textstyle> *textstyle_name* **</textstyle>**

<angle> *angle_dec_deg_real* **</angle>**

<x_factor> *x_factor_real* **</x_factor>**

<slant> *slant_dec_deg_real* **</slant>**

<offset> *offset_real* **</offset>**

<raise> *raise_real* **</raise>**

<text_colour> text_colour_name **</text_colour>**

<justify> *text_justification_text* **</justify>**

where

world_size_real is the size of the text in world units.

textstyle_name is the name of the textstyle for the text.

angle_dec_deg_real is the angle of the text. The value is in decimal degrees and is measured in a counter clockwise direction from the segment.

x_factor_real is the factor to apply to the width of the text.

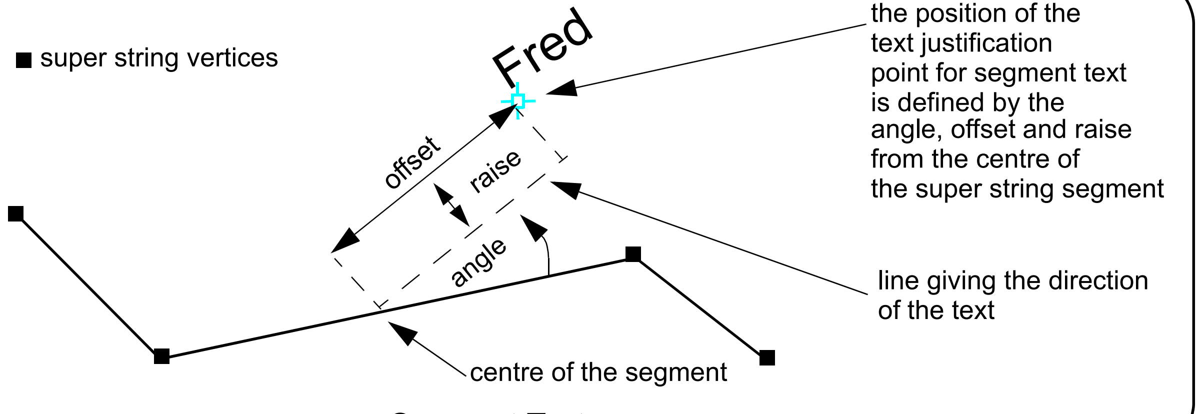
slant_dec_deg_real is the angle the text is slanted from the vertical. The value is in decimal degrees and is measured in a clockwise direction from the positive y-axis.

offset_real is distance to offset the text from the centre of the segment.

raise_real is the perpendicular distance the text is off the direction line of the text.

text_colour_name is the colour of the text. This should be the same as the colour in the *string_header_block*.For the syntax of colour_block, see 35.3.2 Colour.

text_justification_text is the text giving the justification point of the text.



Segment Text

35.6.5 Arc String

The format for the **string_arc** element is:

<string_arc>

string_header_block

centre_block

radius_block

chord_arc_block

start_block

end_block

</string_arc>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

centre_block

The format of the **centre_block** is:

<centre> *x_centre_real y_centre_real z_centre_real* </centre>

where

(*x_centre_real,y_centre_real,z_centre_real*) is the centre of the arc.

radius_block

the radius of the arc. For the syntax of radius_block, see 35.3.9 Breakline.

A positive radius means that the arc goes from the start point in a clockwise direction (goes to the right) and a negative radius means that the arc goes is in a counter clockwise direction (goes to the left).

chord_arc_block

The format of the **chord_arc_block** is:

<chord_arc>*chord_arc_real* </chord_arc>

where

chord_arc_real is a real number and is the chord to arc tolerance to use to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

start_block

The format of the **start_block** is:

<start> *x_start_real y_start_real z_start_real* </start>

where

(*x_start_real,y_start_real,z_start_real*) is the start coordinate of the arc.

end_block

The format of the **end_block** is:

<end> *x_end_real y_end_real z_end_real* </end>

where

(*x_end_real,y_end_real,z_end_real*) is the end coordinate of the arc.

For example

```
<string_arc>
  <name>arc</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>yellow</colour>
  <style>1</style>
  <weight>2</weight>
  <time_created>28-Apr-2015 07:46:57</time_created>
  <time_updated>28-Apr-2015 07:46:57</time_updated>
  <interval>10</interval>
  <centre>1067.40263766 530.14953857 0</centre>
  <radius>226.6814323</radius>
  <chord_arc>0.1</chord_arc>
  <start>867.42825529 423.40349345 0</start>
  <end>1118.02452861 751.10631241 0</end>
</string_arc>
```

Continue to the next section 35.6.6 Circle String or return to 35.6.3 String Header Block or 35 12d XML File Format.

35.6.6 Circle String

The format for the **string_circle** element is:

<string_circle>

string_header_block

centre_block

radius_block

chord_arc_block

</string_arc>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

centre_block

The format of the **centre_block** is:

<centre> *x_centre_real* *y_centre_real* *z_centre_real* </centre>

where

(*x_centre_real,y_centre_real,z_centre_real*) is the centre of the circle.

radius_block

the radius of the circle. For the syntax of radius_block, see 35.3.9 Breakline.

A positive radius means that the circle goes in a clockwise direction (goes to the right) and a negative radius means that the circle goes is in a counter clockwise direction (goes to the left).

chord_arc_block

The format of the **chord_arc_block** is:

<chord_arc>*chord_arc_real* </chord_arc>

where

chord_arc_real is a real number and is the chord to arc tolerance to use to temporarily insert vertices into the circle when the circle is included in a triangulation to form a tin.

For example

```
<string_circle>
  <name>circle</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>yellow</colour>
  <style>1</style>
  <weight>5</weight>
  <interval>10</interval>
  <time_created>28-Apr-2015 07:45:53</time_created>
  <time_updated>28-Apr-2015 07:46:23</time_updated>
  <centre>409.93551 548.76354 null</centre>
  <radius>100</radius>
  <chord_arc>0.1</chord_arc>
</string_circle>string circle
```

Continue to the next section 35.6.7 Drainage String or return to 35.6.3 String Header Block or 35 12d XML File Format.

35.6.7 Drainage String

The full 12dXML definition of the drainage string is:

<string_drainage>

string_header_block

outfall_block

flow_direction_block

use_pit_con_points_block

drainage_sewer_block

data_3d_block

radius_data_block

major_data_block

pit_records

pipe_records

</string_drainage>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

There are also some special attributes in the string attributes in the String Header Block that provide extra information for the drainage string.

outfall_block

<outfall> *outfall_real* **</outfall>**

where *outfall_real* is the z-value of the outfall (the low end of the string.

flow_direction_block

<flow_direction> *flow_direction_flag* **</flow_direction>**

where *flow_direction_flag* is **1** if the flow is the same as the string direction, or **0** if the flow is opposite to the string direction.

use_pit_con_points_block

<user_pit_con_points> *use_pit_connection_points_logical_text* **</user_pit_con_points>**

where *use_pit_connection_points_logical_text* is **true** if pit connection points are used, or **false** if pit connection points are not being used and hence the pipes go to the centre of he pits.

drainage_sewer_block

<drainage_sewer> *drainage_sewer_choice_text* **</drainage_sewer>**

where *drainage_sewer_choice_text* is **drainage** (storm water) if it is for drainage and **sewer** if it is for sewer (foul water).

data_3d_block, radius_data_block and major_data_block

the drainage string has an underlying string that is used to define locations of the pits and the geometry for the pipes. The underlying string can have straight and arc segments.

The vertex data for the underlying string is given in a **data_3d** block, and if there any arcs, then these are specified in **radius_data** and **major_data** blocks. See 35.3.13 data_3d and 35.3.14 radius_data and major_data.

pit_records

In plan the pits sit on the underlying string and there is one pit record for each pit. The pits do not have to be on a vertex of the underlying string.

There is one **pit** block for each pit in the string and they are in the order that they occur along the string.

The information for each **pit** is:

<pit>

<name> *pit_name_text* **</name>**

<type> *pit_type_text* **</type>**

<chainage> *pit_chainage_real* **</chainage>**

<ip> *pit_ip_text* **</ip>**

<ratio> *pit_ratio_real* **</ratio>**

<x> *pit_x_real* **</x>**

<y> *pit_y_real* **</y>**

<z> *pit_z_real* **</z>**

<road_chainage> *pit_road_chainage_real* **</road_chainage>**

<diameter> *pit_diameter_real* **</diameter>**

<width> *pit_width_real* **</width>**

<sump_level> *pit_sump_level_real* **</sump_level>**

<floating_sump> *pit_floating_sump_flag* **</floating_sump>**

<thickness> *pit_thickness_real* **</thickness>**

<thickness_bottom> *pit_thickness_bottom_real* **</thickness_bottom>**

<thickness_back> *pit_thickness_back_real* **</thickness_back>**

<thickness_left> *pit_thickness_left_real* **</thickness_left>**

<thickness_right> *pit_thickness_right_real* **</thickness_right>**

<con_point_mode> *pit_con_points_mode_text* **</con_point_mode>**

<floating> *pit_floating_logical_text* **</floating>**

<hgl> *pit_hgl_real* **</hgl>**

pit_attributes_block

</pit>

where

pipe_records

In plan the pipes sit on the underlying string and the plan geometry is based on the underlying string. Each pipe goes between two adjacent pits.

There is one **pipe** block for each pipe in the string and they are in the order that they occur along the string.

<pipe>

<name> *pipe_name_text* **</name>**

<type> *pipe_type_text* **</type>**

<colour> *pipe_colour_text* **</colour>**

<diameter> *pipe_diameter_real* **</diameter>**

<nominal_diameter> *pipe_nominal_diameter_real* **</nominal_diameter>**
<width> *pipe_width_real* **</width>**
<top_width> *pipe_top_width_real* **</top_width>**
<thickness> *pipe_thickness_real* **</thickness>**
<thickness_bottom> *pipe_thickness_bottom_real* **</thickness_bottom>**
<thickness_back> *pipe_thickness_back_real* **</thickness_back>**
<thickness_left> *pit_thickness_left_real* **</thickness_left>**
<thickness_right> *pipe_thickness_right_real* **</thickness_right>**
<separation> *pipe_separation_real* **</separation>**
<number_of_pipes> *pipe_number_of_pipes_integer* **</number_of_pipes>**
<us_level> *pipe_us_level_real* **</us_level>**
<ds_level> *pipe_ds_level_real* **</ds_level>**
<us_hgl> *pipe_us_hgl_real* **</us_hgl>**
<ds_hgl> *pipe_ds_hgl_real* **</ds_hgl>**
<flow_velocity> *pipe_flow_velocity_real* **</flow_velocity>**
<flow_volume> *pipe_flow_volume_real* **</flow_volume>**
pipe_attributes_block
</pipe>

```

}
```

```
}                    // end of drainage-sewer data
```

Continue to the next section 35.6.8 Feature String or return to 35.6.3 String Header Block or 35 12d XML File Format.

35.6.8 Feature String

The full 12dXML definition of the drainage string is:

<string_feature>

string_header_block

<radius> *feature_radius_real* **</radius>**

<centre> *x_centre_real y_centre_real   z_centre_real* **</centre>**

</string_feature>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

There are also some special attributes in the string attributes in the String Header Block that provide extra information for the drainage string.

feature_radius_real is the radius of the feature string.

(xcentre_real, y_centre_real, z_centre_real) is the centre of the feature string.

For example

```
<string_feature>
  <name>Line 1</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>cyan</colour>
  <style>1</style>
  <time_created>2015-05-19T08:06:01Z</time_created>
  <time_updated>2015-05-19T08:06:01Z</time_updated>
  <centre>42200.06055 37384.05873 null</centre>
  <radius>20</radius>
</string_feature>
```

Continue to the next section 35.6.9 Plot Frame String or return to 35.6.3 String Header Block or 35 12d XML File Format.

35.6.9 Plot Frame String

The format for the **string_plot_frame** element is:

<string_plot_frame>

info_block

time_created_block

time_updated_block

sheet_details_block

title_block_block

origin_block

scale_block

rotation_block

plotter_details_block

</string_plot_frame>

where

info_block

The format of the **info_block** is:

<info>

<name> *plot_frame_name_text*</name>

<colour> *plot_frame_name_colour_text*</colour>

<plot_file> *plot_file_name_text*</plot_file>

</info>

where

plot_frame_name_text is a string of allowable characters that is the name of the plot file string. For the characters that can make up a string_name, see String names.

plot_frame_colour_text is the colour of the plot frame. For the syntax of colour_block, see 35.3.2 Colour.

plot_file_name_text is the name of file that the plot frame will plot to.

time_created_block

is the time the plot frame was originally created, This is optional. For the syntax of the time_created_block see 35.3.7 Time Created.

time_updated_block

is the last time the plot frame was last modified, This is optional. For the syntax of the time_updated_block see 35.3.8 Time Updated.

sheet_details_block

The format of the **sheet_details_block** is:

<sheet_details>

<sheet_code> *sheet_code_text*</sheet_code>

<width> *sheet_width_real*</width>

<height> *sheet_height_real*</height>

<left_margin> *sheet_left_margin_real*</left_margin>

<right_margin> *sheet_right_margin_real*</right_margin>

<top_margin> *sheet_top_margin_real*</top_margin>

<bottom_margin> *sheet_bottom_margin_real*</bottom_margin>

<border> *sheet_border_text_logical*</border>

<viewport> *sheet_viewport_text_logical*</viewport>

</sheet_details>

where

sheet_code_text is the name of the sheet. This can be blank.

sheet_width_real, sheet_height_real, sheet_left_margin_real, sheet_right_margin_real, sheet_top_margin_real, sheet_bottom_margin_real are all real values and give the size and margins for he sheet that the plot frame will plot. The units for all of them is millimetres.

plot_frame_border_text_logical and *plot_frame_viewport_text_logical* are text and can only have the value **true** or **false**.

origin_block

The format of the **origin_block** is:

<origin> *x_real   y_real   z_real*</origin>

where

(*x_real,y_real,z_real*) is the coordinates of the origin of the plot frame.

scale_block

The format of the **scale_block** is:

<scale> *scale_real*</scale>

where

scale_real is the 1: scale for the plots created by the plot frame.

rotation_block

The format of the **rotation_block** is:

<rotation> *rotation_dec_deg_real*</rotation>

where

rotation_dec_deg_real is rotation of the plot frame. The value is in decimal degrees and is measured in a counter clockwise direction from the positive x-axis.

plotter_details_block

The format of the **plotter_details_block** is:

<plotter_details>

<title_1>*title_1_text*</title_1>

<title_2>*title_2_text*</title_2>

<use_title_file> *title_file_text_logical*</border>

<title_file> *title_file_name_text*</title_file>

<text_size> *title_text_size_real*_mm</text_size>

<textstyle> *title_text_style*</textstyle>

</plotter_details>

where

title_1_text and *title_2_text* are two lines of text for the title block. They can be blank.

use_title_file_text_logical is text and can only have the value **true** or **false**.

title_file is the path name of the file to use as a title block file. This can be blank.

title_text_size_real_mm is the size of the text in the title block. The units are millimetres.

For example

```
<string_plot_frame>
  <info>
    <name>Plot frame</name>
    <colour>green</colour>
    <plot_file>plot</plot_file>
  </info>
  <sheet_details>
    <sheet_code>A0</sheet_code>
    <width>1189</width>
    <height>841</height>
    <left_margin>5</left_margin>
    <right_margin>10</right_margin>
    <bottom_margin>5</bottom_margin>
    <top_margin>10</top_margin>
    <border>true</border>
    <viewport>true</viewport>
  </sheet_details>
  <title_block>
    <title_1>Title 1</title_1>
    <title_2>Title 2</title_2>
    <use_title_file>true</use_title_file>
    <title_file>A0 title.tbf</title_file>
    <text_size>5</text_size>
    <textstyle>1</textstyle>
  </title_block>
  <origin>695.2353 1464.6248</origin>
  <scale>100</scale>
  <rotation>45</rotation>
  <plotter_details>
    <id>9</id>
    <type>model</type>
    <mode>""</mode>
    <names>""</names>
  </plotter_details>
  <time_created>29-Apr-2015 01:11:52</time_created>
  <time_updated>29-Apr-2015 01:11:52</time_updated>
</string_plot_frame>
```

Continue to the next section 35.6.10 Super String or return to 35.6.3 String Header Block or 35 12d XML File Format.

35.6.10 Super String

Because the super string is so versatile, its 12d XML format looks complicated but it is very logical and actually quite simple.

In its most primitive form, the super string is simply a set of (x,y) values as in a 2d string, or (x,y,z) values as in a 3d string.

Additional blocks of information can extend the definition of the super string and only need to be included if they exist. For example, segment arcs or transitions, vertex ids, vertex and segment text, round pipe diameters or box pipes widths and heights and tinability.

Some of the properties of the super string can be constant for the entire string or can vary for each vertex and/or segment. For example, there can be one colour for the entire string or individual colours for each segment.

For user attributes, the super string not only has the standard user attributes defined for the entire string (string attributes), but also can have user attributes for each vertex (vertex attributes) and for each segment (segment attributes).

Being closed or not is another property of the super string and if the super string is closed then the super string knows there is an additional segment going from the last vertex back to the first vertex. This means that there is no duplication of the first and last vertex needed.

Thus if a super string has *n* vertices, then an open super string has *n-1* segments joining the vertices and a closed super string has *n* segments since there is an additional segment from the last to the first vertex.

With the additional data for vertices and/or segments in the super string, the data is in vertex or segment order.

So for a string with *n* vertices, there must be *n* bits of vertex data.

For segments, if the string is open then there only needs to be *n-1* bits of segment data but for closed strings, there must be *n* bits of data.

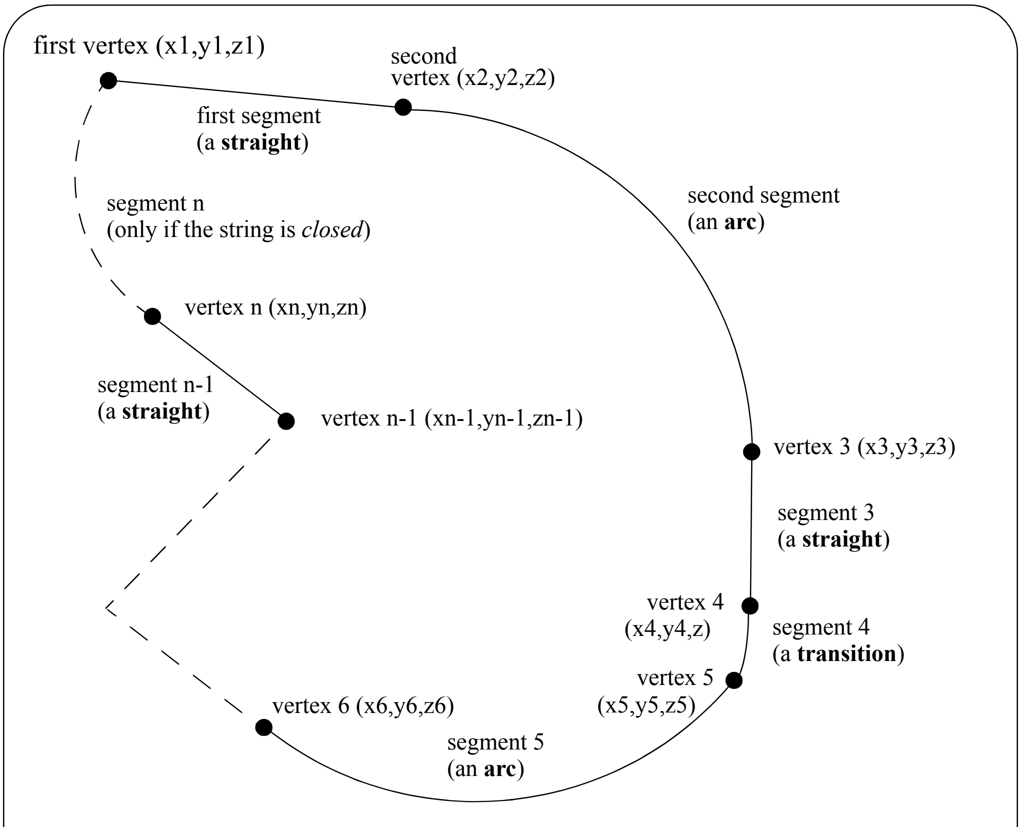
For an open string, *n* bits of segment data can be specified and the *nth* bit will be read in and stored. If the string is then closed, the *nth* bit of data will be used for the extra segment.

Important Note

For a super string, the arcs, transitions and offset transitions are that shape in plan.

Hence an arc with a z-value at each end is actually a **helix** and **NOT** part of a three dimensional circle.

Transitions and offset transitions are helixes with a constantly changing radius.



Vertices and Segments Forming the Super String

The 12dXML definition of the super string is:

<string_super>

string_header_block

closed_block

interval_block

blocks_of_info_1

blocks_of_info_2

...

blocks_of_info_n

</string_super>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

closed_block

<closed> closed_text_logical **</closed>**

where *closed_text_logical is* **true** if the super string is closed and **false** if the super string is open.

interval_block

The interval_block for a super string has a *distance* (a chainage interval) and a *chord_to_arc*_real

where

the ***distance*** to temporarily introduce extra vertices into the string at the given chainage distance when the string is in a triangulation to form a tin.

chord_arc_real is a real number and is the chord to arc tolerance to use on any arcs in the super string to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

blocks_of_info

The blocks of info can be broken up into four types.

(a) blocks defining the position of the vertices in z, y and z

Each vertex must have at least an (x,y) value but there may be one z-value for the entire string and (x,y) at each vertex (data_2d), **or** an (x,y,z) for each vertex (data_3d).

See 35.6.10.1 Defining the Coordinates of the Vertices

(b) blocks defining the geometry of the segments

Segments can be straights, arcs, transitions or offset transitions.

radius_data and *major_data* **or** *geometry_data.*

See 35.6.10.2 Geometry of the Horizontal Segments

(c) extra information for the vertices and/or segments such as colour, attributes, vertex ids, symbols tinability etc.

The definition for the blocks of each type now follows.

35.6.10.1 Defining the Coordinates of the Vertices

35.6.10.2 Geometry of the Horizontal Segments

35.6.10.3 Colour

35.6.10.4 String, Vertex and Segment Attributes

35.6.10.5 Vertex Id’s (Point Id’s)

35.6.10.6 Symbols at Vertices

35.6.10.7 Tinability

35.6.10.8 Round or Box (Culvert) Pipes

35.6.10.9 Vertex Text and Vertex Annotation

35.6.10.10 Segment Text and Segment Annotation

35.6.10.1 Defining the Coordinates of the Vertices

See

35.6.10.1.1 One Z or No Z for the String
35.6.10.1.2 Varying Z Values along the String

35.6.10.1.1 One Z or No Z for the String

If there is a non-null constant z value for the entire string then the z value is given by a **z** block:

<z> *z_value* **</z>**

where *z_value* is the constant z value for the entire string.

And when there is a constant z, or no z, for the string, then only the (x,y) coordinates are required for each vertex and these are given in a ***data_2d*** block. See 35.3.12 data_2d

35.6.10.1.2 Varying Z Values along the String

If the z value can vary for different vertices along the string then the (x,y,z) values must be given for each vertex and the data is then written out as a ***data_3d*** block. See 35.3.13 data_3d.

35.6.10.2 Geometry of the Horizontal Segments

If the segments are straight lines only then that is the default and no further information is required.

If the segments are only straight lines and arcs, then the ***radius_data*** and **major_data** blocks are used to define a ***radius*** and ***bulge_flag*** data for each segment of the super string. See 35.6.10.2.1 Only Straights and Arcs for Segments.

If any of the segments are transitions or offset transitions then ***geometry_data*** must be used for each segment. ***geometry_data*** can represent a straight, arc, transition or offset transition. See 35.6.10.2.2 Straights, Arcs and Transitions for Segments.

35.6.10.2.1 Only Straights and Arcs for Segments

If there are only straight and arc segments for the string, then for either **data_2d** or **data_3d**, it is possible to add a radius and major/minor arc flag for each segment of the super string using the ***radius_data*** and **major_data** blocks respectively. See 35.3.14 radius_data and major_data.

35.6.10.2.2 Straights, Arcs and Transitions for Segments

When some of the segments are transitions or offset transitions, then the ***geometry_data*** block **must** be used the give the geometry for each segments.

Either a **data_2d** or **data_3d** block defines the coordinates for the vertices and the ***geometry_data*** block defines for each segment whether the segment is a straight, an arc or a transition or offset transition.

The definition of the ***geometry_data*** block is

<geometry_data>

info_for_segment_1_block

info_for_segment_2_block

...

info_for_segment_m_block

</geometry_data>

where

info_for_segment_i_block is the information defining the i'th segment as either a straight, an arc or an offset transition (offset transition or transition), and

m = n-1 for an open string or m = n for a closed string.

For the definition of *info_for_segment_i_block* see:

35.6.10.2.2.1 Straight

35.6.10.2.2.2 Arc

35.6.10.2.2.3 Offset Transitions

35.6.10.2.2.1 Straight

No parameters are needed for defining a straight segment. The *straight* block is simply:

<straight> </straight>

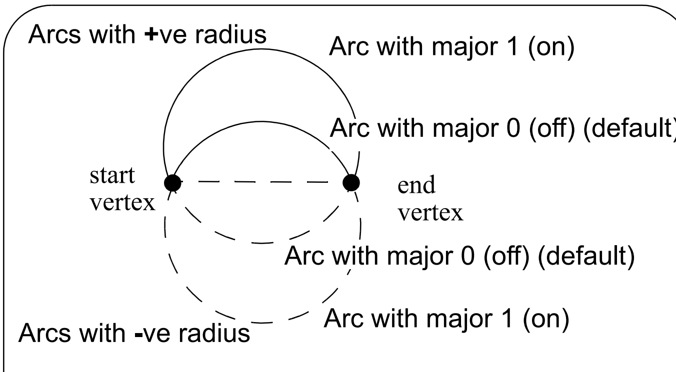
or simply

<straight/>

35.6.10.2.2.2 Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius, and a flag *major* which can be set to 1 (on) or off (0) to differentiate between the four possibilities.



Arcs with same radius but with major on or off

The *arc* block is:

<arc>

<radius> *radius_for_segment*</radius>

<major> *major_flag_for_segment*</major>

</arc>

where

radius_for_segment is the radius for the segment and

major_flag_for_segment is 1 if the arc is a major arc and 0 if it is a minor arc.

35.6.10.2.2.3 Offset Transitions

An ***offset transition*** is a fixed perpendicular offset (***offset_real)*** of a base transition where the base transition is a Euler spiral (or a certain approximation to it) or some other specially defined curve. The base transition has a start point where the absolute radius of the curve is infinity and then has a continuously decreasing absolute radius as you continue along the curve (this may be in a forward or reverse direction).

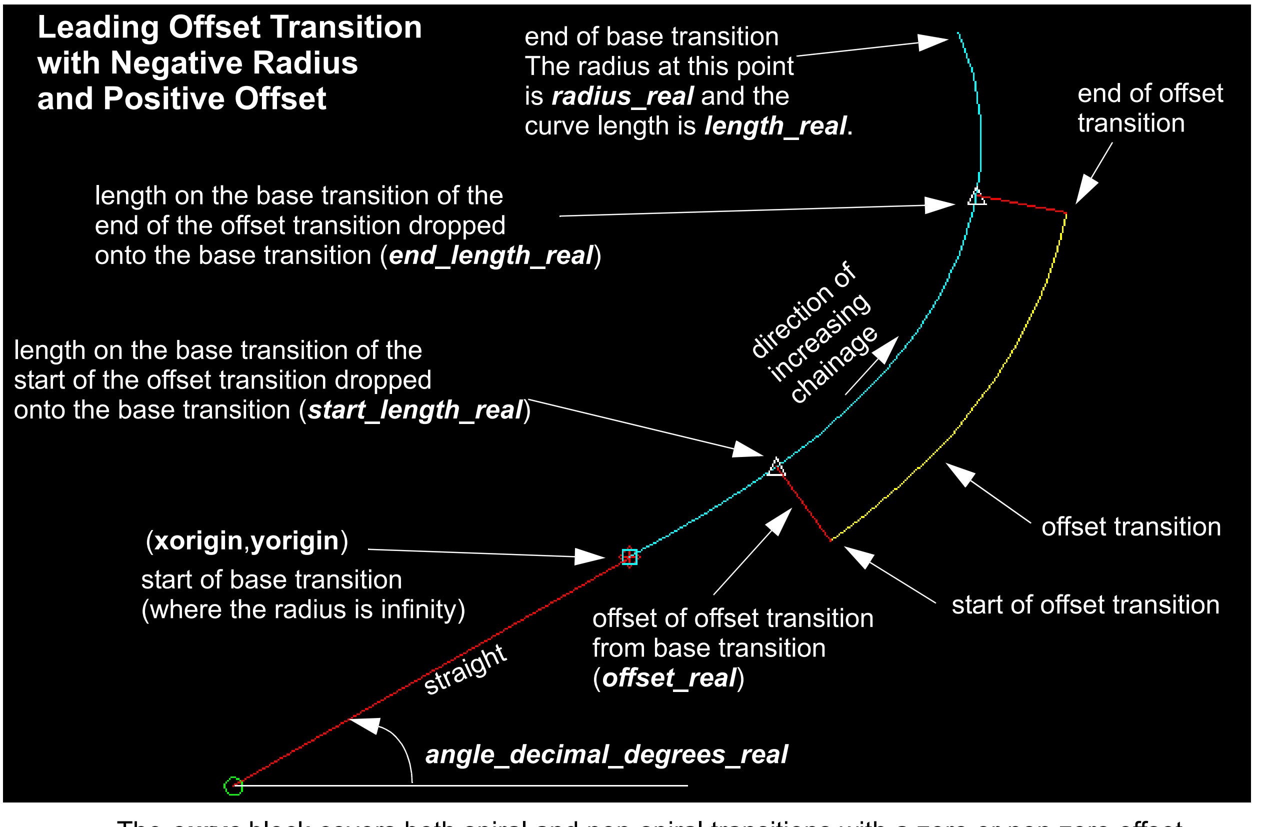
The ***base transition*** is defined by giving its starting point **(xorigin, yorigin)** where the radius is infinity and the angle of the tangential line at the start point is ***angle_decimal_degrees_real*** and the fact that the radius ***radius_real*** occurs at a given curve length ***length_real*** along the base transition.

The ***offset transition*** is a fixed offset (***offset_real***) from the base transition and goes from a start point that is specified by giving the length on the base transition where the start point drops perpendicularly onto the base transition (***start_length_real***) and to the end point that is specified by length on the base transition where the end point drops perpendicularly onto the base transition (***end_length_real***). The offset can be positive or negative.

If you are travelling along the curve in a forward direction (increasing chainage) then the base transition is said to be a **leading transition** if the absolute radius decreases as you go along the curve, and a **trailing transition** if the absolute radius decreases.

The ***end radius*** can be ***positive*** or ***negative***.

If you are travelling along the curve in a forward direction then for a leading transition, if the **end radius** is **positive** then the curve curls to the right, and for a negative end radius, the curve curls to the left.



The ***curve*** block covers both spiral and non-spiral transitions with a zero or non zero offset.

The *curve* block is:

<curve>

<curve_type> *curve_type_text*</curve_type>

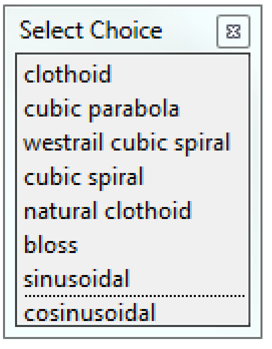
<leading> *leading_logical_text*</leading>

<xorigin> *xorigin_real*</xorigin>
<yorigin> *yorigin_real*</xorigin>
<radius> *radius_real*</radius>
<length> *length_real*</length>
<start> *start_length_real*</start>
<end> *end_length_real*</end>
<angle> *angle_decimal_degrees_real*</angle>
<offset> *offset_real*</offset>
<mvalue> *mvalue_real*</mvalue>

</curve

where

curve_type_text is the type of base transition.



For more information on the choices, see 35.3.15 Available Transition Types.

leading_logical_text is ***true*** if it is a **leading** base **transition** or *false* if is a trailing base transition.

*(**xorigin**, **yorigin**)* is the origin of the base transition. That is, where the radius is infinity.

radius_real is the radius at the end of the base transition. The radius is positive if the curve goes to the right when travelling in decreasing absolute radius.

length_real is the curve length and the end of the base transition and the radius is radius_real.

start_length_real is the curve length on the base transition where the start of the offset transition drops perpendicularly onto the base transition.

end_length_real is the curve length on the base transition where the end of the offset transition drops perpendicularly onto the base transition.

angle_decimal_degrees_real is the angle of the tangent of the base transition at the origin of the base transition. It is measured in decimal degrees in a counter clockwise direction from the positive x-axis.

offset_real is the perpendicular offset distance of the transition from the base transition. For a leading transition, a positive value offsets the base transition to the right and a negative value offsets it to the left as you travel in a forward direction.

mvalue_real *- if the transition is a cubic parabola then mvalue_real* is the mvalue for the cubic parabola, otherwise, *mvalue_real* is zero.

For example, for a string with four segments

```
<geometry_data>
```

```
  <arc>
    <radius>-222.77841769</radius>
    <major>0</major>
  </arc>
  <curve>
    <type>clothoid</type>
    <leading>false</leading>
    <xorigin>114.78632204</xorigin>
    <yorigin>22.22840069</yorigin>
    <radius>222.77841769</radius>
    <length>194.18990415</length>
    <start>50.95749554</start>
    <end>194.18990415</end>
     <angle>174.01773651</angle>
    <offset>0</offset>
    <mvalue>0</mvalue>
  </curve>
  <arc>
    <radius>-848.96871636</radius>
    <major>0</major>
  </arc>
  <straight/>
</geometry_data>
```

35.6.10.3 Colour

There can be one colour for the entire super string which is given by the **<colour>** keyword block in the ***string_header_block***, or the colour varies for each segment of the super string and is then specified in a ***<colour_data>*** block.

The order of the entries in the **<colour_data>** block must match the order of the segments in the super string. So there is exactly one entry for each segment.

If all the segment are the string colour, then simply omit the **<colour_data>** block.

For a super string with **n** vertices

<colour_data>

colour_text_for_segment_1

colour_text_for_segment_2

...

colour_text_segment_m

</colour_data>

where

colour_text_segment_i is the colour name or colour number for the i'th segment OR is **no_colour** when no special colour has been set for the segment and the string colour is then used for that segment. If the name includes spaces then it must be enclosed in **"**, and

m = n-1 for an open string or m = n for a closed string.

For example for a string with four segments

```
<colour_data>
    "off yellow" magenta no_colour no_colour
</colour_data>    <leading>false</leading>
```

35.6.10.4 String, Vertex and Segment Attributes

The super string can have attributes for the entire string (string attributes) but can also have attributes for each vertex (vertex attributes) and attributes for each segment (segment attributes).

See

35.6.10.4.1 String Attributes
35.6.10.4.2 Vertex Attributes
35.6.10.4.3 Segment Attributes

35.6.10.4.1 String Attributes

There can be attributes for the entire string. They are part of the String Header Block and are described in 35.6.3 String Header Block.

For example

```
<string_super>
  <name>Line 1</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>cyan</colour>
  <style>1</style>
  <attributes>
    <text>
    <name>Street</name>
    <value>Weemala Road</value>
    </text>
  </attributes>
  <time_created>2015-05-11T09:08:06Z</time_created>
  <time_updated>2015-05-11T11:59:29Z</time_updated>
           ...
```

35.6.10.4.2 Vertex Attributes

Each vertex can have one or more user defined attributes.

For a super string with **n** vertices

<vertex_attribute_data>

vertex_attributes_for_vertex_1_block

vertex_attributes_for_vertex_2_block

...

vertex_attributes_for_vertex_n_block

</vertex_attribute_data>

where

vertex_attributes_for_vertex_j_block is the *attribute_block* for vertex j. The attribute_block is defined in 35.4 Attributes.

For example, for a string with four vertices

```
<vertex_attribute_data>
  <attributes>
    <real>
      <name>Flow</name>
      <value>27.4</value>
    </real>
  </attributes>
  <attributes/>
  <attributes/>
  <attributes/>
</vertex_attribute_data>
```

35.6.10.4.3 Segment Attributes

Each segment can have one or more user defined attributes.

For a super string with **n** vertices

<segment_attribute_data>

segment_attributes_for_segment_1_block

segment_attributes_for_segment_2_block

...

segment_attributes_for_segment_m_block

</segment_attribute_data>

where

segment_attributes_for_segment_j_block is an *attribute_block* for segment j. The attribute_block is defined in 35.4 Attributes, and

m = n-1 for an open string or m = n for a closed string.

For example, for an open string with four vertices

```
<segment_attribute_data>
  <attributes>
    <real>
      <name>Material</name>
      <value>clay</value>
    </real>
  </attributes>
  <attributes/>
  <attributes/>
  <attributes/>
</segment_attribute_data>
```

35.6.10.5 Vertex Id's (Point Id's)

Each vertex can have a vertex id (point id).

This is not the number position of the vertex in the string but is a separate id which is usually different for every vertex in every string.

The ***vertex id*** can be alphanumeric and include spaces.

The definition is:

For a super string with **n** vertices

<point_data>

point_id_text_for_vertex_1

point_id_text_for_vertex_2

...

point_id_text_for_vertex_n

</point_data>

where

point_id_text_for_vertex_i is the point id of the i'th vertex.

m = n-1 for an open string or m = n for a closed string.

point_id_text_for_vertex_i is the actual text enclosed in **"**, even if the text does not include spaces. If the point id has not been set for a vertex, the value should be included as "".

For example "Point 1" or "Point2" or "".

If the ***point_data*** block does not exist then there are no Vertex Ids.

For example, for a string with 4 vertices

```
<point_data>
  "Point 1" "Point2" "" ""
</point_data>
```

35.6.10.6 Symbols at Vertices

There can be no symbols at all, or the same symbol for every vertex in the using the ***symbol_value*** block or the symbol varies for each vertex of the super string using the ***symbol_data*** block.

If a symbol does not have a colour, or there is no colour in the symbol definition, then it uses the string colour.

The definitions are:

<symbol_value>

symbol_properties_block

</symbol_value>

where

symbol_properties_block is the description for the symbol to be used at every vertex of the super string, and

OR

For a super string with **n** vertices

<symbol_data>

symbol_properties_for_vertex_1_block

symbol_properties_for_vertex_2_block

...

symbol_properties_for_vertex_n_block

</symbol_data>

where

symbol_properties_for_vertex_i_block is the description for the symbol at vertex i.

The format of ***symbol_properties_block*** and ***symbol_properties_for_vertex_i_block*** is:

<properties>

<style> *symbol_name_text* </style>

<colour> *symbol_colour_name_text* </colour>

<size> symbol_size_*real* </size>

<rotation> *angle_dec_deg_real*</rotation>

<offset_x> *symbol_offset_x_real* </offset_y>

<offset_y> *symbol_offset_y_real* </offset_y>

</properties>

where

symbol_name_text is the name of the symbol.

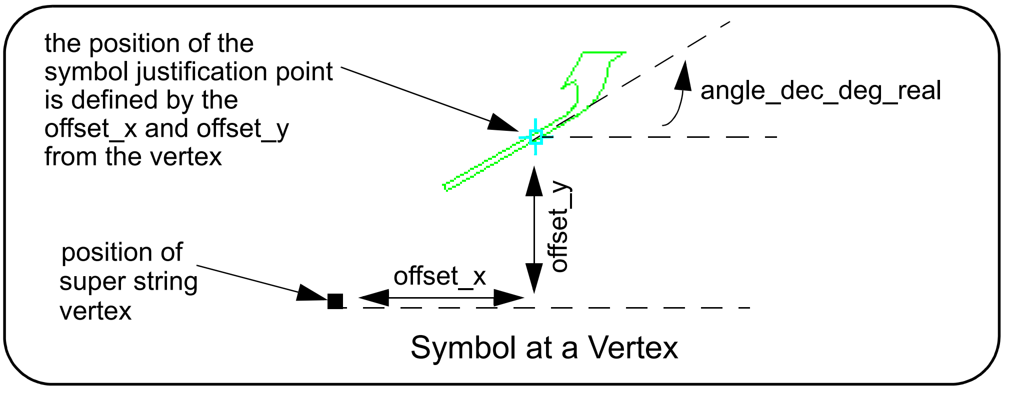
symbol_colour_name is the colour of the symbol is there is no colours in the symbol definition. If the ***colour*** block is missing and there is no colours in the symbol definition then the string colour is used. For the syntax of the ***colour*** block, see 35.3.2 Colour.

symbol_size_real is the size of the symbol in the units of the symbol.

angle_dec_deg_real is the angle of the symbol. The value is in decimal degrees and is measured in a counter clockwise direction from the positive x-axis.

offset_x_real is x distance to offset the symbol from the super string vertex.

offset_y_real is the y distance to offset the symbol from the super string.



35.6.10.7 Tinability

Tinability

For a *super string*, the concept of breakline has been extended to a property called **tinable** which can be set independently for each vertex and each segment of the super string.

If a vertex is tinable, then the vertex is used in triangulations. If the vertex is not tinable, then the vertex is ignored when triangulating.

If a segment is tinable, then the segment is used as a side of a triangle during triangulation. This may not be possible if there are *crossing* tinable segments.

Vertex tinability is given by the ***vertex_tinable_data*** block where for a string of n vertices,

<vertex_tinable_data>

tinable_flag_for_vertex_1

tinable_flag_for_vertex_2

...

tinable_flag_for_vertex_n

</vertex_tinable_data>

where

tinable_flag_for_vertex_i for the i'th vertex is 1 or t if the vertex is tinable, or 0 or f if the vertex is not tinable.

Segment tinability is given by the ***segment_tinable_data*** block where

<*segment_tinable_data*>

tinable_flag_for_segment_1

tinable_flag_for_segment_2

...

tinable_flag_for_segment_m

</*segment_tinable_data*>

where

tinable_flag_for_segment_i for the i'th segment is 1 or t if the segment is tinable, or 0 or f if the segment is not tinable, and

m = n-1 for an open string or m = n for a closed string.

For example, for a open string with four vertices

```
<vertex_tinable_data>
  t t f t
</vertex_tinable_data>
<segment_tinable_data>
  f t t
</segment_tinable_data>
```

Note that even if a segment is set to tinable, it can only be used in a triangulation if both its end vertices are also tinable.

35.6.10.8 Round or Box (Culvert) Pipes

All the super string segments can be round or all box (culvert). That is, some can't be round and others box.

There is also a justification that applies to all round pipes or box pipes in the string.

See

35.6.10.8.1 Pipe Diameters
35.6.10.8.2 Culvert Dimensions
35.6.10.8.3 Justification for Round or Culvert Pipes

35.6.10.8.1 Pipe Diameters

There can be one pipe diameter value for the entire super string using the ***pipe_value*** block **or** the pipe diameter varies for each segment of the super string using the ***pipe_data*** block.

The definitions are:

<pipe_value> *pipe_diameter_real* **</pipe_value>**

where *pipe_diameter_real* is the diameter for ***every*** segment of the string.

OR

For a super string with **n** vertices

<pipe_data>

<properties>

<diameter> pipe_diameter_for_segment_1 </diameter>

</properties>

<properties>

<diameter> pipe_diameter_for_segment_2 </diameter>

</properties>

...

<properties>

<diameter> pipe_diameter_for_segment_m </diameter>

</properties>

</pipe_data>

where

pipe_diameter_for_segment_i is the pipe diameter for the i'th segment, and

m = n-1 for an open string or m = n for a closed string.

35.6.10.8.2 Culvert Dimensions

There can be one culvert width and height for the entire super string using the ***culvert_value*** block **or** the culvert width and height vary for each segment of the super string using the ***culvert_data*** block.

The definitions are:

<culvert_value>

<width> *pipe_width_real* **</width>**

<height> *pipe_height_real* **</height>**

</culvert_value>

where *pipe_width_real* is the width and *pipe_height_real* is the height for every segment of the string.

OR

For a super string with **n** vertices

<culvert_data>

<properties>

<width> pipe_width_for_segment_1 </width>

<height> pipe_height_for_segment_1 </height>

</properties>

<properties>

<width> pipe_width_for_segment_2 </width>

<height> pipe_height_for_segment_2 </height>

</properties>

...

<properties>

<width> pipe_width_for_segment_m </width>

<height> pipe_height_for_segment_m </height>

</properties>

</culvert_data>

where

pipe_width_for_segment_i is the width and *pipe_height_for_segment_i* is the height for the i'th segment and

m = n-1 for an open string or m = n for a closed string.

35.6.10.8.3 Justification for Round or Culvert Pipes

There can be only one justification for all the round or culvert pipe segments in the super string.

The definition is:

<justify> *pipe_justification_text* **</justify>**

where

pipe_justification_text is the justification for the entire pipe and can have the values **centre**, **top**, **obvert**, **bottom** or **invert**.

If the ***justify*** block is missing then the round pipe or culvert pipe is **centre** justified.

35.6.10.9 Vertex Text and Vertex Annotation

See

[35.6.10.9.1 Vertex Text](#)
[35.6.10.9.2 Vertex Annotation](#)

35.6.10.9.1 Vertex Text

There can be not text at each vertex, the same piece of text for every vertex in the super string or a different text for each vertex of the super string.

Note: How the vertex text is drawn is specified by the vertex annotation. See 35.6.10.9.2 Vertex Annotation.

If there is a constant text value for each vertex in the string, then the text value is given by a **vertex_text_value** block:

<vertex_text_value> *text_value_text* **</vertex_text_value>**

where *text_value_text* is the constant text value for each vertex in the string.

For example, for a string of 5 vertices

```
<vertex_text_value>Constant text</vertex_text_value>
```

If there is a different text value for each vertex in the string, then the value of the text for each vertex is given in a ***vertex_text_data*** block.

<***vertex_text_data***>

<p> *text_value_for_vertex_1*</p>

<p> *text_value_for_vertex_2*</p>

...

<p> *text_value_for_vertex_n*</p>

</***vertex_text_data***>

where *text_value_for_vertex_i* is the vertex text for the i'th vertex.

For example, for a string of four vertices

```
<vertex_text_data>
  <p>First vertex</p>
  <p>Second vertex</p>
  <p/>
  <p/>
  </vertex_text_data>
```

35.6.10.9.2 Vertex Annotation

How the vertex text is drawn at each vertex is specified by the vertex annotation.

There can be no vertex annotations at all, or the same vertex annotation is used for every vertex in the string using the ***vertex_annotation_value*** block, or the vertex annotation varies for each vertex of the super string using the ***vertex_annotation_data*** block.

Note that in vertex annotations, the size of the text for all vertices must be either world size or all paper size or all screen size. That is, world size, paper size and screen size can not be mixed. The first one found is used for all vertices.

The definitions are:

<vertex_annotate_value>

vertex_annotation_information

</vertex_annotate_value>

where

vertex_annotation_information is the annotation to be used for drawing the text at every vertex of the super string. For the definition of *vertex_annotation_information* see 35.6.4.1 Vertex Annotation Information.

OR

For a super string with **n** vertices

<vertex_annotation_data>

annotation_for_vertex_1_block

annotation_for_vertex_2_block

...

annotation_for_vertex_n_block

</vertex_annotation_data>

where

annotation_for_vertex_i_block is the description for the vertex annotation for vertex i.

The format of the ***annotation_for_vertex_i_block*** is:

<properties>

vertex_*annotation_information*

<properties>

where

vertex_annotation_information is the annotation for drawing the text at the vertex. For the definition of *vertex_annotation_information* see 35.6.4.1 Vertex Annotation Information.

35.6.10.10 Segment Text and Segment Annotation

See

35.6.10.10.1 Segment Text
35.6.10.10.2 Segment Annotation

35.6.10.10.1 Segment Text

There can be no text on each segment, the same piece of text for every segment in the super string or a different text for each segment of the super string.

Note: How the segment text is drawn is specified by the segment annotation. See 35.6.10.10.2 Segment Annotation.

If there is a constant text value for each segment in the string, then the text value is given by a **segment_text_value** block:

<segment_text_value> *text_value_text* **</segment_text_value>**

where *text_value_text* is the constant text value for each segment in the string.

For example, for a string of 5 vertices

```
<segment_text_value>Constant text</segment_text_value>
```

If there is a different text value for each segment in the string, then the value of the text for each segment is given in a ***segment_text_data*** block.

<***segment_text_data***>

<p>text_value_for_segment_1</p>

<p>text_value_for_segment_2</p>

...

<p> text_value_for_segment_m</p>

<***/segment_text_data***>

where

text_value_for_segment_i is the segment text for the i'th segment, and

m = n-1 for an open string or m = n for a closed string.

For example, for a string of four segments

```
<segment_text_data>
  <p>First segment</p>
  <p>Second Segment&#xa;Two lines</p>
  <p>seg3</p>
  <p/>
</segment_text_data>
```

35.6.10.10.2 Segment Annotation

How the segment text is drawn at each segment is specified by the segment annotation.

There can be no segment annotations at all, or the same segment annotation is used for every segment in the string using the ***segment_annotation_value*** block, or the segment annotation varies for each segment of the super string using the ***segment_annotation_data*** block.

Note that in segment annotations, the size of the text for all segments must be either world size or all paper size or all screen size. That is, world size, paper size and screen size can not be mixed. The first one found is used for all segments.

The definitions are:

<segment_annotate_value>

segment_annotation_information

</segment_annotate_value>

where

segment_annotation_information is the annotation to be used for drawing the text at every segment of the super string. For the definition of *segment_annotation_information* see 35.6.4.2 Segment Annotation Information.

OR

For a super string with **n** vertices

<segment_annotation_data>

annotation_for_segment_1_block

annotation_for_segment_2_block

...

annotation_for_segment_m_block

</vertex_annotation_data>

where

annotation_for_segment_i_block is the description for the annotation at segment i, and.

m = n-1 for an open string or m = n   for a closed string.

The format of the ***annotation_for_segment_i_block*** is:

<properties>

segment_*annotation_information*

<properties>

where

segment_annotation_information is the annotation for drawing the text at the segment. For the definition of *segment_annotation_information* see 35.6.4.2 Segment Annotation Information.

Continue to the next section 35.6.11 Super Alignment String or return to 35.6 Elements Contained in Models or 35 12d XML File Format.

35.6.11 Super Alignment String

The 12d XML for the Super Alignment String has not yet been documented.

In an *alignment* string, only the intersection point method (IP's) could be used to construct the horizontal and vertical geometry. The IP definition is actually a *constructive* definition and the tangents points and segments between the tangent points (lines, arcs, transitions etc.) are calculated from the IP definition. For an alignment string, only the IP definitions are included in the 12d XML file.

For a ***super alignment***, the ***horizontal*** and ***vertical geometry*** are also defined separately and with construction definitions but the construction definition can be much more complex than just IP's. For example, an arc could be defined as being tangential to two offset elements, or constrained to go through a given point.

If the horizontal construction methods are consistent then the horizontal geometry can be solved, and the horizontal geometry expressed in terms of consecutive segments (lines, arcs, transitions) that are easily understood and drawn.

Similarly if the vertical construction methods are consistent then the vertical geometry can be solved, and the vertical geometry expressed in terms of consecutive segments (lines, arcs, parabolas) that are easily understood and drawn.

For the *super alignment* **both** the ***construction methods*** (the ***parts***) and the resulting ***vertices*** and ***segments*** (lines, arcs, transitions etc.) that make up the horizontal and vertical geometry (the ***data***) are written out to the 12d XML file.

For most applications such as uploading to survey data collectors or machine control devices, only the ***horizontal data*** and the ***vertical data*** are required, not the *construction* methods (i.e. the ***horizontal*** and ***vertical parts***). So when reading the 12d XML of a *super alignment*, only the ***horizontal*** and ***vertical data*** needs to be read in and the constructive methods (the ***horizontal*** and ***vertical parts***) can be skipped over.

Consequently only the ***horizontal data*** and the ***vertical data*** is full documented for the super alignment.

Notes

1. Just using the horizontal and vertical data is valid ***as long as the super alignment geometry is consistent*** (and solves) and the horizontal and vertical parts can be created.

   There are flags in the 12d XML of the super alignment to say that the horizontal and vertical geometry is consistent and solves.

2. Segments meeting at a common vertex do not have to be tangential although for most road and rail centre lines, they should be.

3. When ***12d Model*** reads in a 12d XML file and there is only ***horizontal_parts*** and no ***horizontal_data*** then if possible, ***12d Model*** generates the ***horizontal_data*** from the horizontal parts.

   This is very useful if you are creating a 12d XML file for a super alignment string that only uses HIP methods as it is fairly simple to create the ***horizontal_parts*** for such a string and that is fully documented in 35.6.11.2 Horizontal_Parts When Geometry is Defined by IP Method Only.

4. When ***12d Model*** reads in a 12d XML file and there is only ***vertical_parts*** and no ***vertical_data*** then if possible, ***12d Model*** generates the ***vertical_data*** from the vertical parts.

   This is very useful if you are creating a 12d XML file for a super alignment string that only uses VIP methods as it is fairly simple to create the ***vertical_parts*** for such a string and that is fully documented in 35.6.11.5 Vertical_parts When VG is Defined by IP Method Only.

The 1**2d XML** definition of the super alignment string is:

<string_super_alignment>

string_header_block

drawables_block

spiral_type_block

closed_block

valid_horizontal_block

valid_vertical_block

synch_vertical_block

label_style_block

horizontal_parts_block

horizontal_data_block

vertical_parts_block

vertical_data_block

geometry_modifiers_block

</string_super_alignment>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

drawables_block

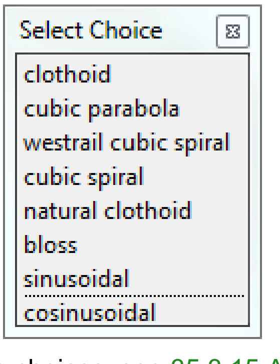
the drawables block contains information on how the super alignment is labelled.

This block is not documented.

spiral_type_block

<spiral_type> *transition_type_text* **</spiral_type>**

where *transition_type_text* is the default transition type use in the super alignment and is one of



For more information on the choices, see 35.3.15 Available Transition Types.

closed_block

<closed> closed_text_logical **</closed>**

where *closed_text_logical is* **true** if the super alignment string is closed and **false** if the super alignment string is open.

valid_horizontal_block

<valid_horizontal> *valid_horizontal_text_logical* **</valid_horizontal>**

where *valid_horizontal_text_logical is* **true** if the super alignment string horizontal geometry solves and **false** if the horizontal geometry does not solve.

If the horizontal geometry does not solve then the *horizontal_data* may be rubbish.

valid_vertical_block

<valid_vertical> *valid_vertical_text_logical* **</valid_vertical>**

where *valid_vertical_text_logical is* **true** if the super alignment string vertical geometry solves and **false** if the vertical geometry does not solve.

If the vertical geometry does not solve then the *vertical_data* may be rubbish.

synch_vertical_block

<synch_vertical> *synch_vertical_text_logical* **</synch_vertical>**

where *synch_vertical_text_logical is* **true** if the super alignment vertical geometry is to be synchronized to the horizontal geometry whenever the horizontal geometry is modified.

This is an internal ***12d Model*** flag.

label_style_block

<label_style> *label_style_text* **</label_style>**

where *label_style_text* is the name of the super alignment label style used for drawing the super alignment.

horizontal_parts_block

the *horizontal_parts* block contains the **methods** to construct the super alignment horizontal geometry. For example float (fillet) an arc of a certain radius between two given lines or create a transition (spiral or non-spiral transition) between a line and an arc.

The parts that make up the horizontal geometry are defined in chainage order from the start to the end of the super alignment.

If the horizontal construction methods are consistent, then they can be solved to form a plan string made up of lines, arcs and transitions and this is given in the ***horizontal_data*** block.

Because the construction methods can be very complex, the horizontal_parts block will only be documented for the case where all the horizontal parts are horizontal intersection points (HIPs) with an arc and leading and trailing transitions. See 35.6.11.2 Horizontal_Parts When Geometry is Defined by IP Method Only.

horizontal_data_block

the *horizontal_data* block contains the segments that define the horizontal geometry.

The *horizontal_data* block needs to be read in.

For the description of the *horizontal_data* block, see 35.6.11.1 Horizontal Data Block.

vertical_parts_block

the *vertical_parts* block contains the **methods** to construct the super alignment vertical geometry. For example float (fillet) an arc of a certain radius between two given lines.

The parts that make up the vertical geometry are defined in chainage order from the start to the end of the super alignment.

If the vertical construction methods are consistent, then they can be solved to form a string in (chainage, offset) space made up of lines, arcs and parabolas and this is given in the ***vertical_data*** block.

Because the construction methods can be very complex, the vertical_parts block will only be documented for the case where all the vertical parts are vertical intersection points (VIPs) with an arc or a parabola on the VIP. See 35.6.11.5 Vertical_parts When VG is Defined by IP Method Only.

vertical_data_block

the *vertical_data* block contains the segments that define the vertical geometry.

The *vertical_data* block needs to be read in.

For the description of the *vertical_data* block, see 35.6.11.3 Vertical Data Block.

geometry_modifiers_block

the *geometry_modifiers_parts* block contains extra construction information for the super alignment.

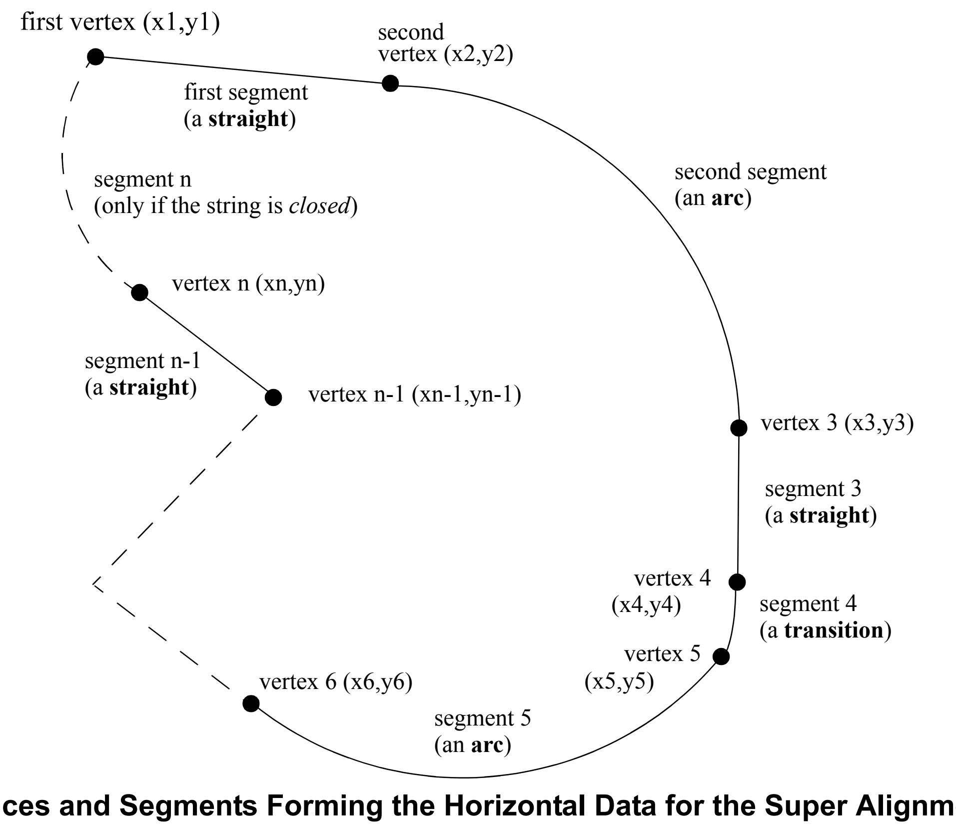
This block is not documented.

35.6.11.1 Horizontal Data Block

The *horizontal_data* block contains the ***solved*** horizontal geometry of the super alignment.

The *solved horizontal geometry* is made up of a series of (x,y) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. Each segment can be a straight line, an arc, a transition or an offset transition.

If the solved horizontal geometry has **n** vertices, then there will be **n-1 segments** for an ***open*** super alignment or **n segments** if the super alignment is ***closed***.



Vertices and Segments Forming the Horizontal Data for the Super Alignment

The format of the *horizontal_data* block is the same as for the segments of a super string except that the data is only in 2D. Unlike a super string where there is just a z-value at each vertex, the third dimension of the super alignment is given by the *vertical_data* block (see 35.6.11.3 Vertical Data Block).

The definition of the *horizontal_data* block is:

<horizontal_data>

string_header_block

closed_block

interval_block

data_2d_block

geometry_data_block

blocks_of_info_1

blocks_of_info_2

...

blocks_of_info_n

</horizontal_data>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block. This provides information such as colour for the horizontal data.

interval_block

The interval_block for a super string has a *distance* (a chainage interval) and a *chord_to_arc_*real

where

the ***distance*** to temporarily introduce extra vertices into the string at the given chainage distance when the string is in a triangulation to form a tin.

chord_arc_real is a real number and is the chord to arc tolerance to use on any arcs in the horizontal data to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

data_2d_block

the *data_2d* block defines the (x,y) value of the vertices that makes up the horizontal data.

For the definition of the data_2d block, see 35.3.12 data_2d.

geometry_data_block

the segments of the horizontal data can be straights, arcs, transitions or offset transitions.

For the definition of the *geometry_data* block*, see* 35.6.10.2 Geometry of the Horizontal Segments

blocks_of_info

extra information for the vertices and/or segments such as colour, attributes, vertex text, vertex uids etc are defined in the same way as for super strings.

35.6.11.2 Horizontal_Parts When Geometry is Defined by IP Method Only

When the horizontal geometry is defined by IP methods only, then the ***horizontal_parts*** is fairly straight forward.

When ***12d Model*** reads in a 12d XML file and there is no ***horizontal_data*** section, then ***12d Model*** will calculate the ***horizontal_parts***. So you are writing a 12d XML with only IP methods for the horizontal geometry then simply leave out the ***horizontal_data*** section and ***12d Model*** will calculate it for you.

For a horizontal geometry is defined by IP methods only, the ***horizontal_parts*** definition is:

<horizontal_data>

info_for_HIP_1_block

info_for_HIP_2_block

...

info_for_HIP_n_block

</horizontal_data>

where ***info_for_HIP_i_block*** is the information about the successive HIPs in the super alignment and is one of:

(a) A horizontal intersection point (HIP) with no arc.

This is defined by:

<ip>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</ip>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

x_ip_coordinate_real is the x coordinates of the HIP.

y_ip_coordinate_real is the y coordinates of the HIP.

(b) A horizontal intersection point (HIP) with an arc of a given radius at the HIP.

This is defined by:

<arc>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<r> *arc_radius_real* **</r>**

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</arc>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

arc_radius_real is the radius of the arc on the HIP.

x_ip_coordinate_real is the x coordinate of the HIP.

y_ip_coordinate_real is the y coordinate of the HIP.

(c) A horizontal intersection point (HIP) with an arc of a given length at the HIP

This is defined by:

<length>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<l> *arc_length_real* </l>

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</length>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

arc_length_real is the length of the arc on the HIP.

x_ip_coordinate_real is the x coordinate of the HIP.

y_ip_coordinate_real is the y coordinate of the HIP.

(d) A horizontal intersection point (HIP) with an arc and transitions

This is defined by:

<spiral>

<id> *part_id_integer* </id>

time_created_block

time_updated_block

transition_type_block

<r> *arc_radius_real* **</r>**

<l1> *leading_transition_length_real* **</l1>**

<l2> *trailing_transition_length_real* **</l2>**

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</spiral>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

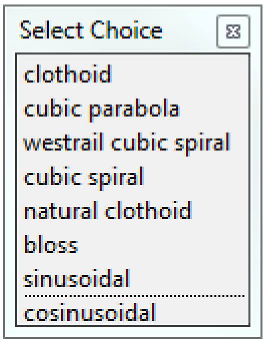
time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

transition_type_block

<transition_type> *transition_type_text* **</transition_type>**

where *transition_type_text* is the default transition type use in the super alignment and is one of



This block is optional and if it is missing then the ***default transition type*** for the super alignment is used.

For more information on the choices, see 35.3.15 Available Transition Types.

arc_radius_real is the radius of the arc on the HIP.

leading_transition_length_real is the length of the leading transition on the HIP.

trailing_transition_length_real is the length of the trailing transition on the HIP.

x_ip_coordinate_real is the x coordinate of the HIP.

y_ip_coordinate_real is the y coordinate of the HIP.

Notes

1. A <length> block with *arc_length_real* equal to zero, or a <spiral> block with the *arc_radius_real*, *leading_transition_length_real* and *trailing_transition_length_real* all zero,

will also represent a HIP with no arcs or transitions on it.:

<length>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<l> *0* </l>

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</length>

OR

<spiral>

<id> *part_id_integer* </id>

time_created_block

time_updated_block

transition_type_block

<r> *0* **</r>**

<l1> *0* **</l1>**

<l2> *0* **</l2>**

<x> *x_ip_coordinate_real* **</x>**

<y> *y_ip_coordinate_real* **</y>**

</spiral>

2. If the HIP is the first HIP or the last HIP then no arc or transitions will be drawn even if the relevant parameters are non zero.

As an example of horizontal_parts with only HIP methods:

```
<horizontal_parts>
  <ip>
    <id> 100 </id>
    <x> 42606.66161172 </x>
    <y> 37239.28824481 </y>
  </ip>

  <ip>
    <id> 200 </id>
    <x> 43134.36832349 </x>
    <y > 37330.26705997</y>
  </ip>

  <spiral>
    <id> 300 </id>
    <r> 50 </r>
    <l1> 30 </l1>
    <l2> 40 </l2>
    <x> 43336.6595 </x>
    <y> 37469.2563 </y>
  </spiral>

  <arc>
    <id> 400 </id>
    <r> 75 </r>
    <x> 43481.15324268 </x>
    <y> 37331.6431906 </y>
  </arc>

  <ip>
    <id> 500 </id>
    <x> 43627.02308964 </x>
    <y> 37544.94343852 </y>
  </ip>
</horizontal_parts>
```

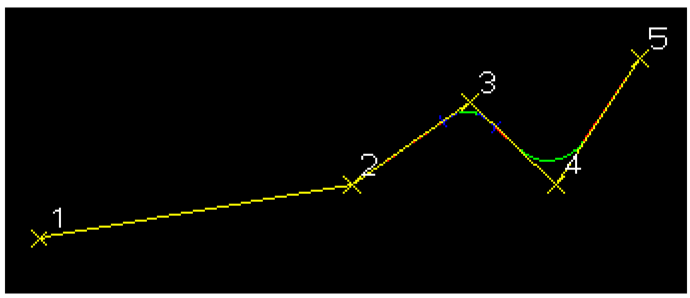
Super Alignment Being Edited



Horizontal Parts with IP Methods Only

35.6.11.3 Vertical Data Block

The *vertical_data* block contains the ***solved*** vertical geometry of the super alignment.

The *solved vertical geometry* is made up of a series of (chainage,height) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, a parabola or an arc.

Note that the ***chainage*** is the chainage of the horizontal geometry defined in the *horizontal_data* block (see 35.6.11.1 Horizontal Data Block).

If the vertical geometry has **n** vertices, then there will be **n-1 segments** for an ***open*** super alignment or **n segments** if the super alignment is ***closed***.

The format of the *vertical_data* block is the same as for the segments in a horizontal_data block except that the data is (chainage, height) rather than (x,y) and there is no transitions but a parabola instead.

The definition of the *vertical_data* block is:

<vertical_data>

string_header_block

closed_block

interval_block

data_2d_block

geometry_data_block

blocks_of_info_1

blocks_of_info_2

.**...**

blocks_of_info_n

</vertical_data>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block. This provides information such as colour for the vertical data.

interval_block

The interval_block for a super string has a *distance* (a chainage interval) and a *chord_to_arc*_real

where

the ***distance*** to temporarily introduce extra vertices into the string at the given chainage distance when the string is in a triangulation to form a tin.

chord_arc_real is a real number and is the chord to arc tolerance to use on any arcs in the vertical data to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

data_2d_block

the *data_2d* block defines the (chainage,height) value of the vertices that makes up the vertical data.

For the definition of the data_2d block, see 35.3.12 data_2d where x is chainage and y is height.

geometry_data_block

the segments of the vertical data can be straights, arcs or parabolas.

For the definition of the *geometry_data* block*, see* 35.6.11.4 Geometry of the Vertical Segments

blocks_of_info

extra information for the vertices and/or segments such as colour, attributes, vertex text, vertex uids etc are defined in the same way as for super strings.

35.6.11.4 Geometry of the Vertical Segments

If the segments are straight lines only then that is the default and no further information is required.

If the segments are only straight lines and arcs, then the ***radius_data*** and **major_data** blocks are used to define a ***radius*** and ***bulge_flag*** data for each segment of the super string. See 35.6.11.4.1 Only Straights and Arcs for Segments.

If any of the segments are parabolas then ***geometry_data*** must be used for each segment. ***geometry_data*** can represent a straight, arc, transition or offset transition. See 35.6.11.4.2 Straights, Arcs and Parabolas for Segments.

35.6.11.4.1 Only Straights and Arcs for Segments

If there are only straight and arc segments for the string, then for the **data_2d** it is possible to add a radius and major/minor arc flag for each segment of the super string using the ***radius_data*** and **major_data** blocks respectively. See 35.3.14 radius_data and major_data.

35.6.11.4.2 Straights, Arcs and Parabolas for Segments

When some of the segments are parabolas then the ***geometry_data*** block **must** be used the give the geometry for each segments.

When the vertical_data has **n** vertices, then the definition of the ***geometry_data*** block is

<geometry_data>

info_for_segment_1_block

info_for_segment_2_block

...

info_for_segment_m_block

</geometry_data>

where

info_for_segment_i_block is the information defining the i'th segment as either a straight, an arc or an parabola and m = n-1 for an open string or m = n for a closed string.

For the definition of *info_for_segment_i_block* see:

35.6.11.4.2.1 Straight

35.6.11.4.2.2 Arc

35.6.11.4.2.3 Parabola

35.6.11.4.2.1 Straight

No parameters are needed for defining a straight segment. The *straight* block is simply:

<straight> </straight>

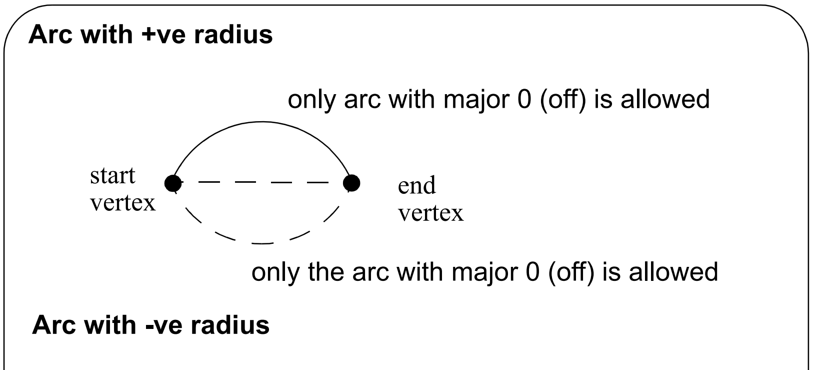
or simply

<straight/>

35.6.11.4.2.2 Arc

Since vertical geometry can't go backwards in chainage value, the majors arcs can not be used and hence there are only possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius to differentiate between the four possibilities.



Arcs with same absolute radius

The *arc* block is:

<arc>

<radius> *radius_for_segment*</radius>

<major> *major_flag_for_segment*</major>

</arc>

where

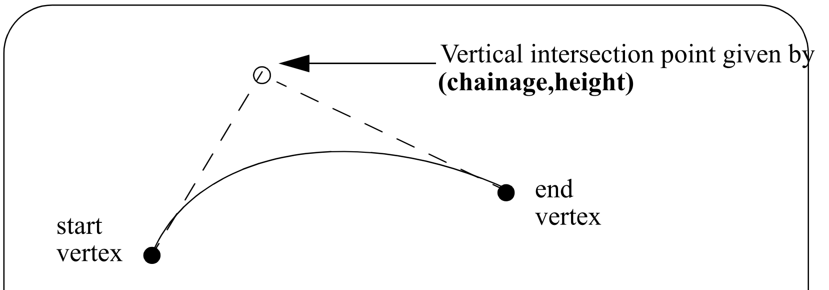
radius_for_segment is the radius for the segment where positive is above the line connecting the vertices.

major_flag_for_segment is ignored because only minor arcs are allowed.

35.6.11.4.2.3 Parabola

There can be a parabola between adjacent vertices. The parabola is defined by giving the coordinates of the vertical intersection point for the parabola

chainage chainage of the VIP of the parabola
height height of the VIP of the parabola



Example of a Parabola

The *parabola* block is:

<parabola>

<chainage> *vip_chainage_real* </chainage>

<height> *vip_height_real* </height>

</parabola

where

vip_chainage_real is the chainage of the VIP of the parabola

vip_height_real is the height of the VIP of the parabola

35.6.11.5 Vertical_parts When VG is Defined by IP Method Only

When the vertical geometry is defined by IP methods only, then the ***vertical_parts*** is fairly straight forward.

When ***12d Model*** reads in a 12d XML file and there is no ***vertical_data*** section, then ***12d Model*** will calculate the ***vertical_parts***. So if you are writing a 12d XML with only VIP methods for the vertical geometry then simply leave out the ***vertical_data*** section and ***12d Model*** will calculate it for you.

For a vertical geometry is defined by VIP methods only, the ***vertical_parts*** definition is:

<vertical_data>

info_for_VIP_1_block

info_for_VIP_2_block

...

info_for_VIP_n_block

</vertical_data>

where ***info_for_VIP_i_block*** is the information about the successive VIPs in the super alignment and is one of:

(a) A vertical intersection point (VIP) with no arc or parabola.

This is defined by:

<ip>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</ip>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

(b) A vertical intersection point (VIP) with an parabola of a given chainage length at the VIP

This is defined by:

<length>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<l> *parabola_chainage_length_real* </l>

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</length>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_chainage_length_real is the chainage length of the parabola on the VIP.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

(c) A vertical intersection point (VIP) with an parabola of a given k value at the VIP

This is defined by:

<kvalue>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<k> *parabola_k_value_real* </k>

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</kvalue>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_k_value_real is the k value of the parabola on the VIP.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

(d) A vertical intersection point (VIP) with an parabola of a given effective radius value at the VIP

This is defined by:

<radius>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<r> *parabola_effective_radius_value_real* </r>

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</kvalue>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_effective_radius_value_real is the effective radius of the parabola on the VIP.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

(e) A vertical intersection point (VIP) with an arc of a given radius at the VIP.

This is defined by:

<arc>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<r> *arc_radius_real* **</r>**

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</arc>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

arc_radius_real is the radius of the arc on the VIP.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

(f) A vertical intersection point (VIP) with an asymmetric parabola defined by the start and end chainage lengths at that VIP

This is defined by:

<asymmetric>

<id> *part_id_integer* **</id>**

time_created_block

time_updated_block

<l1> *parabola_start_chainage_length_real* **</l1>**

<l2> *parabola_end_chainage_length_real* **</l2>**

<x> *chainage_ip_coordinate_real* **</x>**

<y> *height_ip_coordinate_real* **</y>**

</asymmetric>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block

is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block

is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_start_chainage_length_real is the start chainage length of the asymmetric parabola on the VIP.

parabola_end_chainage_length_real is the end chainage length of the asymmetric parabola on the VIP.

chainage_ip_coordinate_real is the chainage of the VIP.

height_ip_coordinate_real is the height of the VIP.

Notes

1. A <length> block with *arc_length_real* equal to zero, or a <spiral> block with the *arc_radius_real*, *leading_transition_length_real* and *trailing_transition_length_real* all zero, will also represent a HIP with no arcs or transitions on it.:

   <length>

   <id> *part_id_integer* **</id>**

   time_created_block

   time_updated_block

   <l> *0* </l>

   <x> *x_ip_coordinate_real* **</x>**

   <y> *y_ip_coordinate_real* **</y>**

   </length>

   OR

2. If the VIP is the first VIP or the last VIP then no parabola or arc will be drawn even if the relevant parameters are non zero.

As an example of ***vertical_parts*** with only VIP methods:

```
<vertical_parts>
  <ip>
    <id> 600 </id>
    <x>-50.8459652 <x>
    ,<y> 59.79764161 <y>
  </ip>
  <kvalue>
    <id> 700 </id>
    <k> 1.25 </k>
    <x> 38.4627 </x>
    <y> 179.2126 </y>
  </kvalue>
    <length>
    <id> 800 </id>
    <l> 50 </l>
    <x> 172.61694837 </x>
    <y> 154.72967932 <x>
  </length>
  <asymmetric>
    <id> 900 </id>
    <l1> 25 </l1>
    <l2> 75 </l2>
    <x> 270.0182 </x>
    <y> 208.1493 </y>
  </asymmetric>
    <arc>
    <id> 1000 </id>
    <r> 1000 </r>
    <x> 424.2402 </x>
    <y>196.5637 </y>
  </arc>
  <radius>
    <id> 1100 </id>
    <r> 200 </r>
    <x> 526.7263 </x>
    <y> 201.5302 </y>
  </radius>
  <ip>
    <id> 1200 </id>
    <x> 637.69216273 </x>
    <y> 198.71894484 </y>
  </ip>
</vertical_parts>

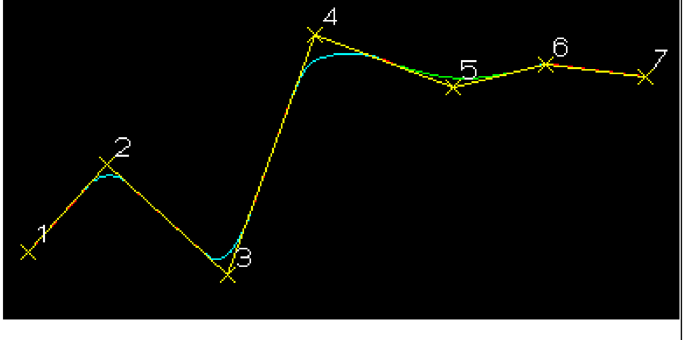
Vertical Geometry Being Edited



Vertical Parts with IP Methods Only

Continue to the next section 35.6.12 Text String or return to 35.6 Elements Contained in Models
or 35 12d XML File Format.

35.6.12 Text String

The format for the **string_text** element is:

<string_text>

string_header_block

point_block

vertex_text_value_block

vertex_annotate_value_block

</string_arc>

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

point_block

The format of the **point_block** is:

<point> *x_real y_real z_real* **</point>**

where

(*x_real,y_real,z_real*) is the vertex of the text.

vertex_text_value_block

The text for the text string.

The format of the **vertex_text_value_block** is:

<vertex_text_value**>** *characters_of_the_text* **</**vertex_text_value**>**

where

characters_of_the_text is the characters of the text with the except of some character that are special characters and are replace by something else.

For example **&** in the text is replaced **&amp** and a new line is given by **
**. See Characters "<", ">" and "&" and Escaping.

vertex_annotate_block

These are the setting for displaying text at a vertex.

The format of the **vertex_annotate_block** is:

<vertex_text_value**>**

vertex_annotation_information

</vertex_text_value**>**

where

vertex_annotation_information is the annotation to be used for drawing the text. For the definition of *vertex_annotation_information* see 35.6.4.1 Vertex Annotation Information.

For example

```
<string_text>
    <name>text</name>
    <chainage>0</chainage>
    <breakline>line</breakline>
    <colour>yellow</colour>
    <style>1</style>
    <time_created>28-Apr-2015 07:48:35</time_created>
    <time_updated>28-Apr-2015 07:49:33</time_updated>
```

```
    <point>1230.93054186 517.0328703 null</point>
    <vertex_text_value>First line&#xa;Second line</vertex_text_value>
    <vertex_annotate_value>
        <worldsize>20</worldsize>
        <textstyle>Arial</textstyle>
        <angle>45</angle>
        <x_factor>1</x_factor>
        <slant>0</slant>
        <offset>0</offset>
        <raise>0</raise>
        <text_colour>yellow</text_colour>
        <justify>middle-centre</justify>
    </vertex_annotate_value>
</string_text>
```

Continue to the next section 35.6.13 Trimesh or return to 35.6 Elements Contained in Models or 35 12d XML File Format.

35.6.13 Trimesh

A trimesh is a special type of primitive_3 object.

A trimesh is made up of 3D triangles and can be described by giving the list of ***m*** vertices in the trimesh and the three vertices that make up each of the ***n*** triangular faces.

The 12d XML definition of a trimesh is:

<primitive_3d>

string_header_block

trimesh_3d_block

</primitive_3d>

where

string_header_block

the common header block for each string. For the contents and the syntax, see 35.6.3 String Header Block.

The ***colour*** in the *string_header_block* is the base colour for the trimesh.

trimesh_block

The trimesh block gives the vertices of the trimesh and then the faces of the trimesh in terms of the vertex numbers.

<trimesh_3d>

<***vertices***>

<v> *x_value_1* *y_value_1* *z_value_1* **</v>**

<v> *x_value_2* *y_value_2* *z_value_2* **</v>**

...

<v> *x_value_n* *y_value_n* *z_value_n* **</v>**

</***vertices***>

<***faces***>

<f> *face_1_vertex_1* *face_1_vertex_2* *face_1_vertex_3* **</f>**

<f> *face_2_vertex_1* *face_2_vertex_2* *face_2_vertex_3* **</f>**

...

<f> *face_m_vertex_1* *face_m_vertex_2* *face_m_vertex_3* **</f>**

</***vertices***>

</trimesh_3d>

where

n is the number of vertices and (*x_value_i*, *y_value_i*, *z_value_i*) are the 3D coordinates of the ***i***'th vertex

m is the number of faces in the trimesh and *face_j_vertex_1*, *face_j_vertex_2*, *face_j_vertex_3* are the number of the vertices in the ***vertex*** block for the j'th face.

36 12d Survey Guide

The information contained in this appendix outlines the general options, terminology, definitions and methods used by 12d Model for the purpose of the input, reduction and output of survey information. It is a general guide, with the appendices following relating to specific instruments and the interactions with 12d Model.

See

Guide to Survey Reduction in 12d Model
Guide to Survey Coding in 12d Model
Field Coding
Field Templates
Shape field coding
Traverse coding

Data Collector Definitions
The 12d Field File Format
Batch Typed Entry

Please continue to the next section 36.1 Guide to Survey Reduction in 12d Model.

36.1 Guide to Survey Reduction in 12d Model

The ***12d Model*** **survey** options are used to reduce electronically recorded survey information and produce 12d Model strings, a process called **survey reduction**.

In the most general case, there are three steps involved:

1. 12d Model downloads raw data from a data collector and stores it on the computer.
2. The raw data file is converted to a standard 12d Model raw field file format, normally with extension of ".fld". For simplicity, the standard 12d Model raw field file is called the "12d field file".
3. The 12d field file is read into a ***12d Model*** Survey Reduction function (12d Survey function) and reduced. If errors occur, the field data for 12d Survey function can be interactively and/or graphically edited. The reduction produces 12d Model super strings in one or many ***12d Model*** models.

In some circumstances, not all steps are necessary.

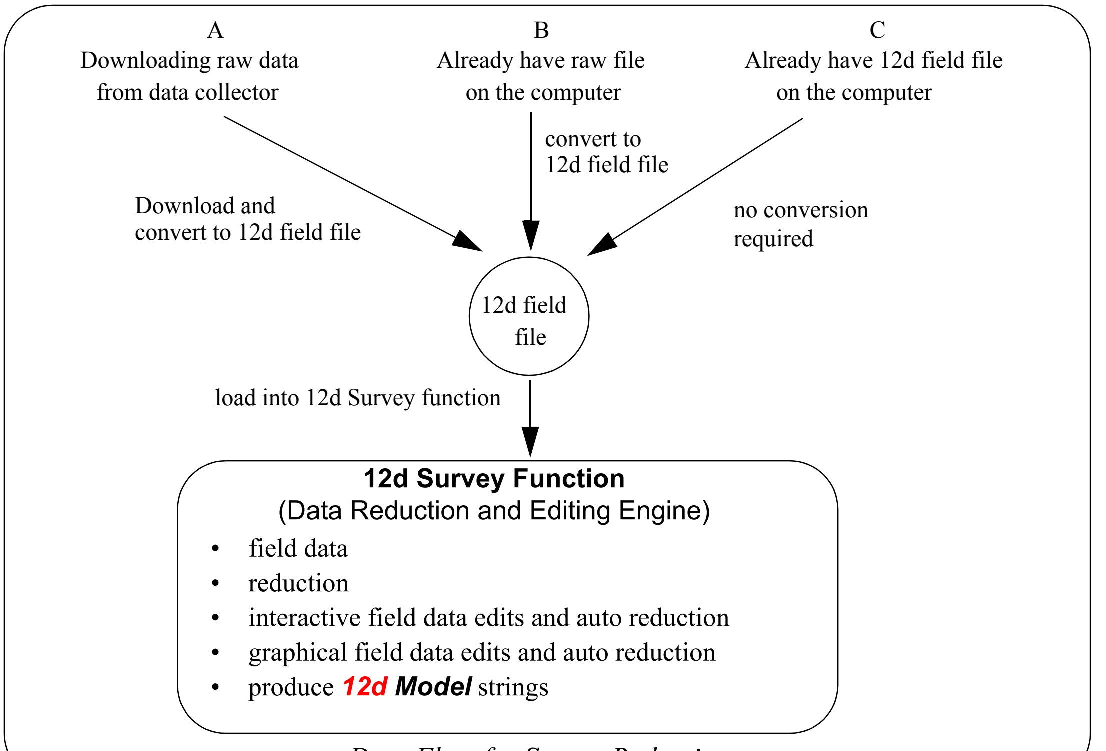
For example, Step 1 is not necessary when the raw data file is already on the computer (and hence doesn't need downloading).

This often occurs when data collectors have PCMCIA cards and PCMCIA card readers on the computer. Another example is when the raw data file has already been downloaded to the computer using another package such as HyperTerminal. Or maybe the raw data file has already been downloaded in a previous 12d Model session.

Steps 1 and 2 are not necessary when the data is already in the form of a 12d field file.

This occurs when other software packages, such as TP Setout, can produce a 12d field file. Or the 12d field file was created in a previous 12d Model session, maybe even on a different computer.

A data flow diagram for the survey reduction process is:



Data Flow for Survey Reduction

Please continue to the next section 36.2 Guide to Survey Coding in 12d Model.

36.2 Guide to Survey Coding in 12d Model

At first the whole process may seem confusing because there are a multitude of methods of setting up coding in the field. Why isn't there just one way of doing things?

Firstly, each brand of survey instrument has a totally different format for recording information. Unfortunately there is no industry standard. In fact, different instruments from the same survey instrument manufacturer can have different formats for recording data.

Secondly, many of our customers were already familiar with another survey package and if possible, wished to continue field coding in the same way. Where possible, ***12d Model*** has tried to accommodate this wish. Since ***12d Model*** has replaced a number of survey packages, this led to yet more possible configurations.

12d Model has also been developing its own preferred method of field coding for each instrument. It is not compulsory to use the 12d method but of course it is the only way of taking advantage of features that are not available in other coding systems. For example, defining and using field templates and recording user-defined attributes on points and segments.

So to make help guide you through survey coding section:

(a) There are field coding concepts used in ***12d Model*** that are common to all instruments. For example, feature codes and string numbers, offset, close strings etc.

These are described in 36.3 Field Coding

(b) There are template field coding concepts used in ***12d Model*** that are common to all instruments. These are described in 36.4 Field Templates

(c) There are shape field coding concepts used in ***12d Model*** that are common to all instruments. These are described in 36.5 Shape field coding

(d) There are traverse field coding concepts used in ***12d Model*** that are common to all instruments. These are described in 36.6 Traverse coding

(e) For leica instruments, the coding methods are different from most other types. These are described in 36.7 Field Coding for Leica Instruments

(f) For non-leica instruments, the concepts used in coding are similar for each type. These are described in 36.8 Field Coding for Non Leica Instruments

36.3 Field Coding

EDM equipment is used to make readings of points in the field.

However, rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information.

Unfortunately, there is no industry standard for this extra coding and it is software specific.

In 12d Model, the extra information is included in one or both of

- a *feature code* and *string number*
- extra commands called *field codes*

How the *feature codes*, *string number* and *field codes* are added in the field depends on the data collector being used and the coding convention set up by the user in ***12d Model***.

For example, some surveyors like to enter the *feature code* before the *string number*, others like to enter the *feature code* after the *string number*. Other surveyors don't use string numbers at all but prefer to use a *New String* command to start new strings (mainly ex SDR Map users).

In ***12d Model***, a particular *field coding convention* is defined by the user and stored with a ***unique*** name as a *data collector definition* in the file survey.4d. New data collector definitions can be created and existing ones modified using the *Survey Data Collectors* section of *Project=>Browse*.

12d Model converts all the raw data files from the different survey instruments and data recorders with different coding conventions, into the one 12d Model standard field file format before being loaded into a ***12d Model*** Survey Reduction function and reduced. The 12d Model standard field file will simply be referred to as the 12d field file or just the field file.

The use of many of the commands allowed in the 12d field file will now be described. The complete definition of all the 12d field file commands will be described later.

The coding methodology for specific data recorders will be described in separate Sections.

Please continue to the next section 36.3.1 Stringing in the Field.

36.3.1 Stringing in the Field

In the coding convention, it is possible to specify that

(a) *feature codes* and *string numbers* are used
or
(b) just feature codes.

Case (a) ***feature codes*** **and** ***string numbers***

If *feature codes* and *string numbers* are entered with measurements in the field, a coding methodology is used so that strings are automatically created during the reduction process.

To allow this stringing, the **feature code** and **string number** are interpreted in the following manner:

During reduction, 12d Model connects measurement points with the **same** *feature code* **and** *string number* in the order they are measured in. That is, the feature code **and** string number determines which points are joined together to form the vertices of a super string. At the end of the reduction, the *string number* is dropped and just the *feature code* remains as the *name* for the super string.

Hence the *feature code* and *string number* combination allows any number of different super strings with the same name (feature code) to be produced.

If the *string number* is zero, then the point-line type of the super string is set to *point*. If the *string number* is non-zero, the point-line type of the super string is set to *line*.

Finally, during reduction, the *feature code* can be used as the key to a Map File to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes and string numbers can be intertwined. That is, *not* all the points in one super string need to be measured before the points in a different super string.

Hence at the end of the reduction, 12d Model super strings are created for each unique *feature code* and *string number* combination in the input data.

Note - if the *string number* is blank, the *string number* defaults to 0

Case (b) just ***feature codes***

If just *feature codes* are used then a *New String* command is used to start a new super string rather than giving a new string number.

During reduction, 12d Model connects measurement points with the **same** feature code in the order they are measured in until a *New String* command is found. That is, just the feature code determines which points are joined together to form a super string and the *New String* command defines when a new super string begins.

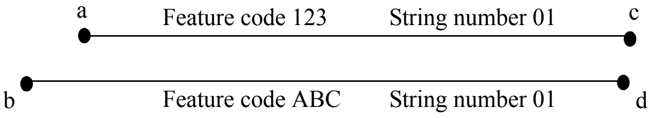
At the end of the reduction, the *feature code* remains as the *name* for the super string.

Also during reduction, the *feature code* can be used as the key to a Map File to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes can be intertwined. That is, *not* all the points in one super string need to be measured before the points in a different super string.

An Example of Coding to String Points Together

Two super strings are to be created, one joining points **a** and **c**, the other joining points **b** and **d**.



Points may be measured and assigned *feature codes* and *string numbers* as follows:

Measurement to point	Feature code	String Number
a	123	01
b	ABC	01
c	123	01
d	ABC	01

Alternatively, the points could have been measured in the order a, c, b, d as long as the correct *feature codes* and *string numbers* were entered.

Measurement to point	Feature code	String Number
a	123	01
c	123	01
b	ABC	01
d	ABC	01

Because the *string numbers* are non-zero, the default *point-line* type for both super strings is *line*.

Please continue to the next section 36.3.2 Offsets.

36.3.2 Offsets

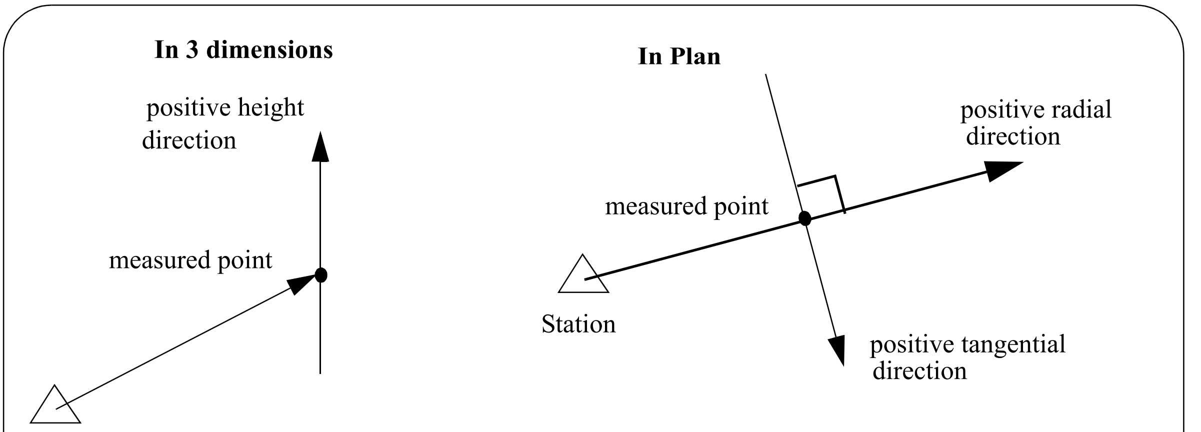
It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the co-ordinates of the required point.

The three offsets that are allowed in the 12d field file are:

Height - The *height offset* adjusts the height of a non-null point. A positive offset adds to the height and a negative offset reduces the height.

Radial - The *radial offset* adjusts the position of the specified point by a *plan* distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station and a negative offset is toward the station.

Tangential - The *tangential offset* adjusts the position of the specified point by a *plan* distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A positive offset is to the right (looking from the station to the point) and a negative offset is to the left.



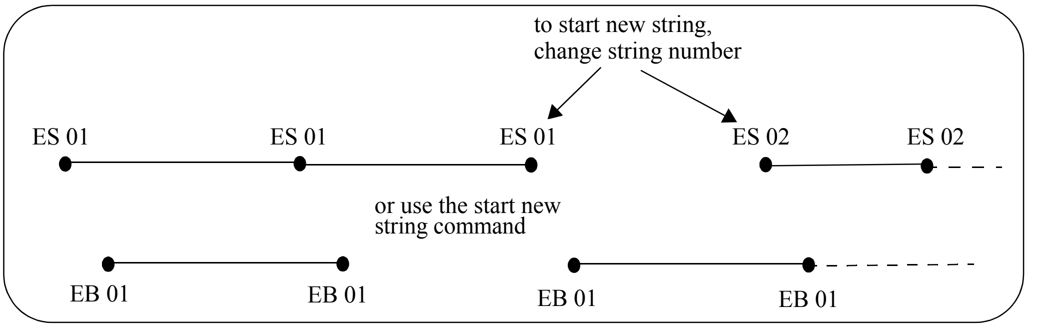
Offset Directions

Please continue to the next section 36.3.3 Start New String.

36.3.3 Start New String

A new string is automatically started whenever a different string number is used. However there is also a ***start new string*** command which begins a new super string even if the string number is the same as the string number for previous points.

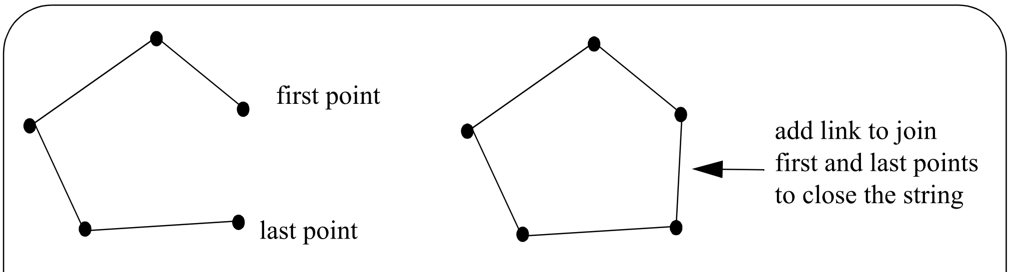
The *New String* command is particularly useful for correcting the field error of forgetting to change the string number.



Please continue to the next section 36.3.4 Close String.

36.3.4 Close String

The close string command closes a super string by joining the first and last points of the super string. If a super string is already closed, then the close has no effect. The string closed command can be given at the recording of any point of the string, and the entire string is closed.



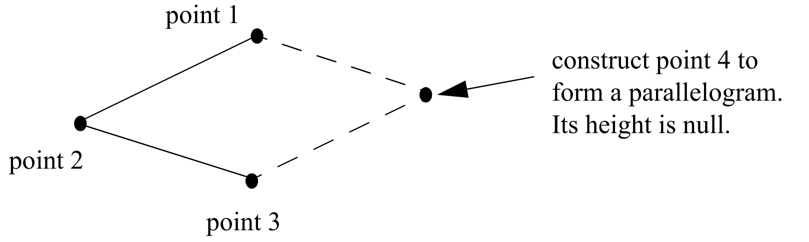
Close String

Please continue to the next section 36.3.5 Rectangle.

36.3.5 Rectangle

The rectangle command acts on last three points of a string and adds a new point after the last point to form a parallelogram (squashed rectangle). The string is then closed.

The height of the added point is set to null.



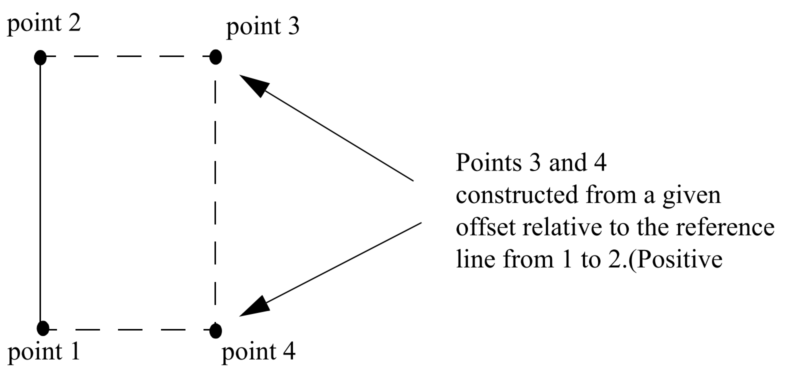
Form Rectangle

Please continue to the next section 36.3.6 Rectangle by 2 Points.

36.3.6 Rectangle by 2 Points

The rectangle by 2 pts command acts on last two points of a string and adds two new points at a given offset after the last point to form a rectangle. The string is then closed.

The height of the added points are set to null.



Form Rectangle By 2 Points

Please continue to the next section 36.3.7 Feature.

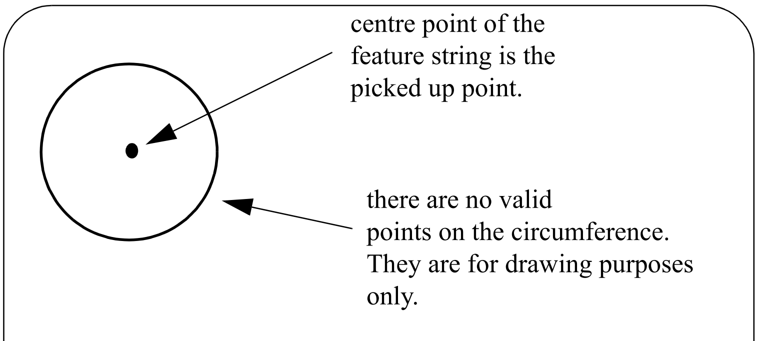
36.3.7 Feature

A *feature string* is a circle with a z-value at the centre but only null values on the circumference of the circle.

The feature commands creates a *feature string* with the picked up point as its centre and the radius/diameter being set by the feature command.

If a feature string is given a ***world*** line style, then the style is centred on the centre point of the feature string and scaled up to the radius of the feature string.

If a feature string is given a ***screen*** or ***paper*** line style, then the style is wrapped around the circumference of the feature string.



Feature String

Please continue to the next section 36.3.8 Joining Strings.

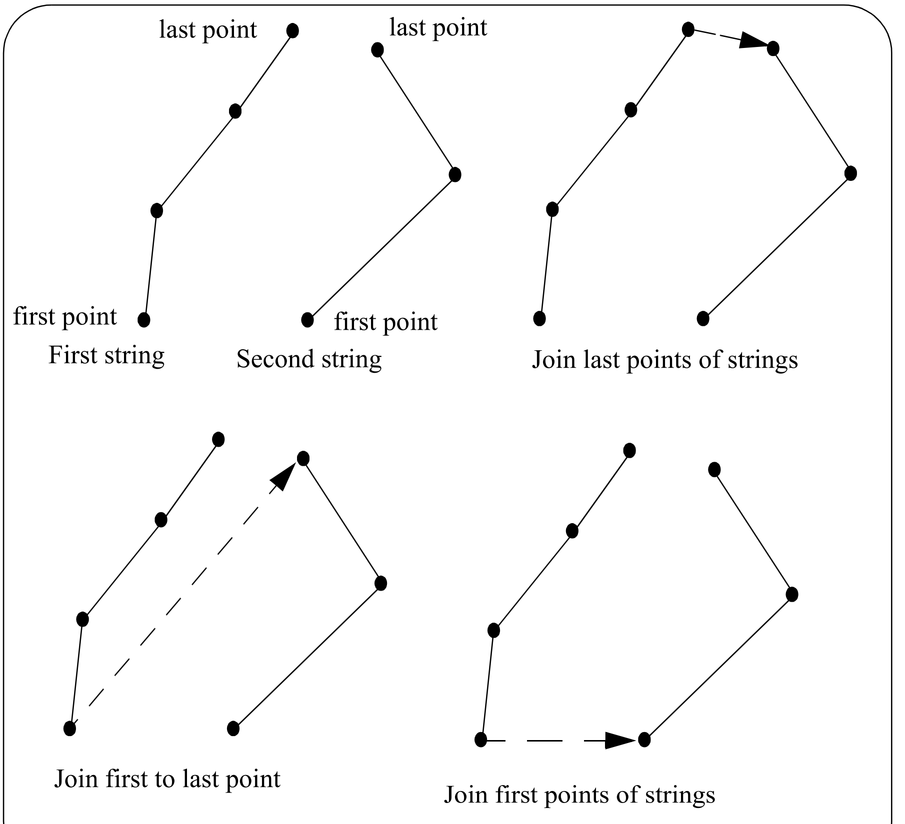
36.3.8 Joining Strings

There are three commands for joining two strings together.

Join last points of strings - the last point of the first string is joined to the last point of the second string. The direction of the final string is along the forward direction of the first string, across to the end of the second string and then in the reversed direction of the second string.

Join first to last points of strings - the first point of the first string is joined to the last point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.

Join first points of strings - the first point of the first string is joined to the first point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.



Join Strings

Please continue to the next section 36.3.9 Arcs Through Points.

36.3.9 Arcs Through Points

There are a number of commands to fit arcs through sequences of three or more points. Note that this is an **arc** in **plan**, with different z-values at each of the three points. The z-values are linearly interpolated around the arc between the points.

Hence it is a **helix** and **not** a circle in the plane containing the three points. Note that an 3d-arc in a plane not parallel to the x-y plane does **not** project onto an arc in the x-y plane.

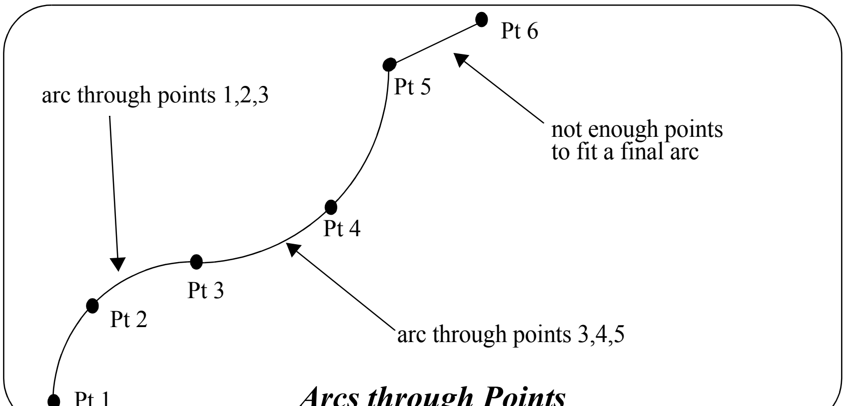
There are arc commands to

(a) fit an arc through the next three points

(b) fit an arc through the previous three points.

(c) fit arcs to sets of three points until stopped.

The first two cases need no explanation but in the final case, a arc is fitted to the first three points, and then another arc to points 3, 4 and 5 and then an arc through 5,6 and 7 and so on. If at any stage there is only one point left, then no arc can be fitted and a straight line is drawn to the final point.



Arcs through Points

Please continue to the next section 36.4 Field Templates.

36.4 Field Templates

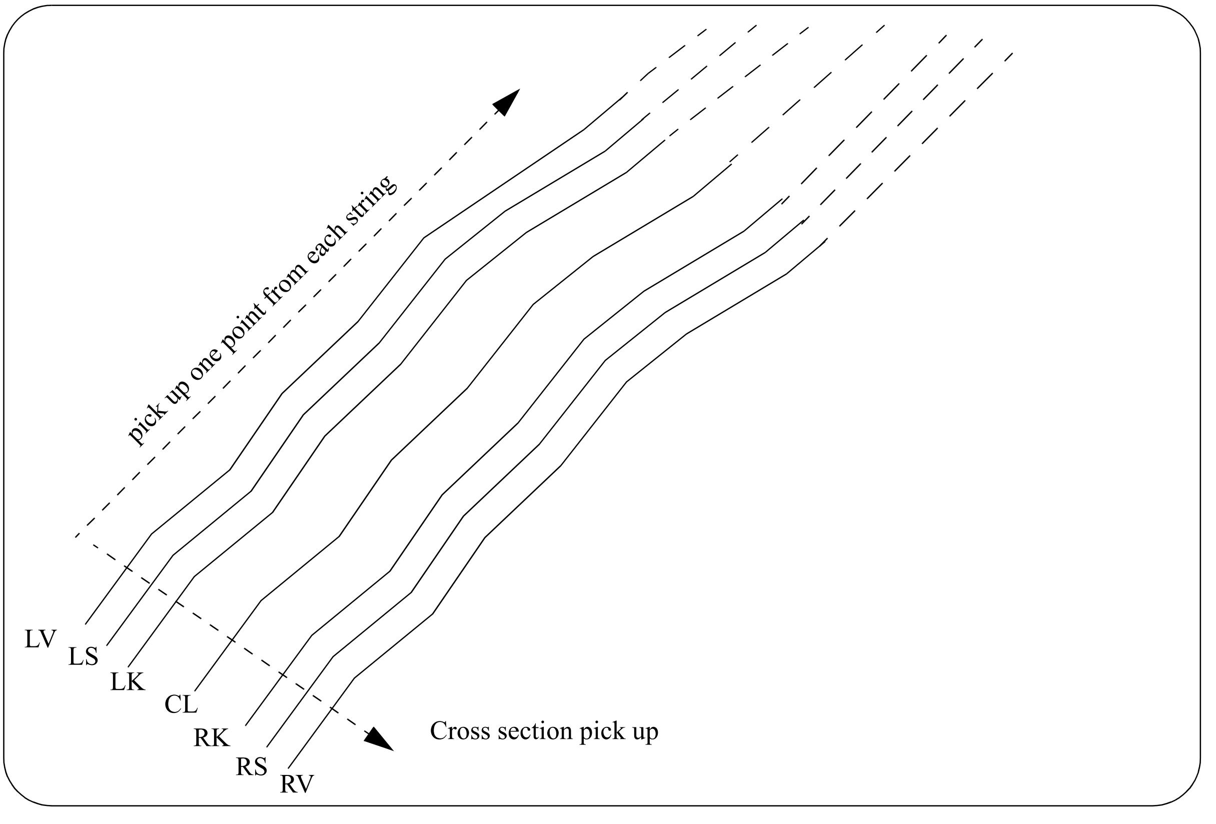
If a series of points are being picked up along the one string then the *feature code* and *string number* only need to be entered once since the default is for a measurement to use the last *feature code* and *string number* if no new ones are given.

However it is often much more efficient to pick up one point from a number of strings before moving onto the next point of each string (this is called a cross section pick up).

For example when picking up a road, it would be preferable to pick up the points for a section across the road and then move onto the next section rather than picking up all of one string at a time.

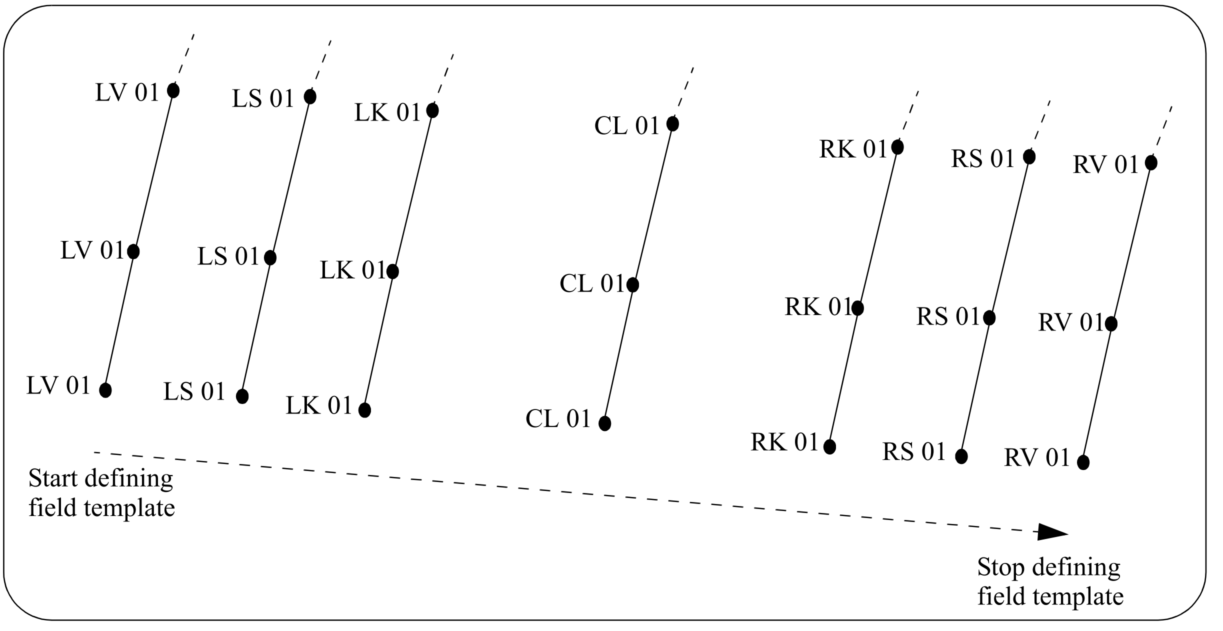
In the diagram below, this means picking up one point from each of the strings LV, LS, LK, CL, RK, RS, RV and then moving onto the next cross section rather than picking up all of LV and then all of LS and so on.

Normally if each measurement is from a different string, then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, ***12d* Model** uses ***field templates***.



Basically, a ***12d* Model** *field template* consists of defining a sequence of *feature codes* and s*tring numbers* pairs for the field template. The field template can be given a unique name or have no name at all.

When a field template is used, measurements are taken without entering a *feature code* and *string number* and the *feature code* and *string number* for the measurement come from the *field template definition*.



For example, a field template could be defined as the sequence:

LV 01, LS 01, LK 01, CL 01, RK 01, RS 01, RV 01

When the field template is used, measurements are taken without giving a feature code or string number and the measurements will be sequentially given the codes LV 01, LS 01, LK 01 etc.

To define a ***12d Model*** *field template*, there is a command to *start recording* the field template.

The *feature code*s and *string numbers* for the next series of measurements until the *stop recording* command is given, are stored as the field template. There are also commands to *insert* and *delete* a point in the template when it is being used for picking up points.

When a field template is used, the feature code and string number from the field template can be used:

(a) in the same order as the codes are defined in the field template (forward direction).

(b) in the opposite order to how the codes are defined in the field template (reverse direction).

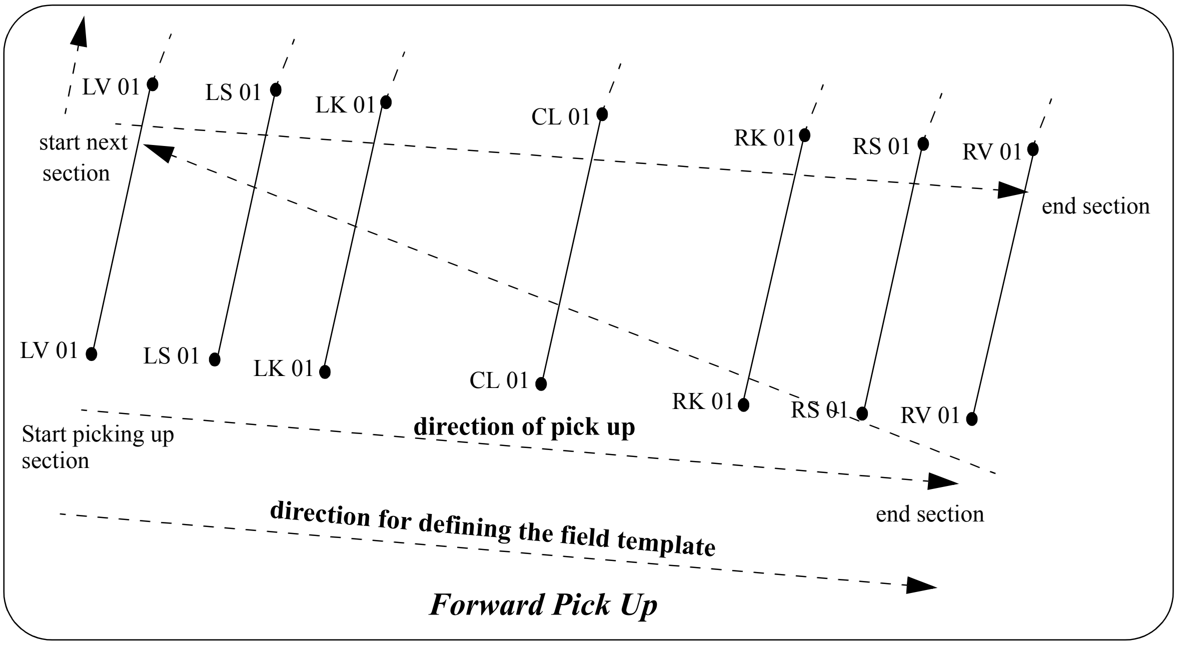
(c) in an alternating same and opposite order that the codes are defined in field template (zig-zag)

These three modes of usage of a field template will be described in the following sections.

Please continue to the next section 36.4.1 Forward Direction.

36.4.1 Forward Direction

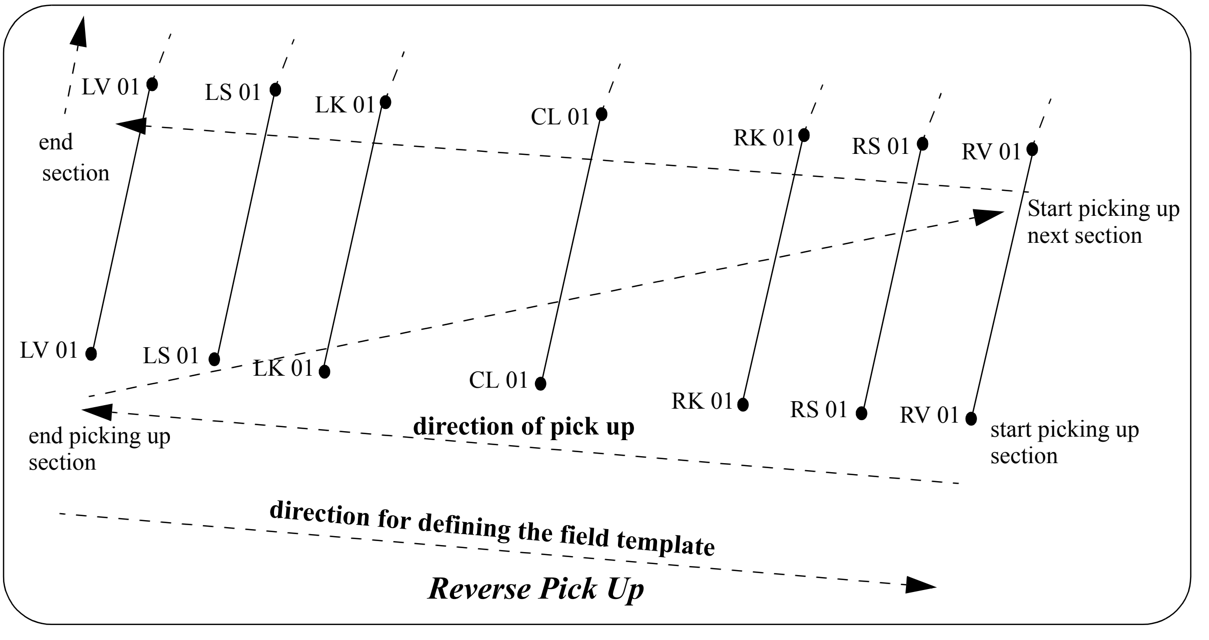
If the field template is used in the *forward* direction, then the feature codes and string numbers are used in the same order that they were defined to be in the field template. Once the end of the field template is reached, the feature codes and string numbers re-start at the beginning of the field template.



Please continue to the next section 36.4.2 Reverse Direction.

36.4.2 Reverse Direction

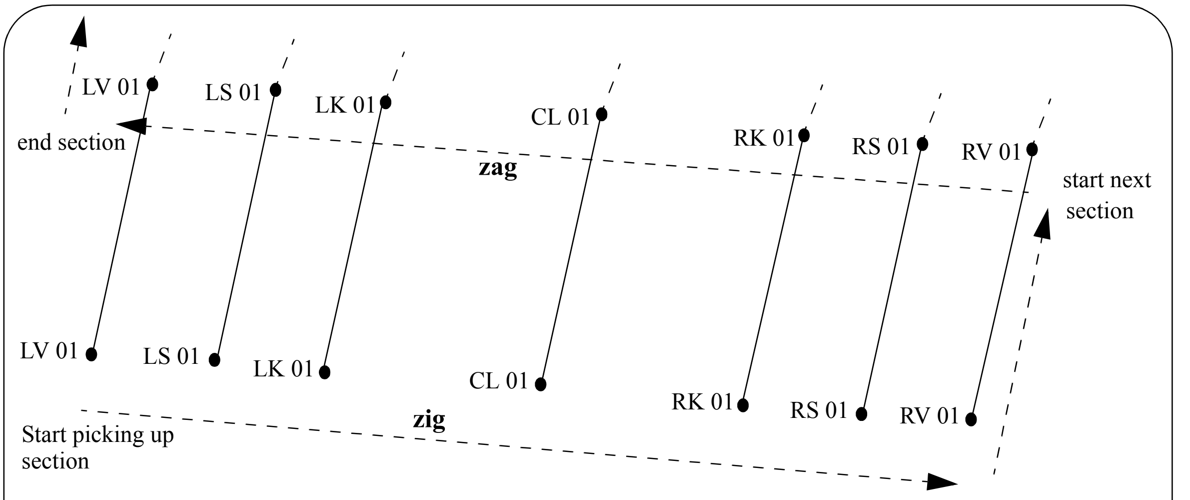
If the field template is used in the *reverse* direction, then the feature codes and string numbers are used in the reverse order to what they were defined to be in the field template. That is the feature codes and string numbers start at the *end* of the field template definition and are used in the reverse order. Once the beginning of the field template is reached, the feature codes and string numbers re-start at the end of the field template and are used in the reverse order.



Please continue to the next section 36.4.3 Zig-Zag.

36.4.3 Zig-Zag

When picking up a road in sections, it is often quickest to pick up the first section going from one side of the road to the other side, and then move onto to the next section point on the other side of the road and pick up points coming back across the road. Hence the points for the second section are in the reverse order to those in the first section. This process is known as zig-zagging.



Zig-Zag Pick Up

This situation can be covered in two ways. A field template could be defined containing all the points for two sections and the field template used in the forward (or reverse) direction. For example, the field template to be used in the forward mode could be defined as:

LV 01, LS 01 LK 01, CL 01, RK 01, RS 01, RV 01, RV 01, RS 01, RK 01, CL 01, LK 01, LS 01, LV 01

However, in ***12d Model*** it is only necessary to define the *one* section

LV 01, LS 01 LK 01, CL 01, RK 01, RS 01, RV 01

and when the field template is used, it is specified that it is being used as a *zig-zag* field template starting on either the *zig* (the forward direction of the field template) or the *zag* (the reverse direction of the field template).

Once a *zig* is completed, ***12d Model*** automatically uses the reverse order of the field template and hence produces a *zag*. Similar, once a zag is completed, ***12d Model*** uses the forward order of the field template and produces a zig.

Thus a zag automatically follows a zig and a zig follows a zag.

Hence if a field template is used in the zig-zag mode, it can be used as either:

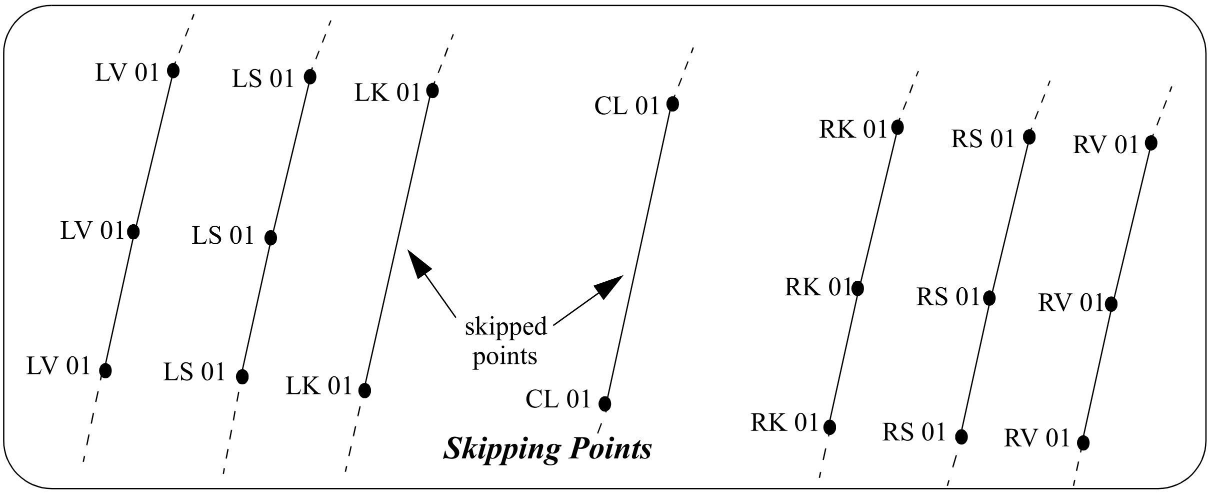
(a) a zig-zag field template starting on the zig

(b) a zig-zag field template starting on the zag.

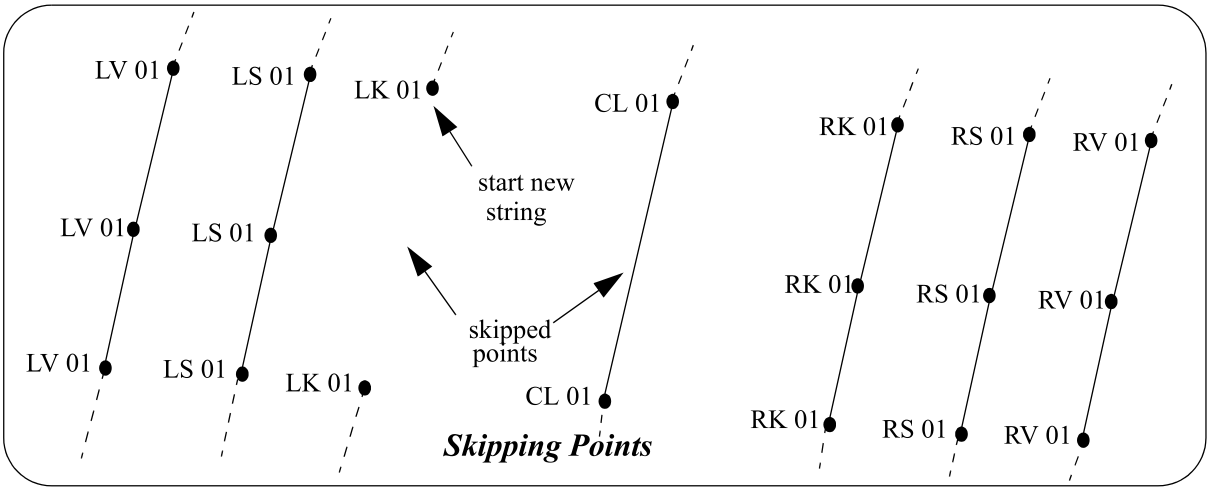
Please continue to the next section 36.4.4 Skipping Field Template Points.

36.4.4 Skipping Field Template Points

When picking up points using a field template, ***12d Model*** allows for one or more points to be skipped. By default, the points on the strings on either side of the skipped points will then be joined together.



By combining skipping points and start new string commands, points can be skipped and new strings started on the other side of the skipped points.



Please continue to the next section 36.4.5 Insert Template Points or Insert Multiple Codes.

36.4.5 Insert Template Points or Insert Multiple Codes

When picking up points using a field template, ***12d Model*** allows for one or more points to be inserted. The inserted points ***change*** the template from that point onwards so that extra strings can be picked up as they arise.

If the insert point command is given after the last point of a template, a flag can be applied to specify which template pick-up the inserted point is to be added to. That is, add it to the last series of points or the next series. This flag is called the "insert special" flag.

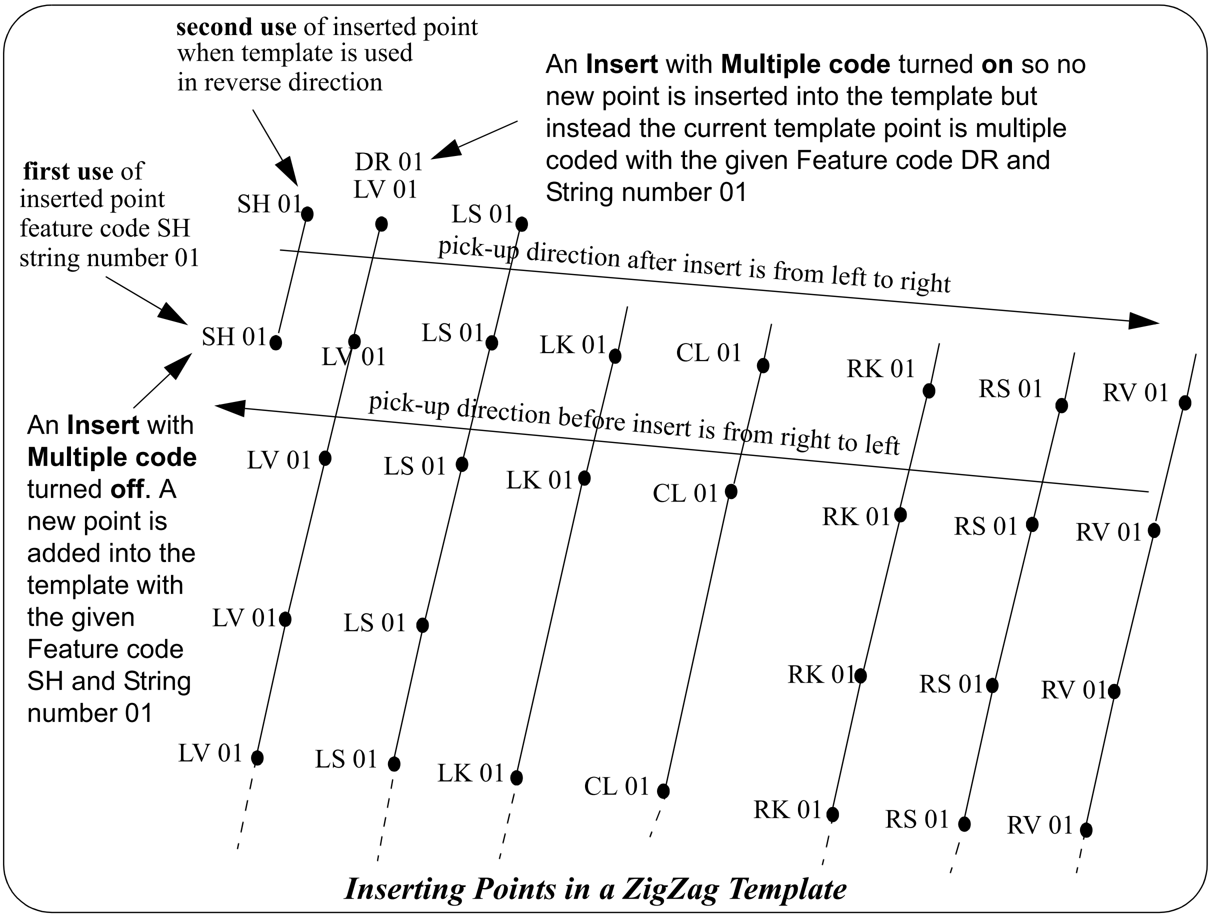
If ticked on in the insert panel, or if the flag given in the offset code is 1, the point will be added to the current series of points in the template being picked up.

In the case shown below where SH 01 is inserted, the insert special flag should be set to on so that the next picked up point will be on the current template. The insert would have been made after the last LV 01 observation in the last pick-up direction. The following pick-up will use the redefined template definition.

Note - in the example below, it is a zig-zag template so SH 01 is then used again straight away as the first point of the pickup when coming from left to right.

With the Insert, rather than insert new template points, it is also possible to give multiple codes to existing points in the template so that more than one code can be assigned to the one pick-up point (insert multiple codes).

In the case shown below, an insert was made on the next pick-up direction after the LV 01 observation. The multiple code tick box or flag was set on so that the last picked up point will be assigned the extra code specified, in this case DR 01. The template will be applied to all subsequent measurements so that the observed LV 01 string will also be coded DR 01.



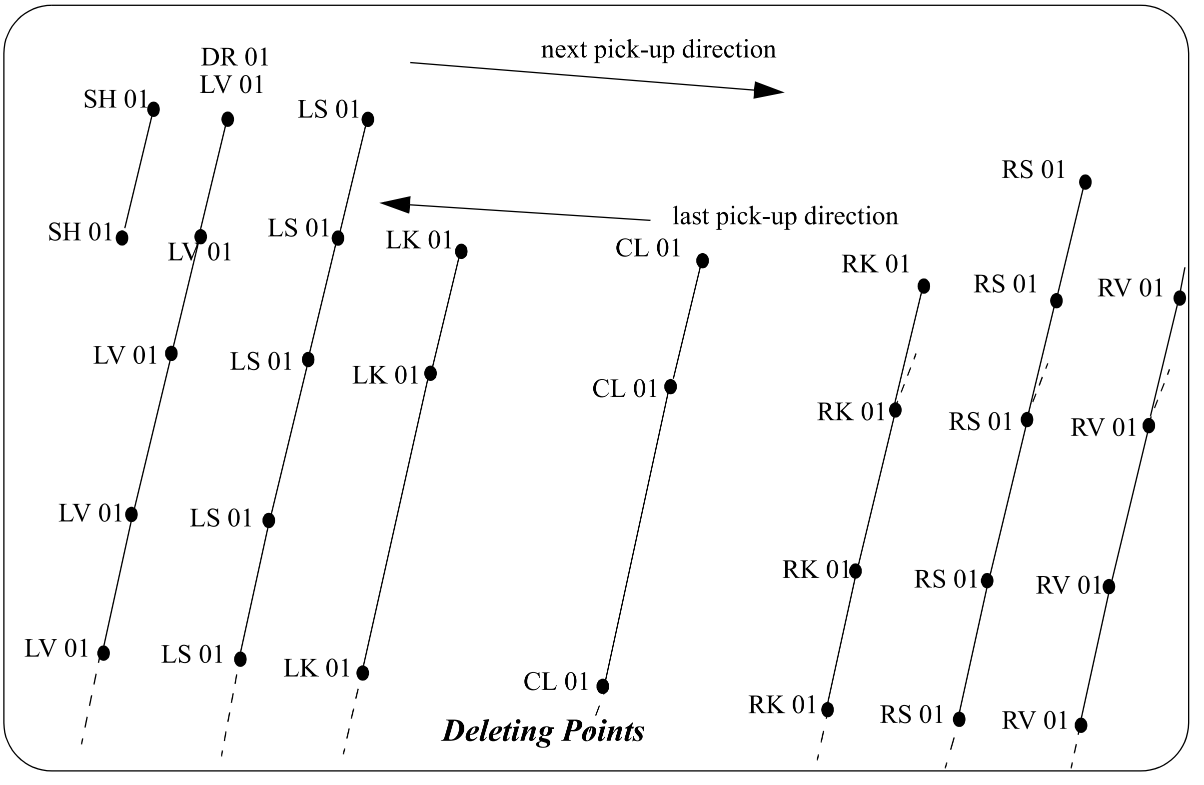
Inserting Points in a ZigZag Template

Please continue to the next section 36.4.6 Delete Template Points.

36.4.6 Delete Template Points

When picking up points using a field template, ***12d Model*** allows for one or more points to be deleted. The deleted points change the template from the next specified number of points inclusive of the current point. i.e. They are removed from the template.

If a template delete command was given after the LS 01 string in the next pick-up direction, and the number of specified points were 3, the template will be altered such that the next observed string will be RS 01.



Deleting Points

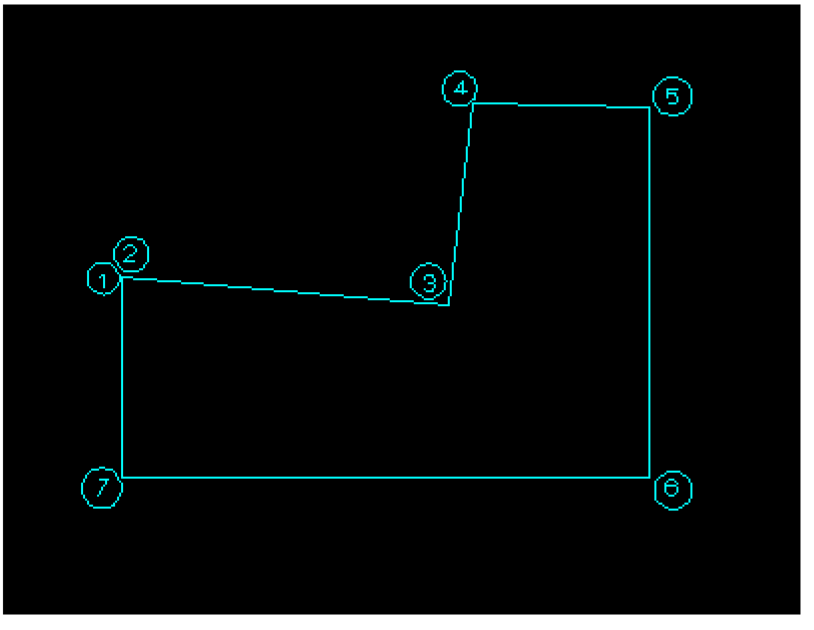
36.5 Shape field coding

If a an object of a standard section is to picked up such as a length of kerb, a shape can be defined and extruded/parallelled along a single pick-up string related to that shape.

For example, a kerb shape can be defined by observing all points on a typical section of the kerb and assigned a shape name. Then when picking up the length of kerb, only one reference string to the shape (defined when recording the shape) has to be picked up e.g. lip of kerb. On reduction, 12d can extrude or parallel the shape such that the strings/shape of the kerb are produced for the entire kerb pick-up.

Normally if each measurement is from a different string e.g back of kerb, lip kerb etc., then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, ***12d Model*** uses *shape field coding.*

Basically, a ***12d Model*** *shape* consists of observing a number of points on a given section of an object. The shape can be given a unique name or have no name at all.



For example, a shape can be defined by observations shown in order above

1- being the reference point, 2- 7 being the shape points. In this case, the 1st point of the shape pick-up coincides with the reference point.

To define a ***12d Model*** *shape*, there is a command to *start and end the recording* of the shape. The *feature code*s and *string numbers* for the next series of measurements until the *stop recording* command is given, are stored in the final shape.

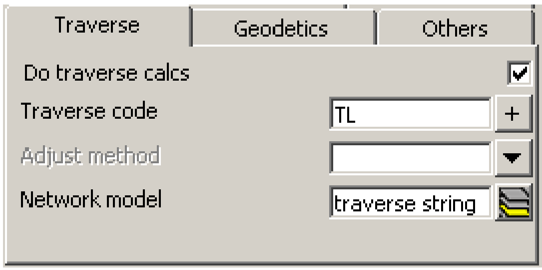
As the shape is defined, other field codes can be used in conjunction such as offset. In this example an observation may be made at 5 for the position of 6 using a vertical offset. Similarly for point 7 using the observation at a point near point 2. In addition, points 6 and 7 can be made non-tinable so that formation of a tin is constrained to the surface of the kerb.

The next step is to pick up the entire length of the kerb at the reference string position using the same *feature code* and *string number* used for the reference string in the shape pick-up. In this example the lip of kerb.

Once completed, the shape can be extruded or parallelled using the extrude or parallel commands. The parallel command will create a number of strings according to the number of points on the shape. The extrude will create a super string with a shape defined like a pipe string.

36.6 Traverse coding

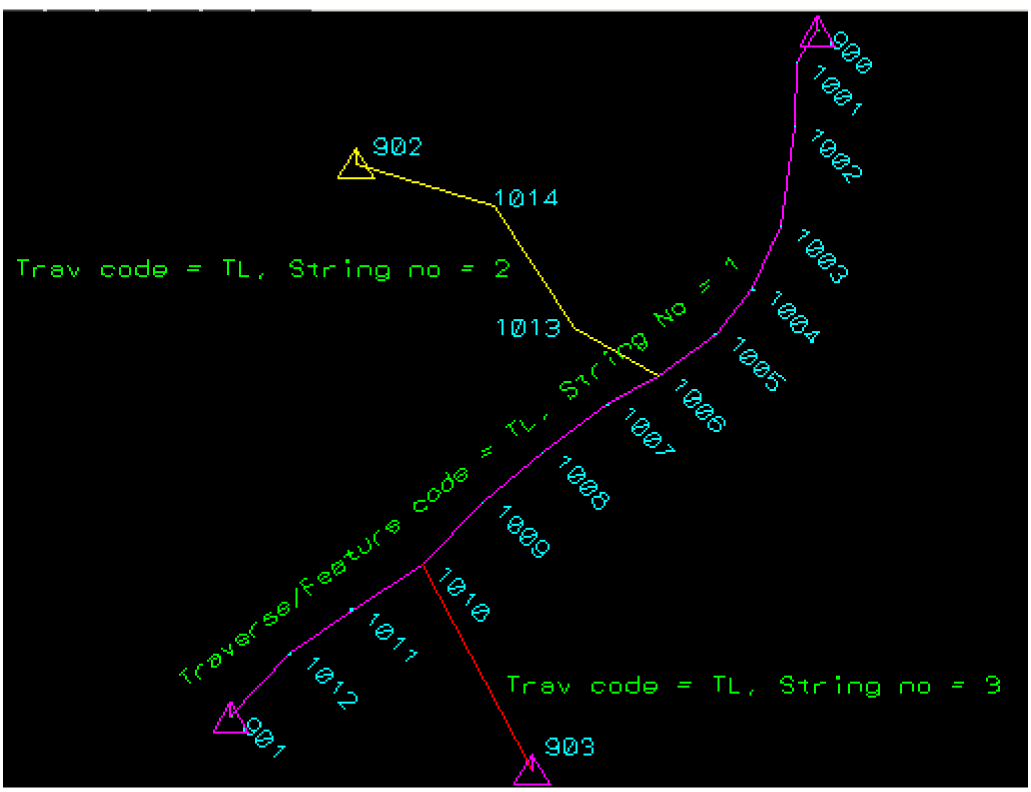
If a traverse is undertaken as part of a survey, a traverse code and string number can be coded so that 12d can extract the traverse information. The specific traverse code can be supplied in the survey reduction panel under the traverse tab. An example is shown below:



In this case, the feature code of TL will be searched in the field file on reduction, so that a traverse string can be extracted. The user is required to nominate the foresight measurement with the TL code in this example. If they also include the TL code in a backsight to a previously defined traverse leg, a reciprocal calculation will be made. It uses the pair of observations (Foresight and Backsight observations of the same line e.g. Foresight 1001 to 1002 and backsight from 1002 to 1001). This reciprocal calculation takes the mean of the distance and vertical angles eliminating the effects of refraction.

A number of separate but interrelated traverses can be extracted using differing string numbers in the field.

The traverse code also allows for adjustments to be made between known stations. This adjustment maybe be chosen in the reduction panel. This field is optional.



36.7 Field Coding for Leica Instruments

For Leica instruments, the Leica GSI format breaks lines of data into fixed length 'words' and cannot use the same encoding method as the other instruments. The ***12d Model*** coding system for the Leica TPS instruments is covered in the section 37.1 12d and Leica TPS Instruments.

36.8 Field Coding for Non Leica Instruments

EDM equipment is used to make readings of points in the field.

Rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information. Unfortunately, this extra coding is non-standard and software specific.

In ***12d Model***, all the raw data files from different data collectors are converted into the one standard field file format (the ***12d Model*** field file) before being loaded into a ***12d Model*** Survey Reduction function and reduced. Hence the method for coding information in the data collector in the field needs to be well defined so that it can be sensibly converted into a ***12d Model*** field file (the section 36.10 The 12d Field File Format contains the complete description of the 12d field file).

When a measurement is taken, most data collectors (Sokkia, Geodimeter, Topcon, Nikon etc.) allow the user to enter text which is then output with the measurement data. Depending on the data collector, the total number of characters of text may be strictly limited and may also be restricted to only one line of text. In ***12d Model***, a coding system has evolved so the text can be interpreted in a meaningful way.

36.8.1 Blocks and the Block (Command) Delimiter

To allow the one line of text to hold a variety of different information, the line of text is broken up into smaller blocks and each block is processed separately.

The character (or characters) used as the block separator is called the *command delimiter* or *block delimiter*.

Obviously the command delimiter can not appear in any of the commands inside a block.

What is used for the *command delimiter* is user defined in the data collector definition and is found on the *Delimiters* tab of the *Survey.4d Create/Edit* panel in the section 36.9 Data Collector Definitions.

The default command delimiter is * and this will be used in the examples in this appendix.

Hence using the command delimiter, the text line is broken into separate blocks for processing.

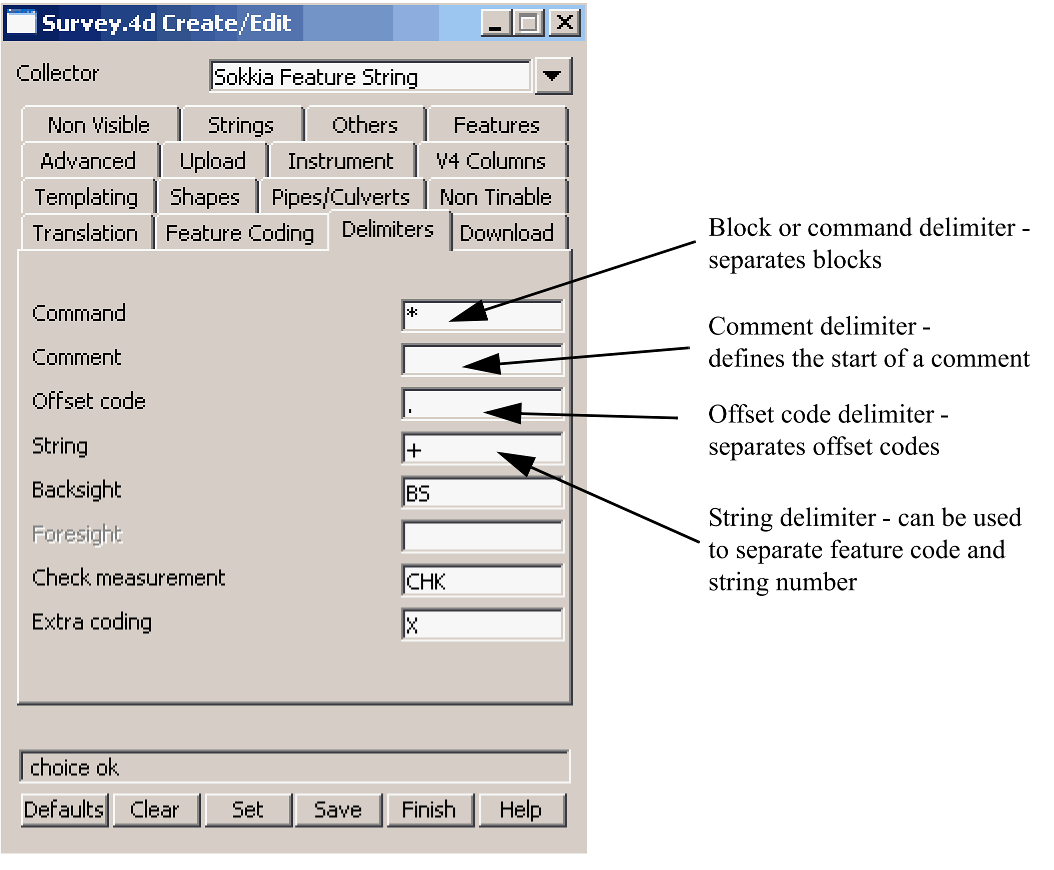
For example, the text string

EB01*XA.road

breaks into the separate blocks.

EB01

XA.road



A block can be either a ***control code block*** or a ***feature code block***.

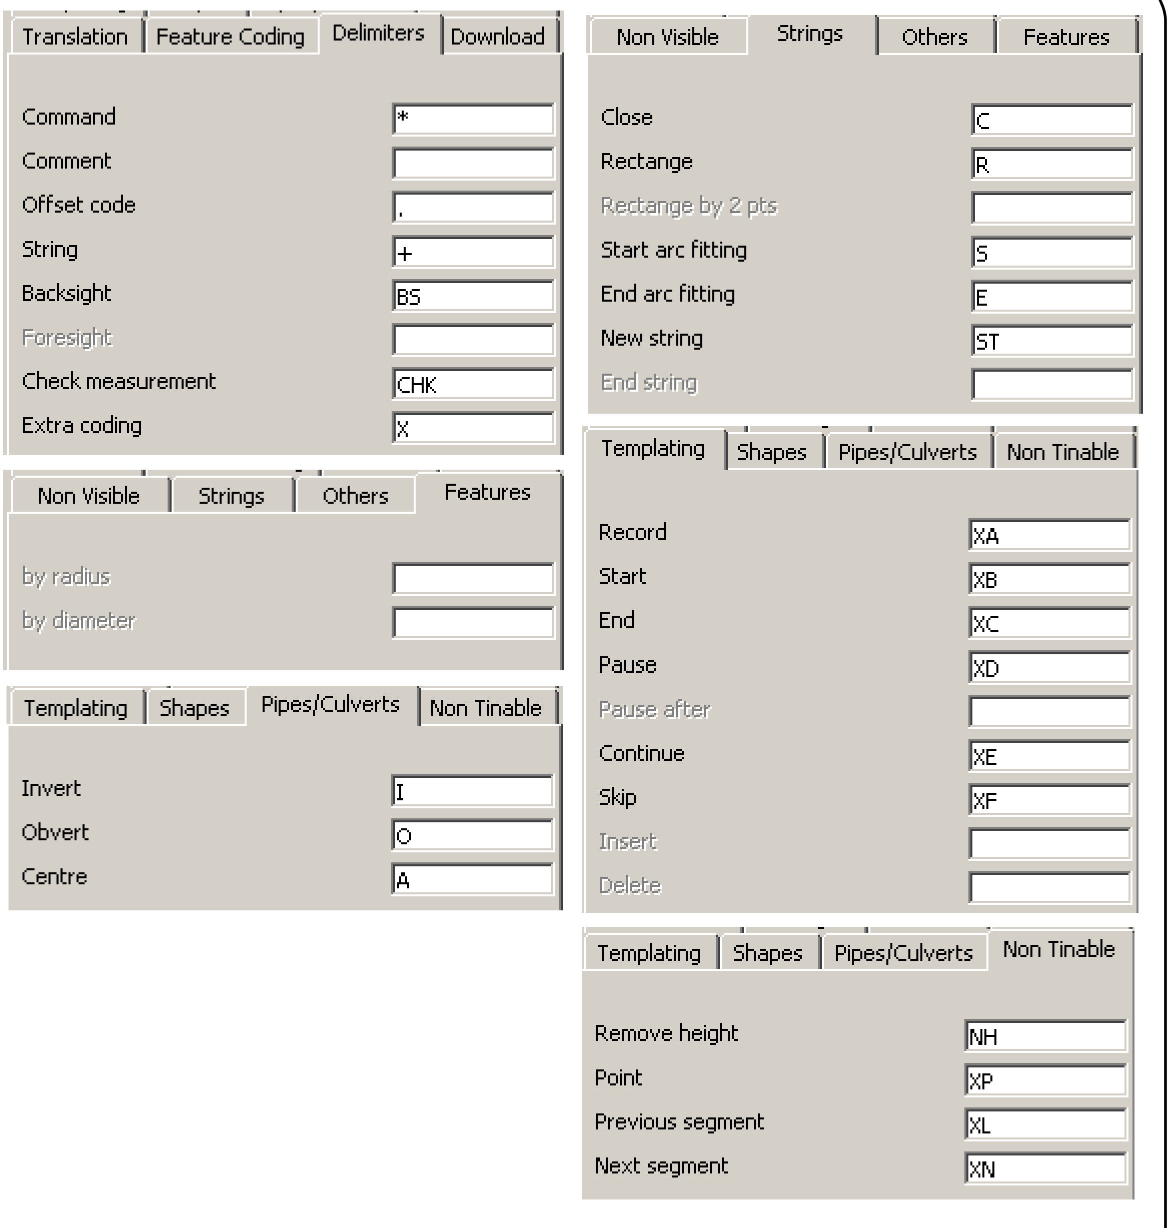
A *control code block* is any block that start with a valid *control code*.

Valid control codes are simply the one or more characters of text designated in the *Delimiters*, *Features*, *Templating*, *Pipes/Culverts*, *Not Tinable* and *Strings* tabs in the **Survey.4d Create/Edit** panel for the selected data collector definition.

If no control code appears at the start of the block, then the block is taken to be a *feature code* *block*.

For example, for the *Sokkia Feature String* data collector definition which is installed with ***12d Model***, the *valid control codes* are *****, dot (**.**), space,**+**, **BS**, **CHK**, **X**, **C**, **R**, **S**, **E**, **ST**, **XA**, **XB**, **XC**, **XD**, **XE**, **XF**, **NH**, **XP**, **XL**, **XN**, **I**, **O** and **A**

Any block starting with any of above control codes is a *control code block*. Blocks that aren't control code blocks are *feature code blocks*.



Tabs on the *Sokkia Feature String* data collector definition which define Control Codes

Blocks can include *comments* and how a comment in specified is given in the next section 36.8.2

Comments in a Block.

The feature code block is discussed in the section 36.8.3 Feature Code Blocks.

The explanation of each control code is given in the section 36.8.4 Control Code Blocks.

Please continue to the next section 36.8.2 Comments in a Block.

36.8.2 Comments in a Block

Comments are supported in a block. There is a *Comment* delimiter and all characters after the *comment* delimiter to the ***end*** of the ***block*** are treated as a comment.

Comments are attached to the measurement point as ***text***.

Hence the *measurement* will create a vertex on a super string and the *comment* will create text at that vertex of the super string.

The default for the *Comment* delimiter is **/** and it is defined by the *Comment* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

For example, if * is the command (block) delimiter and / is the comment delimiter, then in

EB01/first point of a template*XA.road

there are two blocks *EB01/first point of a template* and *XA.road*

and the text "first point of a template" in the first block is a comment and will be added to the super string as vertex text.

Another common character to use as a *comment delimiter* is a space (' '). For example, if * is the command delimiter and space is the comment delimiter, then in

EB01 first point of a template*XA.road

"first point of a template" is a comment.

The *comment* delimiter for the *Sokkia Feature String* data collector is a space

Please continue to the next section 36.8.3 Feature Code Blocks.

36.8.3 Feature Code Blocks

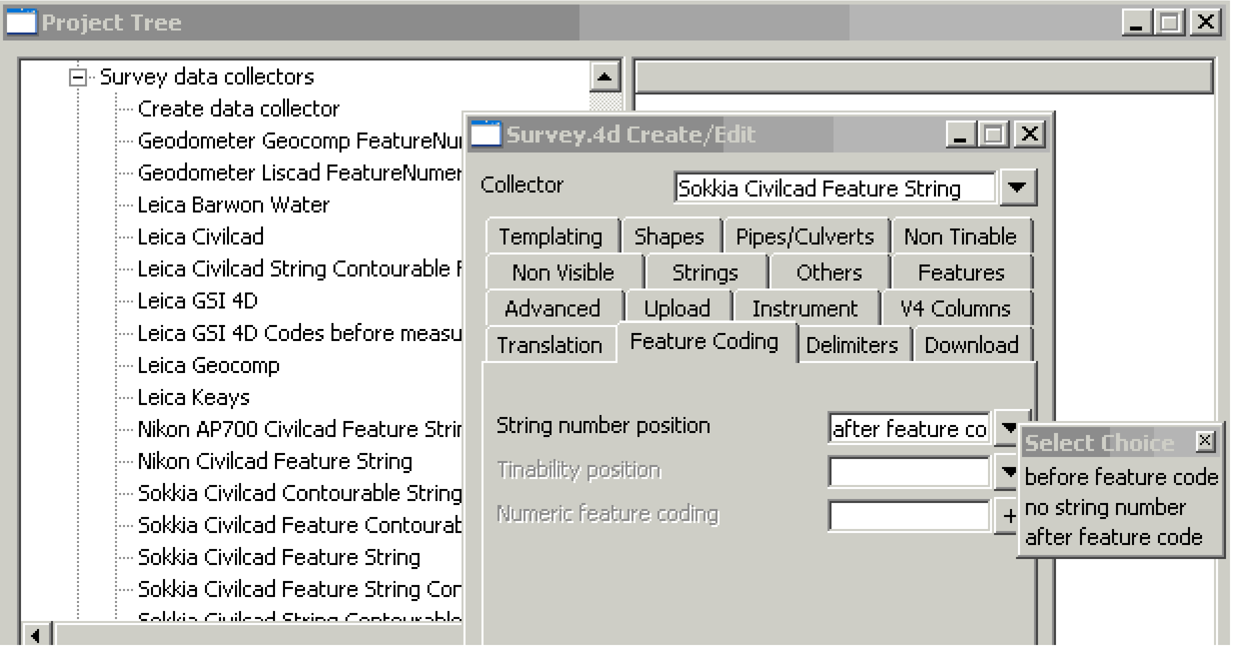
Feature Code, String Number and String Delimiter

In a feature code block, the *feature codes* and *string numbers* are given so that strings are automatically created during the reduction process.

The *feature code* and *string number* appear at the start of the feature code block and can be entered in a variety of ways.

Some surveyors like to enter the *string number* before the *feature code* and other surveyors prefer to enter the *string number after the feature code*. Some surveyors prefer to use *no string numbers* at all (SDRmap users) and use a *new string* control code to start a new string.

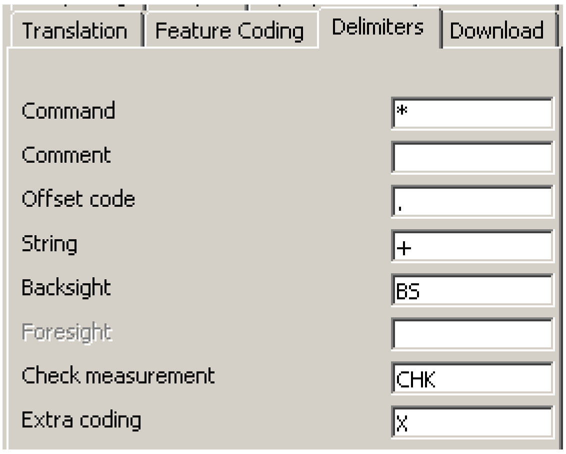
All three methods are supported in 12d. The setting is made on the *String number position* field on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel. The default is 'before feature code'.



If string numbers are going to be used (either *before feature code* or *after feature code*) then there are rules for determining what is the feature code and what is the string number. Note that the *string number* is always *numeric* and can be any length.

Firstly, the *feature code* and *string number*s can be separated by an ***optional String*** delimiter given by the *String* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel. The default character for the *string delimiter* is **+**.

For example, 20+110KVA is interpreted as string number '20' and feature code '110KVA' if the string number comes before the feature code.



Delimiters Tab on the *Survey.4d Create/Edit* Panel

If a String delimiter is not used, then there are ***some restrictions*** on the feature code so that the feature code and string number can be split apart. Note that the *string number* is always *numeric* and can be any length.

If a string delimiter is not used, then either

(a) the *feature code* must be *purely alpha* and then the feature code can be of any length.

or

(b) the *feature code* is purely numeric. Then the feature code must the ***fixed length*** given by the *Numeric feature coding* field on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel. If the *Numeric feature coding* field is not set and the feature code is numeric, then the whole thing is interpreted as a feature code with a string number of 0.

If a *feature code* is a ***mixture of alpha and numeric***, then a ***string delimiter must be used*** to separate the feature code from the string number. Once a string delimiter is used, feature code can be any length.

Tinability as Part of the String Number

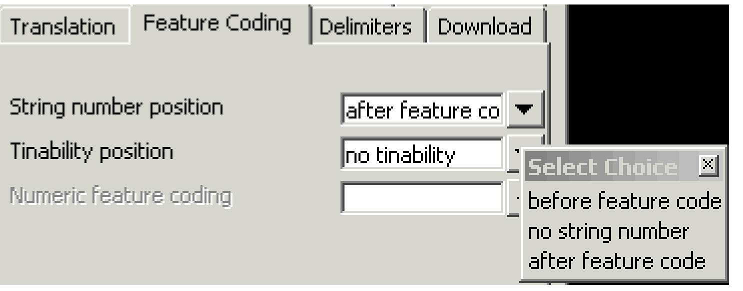
For compatibility with other software coding schemes, the tinability of a point can be included as part of the string number. This is ***not normally recommended*** since 12d has more flexible methods of defining tinability.

The field *Tinability position* on the *Feature Coding* tab of the *Survey.4d Create/Edit* panel controls whether it is used or not. The default is 'no tinability' as part of the string number.

If tinability is used as part of the string number, then it consists of either a **0** or a **1**.

If *Tinability position* is set to *before string*, the first character of the *string number* is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.

If *Tinability position* is set to *after string*, the last character of the *string number* is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.



Offset Codes

It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the co-ordinates of the required point. The three offsets that are allowed in ***12d Model*** are height, radial and tangential. See the Section 36.3.2 Offsetsfor more information.

The three offsets height, radial and tangential have the codes H, R and T respectively.

The *offset codes* come after the feature code-string number combination and are separated by the ***Offset code*** delimiter whose default value is a decimal point (**.**) and is defined by the *Offset code* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

After the *offset code delimiter*, the offset code is given as either H, R or T and then a real value for the offset (with no spaces in between). The offset can be positive or negative with the sign only being recorded if negative. A second and third offset code (H, R or T) can follow the first but no offset code delimiter is used for the second or third offset codes. The offset code delimiter is only used to separate the field code-point number from the offset codes.

In the example 20+110KVA**.**H2.1T0.5 there is a horizontal offset of 2.1 and a tangential offset of 0.5.

Multiply Coded Points

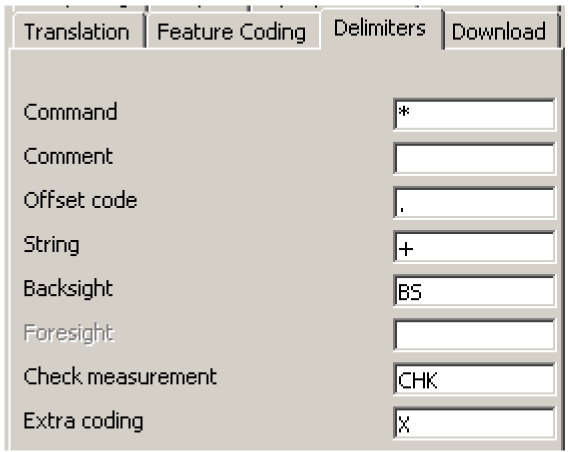
It is possible to have more than one *Feature code block* and this will create a multiply coded point.

For example, if the command delimiter is *, then EB01*PP would have the two feature code blocks ’EB01’ and ’PP’.

Please continue to the next section 36.8.4 Control Code Blocks.

36.8.4 Control Code Blocks

Control Codes on the Delimiters tab



Delimiters Tab on the *Survey.4d Create/Edit* Panel

Extra Coding

This code is only for the instruments supporting the Sokkia SDR format.

The default for the *extra coding* control code is **X** and it is defined by the *Extra coding* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

For some instruments, extra lines of information can be entered after a measurement. For example on a Sokkia by using the note (13NM) to add more information to the previous measurement line (07).

The *extra coding* control code is used to append this additional information to the information on the measurement line. Hence it is then possible to have extra blocks of information on the line (or lines) following the measurement line.

The block containing the *extra coding* control code must be the last block on the measurement line.

For example,

EB01/first point of a template*XA.road*X
/ this is some extra info that happens to be a comment

is the same as

EB01/first point of a template*XA.road*/ this is some extra info that happens to be a comment

Note that there must be a feature code block on the measurement line otherwise a point will be created with no name.

Backsight

The default for the *backsight* control code is **BS** and it is defined by the *Backsight* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *backsight control code* is the name of the station that the backsight was to, or the point number that the backsight was to.

For example, if *BS* is the backsight control code

BSPSM3

would designate a backsight to the station PSM3.

If only the backsight control code exists, the point number from the reading is taken as the point number for the backsight. This may be data collector dependent.

Warning for feature codes starting with the *backsight* control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements ***can not*** start with the backsight control code because they would be interpreted as backsight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the backsight control code, a string number (which may be zero for a point string) ***must*** be used otherwise the feature code will be interpreted as a backsight measurement and no measurement point would be created.

Foresight

There is no default for the *foresight* control code. It is defined by the *Foresight* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *foresight control code* is the name of the station that the foresight was to, or the point number that the foresight was to.

For example, if *FS* is the backsight control code

FSPSM3

would designate a backsight to the station PSM3.

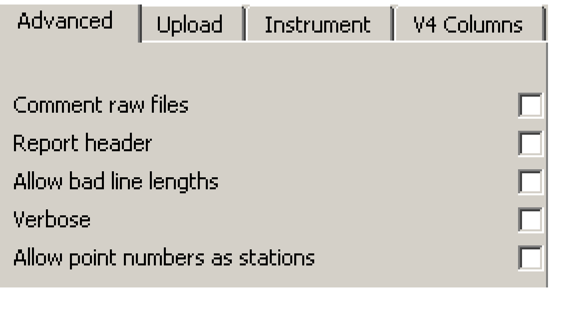
If only the foresight control code exists, the point number from the reading is taken as the point number for the foresight. This may be data collector dependent.

Warning for feature codes starting with the *foresight* control code if the *Allow point numbers as stations* flag is *not set* on the Advanced tab of the *Survey.4d Create/Edit* panel.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the foresight control code because they would be interpreted as foresight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) must be used otherwise the feature code will be interpreted as a foresight measurement.

If the *Allow point numbers as stations* flag is set on, then a point number used as a foresight will create a measurement point for that point number.



Advanced tab on the *Survey.4d Create/Edit* Panel

Check Measurement

The default for the *check measurement* control code is **CHK** and it is defined by the *Check measurement* field on the *Delimiters* tab of the *Survey.4d Create/Edit* panel.

The rest of the block after the *check measurement control code* is the name of the station that the check measurement was to, or the point number that the check measurement was to.

For example, if *CHK* is the check measurement control code

CHKPSM3

would designate a check measurement to the station PSM3.

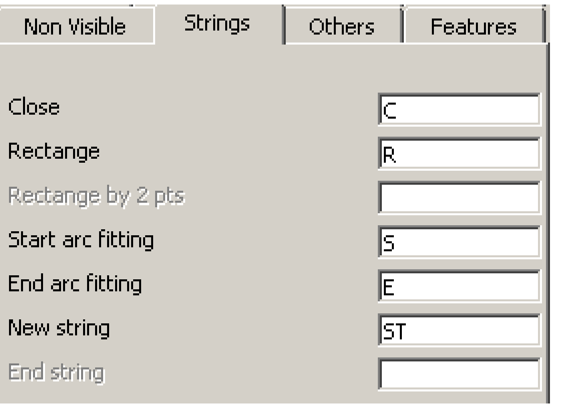
If only the check measurement control code exists, the point number from the reading is taken as the point number that the check measurement is made to. This may be data collector dependent.

Warning for feature codes starting with the *check measurement* control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements ***can not*** start with the check measurement control code because they would be interpreted as check measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) ***must*** be used otherwise the feature code will be interpreted as a check measurement and no measurement point would be created.

Control Codes on the Strings tab



Strings tab on the *Survey.4d Create/Edit* Panel

Close String

The default for the *close string* control code is **C** and it is defined by the *Close* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *close string* control code closes the string that the measurement is a point of.

See the Section 36.3.4 Close String for more information on closing a string.

Rectangle

The default for the *rectangle* control code is **R** and it is defined by the *Rectangle* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *rectangle* control code uses the current point and the previous two points in the same string (three points total) and creates a new point to form a parallelogram.

See the Section 36.3.5 Rectangle for more information on forming a rectangle.

Rectangle by 2 Pts

A *rectangle_2* control code can be defined by the *Rectangle by 2 pts* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *rectangle_2* control code uses the current point, last point and an offset. The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If no Description is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.

If the feature code and string number exist, then a search is made for the last occurrence of two points with the same feature code and string number. If found, then these points are used to define the reference side of the rectangle.

If the point number exists, then a search is made for the last occurrence of two points with the same feature code and string number as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See the Section 36.3.6 Rectangle by 2 Points for more information on forming a rectangle by 2 points.

Start Arc Fitting

The default for the *start arc fitting* control code is **S** and it is defined by the *Start arc fitting* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *start arc fitting* control code starts arc fitting with the current point.

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

End Arc Fitting

The default for the *end arc fitting* control code is **E** and it is defined by the *End arc fitting* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

The *end arc fitting* control code ends arc fitting at the current point. That is, the current point is included in the arc fitting but it is the last point used in the arc fitting.

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

New String

The default for the *new string* control code is **ST** and it is defined by the *New string* field on the *Strings* tab of the *Survey.4d Create/Edit* panel.

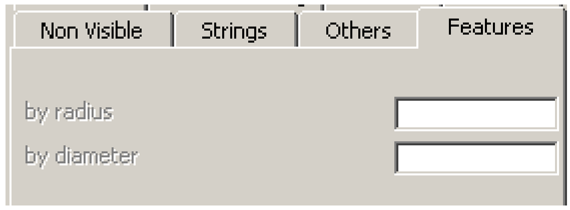
The *new string* control code starts a new string with the current point even if the feature code and string number haven't changed.

See the Section 36.3.3 Start New String for more information on starting a new string.

End String

The *end string* control code ends the current string even if the feature code and string number haven't changed for the next point.

Control Codes on the Features tab



Features tab on the *Survey.4d Create/Edit* Panel

Feature by Radius

There is no default for the *feature by radius* control code. It it is defined by the *by radius* field on the *Features* tab of the *Survey.4d Create/Edit* panel.

The *feature by radius* control code denotes that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.

See the Section 36.3.7 Feature for more information on feature strings.

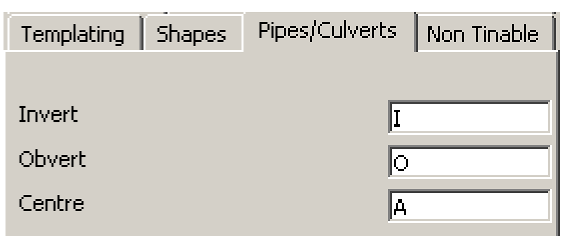
Feature by Diameter

There is no default for the *feature by diameter* control code. It it is defined by the *by diameter* field on the *Features* tab of the *Survey.4d Create/Edit* panel.

The *feature by diameter* control code denotes that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.

See the Section 36.3.7 Feature for more information on feature strings.

Control Codes on the Pipes/Culverts tab



Pipes/Culvert tab on the *Survey.4d Create/Edit* Panel

Invert Point for Pipe or Culvert

The default for the *invert level* control code is **I** and it is defined by the *Invert* field on the *Pipe/ Culverts* tab of the *Survey.4d Create/Edit* panel.

The *invert level* control code denotes that the point is an invert level (bottom).

The invert commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Obvert Point for Pipe or Culvert

The default for the *obvert level* control code is **O** and it is defined by the *Obvert* field on the *Pipe/ Culverts* tab of the *Survey.4d Create/Edit* panel.

The *obvert level* control code denotes that point is an obvert level (top).

The obvert command can also define the diameter of a pipe or width and height of a culvert. For example, O.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. O.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

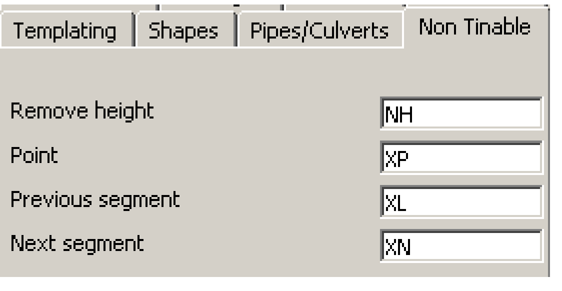
Centre Point for Pipe or Culvert

The default for the *centre level* control code is **A** and it is defined by the *Centre* field on the *Pipe/ Culverts* tab of the *Survey.4d Create/Edit* panel.

The *centre level* control code denotes that point is an centre level (axial).

The centre command can also define the diameter of a pipe or width and height of a culvert. For example, A.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. A.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Control Codes on the Non Tinable tab



Non tinable tab on the *Survey.4d Create/Edit* Panel

Remove Height

The control code to set the height of the current point to null.

The default for the *remove height from point* control code is **NH** and it is defined by the *Remove height* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

Point

The default for the *make point non-tinable* control code is **XP** and it is defined by the *Point* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

The *make point non-tinable* control code makes the current point non-tinable. That is, the point is not used in tins (triangulations).

Previous Segment

The default for the *make previous segment non-tinable* control code is **XL** and it is defined by the *Previous segment* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

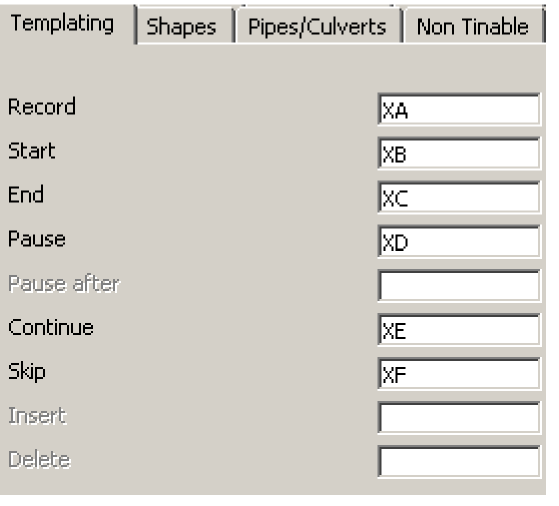
The *make previous segment non-tinable* control code makes the previous segment non-tinable. That is, the segment that the current point is the end of is non-tinable and hence not used as a breakline in tins (triangulations).

Next Segment

The default for the *make next segment non-tinable* control code is **XN** and it is defined by the *Next segment* field on the *Non-Tinable* tab of the *Survey.4d Create/Edit* panel.

The *make next segment non-tinable* control code makes the next segment point non-tinable. That is, the segment that the current point is the start of is non-tinable and hence not used as a breakline in tins (triangulations).

Control Codes on the Templating tab



Templating tab on the *Survey.4d Create/Edit* Panel

Record

The control code to denote that this is the first point of a new field template definition. The field template definition continues until the next *stop recording a field template* control code or a *start using a field template* control code.

If the field template is to have a name, then the *start recording* control code is followed by the *offset code* delimiter and then the name for the field template. If no name is given, then the field template defines the default field template.

For example, if *XA* starts recording for the default template, *XA.road* starts recording the field template called road

The default for the *start recording a field template* control code is **XA** and it is defined by the *Record* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Start

The control code to denote that a field template is being used. This point takes the feature code and string number from the field template. If it is a named field template, then the control code is followed by the *offset code* delimiter and then the name of the field template.

The field template can also be used as a forward template, a reverse template or as a zig-zag template starting on either a zig or on a zag.

The denote using the field template as a forward template, add the *offset code* delimiter and *for.*

To denote using the field template as a reverse template, add the *offset code* delimiter and *rev.*

To denote zig-zag mode starting on a zig, add the *offset code* delimiter and *zig.*

To denote zig-zag mode starting on a zag, add the *offset code* delimiter and *zag.*

If anything other than ’for’, ’rev’ or ’zag’ is given, the field template is used as a zig-zag template starting on a zig.

For example, if *XB* starts using the default template, *XB.road*.zag starts using the field template called road as a zig-zag field template starting on a zag.

The default for the *start using a template* control code is **XB** and it is defined by the *Start* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

End

The control code to end the use of the current field template after the current point. That is, the current point uses the field template but subsequent measurements don’t.

The default for the *stop using a template* control code is **XC** and it is defined by the *End* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Pause

The control code to pause using the current field template. The current point does not use the field template.

The default for the *pause using a template* control code is **XD** and it is defined by the *Pause* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Pause after

The control code to pause using the current field template and the current point does use the field template.

There is no default for the *pause after* control code and it is defined by the *Pause after* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Continue

The control code to continue the use of a paused field template. The current point uses the field template.

The default for the *continuing using a field template* control code is **XE** and it is defined by the *Continue* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Skip

The control code to skip point one or more points of the field template. The current point uses the next point *after* the skipped points from field template.

If more than one point is to be skipped then the control code is followed by the *offset code* delimiter and then number of points to be skipped.

For example, if *XF* is the skip points control code, *XF.2* skips two points. Note that just XF skips one point and the ’.1’ is not required.

The default for the *skipping field template points* control code is **XF** and it is defined by the *Skip* field on the *Templating* tab of the *Survey.4d Create/Edit* panel.

See the Section 36.4 Field Templates for more information on field templates.

Insert

A default control code to insert a point in the field template can be added to this field. The point in inserted after the last point.

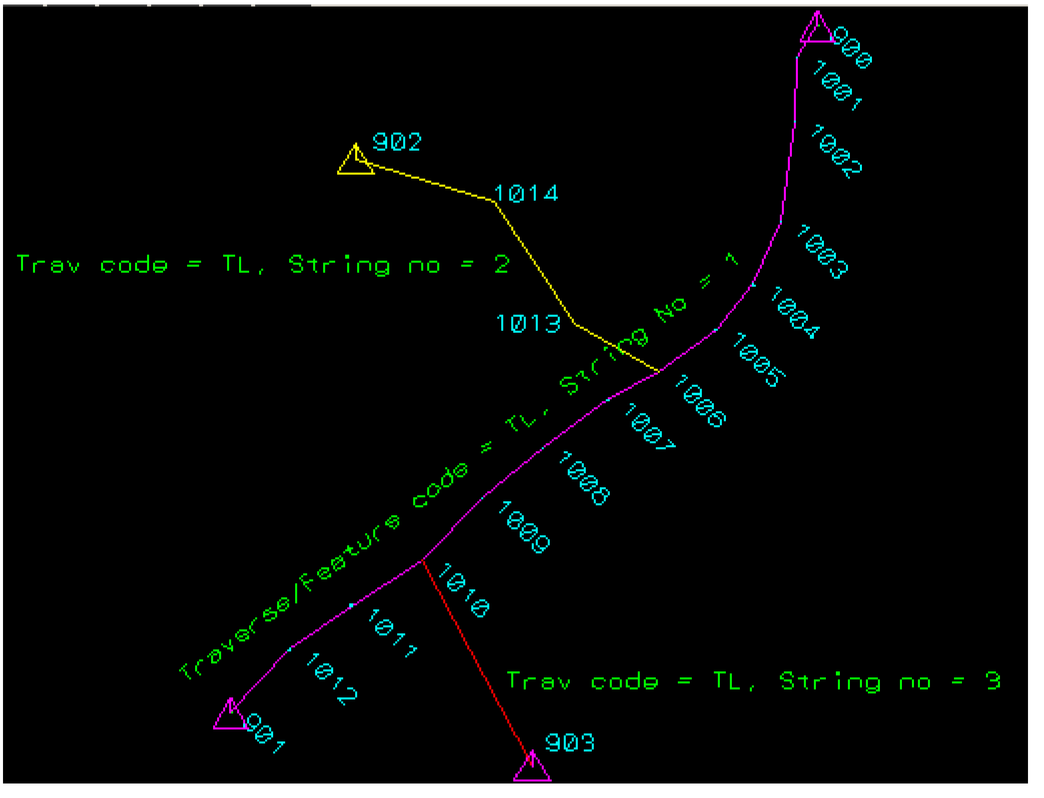
See the Section 36.4 Field Templates for more information on field templates.

Delete

A default control code to delete a point in the field template can be added to this field. a number of points can be nominated for deletion.

See the Section 36.4 Field Templates for more information on field templates.

36.8.5 Feature coding for traverse extraction (Non- Leica instruments)



In the example shown above, three distinct traverses were observed. The main traverse between stations 900 and 901 were given a feature code of TL and a string number of 1 (TL1). A typical observation description follows:

Setup on station 900. A foresight measurement was taken from 900 to 1001. A typical feature code may be:

TL1 FS1001. Where the block delimiter is a space(" ") breaking the feature code up into TL1 and FS1001. This tells the reduction that the observation was a traverse because it has a feature code of TL as specified in the traverse tab of the reduction panel. The foresight control code may be FS, telling the reduction that the observation is a foresight observation to a named point

Setup on station 1001. A backsight to station 900 was observed. A typical feature code may be:

TL1 BS900. Where BS is the backsight control code

A foresight to 1002 may be coded as:

TL1 FS1002.

And so forth.

The observation to station 1013 may be made at the same time as when observing to station 1007 from the setup station 1006. Simply changing the string number to 2 for the observation to 1013 will ensure that it is treated as a different traverse, *i.e.* TL2 FS1013.

The second traverse between stations 1006 and 902 were given a feature code of TL and a string number of 2 whilst the traverse between stations 1010 and 903 were given a feature code of TL and a string number of 3.

The feature code/ string number needs to be present for at least the foresight or measured leg of each of the traverse legs. If they are also present for the backsight, then foresight/backsight pairs will be grouped together and reciprocal calculations done for that leg.

36.9 Data Collector Definitions

Unfortunately, each brand of data collector has its own method of communicating with a computer and a software package.

To allow for a variety of data collectors, ***12d Model*** lets the user create and edit data collector definitions which are simply user defined sets of data collector parameters stored under user specified names.

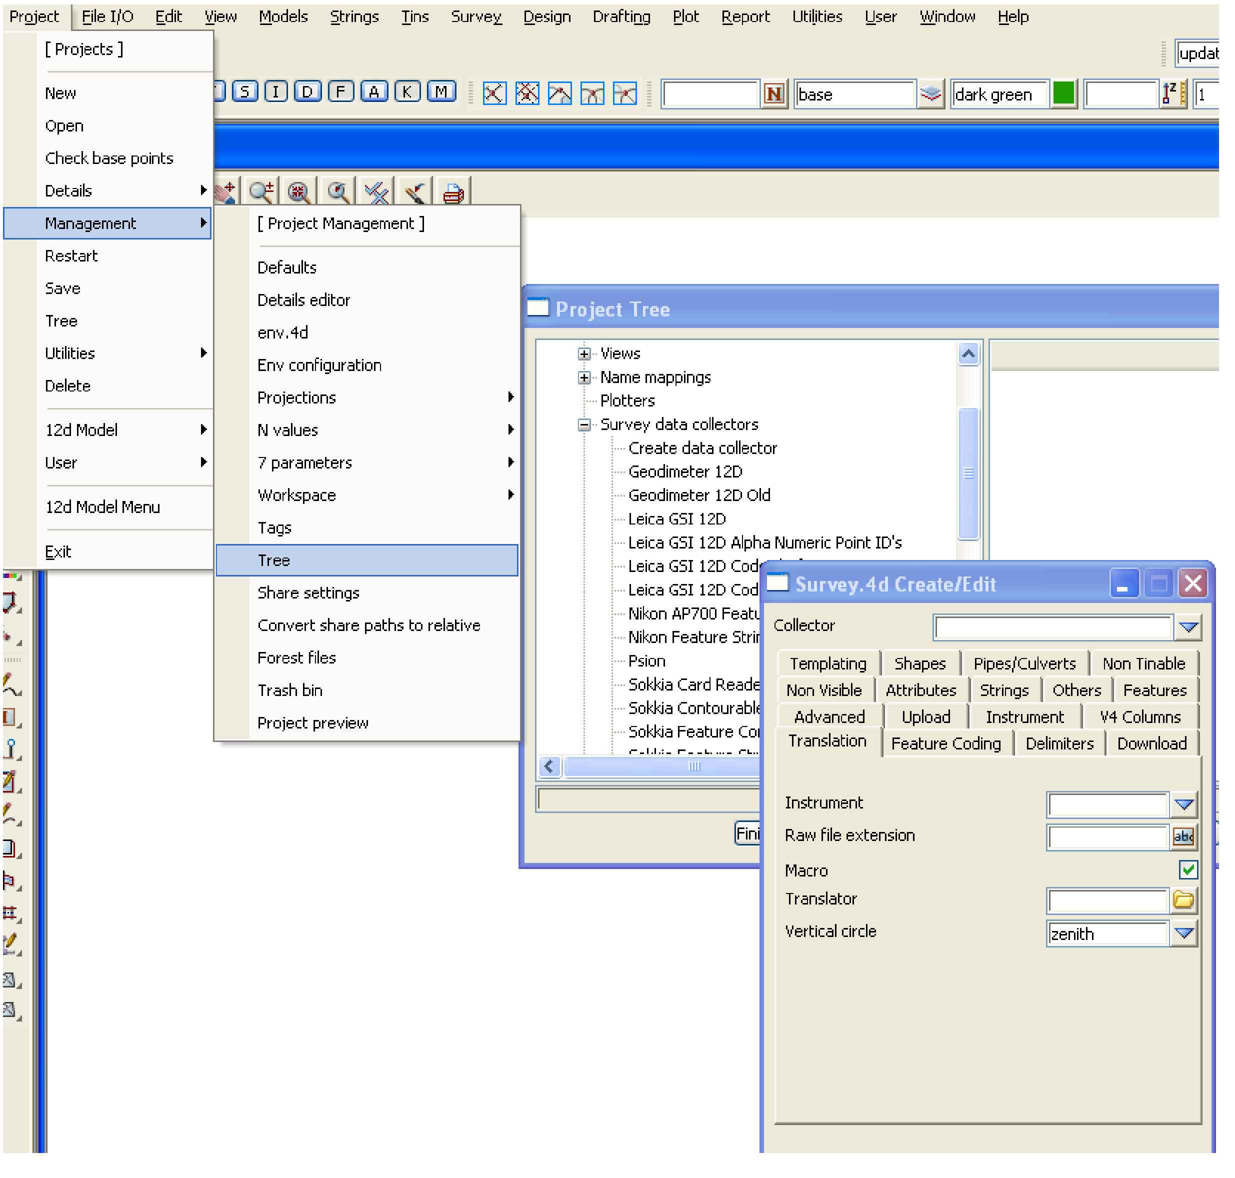
The set of data collector definitions are stored in a file but are created and edited using the ***12d Model*** panel *Survey.4d Create/Edit*.

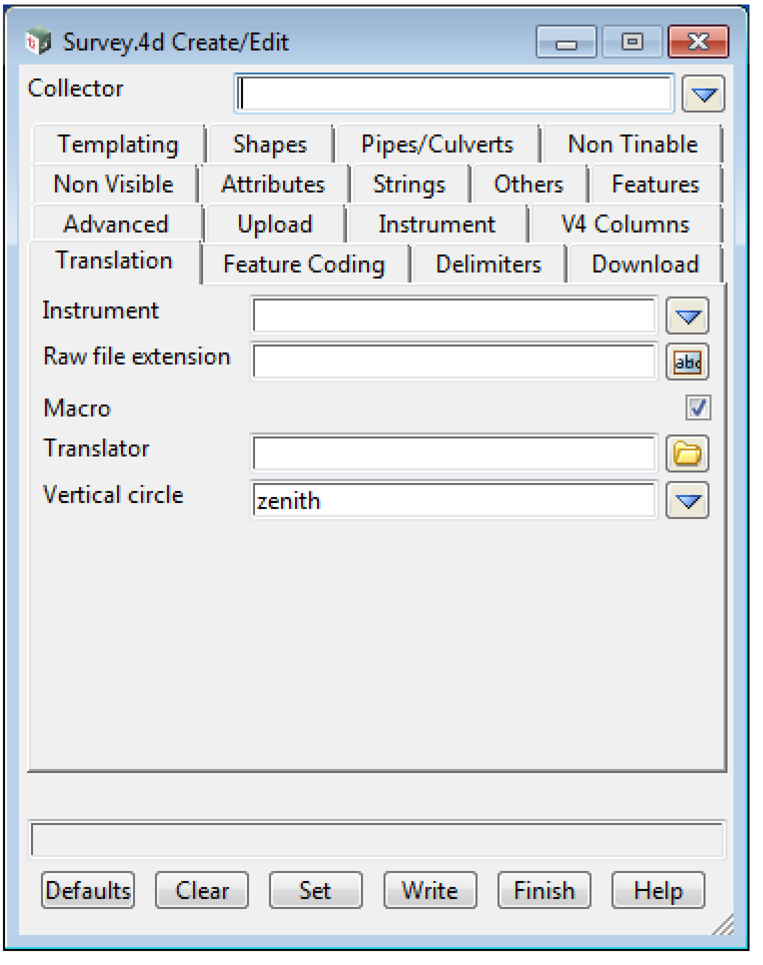
The *Survey.4d Create/Edit panel* is accessed via **Project** => **Management** =>**Tree**.

First select **Project** => **Management** =>**Tree** and then click on the **+** beside the Project name to expand the list of available information for the project. Then click on the **+** beside *Survey data collectors* to see the list of existing 12d data collector definitions.

Double click LB on *Create data collector* to create a new data collector definition, or double click LB on an existing data collector definition to examine and/or modify it.

The **Survey.4d Create/Edit** panel will then appear.





The fields and buttons used in this panel have the following functions.

Field Description	Type	Defaults	Pop-Up
Collector	input		available data collectors

name of the data collector to create/edit.

Defaults button

set all the panel fields to default values.

Clear button

clear the values in the panel fields in all the tabs.

Set button

set the values in the panel fields for the given data collector for this session of **12d Model**.

WARNING - Set does not save the changes to the survey.4d file. To save the changes, click on the 'Save' button.

Save button

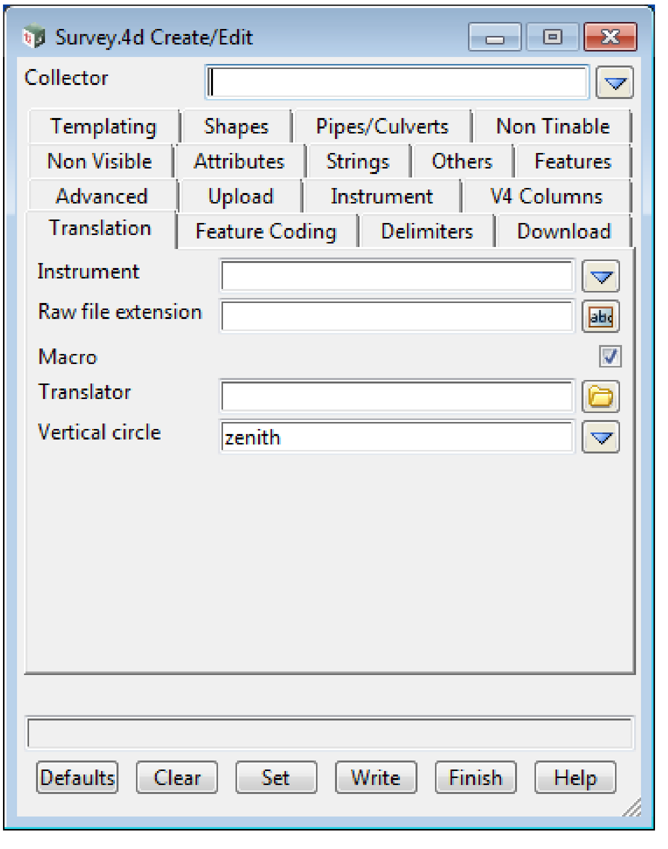
store the data collector definitions to the survey.4d file.

For descriptions of each of the tabs on the panel, go to:

Translation Translation tab
Feature coding Feature Coding tab
Delimiters Delimiters tab
Download Download tab

Advanced	Advanced tab
Upload	Upload tab
Instrument	Instrument tab
V4 Columns	V4 Columns tab
Templating	Templating tab
Shapes	Shapes tab
Pipe/Culverts	Pipes/Culverts tab
Non tinable	Non Tinable tab
Non visible	Non visible tab
Attributes	Attributes tab
Strings	Strings tab
Other	Others tab
Features	Features tab

Translation tab



Instrument input Geodimeter, Leica
Nikon DR1, Nikon AP700, Sokkia 20/33
Topcon GT700, Topcon FC5

type of data collector format.

Raw file extension input

file ending to use for the raw file when it is downloaded.

Macro tick box tick

if tick, then the Translator *pop-up list only shows* **12d Model** *macros.*
If not ticked, then the Translator *pop-up list only shows programs.*

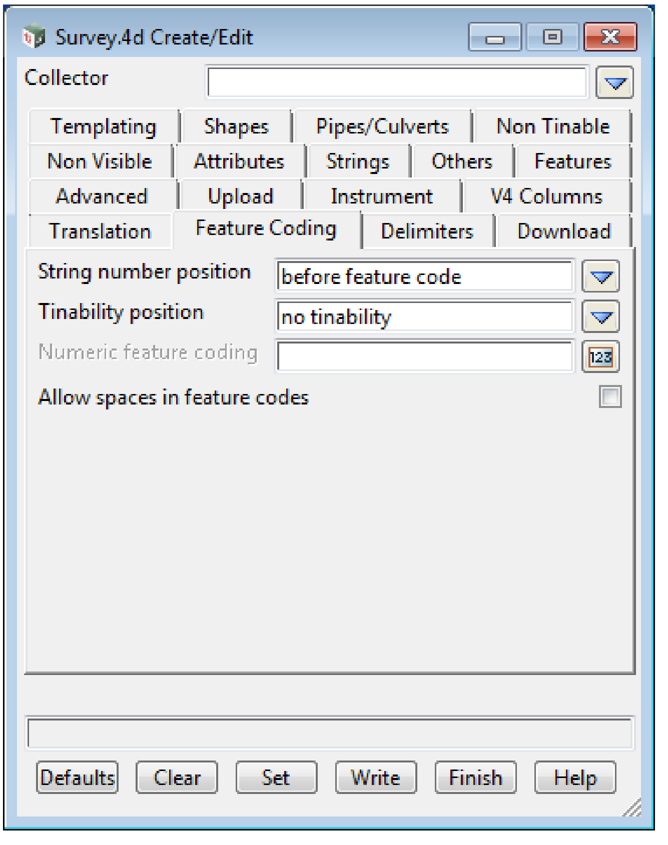
Translator input list of translators in library

name of the macro/program to translate the raw survey file into the 12d field file format.

Vertical circle input zenith zenith, nadir

define the vertical circle zero.

Feature Coding tab



String number position input before before feature code
no string number
after feature code

defines if the string number is before or after the feature code or is not used at all (no string number). When 'no string number' then the New string command is used to start new strings with the same feature code.

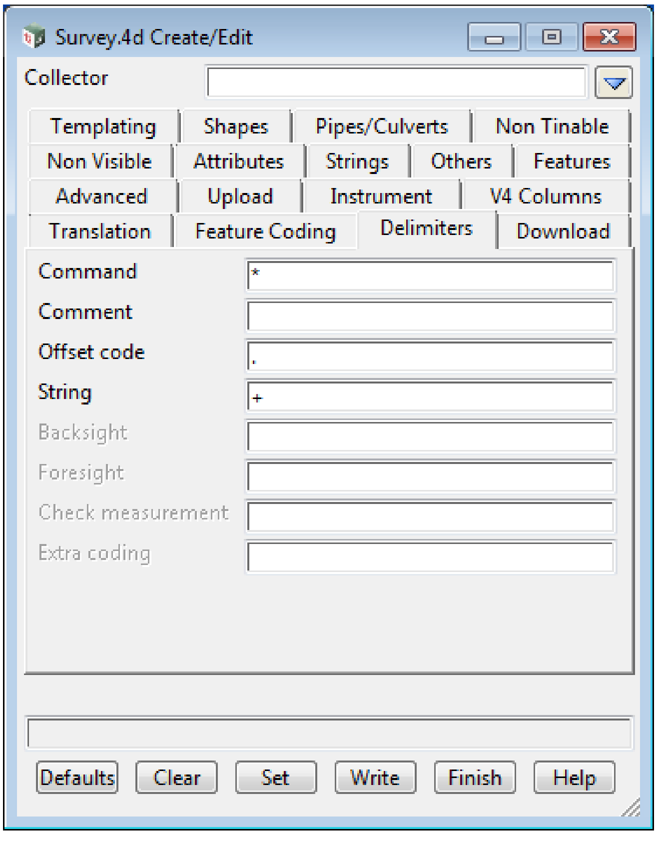
Tinability position input no tinability before string
no tinability
after string

defines the position or absence, of the tinability flag. This should only be used for compatibility with data coded for other systems such as CivilCAD. 12d has more flexible methods of defining tinability.

Numeric feature coding integer

if 'no string number' is given for String number position then Number feature coding is ignored.
If a number is given, then the feature code must be numeric and the given number is the length of the feature code (that is, the number of digits in the feature code).
If no number is given, then feature codes are alphabetical characters only except when a String code is used to separate the feature code and string number.

Delimiters tab



Command input *

defines the separator between the feature code/string number and op code commands. The delimiter characters can not be used in any other part of the command line.

Comment input /

defines the separator for comments. Note that this can be a space.

Offset code input dot (.)

defines the beginning of the offset code block. If the offset code block exists, it must come immediately after the Feature code/string number/tinability block. The offset code used R for radial, T for tangential, H for height.

String input +

separates the feature code from the string number. Used when the feature code includes numbers. For example 110KVA+20   would be a feature code of 110KVA and a string number of 20.

Backsight input BS

if the feature code is this control code then the measurement is to a backsight and not a point.

Foresight input

if the feature code is this control code then the measurement is to a foresight and not a point.

Check measurement input CHK

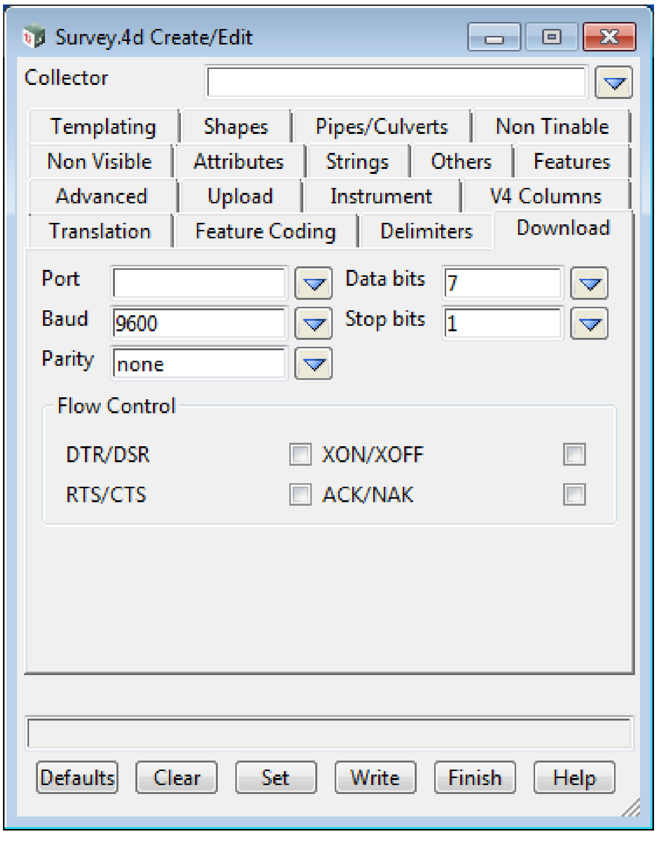
if the feature code is this control code then the measurement is a check measurement and not a point.

Extra coding input X

denotes that the information following is appended to the previous information for the measurement. This allows extra coding than may be allowed for on the measurement line. Mainly for Sokkia using the note (13NM) to add more information to the previous measurement line (07).

A feature code block must be on the measurement line or a measurement with no name will be created. Also a command block can't be split between two lines.

Download tab



Port	input	COM1	COM1 to COM4

port on the computer to use to communicate with the data collector for downloads.

Baud rate	input	9600	110, 300 ... 256000

baud rate to use for the computer port.

Data bits	input	7	5, 6, 7, 8

number of data bits to use.

Stop bits	input	1	0, 1, 1.5, 2

number of stop bits to use.

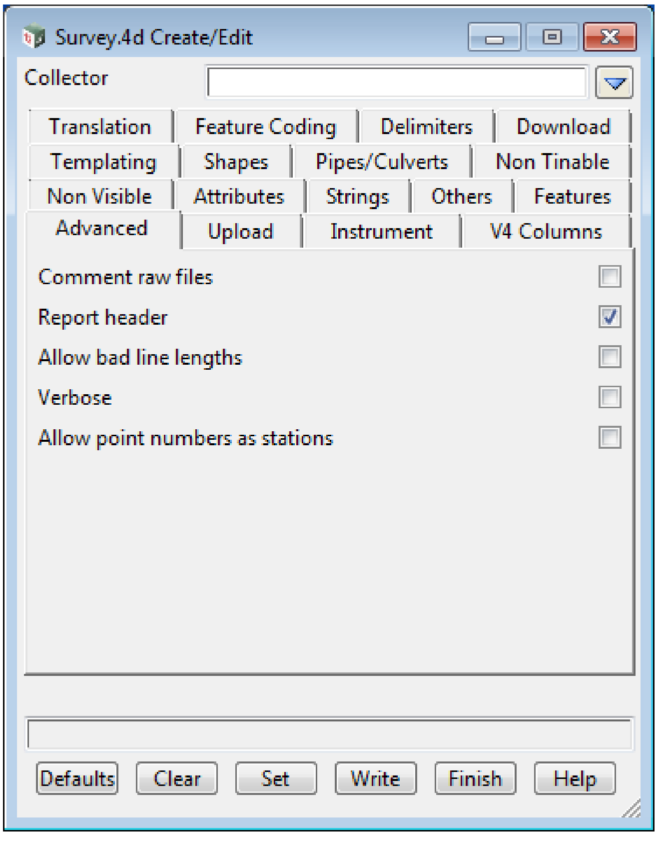
Parity	input	none	none, even, odd, mark, space

parity to use.

DTR/DSR, RTS/CTS, XON/XOFF,ACK/NAK tick boxes

flow control settings.

Advanced tab



Comment raw files tick box

if tick, include the data from the raw survey file as comments in the 12d field file.

Report header tick box

if tick, include some header information as comments in the 12d field file.

Allow bad line lengths tick box

if tick, ignore the fact that the length of the line from the data collector is incorrect. This may lead to other errors so it should be used sparingly.

Verbose tick box

if tick, then extra information is written to the Output window.

Allow point numbers as stations tick box

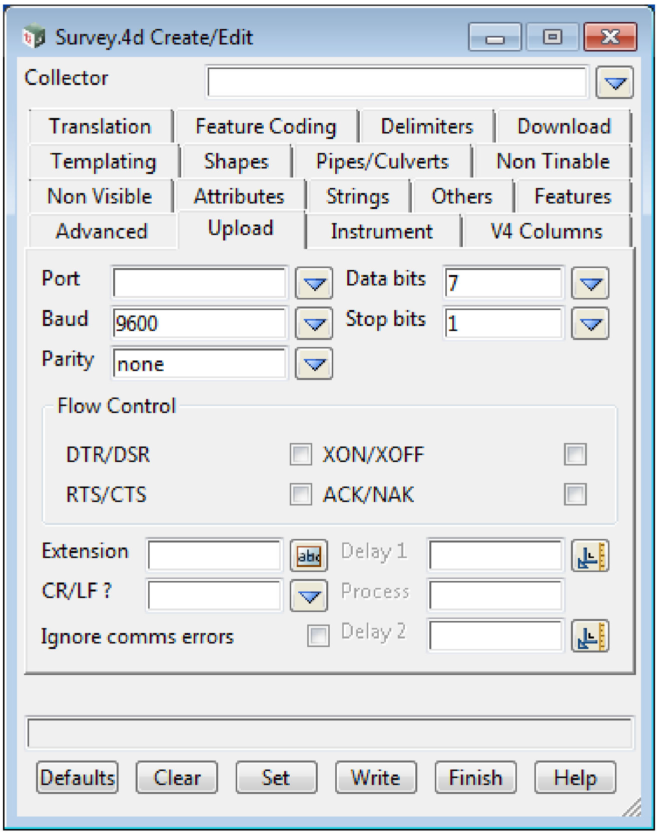
if tick, the point numbers for previous measurements can be used as stations for instrument setups, backsights, foresights and check measurements.

Note

When 12d Model starts up, it checks to see if an environment variable called DATA_COLLECTORS_4D exists and if it does, then the file it points to is used to provide the definitions for the data collectors.

If the environment variable is not set, then 12d Model searches for a file called **survey.4d** (this was **data_collectors_definitions** in V3.0) in the standard 12d Model search sequence for set up files.

Upload tab



Port input COM1 COM1 to COM4

port on the computer to use to communicate with the data collector for uploads.

Baud rate input 9600 110, 300 ... 256000

baud rate to use for the computer port.

Data bits input 7 5, 6, 7, 8

number of data bits to use.

Stop bits input 1 0, 1, 1.5, 2

number of stop bits to use.

Parity input none none, even, odd, mark, space

parity to use.

DTR/DSR, RTS/CTS, XON/XOFF,ACK/NAK tick boxes

flow control settings.

Extension input

ending of the file that will be uploaded. For example, typing in **sdr** means the file to upload ends in ".sdr"

CR/LF ? input cr, lf, crlf, lfcr,none

end of line characters - characters needed by the data recorder to denote the end of a line of data being uploaded to the data recorder.

Delay 1 input

the time between sending lines of data to the data recorder.

Process input

for some data recorders after a data line is sent, a text string needs to be sent to the data recorder to make it process the data line (e.g. GRE3 used a P).

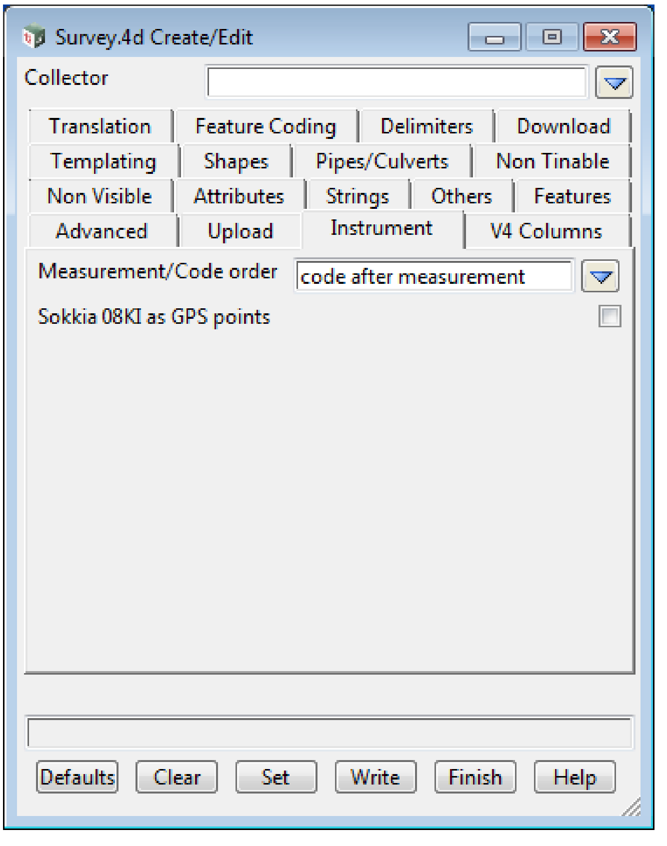
Delay 2 input

the time between sending the process string and sending the next data line.

Ignore comms errors tick box

if tick, ignore any communication errors whilst uploading to the data recorder.

Instrument tab



Measurement/code order input after measurement code before measurement

code after measurement

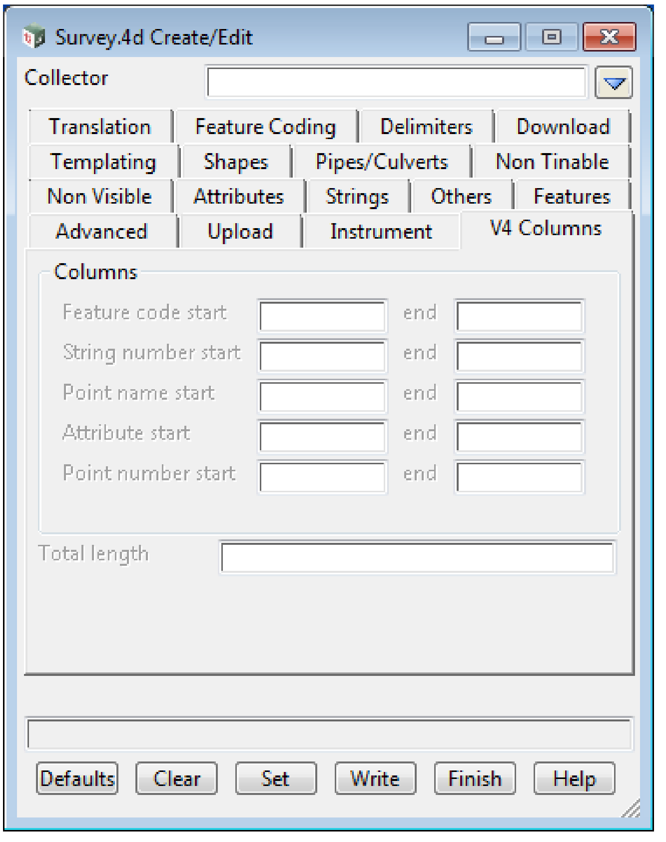
For Leica only where the feature code/string number record is separate to the measurement record. For all other data recorders the feature code block is in the same record as the measurement.

If 'code before measurement', then the feature code/ string number record for a measurement is entered before taking the measurement.
If 'code after measurement', then the feature code/ string number record for a measurement is entered after taking the measurement.

Sokkia 08KI as GPS points tick box

if tick, when converting reading an Sokkia SDR file, the "08KI" records are treated as points and no directly entered station co-ordinates.

V4 Columns tab



The V4 columns tab is for compatibility with ***12d Model*** V4 field files which were of fixed column widths.

Feature code start/end input 1/6

the start and end column position for the feature code in the field file record.

String number start/end input 7/9

the start and end column position for the string number in the field file record.

Point name/Attribute/Point number start/endinput 22/30, 10/16, 17/20

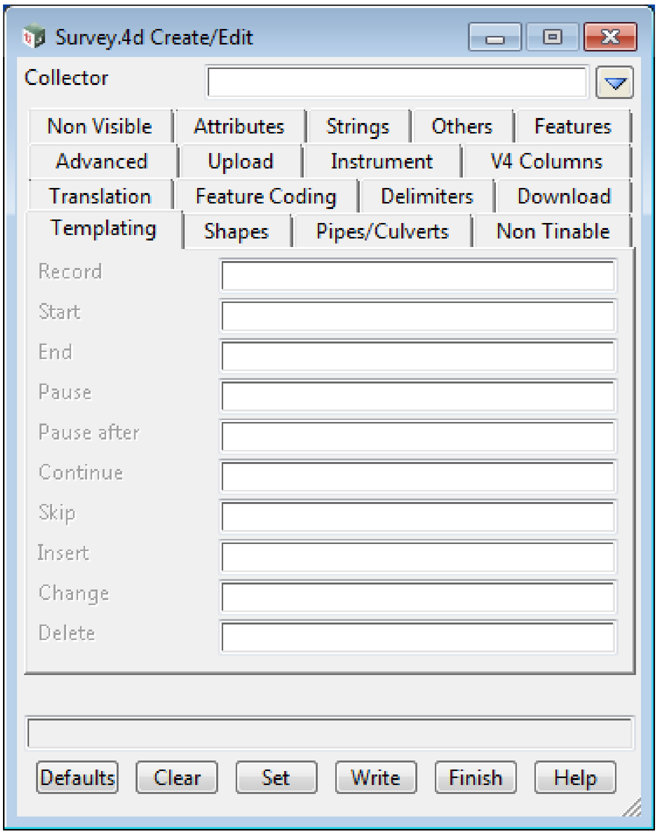
the start and end column position for the point name/Attribute/Point number in the field file record.

Total length input

the total length of line expected.

Templating tab

For information on field templating, see 36.4 Field Templates.



Record input XA text

characters to denote the start of recording a field template. For example XA starts recording for the default template, XA.road starts recording the field template called road. See 55 Start recording a field template.

Start input XB text

characters to denote the start of using a field template. For example XB starts using the blank field template, XB.road starts using the field template called 'road'. XB.road.zig starts using 'road' a zig-zag field template and begins as a zag. See 51 Start using an existing field template.

End input XC text

characters to denote stop using the current field template. See 52 Finish using a field template or finish recording a field template.

Pause input XD text

characters to denote temporarily stop using the current field template to take other measurements. The current point does not use the field template. See 53 Pause using the current field template.

Pause after input XD text

characters to denote temporarily stop using the current field template to take other measurements. The current point does use the field template. See 51 Start using an existing field template.

Continue input XE text

characters to denote continuing to use the current field template after a pause. See 54 Continue the current field template.

Skip input XF text

characters to denote that template points are to be skipped. For example XF means skip one field template point, XF.3 means skip three field template points. See 56 Skipping picking up points when using a field template.

Insert input XI text

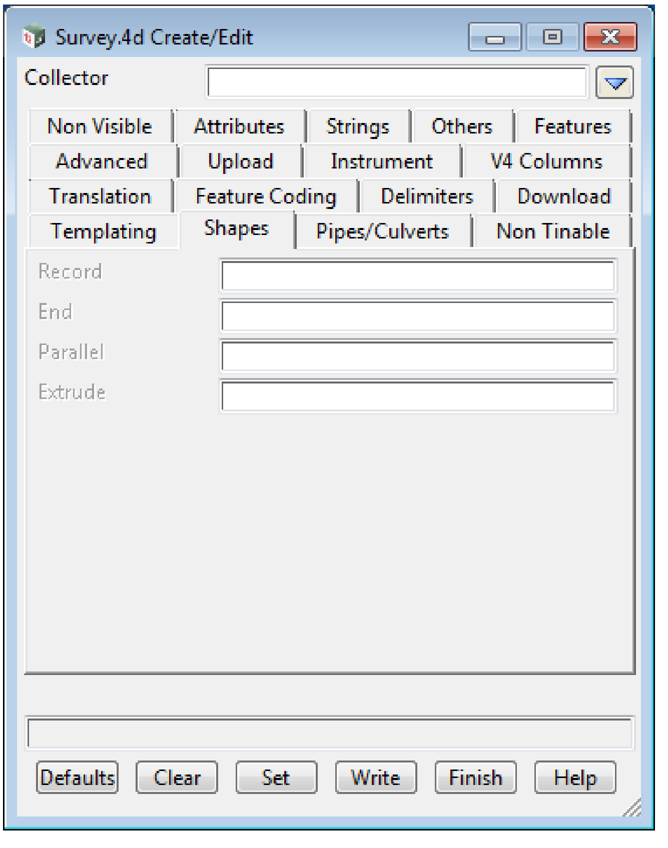
characters to denote that template points are to be inserted. For example XI.FE01 means insert a template point of FE01 into the template after the last measured template point. See 58 Insert points when using a field template - after the measurement of last point.

Delete input XQ text

characters to denote that template points are to be deleted. For example XQ.3 means delete the next 3 pts from the template after the last measured template point. See 57 Delete points on a field template - after the measurement of last point.

Shapes tab

For information on shapes, see 36.5 Shape field coding.



Record input text

characters to denote the start of recording a shape. For example if RS was used, the code RS starts recording for the default shape, RS.shape_name defines the recording of a shape of name shape_name. See 83 Start recording a shape - before the measurement.

End input text

characters to denote stop using the current shape. See 84 Finish using a shape definition or finish recording a shape - after the measurement.

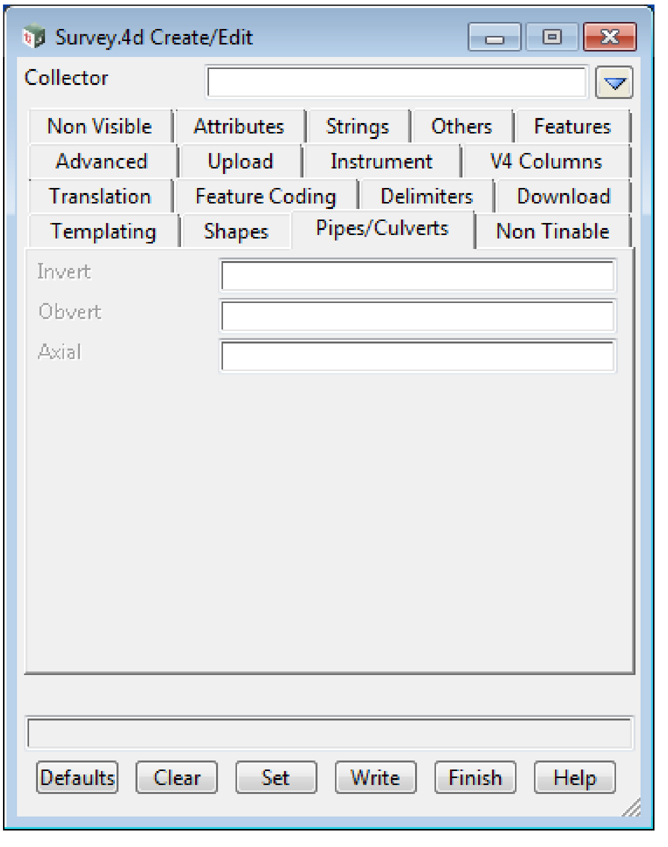
Parallel input text

*characters to denote the application of a shape by parallelling to the shape reference string. The code may be LK01*PS.shape_name*
Where the Parallel command is PS, the shape reference string is LK01 and the shape name = shape_name. See 85 Shape parallel.

Extrude input text

*characters to denote the application of a shape by extrusion to the shape reference string. The code may be LK01*ES.shape_name*
Where the Extrusion command is ES, the shape reference string is LK01 and the shape name = shape_name. See 86 Shape extrude.

Pipes/Culverts tab



Invert input I text

characters to denote that the measurement was the an invert level. See 80 Pipe invert point (bottom of the pipe).

Obvert input O text

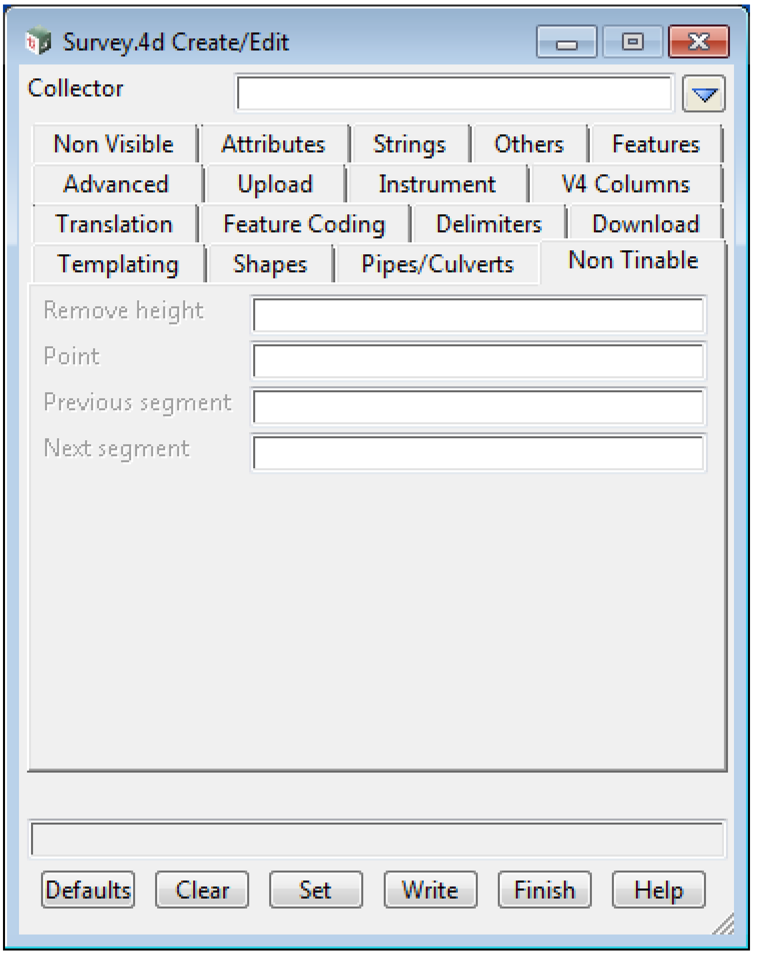
characters to denote that the measurement was the an obvert level. See 82 Pipe obvert point (top of the pipe).

Centre input C text

characters to denote that the measurement was the a centreline (axial) level. See 81 Pipe axial point (centre of the pipe).

Note that these commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Non Tinable tab



Remove height

characters to denote that the measurement has a null height. See 30 Remove height from a point - that is make it a null height.

Point

characters to denote that the measurement is a non-tinable point. See 40 Make a point non-tinable

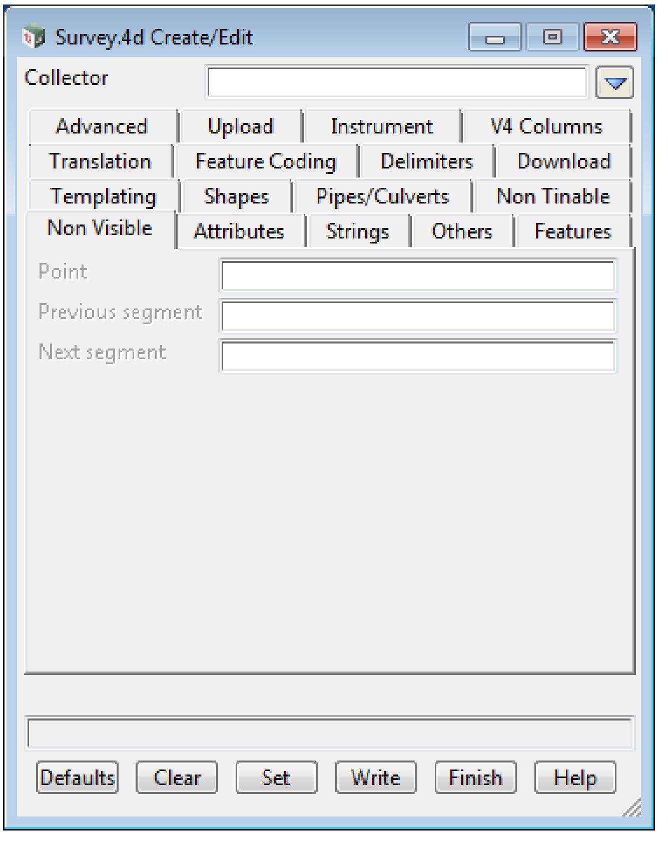
Previous segment

characters to denote that the next segment of the current string is non-tinable. See 38 Make the previous segment non-tinable.

Next segment

characters to denote that the previous segment of the current string is non-tinable. See 39 Make the next segment non-tinable.

Non visible tab



Point input text

characters to denote that the measurement is a non-visible point. That is, the point is not visible and is not included in a triangulation. See 109 Make a point invisible - after the measurement.

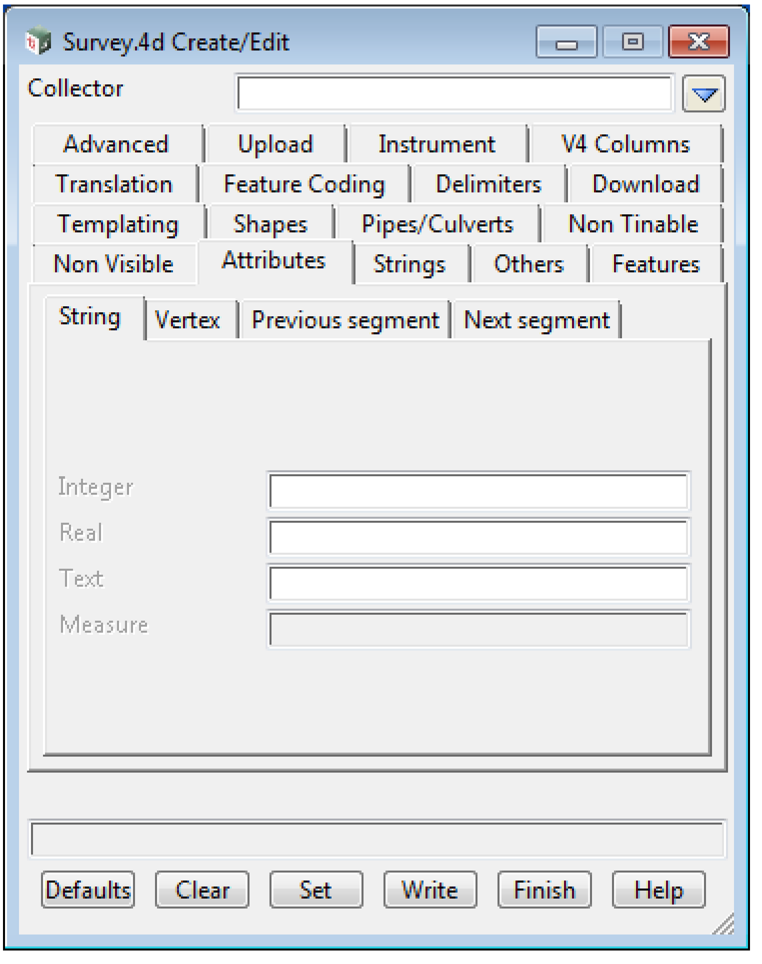
Previous segment input text

characters to denote that the measurement is the end of a non-visible segment. That is, the previous segment is not used as a breakline in a triangulation and it is not visible. See 107 Make the previous segment invisible - after the measurement.

Next segment input text

characters to denote that the measurement is the start of a non-visible segment. That is, the next segment is not used as a breakline in a triangulation and is not visible. See 108 Make the next segment invisible - after the measurement for the first point of the segment.

Attributes tab



String tab (Attributes)

Integer input text

characters to denote that the next text is to be taken as a user defined integer attribute of the current string. See 68 Add an integer user defined attribute to the current string.

Real input text

characters to denote that the next text is to be taken as a user defined real attribute of the current string. See 69 Add a real user defined attribute to the current string.

Text input text

characters to denote that the next text is to be taken as a user defined text attribute of the current string. See 70 Add text user defined attribute to the current string.

Measure input text

Vertex tab (Attributes)

Integer input text

characters to denote that the next text is to be taken as a user defined integer attribute of the current vertex. See 71 Add integer user defined attribute to the current point.

Real input text

characters to denote that the next text is to be taken as a user defined real attribute of the current vertex. See 72 Add real user defined attribute to the current point.

Text input text

characters to denote that the next text is to be taken as a user defined text attribute of the current vertex. See 73 Add text user defined attribute to the current point.

Measure input text

Previous segment tab (Attributes)

Integer input text

characters to denote that the next text is to be taken as a user defined integer attribute of the previous segment. See 77 Add integer user defined attribute to the previous segment.

Real input text

characters to denote that the next text is to be taken as a user defined real attribute of the previous segment. See 78 Add real user defined attribute for the previous segment.

Text input text

characters to denote that the next text is to be taken as a user defined text attribute of the previous segment. See 79 Add text user defined attribute to the previous segment.

Measure input text

Next segment tab (Attributes)

Integer input text

characters to denote that the next text is to be taken as a user defined integer attribute of the next segment. See 74 Add integer user defined attribute to the next segment.

Real input text

characters to denote that the next text is to be taken as a user defined real attribute of the next segment. See 75 Add real user defined attribute to the next segment.

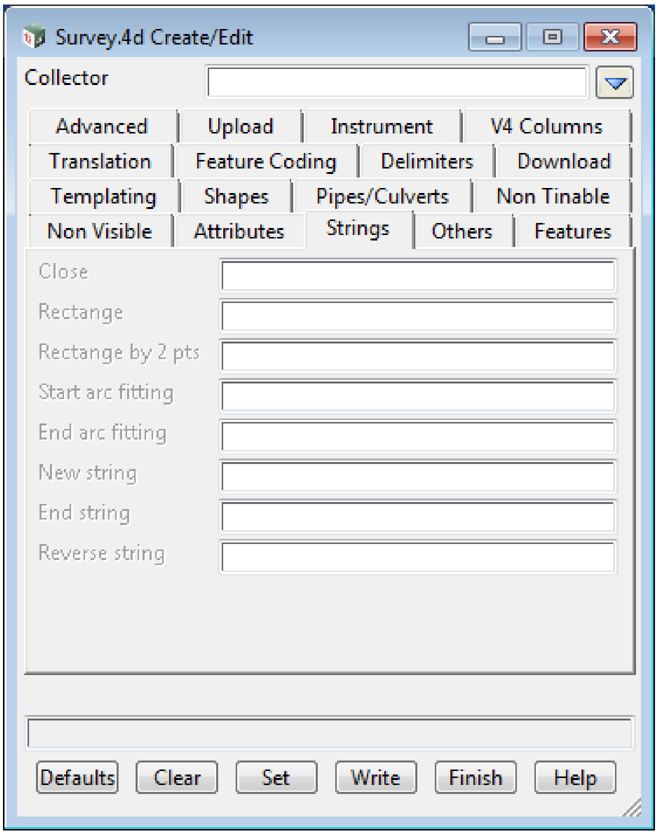
Text input text

characters to denote that the next text is to be taken as a user defined text attribute of the next segment. See 76 Add text user defined attribute to the next segment.

Measure input text

Strings tab

For information on the string commands, see 36.3 Field Coding.



Close input C text

characters to denote that the string is closed. That is the current measurement is joined to the first point of the string. See 20 Close string.

Rectangle input R text

characters to denote that the string is a rectangle. That is the current measurement and the previous two points of the string are three points of a parallelogram and the fourth point is automatically created (and given a null height). See 45 Make a parallelogram from the last three measurement points.

Rectangle by 2 pts input text

characters to denote that the string is a rectangle. That is the previous two points of the string define one side and a offset defines the opposite side. Positive being to the right. The created points are given null height. See 37 Rectangle by two points.

Start arc fitting input S text

characters to denote the start of arc fitting. See 61 Start of arc through sets of three points until end of string, or a 62 occurs.

End arc fitting input E text

characters to denote the end of arc fitting. See 62 End the arcs begun by a 61 command.

New string input ST text

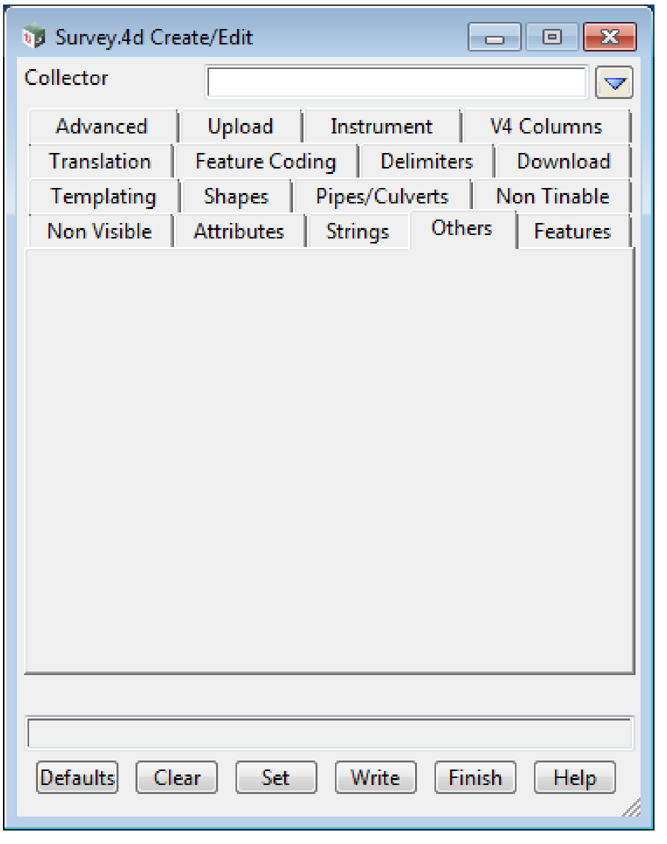
characters to denote the that the current measurement is the start of a new string, even if the string number has not changed. See 47 Start a new string using the same feature code and string number.

End string input text

characters to denote the that the current measurement is at the end of a string, even if the string number has not changed on the next measurement. See 48 End a string.

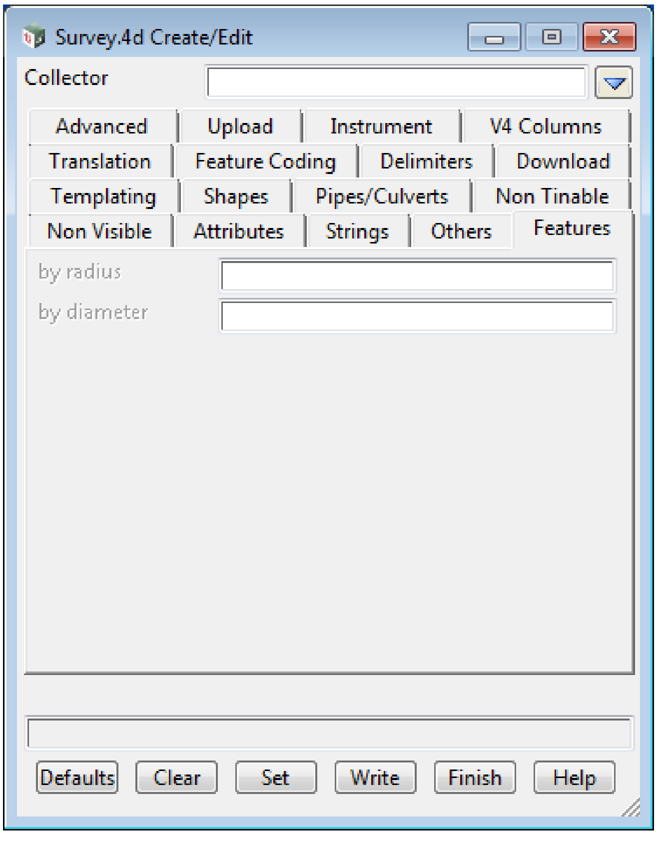
Others tab

Under development.



Features tab

For information on Feature string, see 36.3.7 Feature.



By radius input text

*characters to denote that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.*

There can be more than one set of characters that define 'By radius'. The sets are entered into the By radius field separated by a space. For example

RA RAD RD

would specify that RA and RAD and RD can be used to denote that the feature is defined by radius.

By diameter input text

*characters to denote that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.*

There can be more than one set of characters that define 'By diameter'. The sets are entered into the By diameter field separated by a space. For example

DI DIA DR

would specify that DI and DIA and DR can be used to denote that the feature is defined by diameter.

36.10 The 12d Field File Format

The detailed definition of the standardised 12d Field File will now be given. This is the file that all raw files are converted to before reduction in ***12d Model***.

A few definitions will be given, followed by the complete description of the 12d Field File.

The raw data files from different data collectors are all converted to the 12d field file format.

The 12d field file is text and has a name ending in **.fld**

Each line in the 12d field file is called a record and consists of an ***operation code*** (or *op code* for short) followed by zero or more tabs and pieces of information.

(a) zero fields

What actually follows the fixed header depends on the *op code*.

Hence the 12d field file record is:

op code
99

or

op code	tab	value	...	tab	value
02		abcS			fred

A number of conventions and definitions will be now given, followed by the complete description of the 12d Field File.

Important Note

Op codes are not the same as field codes. *Field codes* are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

Please continue to the next section 36.10.1 Point Description.

36.10.1 Point Description

The *feature codes* and *string numbers* are entered by the surveyor whilst surveying in the field and the *point numbers* are usually automatically created by the surveying instrument but may sometimes be entered into the instrument by the surveyor.

Other information can also be entered by the surveyor using ***field codes*** and associated information. How each field code and associated information is entered in the field *depends on the data recorder* and the *coding convention* being used. This is set up in the *Data Collector definitions* in ***12d Model***.

The data file from the instrument or data collector (raw file) is first converted in 12d Model to the 12d field file ready for loading into a ***12d Model*** Survey Reduction function for reduction.

In most lines of the **12d field file**, a *feature code*, *string number*, *point number*, *point name* and *point text* are given and are stored next to each other separated by tabs.

The **feature code** and **string number** have already been described.

The **point number** is the EDM tacheometry measurement point number which is not normally entered by the user but is written in the raw data file by the data collector. This is stored as the point number for the vertex of the super string.

The **point name** is used to store the name of a station (see the next section on *named measurements*) and is supplied by the user with certain op codes. It is also used by some op codes that do not require an actual point name but have other special information that needs to be stored.

The **point text** is stored as vertex text for that vertex of the super string.

In the 12d field file, the *feature code*, *string number*, *point number*, *point name* and *point text* are given in this order and are separated by tabs. Each can be up to sixty-three characters in length. If the item is missing then a tab is still needed so there may be two or more sequential tabs.

For simplicity in describing the **12d field file**, the feature code, string number, point number, point name and point text are grouped together and called the **point description**.

Hence the **point description** consists of the following pieces of information separated by tabs:

- feature code (string name)
- string number
- point number
- point name
- point text

So it is convenient to think of the *point description* record as five columns of information:

feature code	string number	point number	point name	text
abc	01	1002	STN 4	freddie

Please continue to the next section 36.10.2 Measurements and Named Measurements.

36.10.2 Measurements and Named Measurements

The 12d field file allows five types of measurements that create points (vertices) in super strings. They are

(a) directly entered co-ordinates measurement

(b) EDM measurement (HA,VA,SD, + point_description.)

(c) EDM measurement VD (HA,HD,VD + point_description.)

(d) EDM measurement HT (HA,HD,HT, + point_description.)

(e) three hair stadia measurement

Each type of measurement creates a new point which is appended to the previous points with the same *feature code* and *string number*.

The last such measurement is referred to as the *current measurement point* or *current point* and the string it is appended to is the *current string*.

If a *point_name* exists in the *point_description* for any of the three types of measurements, then it is called a ***named measurement*** and a one point super string of name *point_name* is created and mapped using the Map File. The vertex text for the one point super string is the station prefix followed by *point_name*. The *point_name* is added to an internal list of named points for searching for co-ordinates.

Please continue to the next section 36.10.3 Existing Station Co-ordinates.

36.10.3 Existing Station Co-ordinates

When setting up a new instrument, measuring to a backsight, doing a check measurement or manually entering a bearing to use as the bearing datum difference, the *point_name* or point number from the *point_description* is used to specify a point. The (x,y,z) co-ordinates for *point_name* are found by searching in the following order:

The difference between *point names* and *point numbers* is that *point names* are usually given by the user and should be a unique identifier for a point whilst for that same physical point a number of measurements (and hence point numbers) may be assigned (usually by the data collector). This may be particularly true of control station measurements where measurements are made to a given point name but each measurement is given a different point number by the data collector.

In most instances, a measurement to a point has a point number (from the data collector) and 12d automatically gives it the same point name as it is rare to measure a non-control point more than once (the point name can be over ridden by the user).

The names allow the reduction routine to search for the details of that point (e.g. coordinates) to allow for the reduction of further measurements. The order in which this searching takes place is as follows:

First search the Control model (if it exists):

1. A search is made of the control model for a string whose name is the same as the specified *point name*. If a string is found, the first point of the string is used for the (x,y,z) co-ordinates.
2. A search is made of the control model for a vertex of a string whose point number is the same as the specified *point name*. If a vertex is found its (x,y,z) co-ordinates are used.
3. If only a *point number* was specified, a search is made of the control model for a vertex of a string whose point number is the same as the specified *point number*. If a vertex is found its (x,y,z) co-ordinates are used.

Next search the already entered directly entered co-ordinates (DEC) in the field file:

4. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point name* is the same as the specified *point name*. If a DEC is found, its (x,y,z) co-ordinates are used.
5. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point number* is the same as the specified *point name*. If a DEC is found, its (x,y,z) co-ordinates are used.
6. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose *point number* is the same as the specified *point number*. If a DEC is found, its (x,y,z) co-ordinates are used.

Next search the previous measurements in the field file:

7. A search is made of previous measurements in the field file for a measurement whose *point name* is the same as the specified *point name*. If a measurement is found, its (x,y,z) co-ordinates are used.
8. A search is made of previous measurements in the field file for a measurement whose *point number* is the same as the specified *point name*. If a measurement is found, its (x,y,z) co-ordinates are used.
9. A search is made of previous measurements in the field file for a measurement whose *point number* is the same as the specified *point number*. If a measurement is found, its (x,y,z) co-ordinates are used.
10. or finally, the user is asked to type in the (x,y,z) co-ordinates in a **Survey Data Define Station** panel. If a model is specified in the Add to model field of the panel, then a new one point super string is created with the name *point_name*, and as the vertex text for the point, the Station label prefix field value followed by *point_name*.

For a summary of the **12d Field File Op Codes**, go to the section 36.10.5 Summary of 12d Field File Op Codes

For the full description of the **12d Field File Op Codes**, go to the section 36.10.4 Full Description of 12d Field File Op Codes

36.10.4 Full Description of 12d Field File Op Codes

For a summary of the **12d Field File Op Codes**, go to the section 36.10.5 Summary of 12d Field File Op Codes.

The record for each *op code* allowed in the 12d field file will now be described in detail.

For each *op code* record, two lines and a paragraph of description are given:

- The first line consists of the *op code* and a short description of the purpose of the code.
- The second line gives the full syntax of the record for that *op code*.
- The paragraph gives a detailed description of the *op code* record.

Optional information is enclosed in the square brackets **[ ]**

All **angles** in the 12d field file are given in ***decimal*** degrees.

Important Note

Op codes are not the same as field codes. *Field codes* are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

Op Code **Description of Record**

1 Four 10 character information blocks

01 block1 block2 block3 block4

This information is ignored.

2 Directly entered coordinate measurement

02 Point_description X Y Z

A *measurement* point is created with the f*eature code* and *string number* from the *point_description* and given (x, y,z) co-ordinates. No reduction is needed.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

3 New instrument point

03 Point_description instrument_height

Setting up an instrument at the point with name given in the *point_name* section of the *point_description*. The (x,y,z) co-ordinates for *point_name* are found by first searching the control model, then the list of previously named point in the reduction, point numbers of previous measurements and finally if *point_name* is still not found, the user is asked to type in the (x,y,z) co-ordinates. A record is written to the report file.

4 Measurement to backsight

04 Point_description horizontal_circle vertical_circle slope_distance azimuth

Measurement to a backsight whose name is given in the *point_name* section of the *point_description.* If the *Display panel for backsights* field in the **Survey Data Reduce** panel is tick, then the **Survey Data Bearing Datum Difference** panel shows the *bearing datum difference* and the *horizontal distance* *difference*. A record is written to the report file. The units for *horizontal_circle* and *vertical_circle* are decimal degrees. The azimuth may be specified where no coordinate for the backsight point exists in decimal degrees.

5 New target height

05 Target_height

Set a new target height.

6 Check measurement

06 Point_description horizontal_circle vertical_circle slope_distance

A check measurement is made to the station given in the *point_name* section of the *point_description*. A two point super string (with name *point_name*) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and the station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

7 Measurement - HA, VA, SD

07 Point_description horizontal_circle vertical_circle slope_distance

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

9 Scale factor for subsequent distances

09 Scale_factor

Scale factor to apply to subsequent slope distances.

10 Three hair stadia measurement

10 Point_description horizontal_circle vertical_circle bottom middle top

Manual measurement. A *measurement* point is created with the *feature code* and *string numbe*r from the *point_description*. The units for *horizontal_circle* and *vertical_circle* are decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

11 Measurement - HA, HD, Height

11 Point_description horizontal_circle horizontal_distance height

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The unit for *horizontal_circle* is decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

12 Measurement - HA, HD, Height difference

11 Point_description horizontal_circle horizontal_distance height_difference

Measurement made by the instrument. A *measurement* point is created with the *feature code* and *string number* from the *point_description*. The unit for *horizontal_circle* is decimal degrees.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

15 Vertical circle correction

09 Vertical_circle_in_decimal_degrees

The *vertical_circle_in_decimal_degrees* is **subtracted** from the vertical circle value in any measurements. The units for *vertical_circle_in_decimal_degrees* is decimal degrees.

16 Multiply coded point

16 Point_description

Additional coding for the current measurement point created by op codes 02, 07 or 10. A new measurement point is created at the same position as the current measurement point but with the *feature code* and *string number* from the *point_description* for this op code.

The *point_number* and *text* from the *point_description* are recorded as the point number and text for that vertex of the super string.

If a *point_name* exists in the *point_description*, then it is a ***named measurement*** and a 4d point string of name *point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *point_name*. The *point_name* is added to the internal list of named points for searching for co-ordinates.

17 Arc through previous three points

17 [Point_description]

If no *point_description* is given, then the current measurement point and the two previous points with the same feature code and string number as the current measurement point, are joined by an arc. If there is less than three such points, no arc is fitted.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, the last three previous measurement points of the same *feature code* and *string number* are joined by an arc. If the current measurement point has that feature code and string number, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If *Point_number* exists, then the *feature code* and *string number* are taken from the previous measurement point **with** that point number. That point and the two measurement points previous to the predefined point of the same *feature code* and *string number*, are joined by an arc. If there is less than three points, no arc is fitted

See 36.3.9 Arcs Through Points

18 Circle Feature

18 Radius

Creates a feature string with the given radius and centred on the current measurement point.

See 36.3.7 Feature

20 Close string

20 [Point_description]

If no *point_description* is given, the current string is closed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, the last previous string with that *feature code* and *string number* is closed.

If the *point number* from the *point_description* exists, then the string containing that point number will be closed.

See 36.3.4 Close String

21 Join last points of strings

21 Feature_code string_number_1 string_number_2

In the final reduction, the last point of the string with the given *feature_code* and *string_number_1* is joined to the last point of the string with given *feature_code* and *string_number_2*. The created string has the given *feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See 36.3.8 Joining Strings

22 Join first to last point of strings

22 Feature_code string_number_1 string_number_2

In the final reduction, the first point of the string with the given *feature_code* and *string_number_1* is joined to the last point of the string with given *feature_code* and *string_number_2*. The created string has the given *feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See 36.3.8 Joining Strings

23 Join first points of strings

23 Feature code string number_1 string number_2

In the final reduction, the first point of the string with the given *feature code* and *string number 1* is joined to the fist point of the string with given *feature code* and *string number 2*. The created string has the given *feature code* (no string number is needed since it is the final reduction when the string numbers are then dropped).

See 36.3.8 Joining Strings

28 Add text to the string name

28 [Point_description] Text

Text is appended to the string name. For example, if 1.200 is entered, “1.200” is appended to the string name.

If no *point_description* is given, *Text* is appended to the string name of the current string.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last previous string with that *feature code* and *string number* has *Text* appended to the string name.

If the *point number* exists, then the string containing that point number has *Text* appended to the string name.

29 **Note or memo**

29 Comments

Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

30 **Remove height from a point - that is make it a null height**

30 [Point_description]

If no *point_description* is given, the height of the current measurement point is set to null.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist*,* then the height of the last point of the previous string with that *feature code* and *string number* is set to null.

If the *point number* exists*,* then the height of the point with that point number is set to null.

37 **Rectangle by two points**

37 [Point_description] offset_in_metres

The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If no *point_description* is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.

If the *feature code* and *string number* exist*,* then a search is made for the last occurrence of two points with the same *feature code* and *string number*. If found, then these points are used to define the reference side of the rectangle.

If the *point number* exists*,* then a search is made for the last occurrence of two points with the same *feature code* and *string number* as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See 36.3.6 Rectangle by 2 Points

38 **Make the previous segment non-tinable**

38 [Point_description]

If no *point_description* is given, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist*,* then the last segment of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists*,* then the segment containing the point with that point number as an end point, is set to non-tinable.

39 **Make the next segment non-tinable**

39 [Point_description]

If no *point_description* is given, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists, then the segment containing the point with that point number as a start point, is set to non-tinable.

40 Make a point non-tinable

40 [Point_description]

If no *point_description* is given, the current measurement point is set to non-tinable. That is, it will not be included in triangulations.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If the *point number* exists, then the point with that point number is set to non-tinable.

41 Add additional text for the current measurement point

41 Text

The given *text* is added to the end of any existing text for the current measurement point. Any spaces from column four onwards will be part of the text.

42 Add a radial offset

42 [Point_description]   Radial_offset_in_metres

The *radial_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

See 36.3.2 Offsets

43 Add a tangential offset

43 [Point_description]   Tangential_offset_in_metres

The *tangential_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

See 36.3.2 Offsets

44 Add a height offset

44 [Point_description] Height_offset_in_metres

If the height of the specified point is not null, then the *height_offset_in_metres* adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.

If no *point_description* is given, the offset is used to adjust the position of the current measured point.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that *feature code* and *string number* is adjusted.

If the *point number* exists, then the point with that point number is adjusted.

See 36.3.2 Offsets

45 Make a parallelogram from the last three measurement points

45 [Point_description]

If no *point_description* is given, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last three points with that *feature code* and *string number* are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If the *point number* exists, then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

See 36.3.5 Rectangle

46 Make the string a breakline or not

46 [Point_description] [mode]

The *point_description* is used to select a string and the *mode* is used specify if the string is a breakline or not.

point_description:

If no *point_description* is given, the current string is selected.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with that *feature code* and *string number* is selected.

If the *point number* exists, then the string containing the point with that point number is selected.

***mode*:**

If no *mode* is given, the selected string is set as a point string (that is, not a breakline).

If *mode* is given, then

if *mode* is 0, the selected string is set to a point string and hence is not a breakline.

if *mode* is 1, the selected string is set to a *line* string and is therefore a breakline

47 Start a new string using the same feature code and string number

47 [Point_description]

If no *point_description* is given, the current string is terminated (without including the current measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same *feature code* and *string number*.

If the *point number* exists, then the previous string containing the point with that point number is terminated *before* the point number point, and the point becomes the first point of a new string with the *same feature code* and *string number*.

See 36.3.3 Start New String

48 End a string

48 [Point_description]

If no *Point_description exist*s, the current string is terminated (including the current measurement point).

If *Feature_code* and *String_number* exist, then the last point of the previous string with that feature code and string number becomes the last point of that string.

If *Point_number* exists, then the previous string containing the point with that point number is terminated *after* the point number point

50 Specify the bearing to correct for true north - used as the bearing datum difference

50 Point_description bearing_in_decimal_degrees

The *bearing_in_decimal_degrees* is used as the bearing datum difference for the current instrument set up. The *point_name* in the *point_description* and the *bearing_in_decimal_degrees* are written to the report file.

51 Start using an existing field template

51 Template_name zig_zag_mode

Start using the field template *Template_name.* If *Template_name* is blank, the default field template is used.
If *mode* is "for", then the field template is used as a *forward* template.
"rev", then the field template is used as a *reverse* template.
"zig", then the field template is used as a zig_zag template and is used in the *forward* definition direction first (that is starts on a zig).
"zag", then the template is used as a zig_zag template and is used in the *reverse* direction first (that is, starts on a zag).
If *mode* is blank, or anything other than "for", "rev", or "zag" then the field template is used as a zig-zag template starting on a *zig*.

See 36.4 Field Templates

52 Finish using a field template or finish recording a field template

52

Stops using the current field template or stops recording a field template.

See 36.4 Field Templates

53 Pause using the current field template

53

Pause using the current field template or defining a field template, until a continue field template (54) or a finish field template (52) code is given.

See 36.4 Field Templates

54 Continue the current field template

54

Continue using or defining the current field template, which has been stopped by a *Pause* field template command (53). The *Continue* command only needs to be given once and applies to all following measurements until another *Pause* or *Finish* command is given.

See 36.4 Field Templates

55 Start recording a field template

55 [Template_name]

Start recording a field template with the name *Template_name*. If *Template_name* is blank, then it is the default field template that is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (52) are stored as the field template. There is no limit to the number of points in a field template.

See 36.4 Field Templates

56 Skipping picking up points when using a field template

56 [num_skipped_points]

Allows the user to skip picking up one or more points from the field template currently being used. The next measurement takes the *feature_code* and *string_number* from the next point of the field template definition. If *num_skipped_points* is missing, then only one point is skipped otherwise *num_skipped_points are skipped.*

See 36.4.4 Skipping Field Template Points

57 Delete points on a field template - after the measurement of last point

57 [num_points_to_delete]

Allows the user to delete one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

See 36.4 Field Templates

58 Insert points when using a field template - after the measurement of last point

58 Feature_code String_number Multiple_code_flag Insert_special_flag

Allows the user to insert points into the field template currently being used, or give an existing point a multiple code.

If the *Multiple_code_flag = 1, then the feature code will be added to the previous defined template point else if Multiple_code_flag = 0 (default), it will be added to the template as a separate point.*

If the insert is done at the end of a section and the *Insert_special_flag = 1 the point will be added to the end of the current template section else it will be at the start of the next section.*

The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

See 36.4.5 Insert Template Points or Insert Multiple Codes

60 Arc through next three points

60 [Point_description]

If no *point_description* is given, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If a *point_description* exists, then either the *feature code* and/or *string number* and/or the *point number* section of the *point_description* can be used.

If the *feature code* or *string number* from the *point_description* exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through this previous measurement and the next two measured points following this previous measurement with the same feature code and string number, as given in *point_description*. If the current point has that feature code and string number, then it is the first of the three points. If there is less than three points, no arc fitted.

If the *point number exists,* then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and an arc is inserted through that point and the next two measurement points with the same *feature code* and *string number*. If there is less than three points, no arc is fitted

See 36.3.9 Arcs Through Points

61 Start of arc through sets of three points until end of string, or a 62 occurs

61 [Point_description]

If no *point_description* is given, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the first of the points.

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number exist*, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the following measured points with the same feature code and string number as given in *point_description*. If the current point has that feature code and string number, then it is the first of the points.

If the *point number* exists*,* then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and arcs are inserted through that point and the following measured points with the same *feature code* and *string number*.

See 36.3.9 Arcs Through Points

62 End the arcs begun by a 61 command

62 [Point_description]

If no *point_description* is given, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the last of the points used in the arc fitting.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* from the *point_description* exist, then the fitting of arcs through the points of the previous string with the same *feature code* and *string number* is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If the *point number* from the *point_description* exists*,* then the point with that point number is the last point used in the arc fitting.

If ***12d Model*** encounters an *End Arcs (62*) but no *Start Arcs through sets of three points* (61) command for the string, then a *Start Arcs through sets of three points* (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

See 36.3.9 Arcs Through Points

There are op codes for adding user defined attributes to:

(a) the current string being measured (i.e. the string containing the current measurement point)

(b) the current measurement point

(c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the *next* measured point *of the same feature code and string number*)

or

(d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point *of the same feature code and string number*).

If there is no name for the attribute (name is just spaces or a tab), then the attribute is *unnamed*. The attributes are coded in the following way:

68 Add an integer user defined attribute to the current string

68 Name Integer

Add an user defined integer attribute to the current string.

69 Add a real user defined attribute to the current string

69 Name Real

Add a real (floating point) user defined attribute to the current string.

70 Add text user defined attribute to the current string

70 Name Text

Add a text user defined attribute to the current string.

71 Add integer user defined attribute to the current point

71 Name Integer

Add an integer user defined attribute to the current measurement point.

72 Add real user defined attribute to the current point

72 Name Real

Add a real (floating point) user defined attribute to the current measurement point.

73 Add text user defined attribute to the current point

73 Name Text

Add a text user defined attribute to the current measurement point.

74 Add integer user defined attribute to the next segment

74 Name Integer

Add an integer user defined attribute to the next segment from the current measurement point.

75 Add real user defined attribute to the next segment

75 Name Real

Add a real (floating point) user defined attribute to the next segment from the current measurement point.

76 Add text user defined attribute to the next segment

76 Name Text

Add a text user defined attribute to the next segment from the current measurement point.

77 Add integer user defined attribute to the previous segment

77 Name Integer

Add an integer user defined attribute to the previous segment for the current measurement point.

78 Add real user defined attribute for the previous segment

78 Name Real

Add a real (floating point) user defined attribute to the previous segment for the current measurement point.

79 Add text user defined attribute to the previous segment

79 Name Text

Add a text user defined attribute to the previous segment for the current measurement point.

In addition, extra codes allow special ***12d Model*** pipe strings to be coded in the field

80 Pipe invert point (bottom of the pipe)

80 [Point_description]

If no *point_description* is given, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

81 Pipe axial point (centre of the pipe)

81 [Point_description]

If no *point_description* is given, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

82 Pipe obvert point (top of the pipe)

82 [Point_description]

If no *point_description* is given, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last point of the previous string with the same *feature code* and *string number* as given in *point_description* is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If the *point number* exists, then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

83 Start recording a shape - before the measurement

83 [Shape_name]

Start recording a shape with the name *Shape_name*. If *Shape_name* is non-blank, then the default field Shape is defined by the *feature_code* and *string_number* of the following measurements until a *Finish* code (84) are stored as the shape. There is no limit to the number of points in a shape.

See 36.5 Shape field coding

84 Finish using a shape definition or finish recording a shape - after the measurement

Stops using the current shape or stops recording a shape.

See 36.5 Shape field coding

85 Shape parallel

85 [Shape_name] [Point_description]

Takes all the points on the defined shape of *Shape_name* and parallels them the entire length of the string. Once paralleled, a number of strings are created.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

See 36.5 Shape field coding

86 Shape extrude

86 [Shape_name] [Point_description]

Takes the defined shape of *Shape_name* and extrudes it along the entire length of the string. Once extruded, only one strings is created which contains all the shape information.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

See 36.5 Shape field coding

92 Remove all z-values for a string (i.e. make all z-values null)

92 [Point_description]

If no *point_description* is given, all z-values for the current string are removed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* has all its z-values removed.

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The point-line type may be overridden by the Map File.

93 Set the Point-line type

93 [Point_description]

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

If no *point_description* is given, the point-line type for the current string is set to *line*.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist*,* the point-line type is set for the last previous string with the same *feature code* and *string number.*

If the *point number* exists*,* then the point-line type is set for the string containing that point number.

The point-line type may be overridden by the Map File.

94 Use name library file/ Map File for vertex text on the string - name mapping

94 [Point_description]

If this op code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn't exist, the map file. If neither exist then the op code is ignored.

> if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for *all* vertices of the string that don't already have vertex text. As a default, the string is set as a point string.
>
> if the map file is used and the feature code of the string is found in the first column of the map file, then the *string name* field of the map file is used as vertex text for all vertices that don't already have text. As a default, the string is set as a point string.

If no *point_description* is given, then name mapping is applied to the current string.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist*,* then name mapping is applied to the last previous string with the same *feature code* and *string number.*

If the *point number* from the *point_description* exists*,* then name mapping is applied to the string containing that point number.

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The point-line type may be overridden by the mapping file.

95 Pipe string

95 [Point_description] diameter

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using op codes 80, 81 and 82.

If no *point_description* is given, the current string is created as a pipe string with the given diameter.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* is created as a pipe with the given diameter.

If the *point number* exists*,* then the string containing that point number is created as a pipe string with the given diameter.

96 Culvert string

96 [Point_description] width height

Culvert strings are always line strings and are stored with the justification of the majority of the string points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of the culvert using op codes 80, 81 and 82.

If no *point_description* is given, the current string is created as a culvert string with the given width and height.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* is created as a culvert with the given width and height.

If the *point number* exists, then the string containing that point number is created as a culvert string with the given width and height.

99 Terminate processing

99

Stop processing the 12d field file at this line. Useful for debugging errors.

107 Make the previous segment invisible - after the measurement

107 [Point_description]

If no *Point_description* exists, the previous segment containing the current measurement point is set to invisible.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to invisible.

108 Make the next segment invisible - after the measurement for the first point of the segment

108 [Point_description]

If no *Point_description* exists, the next segment containing the current measurement point as a starting point is set to invisible.

If the *Feature_code* and *String_number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as a start point, is set to invisible.

109 Make a point invisible - after the measurement

109 [Point_description]

If no *Point_description* exists, the current measurement point is set to invisible.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the point with that point number is set to invisible.

110 Start buildings face observations - before the measurements

110 [Building_name]

Start recording a field template with the name *Building_name*. If *Building_name* is non-blank, then the default building face is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (111) are stored as the building face. There is no limit to the number of points in a building face.

111 End building face observations

111 [Building_name]

If no *Building_name exist*s, the current building face observation set is finished (including the current measurement point).

Notes

1. Arc fitting is applied *after* the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.
2. The *point description* has several pieces of information embedded in it and has been described in the previous section. For some op codes, the *point name* section of the *point description* is used to hold other information.

For a summary of the **12d Field File Op Codes**, go to the section 36.10.5 Summary of 12d Field File Op Codes

36.10.5 Summary of 12d Field File Op Codes

Op Code	Description of Record
-2	Comment
-1	Error
01	Header Information
02	Directly entered coordinate measurement
03	New instrument setup point
04	Measurement to backsight
05	New target height
06	Check measurement
07	Measurement - HA, VA, SD
09	Scale factor for subsequent distances
10	Three hair stadia measurement
11	Measurement - HA, HD, Ht
12	Measurement - HA, HD, Ht diff
15	Vertical circle correction
16	Multiply coded point
17	Arc through previous three points
18	Circle Feature
20	Close string
21	Join last points of strings
22	Join first to last point of strings
23	Join first points of strings
28	Add text to the string name
29	Note or memo
30	Remove height from a point - that is make it a null height
37	Rectangle by two points
38	Make the previous segment non-tinable
39	Make the next segment non-tinable
40	Make a point non-tinable
41	Add additional text for the current measurement point
42	Add a radial offset
43	Add a tangential offset
44	Add a height offset
45	Make a parallelogram from the last three measurement points
46	Make the string a breakline or not
47	Start a new string using the same feature code and string number
48	String end
50	Specify the bearing to correct for true north - used as the bearing datum difference
51	Start using an existing field template
52	Finish a field template or finish recording a field template
53	Pause the current field template until a continue op code (54) or a finish template (52)
54	Continue the current field template
55	Start recording a field template
56	Skip picking up one or more points from a field template
57	Delete one or more points from a field template
58	Insert a point into a field template
60	Arc through next three points
61	Start of arc through sets of three points until end of string, or a 62 occurs
62	End the arcs begun by a 61 command
68	Add an integer user defined attribute to the current string
69	Add a real user defined attribute to the current string
70	Add text user defined attribute to the current string
71	Add integer user defined attribute to the current point
72	Add real user defined attribute to the current point
73	Add text user defined attribute to the current point
74	Add integer user defined attribute to the next segment

75 Add real user defined attribute to the next segment
76 Add text user defined attribute to the next segment
77 Add integer user defined attribute to the previous segment
78 Add real user defined attribute for the previous segment
79 Add text user defined attribute to the previous segment
80 Pipe or culvert invert point (bottom of the pipe or culvert)
81 Pipe or culvert axial point (centre of the pipe or culvert)
82 Pipe or culvert obvert point (top of the pipe or culvert)
83 Start recording/measuring a shape
84 End measuring a shape
85 Parallel an existing shape
86 Extrude an existing shape
92 Remove all z-values for a string (i.e. make all z-values null)
93 Set the Point-line type
94 Use name library file/ mapping file for vertex text on the string - name mapping
95 Pipe string
96 Culvert string
99 Terminate processing
107 Last segment of point invisible
108 Next segment of point invisible
109 Point invisible
110 Building face start recording
111 Building face end recording

36.11 Batch Typed Entry

Typed entry can be used to enter survey data into a 12d Field File and reduced using the Survey data Editor.

12d Model uses the following 12d field file ops code:

Op Code	Description of Record
-2	Comment
-1	Error
01	Header Information
02	Directly entered coordinate measurement
03	New instrument setup point
04	Measurement to backsight
05	New target height
06	Check measurement
07	Measurement - HA, VA, SD
09	Scale factor for subsequent distances
10	Three hair stadia measurement
11	Measurement - HA, HD, Ht
12	Measurement - HA, HD, Ht diff
15	Vertical circle correction
16	Multiply coded point
17	Arc through previous three points
18	Circle Feature
20	Close string
21	Join last points of strings
22	Join first to last point of strings
23	Join first points of strings
28	Add text to the string name
29	Note or memo
30	Remove height from a point - that is make it a null height
37	Rectangle by two points
38	Make the previous segment non-tinable
39	Make the next segment non-tinable
40	Make a point non-tinable
41	Add additional text for the current measurement point
42	Add a radial offset
43	Add a tangential offset
44	Add a height offset
45	Make a parallelogram from the last three measurement points
46	Make the string a breakline or not
47	Start a new string using the same feature code and string number
48	String end
50	Specify the bearing to correct for true north - used as the bearing datum difference
51	Start using an existing field template
52	Finish a field template or finish recording a field template
53	Pause the current field template until a continue op code (54) or a finish template (52)
54	Continue the current field template
55	Start recording a field template
56	Skip picking up one or more points from a field template
57	Delete points from a field template
58	Insert points in a field template
60	Arc through next three points
61	Start of arc through sets of three points until end of string, or a 62 occurs
62	End the arcs begun by a 61 command
68	Add an integer user defined attribute to the current string
69	Add a real user defined attribute to the current string

70 Add text user defined attribute to the current string
71 Add integer user defined attribute to the current point
72 Add real user defined attribute to the current point
73 Add text user defined attribute to the current point
74 Add integer user defined attribute to the next segment
75 Add real user defined attribute to the next segment
76 Add text user defined attribute to the next segment
77 Add integer user defined attribute to the previous segment
78 Add real user defined attribute for the previous segment
79 Add text user defined attribute to the previous segment
80 Pipe or culvert invert point (bottom of the pipe or culvert)
81 Pipe or culvert axial point (centre of the pipe or culvert)
82 Pipe or culvert obvert point (top of the pipe or culvert)
83 Start recording/measuring a shape
84 End measuring a shape
85 Parallel an existing shape
86 Extrude an existing shape
92 Remove all z-values for a string (i.e. make all z-values null)
93 Set the Point-line type
94 Use name library file/ mapping file for vertex text on the string - name mapping
95 Pipe string
96 Culvert string
99 Terminate processing
107 Last segment of point invisible
108 Next segment of point invisible
109 Point invisible
110 Building face start recording
111 Building face end recording

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non Leica Instruments.

The ’13’ record can also be used after a measurement record to add additional information to the preceding blocks using the *extra coding* control code at the end of the previous line (see Extra Coding in the section 36.8.4 Control Code Blocks

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

’Line 248 line incorrect length. required length is 58. received length is 50.’

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

For the full description of the **12d Field File Op Codes**, go to the section 36.10.4 Full Description of 12d Field File Op Codes

37 12d and Survey Instruments

See

37.1 12d and Leica TPS Instruments

The Leica GSI data format produced by the Leica TPS is used as a raw data file by 12d Model and is converted into a 12d Field File. The contents of the recorded data can be manipulated by use of the Leica's recording masks. The setup of which is explained in the section 37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d.

Each line (data block) of the Leica GSI file consists of between 1 and 12 words, with the words containing either 16 (8 characters for data) or 24 (16 characters for data) characters. The two formats will be referred to as the 8 format and 16 format respectively.

Measurement lines in the 8 format start with 11 and code lines start with 41.

For the 16 format, measurement lines start with *11 and code lines start with *41.

For an example of a GSI file in the 8 format, go to the section 37.1.6.7.2 Example of Leica GSI File.

When using a Leica, the Leica screen can be standard or controlled by using a code.hex file on the 1000 series or a Geobasic program or Leica Codelist (.crf file) on the 1100 series.

12d Solutions provide a basic code.hex, Geobasic program and various Codelists(.crf files) on the ***12d Model*** Installation CD in the folder 'Other_Software\Leica'. These can be customised to your requirements - please contact 12d Solutions for more information.

For an example of a Leica screen with standard set-up, Codelist and Geobasic program, please go to the section 37.1.5 Examples of Leica Screens.

See the sections:

37.1.1 Feature Codes and String Numbers

37.1.2 Leica Field Codes

37.1.3 Full Description of Leica Field Codes

37.1.4 Summary of Leica Field Codes

37.1.5 Examples of Leica Screens

37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d

37.1.6.7.2 Example of Leica GSI File

Please continue to the next section 37.1.1 Feature Codes and String Numbers.

37.1.1 Feature Codes and String Numbers

The *feature code* and *string number* for a measurement are entered in the Leica by giving the *feature code* in the first word and the *string number* as the second word of a code line. The feature codes and string numbers can be alpha or numeric and up to 8 (16) characters long.

For example, the feature code ABC with string number 1 is recorded as:

410003+00000ABC 42....+00000001 for the 8 format

or

*410003+0000000000000ABC 42....+0000000000000001 for the 16 format.

Some surveyors like to define the *feature code* and *string number* ***before*** they make a measurement. Other surveyors prefer to define the *feature code* and *string number* ***after*** they make a measurement.

When defining a *Data Collector setup*, ***12d Model*** allows the user to specify whether the feature code comes before or after a measurement:

code before measurement

The given *feature code* and *string number* applies to the **next** measurement and all subsequent measurements until another *feature code* and *string number* is entered.

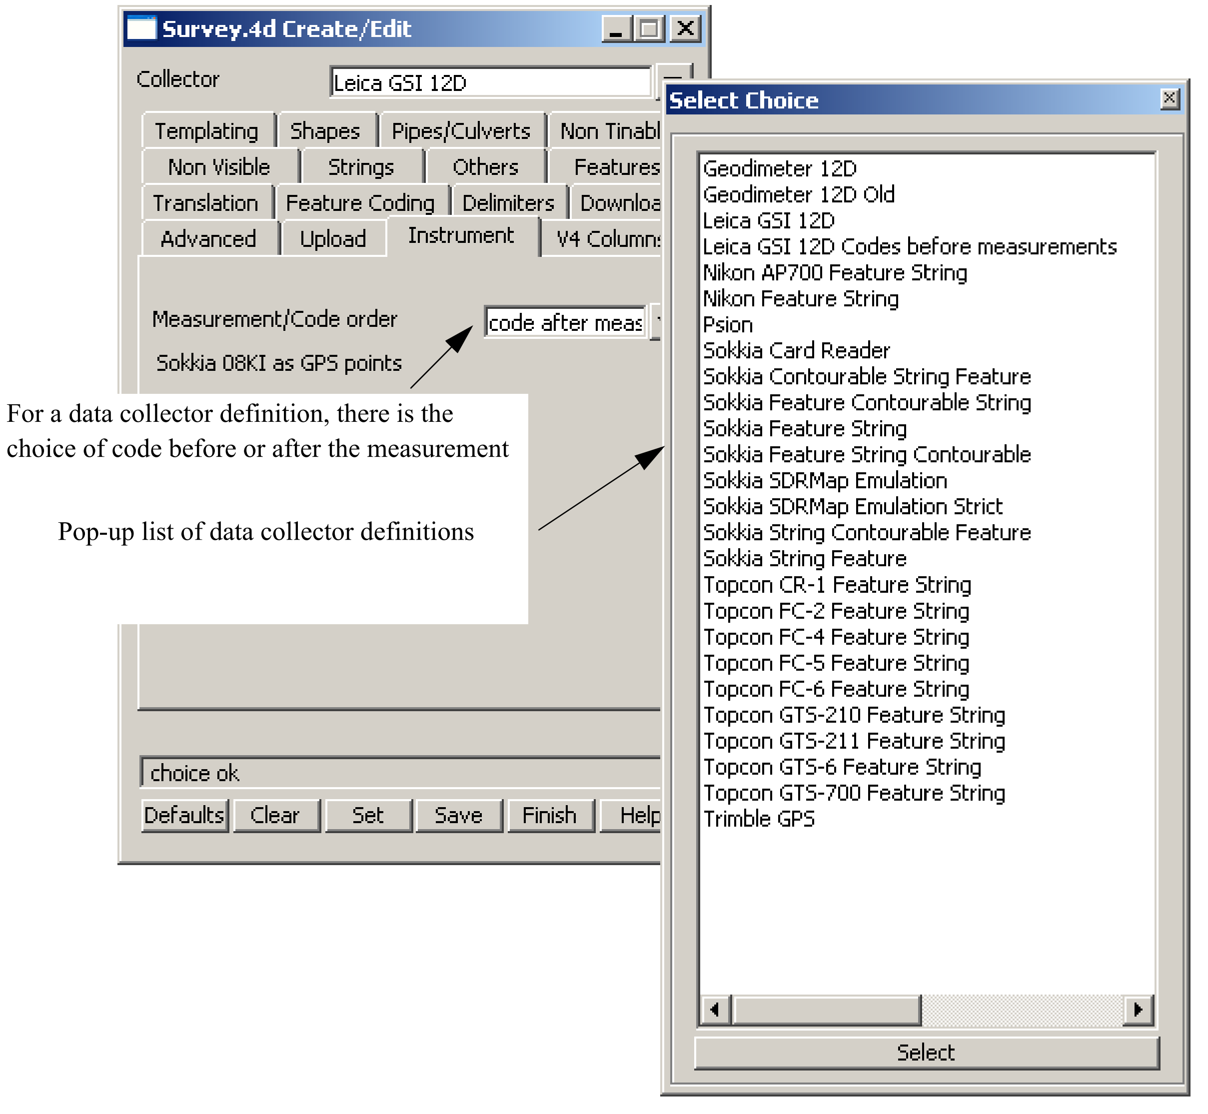
code after measurement

The given *feature code* and *string number* applies to the **last** measurement and all subsequent measurements until another *feature code* and *string number* is entered.

However, for a particular data collector setup, it can be only be defined as one of the two choices. That is you can't change between having feature codes before or after measurements in the one raw file.

Summarising:

Whether feature code definitions come before or after the measurements is defined in the *Survey Data Collector* definition and is set by the *Measurement/Code order* field on the *Instrument* tab of the *Surevy.4d Create/Edit* panel.



Please continue to the next section 37.1.2 Leica Field Codes.

37.1.2 Leica Field Codes

12d Model also uses code lines to supply extra information using field codes.

All *field codes* are entered as the first word of the code line and to differentiated it from a *feature code*, the *field code* is proceeded by a "**.**". Depending on the field code, more information may be required and it is entered in words 2 and above in the code line.

Each *field code* will now be described in detail.

For each *field code*, two lines and a paragraph of description are given:

- The first line consists of the *field code* and a short description of the purpose of the code.
- The second line gives the full syntax of the record for that *field code*.
- The paragraph gives a detailed description of the *field code*.

A 12d Model code list containing 12d Model field codes is available for the TPS to help coding in the field.

Field Code Conventions

In the syntax for the *field codes*, optional Words or groups of Words are enclosed in the square brackets **[ ]**.

However, when the Leica TPS creates the Leica GSI format, the data in all Words is right justified and left filled with zeros. Consequently, 12d Model strips leading zeros from all Words before processing the data.

This means that

(a) an **optional Word** still exists in the file but its data field is simply **filled with zeros**.

(b) any **text** in a Word **cannot start with a zero**. You would need to start with a space and then a zero.

In the *field code* descriptions, the point just measured is referred to as the ***current measurement point***, the ***current point*** or the ***last measurement point***.

The *string* that the current measurement point belongs to is called the ***current string***.

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes

For the full description of the Leica Field Codes, go to the section 37.1.3 Full Description of Leica Field Codes.

For an example of a raw Leica file, please go to the section 37.1.6.7.2 Example of Leica GSI File.

37.1.3 Full Description of Leica Field Codes

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes

Field Code **Description of Record**

.2 Directly entered coordinates

Word 1 .2 Word 2 X Word 3 Y Word 4 Z Word 5 Feature_code

Word 6 String_number [Word 7 Point_number Word 8 Point_name]

A *measurement* point is created with the given f*eature code* and *string number* and given (x, y, z) co-ordinates. No reduction is needed.

If a *Point_name* exists, then it is a ***named measurement*** and in the reduction, a 4d point string of name *Point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *Point_name*. The *Point_name* is added to the internal list of named points for searching for co-ordinates.

Note that the Leica GSI format includes directly entered coordinates in a code line by data blocks with word indices 81, 82, 83 (Easting, Northing and Elevation).

.3 New instrument point - before the measurement

Word 1 .3 Word 2 Point_name Word 3 Instrument_height

Set up an instrument at the point with name *Point_name*. In the reduction, the (x, y, z) co-ordinates for *Point_name* are found by first searching the control model, then the list of previously named points in the reduction, point numbers of previous measurements and finally if *Point_name* is still not found, the user is asked to type in the (x, y, z) co-ordinates.

Note that the Leica GSI format includes setting up on a station in a measurement line by data blocks with word indices 84, 85, 86 (Station easting, Station northing and Station elevation) and 88 (Instrument height).

.4 Next measurement is a backsight - before the measurement

Word 1 .4 Word 2 Station_name [Word 3 Feature_code Word 4 String_number Word 5 Target_height]

The ***next*** measurement is to a backsight with name *Station_name.*

For traverse reduction, if the traverse code specified in the reduction panel matches the Feature code given in Word 3, the data will be included in a traverse reduction, string number can also be specified. Also the target height to the backsight can be given in the backsight command.

.5 New target height for subsequent measurements - before the measurement

Word 1 .5 Word 2 Target_height

Set a new target height to be used for all subsequent measurement points.

Note that the Leica GSI format can include the target height on each measurement line (word index 97).

.6 Next measurement is a Check measurement - before the measurement

Word 1 .6 Word 2 Station_name

The ***next*** measurement is a check measurement made to the station *Station_name*.

During reduction a two point super string (with name *Station_name*) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file.

.9 Scale factor for subsequent distances

Word 1 .9 Word 2 Scale_factor

Scale factor to apply to subsequent slope distances.

.11 Next measurement is to a named station - before the measurement

Word 1 .11 Word 2 Station_name [Word 3 Feature_code Word 4 String_number Word 5 Target_height]

This field code gives a name to a measurement so that it can be used in other field codes for setting up an instrument on, backsighting to or doing a check measurement to.

The ***next*** measurement locates a new instrument station with the name *Station_name*. A point with vertex text of *Station_name* is created. The *Station_name* is added to the internal list of named points for searching for co-ordinates.

If *Feature_code* exists, the point is given that *Feature_code*, otherwise the current feature code is used.

For traverse reduction, if the traverse code specified in the reduction panel matches the Feature code given in Word 3, the data will be included in a traverse reduction, string number can also be specified. Also the target height to the foresight can be given in this command.

.14 Feature code and string number - before or after measurement depends on the data collector definition

Word 1 .14 Word 2 Feature_code Word 3 String_number [Word 5 text Word 6 text] ...

A field code for entering the feature code and string number rather than using the standard method of using word 1 and word 2 This is for use with Leica quick codes which must put out a fixed first word. Any additional *text* is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

This field code is used *always before* or *always after* measurements depending on the *Measurement/code* field on the *Instrument* tab of the **Survey.4d Create/Edit** panel for the selected data collector definition.

.15 Vertical circle correction for subsequent measurements - before the measurement

Word 1 .15 Word 2 Vertical_circle_in_decimal_degrees

The *vertical_circle_in_decimal_degrees* is **subtracted** from the vertical circle value in any subsequent measurements.

.16 Additional code for point (multiply coded point) - after the measurement

Word 1 .16 Word 2 Feature_code Word 3 String_number [Word 4 Point_name] [Word 5 Point_text]

Additional coding for the current measurement point. A new measurement point is created at the same position as the current measurement point but with the *Feature_code* and *String_number* from this field code. The same point number is used as for the current measurement point.

If *Point_text* exists, it is used as the vertex text for that vertex of the super string.

If *Point_name* exists, then it is a ***named measurement*** and during reduction, a 4d point string of name *Point_name* is created and mapped using the Map File. The 4d text is the station prefix followed by *Point_name*. The *Point_name* is added to the internal list of named points for searching for co-ordinates.

.17 Arc through previous three points - after the measurement of last point of arc

Word 1 .17 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, then the current measurement point and the two previous points with the same feature code and string number as the current measurement point, are joined by an arc. If there is less than three such points, no arc is fitted.

If the *Feature_code* and *String_number* exist*,* the last three previous three measurement points of the same *feature code* and *string number* are joined by an arc. If the current measurement point has that feature code and string number, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If *Point_number* exists*,* then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and that point and the two measurement points previous to the pre-defined point of the same *feature code* and *string number*, are joined by an arc. If there is less than three points, no arc is fitted

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

.18 Circle Feature - after the measurement

Word 1 .18 Word 2 Radius [Word 2 Radius **...***]*

Creates a feature string with the given radius and centred on the current measurement point. If there is more than one radius, then separate feature strings are created each with one of the radii.

.20 Close string - after the measurement

Word 1 .20 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exits, the current string is closed.

If the *Feature_code* and *String_number* exist*,* the last previous string with that *feature code* and *string number* is closed.

If *Point_number* exists*,* then the string containing that point number is closed.

See the Section 36.3.4 Close String for more information on closing a string.

.21 Join last points of strings

Word 1 .21 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the last point of the string with the given *Feature_code* and *String_number_1* is joined to the last point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.22 Join first to last point of strings

Word 1 .22 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the first point of the string with the given *Feature_code* and *String_number_1* is joined to the last point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.23 Join first points of strings

Word 1 .23 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the first point of the string with the given *Feature_code* and *String_number 1* is joined to the fist point of the string with given *Feature_code* and *String_number_2*. The created string has the given *Feature_code* (no string number is needed since it is the final reduction when the string numbers are then dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.28 Text appended to a string name

Word 1 .28 Word 2 Text [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

Text is appended to the string name. For example, if 1.200 is entered, “ 1.200” is appended to the string name.

If only *Text* is given, *Text* is appended to the string name of the current string.

If the *Feature_code* and *String_number* exist, then the last previous string with that *feature code* and *string number* has *Text* appended to the string name.

If *Point_number* exists, then the string containing that point number has *Text* appended to the string name.

.29 Note or memo - after the measurement

Word 1 .29 [Word 2 text] [Word 3 text] **...**

Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

.30 Remove height from a point - that is make it a null height - after the measurement

Word 1 .30 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the height of the current measurement point is set to null.

If *Feature_code* and *String_number* exist, then the height of the last point of the previous string with that *feature code* and *string number* is set to null.

If *Point_number* exists, then the height of the point with that point number is set to null.

.37 Rectangle by two points

Word 1 .37 Word 2 offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If *Feature_code* and *String_number* exist, the last two points with that *feature code* and *string number* are used and a fourth points are created to form a rectangle. The height of the two new points are set to null. The string is then closed.

If *Point_number* exists, then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See the Section 36.3.5 Rectangle for more information.

.38 Make the previous segment non-tinable (not a breakline) - after the measurement

Word 1 .38 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to non-tinable.

.39 Make the next segment non-tinable (i.e. not a breakline) - after the measurement for the first point of the segment

Word 1 .39 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the *Feature_code* and *String_number* exist*,* then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists*,* then the segment containing the point with that point number as a start point, is set to non-tinable.

.40 Make a point non-tinable - after the measurement

Word 1 .40 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current measurement point is set to non-tinable. That is, it will not be included in triangulations.

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that *feature code* and *string number* is set to non-tinable.

If *Point_number* exists*,* then the point with that point number is set to non-tinable.

.41 Add additional text to the current measurement point - after the measurement

Word 1 .41 Word 2 text [Word 3 text] ...

The given *text* is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

.42 Add a radial offset - after the measurement

Word 1 .42 Word 2 Radial_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

The *Radial_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If only Word 1 and 2 *exist*, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists*,* then the point with that point number is adjusted.

See the Section 36.3.2 Offsets for more information on offsets.

.43 Add a tangential offset - after the measurement

Word 1 .43 Word 2 Tangential_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

The *Tangential_offset_in_metres* is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If only Word 1 and 2 *exist*, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists*,* then the point with that point number is adjusted.

See the Section 36.3.2 Offsets for more information on offsets.

.44 Add a height offset - after the measurement

Word 1 .44 Word 2 Height_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If the height of the specified point is not null, then the *Height_offset_in_metres* adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.

If only Word 1 and 2 *exist*, the offset is used to adjust the position of the current measured point.

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that *feature code* and *string number* is adjusted.

If *Point_number* exists*,* then the point with that point number is adjusted.

See the Section 36.3.2 Offsets for more information on offsets.

.45 Make a parallelogram from the last three measurement points - after the measurement

Word 1 .45 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If *Feature_code* and *String_number* exist*,* the last three points with that *feature code* and *string number* are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If *Point_number* exists*,* then the *feature code* and *string number* of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

See the Section 36.3.5 Rectangle for more information on forming a parallelogram.

.46 Make the entire string a breakline or not (tinable or non-tinable)

Word 1 .46 [Word 2 Breakline_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

***Word 2: Breakline_type*:**

If *Breakline_type* is 0, the selected string is set to a point string and hence is not a breakline (non-tinable).

If *Breakline_type* is 1, the selected string is set to a *line* string and is therefore a breakline (tinable).

Words 3, 4, and 5:

If none of Words 3, 4 and 5 exist, the *Breakline_type* is applied to the current string.

If *Feature_code* and *String_number* exist*,* the *Breakline_type* is applied to the last string with that *feature code* and *string number.*

If *Point_number* exists*,* then the *Breakline_type* is applied to the string containing the point with that point number.

.47 Start a new string using the same feature code and string number - after the measurement of the first point of the new string

Word 1 .47 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current string is terminated (without including the current measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same *feature code* and *string number.*

If *Point_number* exists*,* then the previous string containing the point with that point number is terminated *before* the point number point, and the point becomes the first point of a new string with the *same feature code* and *string number.*

.48 End a string

Word 1 .48 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current string is terminated (including the current measurement point).

If *Feature_code* and *String_number* exist*,* then the last point of the previous string with that feature code and string number becomes the last point of that string.

If *Point_number* exists, then the previous string containing the point with that point number is terminated *after* the point number point

.50 Specify the bearing to correct for true north - used as the bearing datum difference

Word 1 .50 Word 2 Bearing_in_decimal_degrees [Word 3 Text]

The *Bearing_in_decimal_degrees* is used as the bearing datum difference for the current instrument set up. The *Text* and the *Bearing_in_decimal_degrees* are written to the reduction report file.

.51 Start using an existing field template - before the measurement

Word 1 .51 Word 2 [Template_name] [mode]

Start using the template *Template_name.* If *Template_name* is blank, the default template is used
If *mode* is "for", then the field template is used as a *forward* template.
"rev", then the field template is used as a *reverse* template.
"zig", then the field template is used as a zig_zag template and is used in the *forward* definition direction first.
"zag", then the field template is used as a zig_zag template and is used in the *reverse* direction first
If *mode* is blank, or 0, or anything other than "for", "rev", or "zag", then the field template is used as a *zig-zag* field template starting on a *zig*.

See the Section 36.4 Field Templates for more information on field templates.

.52 Finish using a field template or finish recording a field template - after the measurement

Word 1 .52

Stops using the current field template or stops recording a field template.

.53 Pause using the current field template - after the measurement

Word 1 .53

Pause using the current field template or defining a field template, until a continue template (54) or a finish field template (52) code is given.

.54 Continue the current field template - before the measurement

Word 1 .54

Continue using the current field template or defining the current field template, which has been stopped by a *Pause* command (53). The *Continue* command only needs to be given once and applies to all *following* measurements until another *Pause* or *Finish* command is given.

.55 Start recording a field template - before the measurement

Word 1 .55 Word 2 [Template_name]

Start recording a field template with the name *Template_name*. If *Template_name* is non-blank, then the default field template is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (52) are stored as the field template. There is no limit to the number of points in a field template.

See the Section 36.4 Field Templates for more information on field templates.

.56 Skipping picking up points when using a field template - after the measurement of last point before skipping points

Word 1 .56 Word 2 [num_skipped_points]

Allows the user to skip picking up one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition. If *num_skipped_points* is missing, then only one point is skipped otherwise *num_skipped_points are skipped.*

.57 Delete points on a field template - after the measurement of last point

Word 1 .57 Word 2 [num_points_to_delete]

Allows the user to delete one or more points from the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

.58 Insert points when using a field template - after the measurement of last point before inserting points

Word 1 .58 Word 2 Feature_code Word 3 String_number Word 4 Multiple_code_flag Word 5 Insert_special_flag

Allows the user to insert points into the field template currently being used. The *next measurement* takes the *feature_code* and *string_number* from the next point of the field template definition.

If the *Multiple_code_flag = 1, then the feature code will be added to the previous defined template point else if Multiple_code_flag = 0 (default), it will be added to the template as a separate point.*

If the insert is done at the end of a section and the *Insert_special_flag = 1 the point will be added to the end of the current template section else it will be at the start of the next section.*

.60 Start of arc through next three points - after the measurement of the first point of the arc

Word 1 .60 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If *Feature_code* and *String_number* exist*,* a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the previous measurement and the next two measured points following this previous measurement with the same feature code and string number. If the current point has that feature code and string number, then it is the first of the three point. If there is less than three points, no arc is fitted.

If *Point_number* exists*,* then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and an arc is inserted through that point and the next two measurement points with the same *feature code* and *string number*. If there is less than three points, no arc is fitted

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

.61 Start of arc through sets of three points until end of string, or a 62 occurs - after the measurement of the first point of the arc

Word 1 .61 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If there is less than three points remaining at the end, then no arc is fitted to the end points.

If only Word 1 *exist*s, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the *first* of the points.

If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If the *feature code* and *string number exist*, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the following measured points with the same feature code and string number as given in *point_description*. If the current point has that feature code and string number, then it is the first of the points.

If *Point_number* exists*,* then the *feature code* and *string number* are taken from the previous measurement point **with** that point number, and arcs are inserted through that point and the following measured points with the same *feature code* and *string number*.

If ***12d Model*** encounters a *Start Arcs through sets of three points* but no *End Arcs* command for the string, then an *End Arcs* is assumed at the end of the string.

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

.62 End the arcs begun by a 61 command - after the measurement of the last point of the arcs

Word 1 .62 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exists*, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the *last* of the points used in the arc fitting.

If *Feature_code* and *String_number* exist, then the fitting of arcs through the points of the previous string with the same *feature code* and *string number* is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If *Point_number* exists, then the point with that point number is the last point used in the arc fitting.

If ***12d Model*** encounters an *End Arcs* (62) but no *Start Arcs through sets of three points* (61) command for the string, then an *Start Arcs through sets of three points* (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

See the section 36.3.9 Arcs Through Points for more information on arc fitting.

There are field codes for adding user defined attributes to:

(a) the current string being measured (i.e. the string containing the current measurement point)

(b) the current measurement point

(c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the *next* measured point *of the same feature code and string number*)

or

(d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point *of the same feature code and string number*).

The attributes can be named or unnamed and are coded in the following way:

If Word 2 is missing (i.e. all zeros), then the attribute is an un-named attribute and the rest of the Words on the line is the attribute value. The attribute is given the special name "unnamed attribute n" for n=1, 2, ...

.68 Add an integer user defined attribute to the current string

Word 1 .68 [Word 2 Name] Word 3 Integer

Add an user defined integer attribute to the current string.

.69 Add a real user defined attribute to the current string

Word 1 .69]Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the current string.

.70 Add text user defined attribute to the current string

Word 1 .70 [Word 2 Name] Word 3 Text [Word 4 Text] **...**

Add a text user defined attribute to the current string.

.71 Add integer user defined attribute to the current point

Word 1 .71 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the current measurement point.

.72 Add real user defined attribute to the current point

Word 1 .72 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the current measurement point.

.73 Add text user defined attribute to the current point

Word 1 .73 [Word 2 Name] Word 3 Text [Word 4 Text] **...**

Add a text user defined attribute to the current measurement point.

.74 Add integer user defined attribute to the next segment

Word 1 .74 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the next segment from the current measurement point.

.75 Add real user defined attribute to the next segment

Word 1 .75 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the next segment from the current measurement point.

.76 Add text user defined attribute to the next segment

Word 1 .76 [Word 2 Name] Word 3 Text [Word 4 Text] **...**

Add a text user defined attribute to the next segment from the current measurement point.

.77 Add integer user defined attribute to the previous segment

Word 1 .77 [Word 2 Name] Word 3 Integer

Add an integer user defined attribute to the previous segment for the current measurement point.

.78 Add real user defined attribute for the previous segment

Word 1 .78 [Word 2 Name] Word 3 Real

Add a real (floating point) user defined attribute to the previous segment for the current measurement point.

.79 Add text user defined attribute to the previous segment

Word 1 .79 [Word 2 Name] Word 3 Text [Word 4 text] **...**

Add a text user defined attribute to the previous segment for the current measurement point.

In addition, extra codes allow ***12d Model*** pipe strings to be coded in the field.

.80 Pipe invert point (bottom of the pipe) - after the measurement

Word 1 .80 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist, the last point of the previous string with the same *feature code* and *string number* is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

.81 Pipe axial point (centre of the pipe) - after the measurement

Word 1 .81 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist*,* the last point of the previous string with the same *feature code* and *string number* is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists*,* then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

.82 Pipe obvert point (top of the pipe) - after the measurement

Word 1 .82 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 *exist*s, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Feature_code* and *String_number* exist*,* the last point of the previous string with the same *feature code* and *string number* is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If *Point_number* exists*,* then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

.83 Start recording a shape - before the measurement

Word 1 .83 [Word 2 Shape_name]

Start recording a shape with the name *Shape_name*. If *Shape_name* is non-blank, then the default field Shape is defined by the *feature_code* and *string_number* of the following measurements until a *Finish* code (84) are stored as the shape. There is no limit to the number of points in a shape.

See the Section 36.4 Field Templates for more information on field templates.

.84 Finish using a shape definition or finish recording a shape - after the measurement

Word 1 .84

Stops using the current shape or stops recording a shape.

.85 Shape parallel

Word 1 .85 Word 2 Shape_name [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If *Feature_code* and *String_number* exist*,* the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists*,* then the string containing that point number has the shape applied to the entire length of the string.

Parallelling the shape will produce separate strings for each point of the shape.

.86 Shape extrude

Word 1 .86

Word 1 .85 Word 2 Shape_name [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If *Feature_code* and *String_number* exist*,* the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists*,* then the string containing that point number has the shape applied to the entire length of the string.

Extruding the shape will produce a single string for the shape.

.92 Remove all z-values for a string (i.e. make all z-values null) - after the measurement

Word 1 .92 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 *exist*s, all z-values for the current string are removed.

If *Feature_code* and *String_number* exist*,* the last string with the same *feature code* and *string number* has all its z-values removed.

If *Point_number* exists*,* then the string containing that point number has all its z-values removed.

If *Point_line_type* is 0, the selected string is set to a point string.
If *Point_line_type* is 1, the selected string is set to a *line* string.

.93 Set the Point-line type - after the measurement

Word 1 .93 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 *exist*s, the current string is created as a point string.

If *Feature_code* and *String_number* exist*,* the last previous string with the same *feature code* and *string number* has its point-line type modified.

If the *point number* exists*,* then the string containing that point number has its point-line type modified.

If *Point_line_type* is 0, the selected string is set to a point string.
If *Point_line_type* is 1, the selected string is set to a *line* string.

.94 Use name library/mapping file for vertex text on the string - name mapping - after the measurement

Word 1 .94 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If this field code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn't exist, the map file. If neither exist then the field code is ignored.

> if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for *all* vertices of the string that don't already have vertex text. As a default, the string is set as a point string.
>
> if the map file is used and the feature code of the string is found in the first column of the map file, then the *string name* field of the map file is used as vertex text for all vertices that don't already have text. As a default, the string is set as a point string.

If only Word 1 *exist*s, then name mapping is applied to the current string.

If *Feature_code* and *String_number* exist*,* then name mapping is applied to the last previous string with the same *feature code* and *string number.*

If *Point_number* exists*,* then name mapping is applied to the string containing that point number.

If *Point_line_type* is 0, the selected string is set to a point string.
If *Point_line_type* is 1, the selected string is set to a *line* string.

.95 Circular Pipe string - after the measurement

Word 1 .95 Word 2 Diameter [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using field codes 80, 81 and 82.

If only Word 1 and 2 *exist*s, the current string is created as a pipe string with the given diameter.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* is created as a pipe with the given diameter.

If *Point_number* exists, then the string containing that point number is created as a pipe string with the given diameter.

.96 Box Culvert string - after the measurement

Word 1 .95 Word 2 Width Word 3 Height [Word 4 Feature_code Word 5 String_number] [Word 6 Point_number]

Culvert strings are always line strings and are stored with the justification of the majority of the string points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of the culvert using field codes 80, 81 and 82.

If only Word 1, 2 and 3 *exist*s, the current string is created as a culvert string with the given width and height.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* is created as a culvert with the given width and height.

If *Point_number* exists, then the string containing that point number is created as a culvert string with the given width and height.

.99 Terminate processing

Word 1 .99

Stop processing the field file at this line. Useful for debugging errors.

.107 Make the previous segment invisible - after the measurement

Word 1 .107 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the previous segment containing the current measurement point is set to invisible.

If the *Feature_code* and *String_number* exist, then the last segment of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as an end point, is set to invisible.

.108 Make the next segment invisible - after the measurement for the first point of the segment

Word 1 .108 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the next segment containing the current measurement point as a starting point is set to invisible.

If the *Feature_code* and *String_number* exist, then the segment that is created in the future from the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the segment containing the point with that point number as a start point, is set to invisible.

.109 Make a point invisible - after the measurement

Word 1 .109 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current measurement point is set to invisible.

If *Feature_code* and *String_number* exist, then the last point of the previous string with that *feature code* and *string number* is set to invisible.

If *Point_number* exists, then the point with that point number is set to invisible.

.110 Start buildings face observations - before the measurements

Word 1 .110 Word 2 [Building_name]

Start recording a field template with the name *Building_name*. If *Building_name* is non-blank, then the default building face is defined. The *feature_code* and *string_number* of the following measurements until a *Finish* code (111) are stored as the building face. There is no limit to the number of points in a building face.

.111 End building face observations

Word 1 .111 Word 2 [Building_name]

If only Word 1 *exist*s, the current building face observation set is finished (including the current measurement point).

Notes

1. Arc fitting is applied *after* the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes

37.1.4 Summary of Leica Field Codes

Most of the field codes are entered after the measurement is taken and they will have a (AM) after the description. Some of the field codes are entered before the measurement is taken (mainly set up codes) and will have a (BM) after the description.

Field Code	Description of Record
.2	Directly entered coordinate measurement
.3	New instrument setup point (BM)
.4	Measurement to backsight (BM)
.5	New target height (BM)
.6	Check measurement (BM)
.9	Scale factor for subsequent distances (BM)
.10	Three hair stadia measurement
.11	Measurement to a named station (BM)
.15	Vertical circle correction (BM)
.14	A field code for entering Feature code and String number - BM or AM depends on data collector definition
.16	Multiply coded point (AM)
.17	Arc through previous three points (AM of last point of arc)
.18	Circle Feature (AM)
.20	Close string (AM)
.21	Join last points of strings
.22	Join first to last point of strings
.23	Join first points of strings
.28	Add text to the string name (AM)
.29	Note or memo (AM)
.30	Remove height from a point - that is make it a null height (AM)
.37	Rectangle by two points
.38	Make the previous segment non-tinable (AM of end point of segment)
.39	Make the next segment non-tinable (AM of first point of segment)
.40	Make a point non-tinable (AM)
.41	Add additional text (AM)
.42	Add a radial offset (AM)
.43	Add a tangential offset (AM)
.44	Add a height offset (AM)
.45	Make a parallelogram from the last three measurement points (AM)
.46	Make the string a breakline or not
.47	Start a new string using the same feature code and string number (AM of first point of new string).
.48	End a string -
.50	Specify the bearing to correct for true north - used as the bearing datum difference
.51	Start using an existing field template (BM)
.52	Finish using a field template or finish recording a field template (AM)
.53	Pause the current field template until a continue op code (54) or a finish template (52)
.54	Continue the current field template (BM)
.55	Start recording a field template (BM)
.56	Skip picking up one or more points from a field template (AM of last point before skipping)
.57	Delete one or more points from a field template (AM)
.58	Insert a point into a field template (BM)
.60	Arc through next three points (AM of first point of arc)
.61	Start of arc through sets of three points until end of string, or a 62 occurs (AM of first point of arc)
.62	End the arcs begun by a 61 command (AM of last point of arcs)
.68	Add an integer user defined attribute to the current string (AM of any point of the string)
.69	Add a real user defined attribute to the current string (AM of any point of the string)
.70	Add text user defined attribute to the current string (AM of any point of the string)
.71	Add integer user defined attribute to the current point (AM)
.72	Add real user defined attribute to the current point (AM)
.73	Add text user defined attribute to the current point (AM)

.74 Add integer user defined attribute to the next segment (AM of first point of the segment)
.75 Add real user defined attribute to the next segment (AM of first point of the segment)
.76 Add text user defined attribute to the next segment (AM of first point of the segment)
.77 Add integer user defined attribute to the previous segment (AM of last point of the segment)
.78 Add real user defined attribute for the previous segment (AM of last point of the segment)
.79 Add text user defined attribute to the previous segment (AM of last point of the segment)
.80 Pipe invert point (bottom of the pipe) (AM)
.81 Pipe axial point (centre of the pipe) (AM)
.82 Pipe obvert point (top of the pipe) (AM)
.83 Start recording a shape - before the measurement
.84 Finish using a shape definition or finish recording a shape - after the measurement
.85 Shape parallel
.86 Shape extrude
.92 Remove all z-values for a string (i.e. make all z-values null) (AM of point of the string)
.93 Set the Point-line type
.94 Use name library file/ mapping file for vertex text on the string - name mapping
.95 Circular pipe string with diameter (AM)
.96 Box culvert string with dimensions (AM)
.99 Terminate processing
.107 Make the previous segment invisible - after the measurement
.108 Make the next segment invisible - after the measurement for the first point of the segment
.109 Make a point invisible - after the measurement
.110 Start buildings face observations - before the measurements
.111 End building face observations

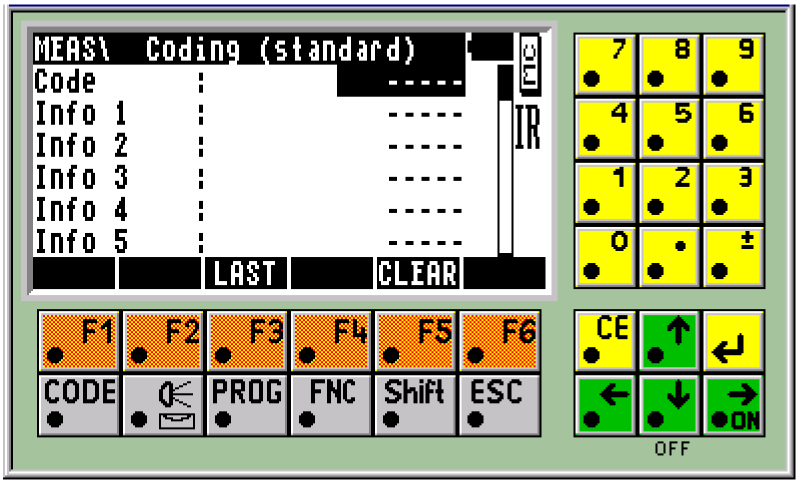
For a full description of the Leica codes, please go to the section 37.1.3 Full Description of Leica Field Codes.

For an example of a raw Leica file, please go to the section 37.1.6.7.2 Example of Leica GSI File.

37.1.5 Examples of Leica Screens

Standard Screen

When using a Leica instrument with no code.hex on the 1000 series, or Geobasic program or Codelist (.crf file) on the 1100 series, hitting the *Code* button brings up the standard Leica screen:

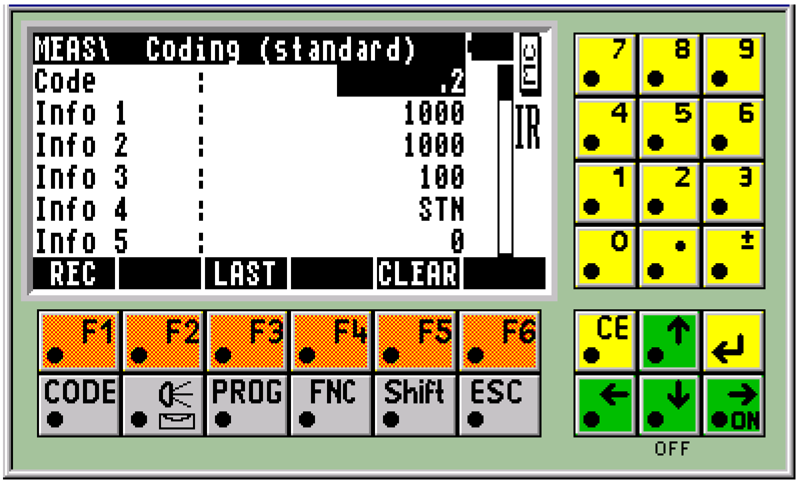


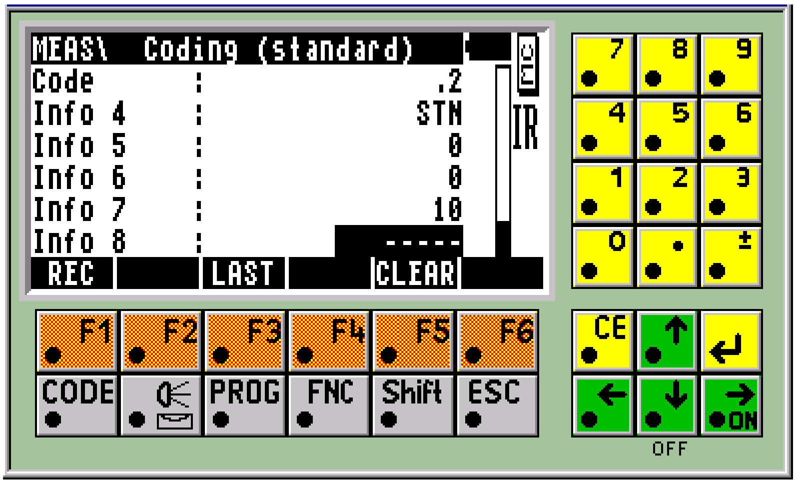
The information entered in *Code* goes to Word 1 of the line written to the Leica GSI file.

The information in *Info 1* to *Info 8* go to Word 2 to Word 9 respectively of the line written to the GSI file.

As an example, to enter a *directly entered co-ordinate* (the 2 field code),

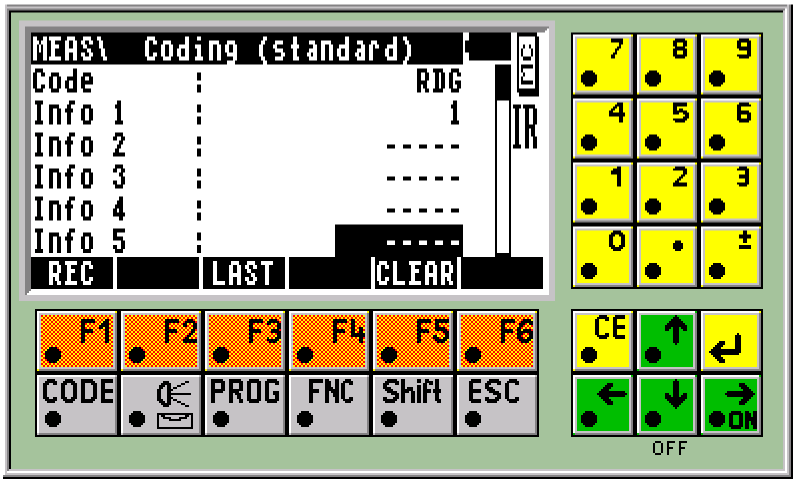
".2" is entered in the *Code* field
X, Y and Z in Info 1, Info 2 and Info 3 respectively.
the feature code (STN) is entered into Info 4
the station name "10" is entered into Info 7





To enter a *feature code and string number* to be used for measurements

the feature code is entered into the *Code* field
the string number is entered into *Info 1*.



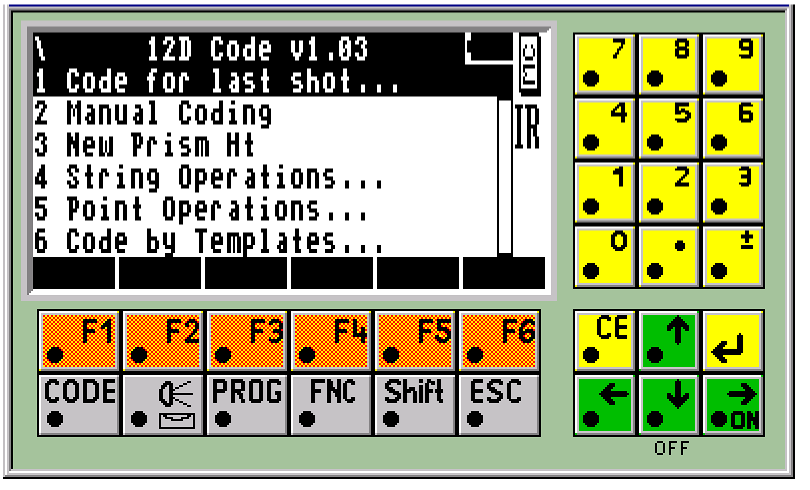
Leica Geobasic Program

A Leica Geobasic program gives the programmer full control over the Leica screen.

WARNING

Only one Geobasic program can exist on the Leica at any one time. Loading a Geobasic program will over write the existing Geobasic program on the instrument. Make sure you have a backup copy of the existing Geobasic program on your computer before loading a new one onto the instrument.

If you do not have a backup copy of the existing Geobasic program, do not load a new one.



The front screen of the 4D Solutions supplied Geobasic program

Leica Codelist

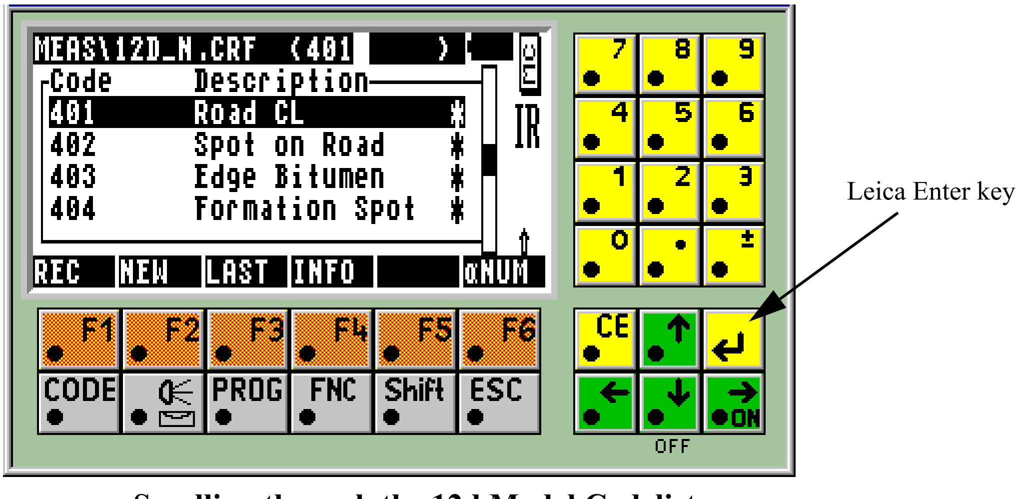
A Leica Codelist (.crf file) controls what is displayed and validated on the Leica screen and what values are recorded whenever the *Code* button is selected. For example, when using the 4D Solutions supplied Codelists , a list of defined feature codes and descriptions are displayed.

The Codelist controls what codes are displayed and whenever a code is selected, what information is required for that code. The Codelist also specifies what information is written out to the GSI file for that code.

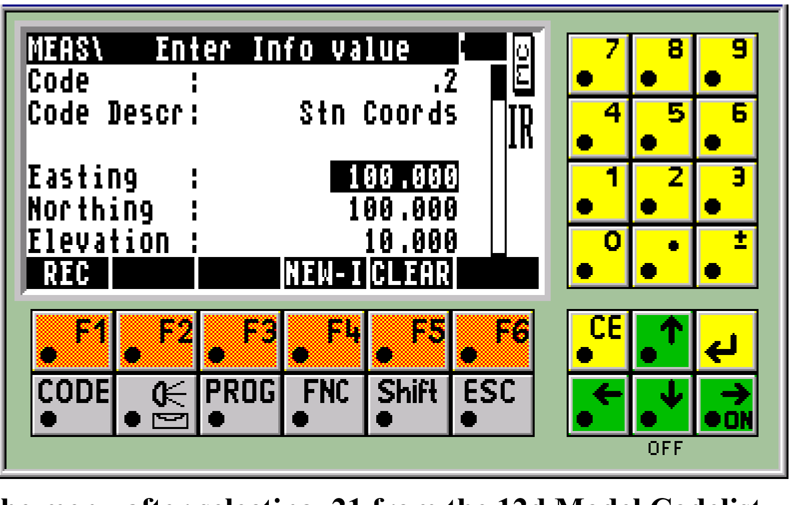
After hitting the *Code* button, the list of codes from the Codelist is displayed in alphanumeric order. Because the ***12d Model*** field codes start with a ".", they will appear at the top of the list.

A code can be typed in or the list can be scrolled through using the arrow keys.

The highlighted code is selected by pressing the Leica Enter Key. The menu for the selected code then appears. The line of data is written out to the GSI file when the F1 (REC) button is selected.



Scrolling through the 12d Model Codelist



The menu after selecting .21 from the 12d Model Codelist

37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d

The following relates to the setup of a Leica 1100 series instrument for topographic/detail pickup and use with 12d.

37.1.6.1 Setting up the Instrument

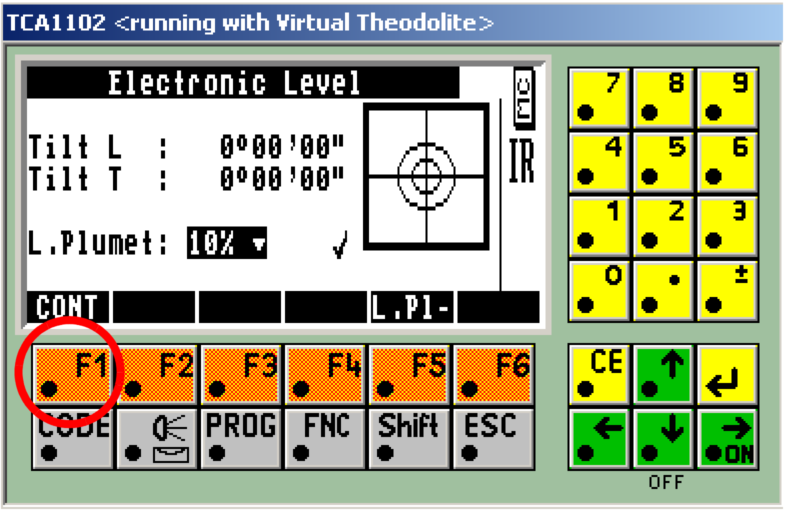
37.1.6.1.1 Copying the CRF file

A number of example .crf files are include on the installation CD. These can be found in the directory Other_Software\Leica\ . For the purpose of this documentation, we will use the file **12D_DS.CRF** which is designed for detail pickup. This file should be copied from the 12d CD to the folder “Code” on the Leica card.

This file contains all of the field codes used in ***12d Model*** along with a sample code listing

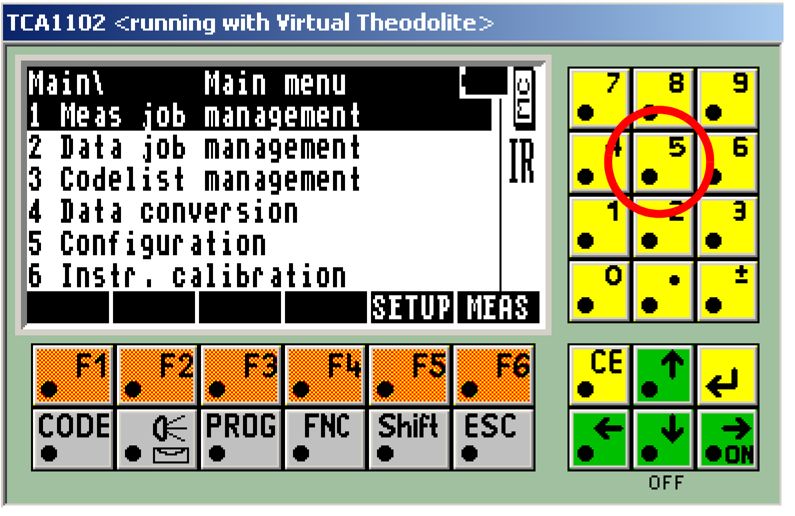
37.1.6.1.2 Set up the display and record masks

Turn on and level instrument

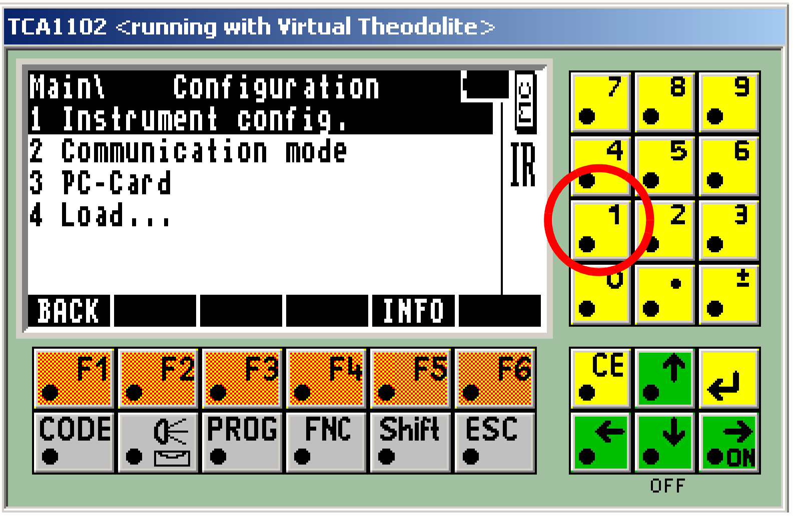


Press F1 to Continue

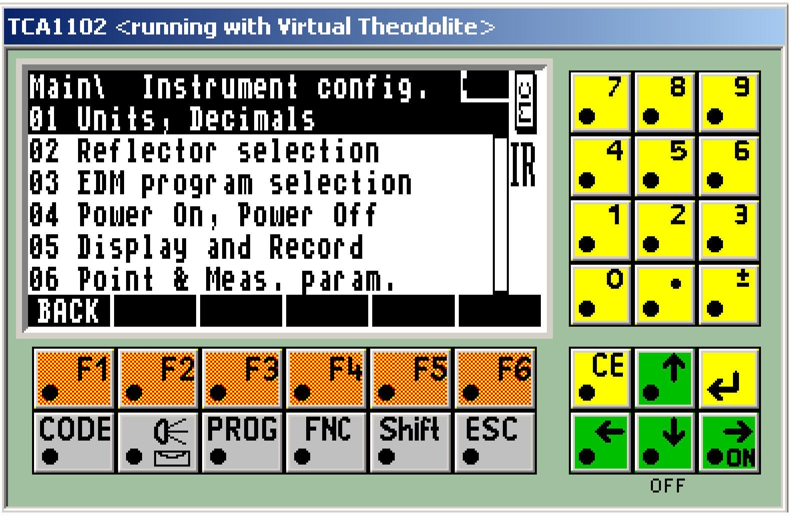
Press 5 to configure the instrument



Press 1 for instrument configuration

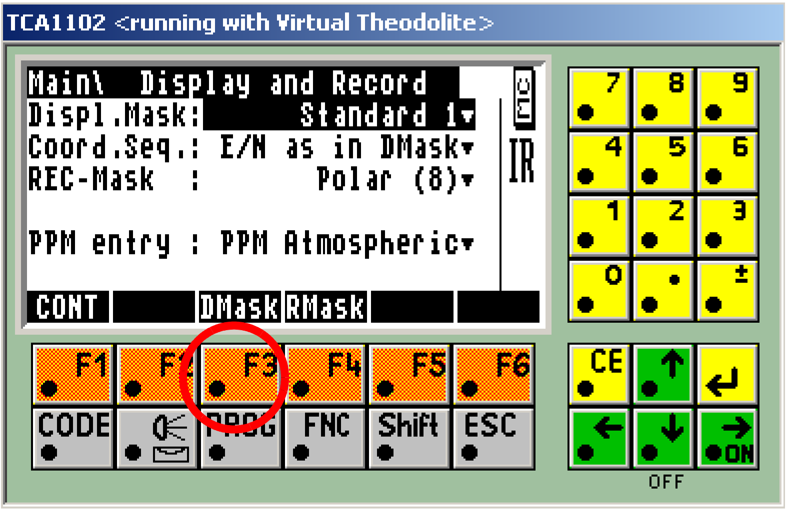


Press 05 for Display and Record mask setup

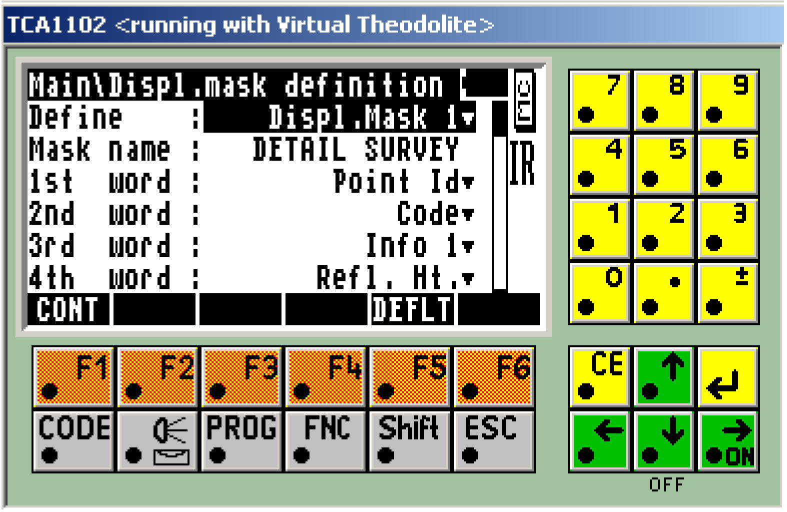


Display mask:

Press F3 to set up display mask



Type in the description DETAIL SURVEY for the Mask name



Select the following settings:

1st Word…….Point Id

2nd Word…….Code

3rd Word…….Info 1

4th Word…….Refl. Ht.

5th Word…….Hz

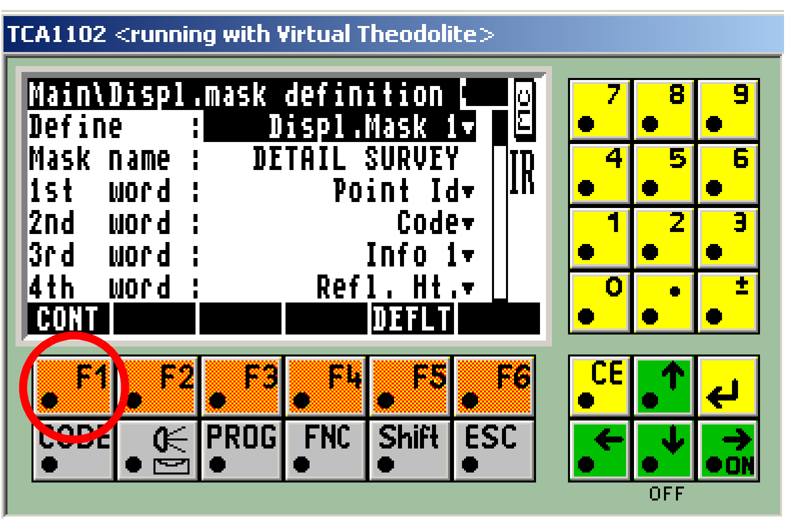
6th Word…….Horiz. Dist

7th Word…….East

8th Word…….North

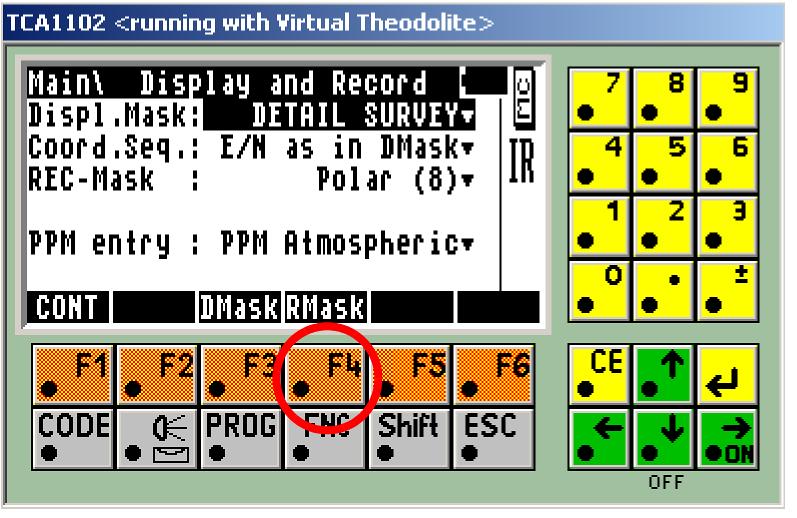
9th Word…….Elev

Press F1

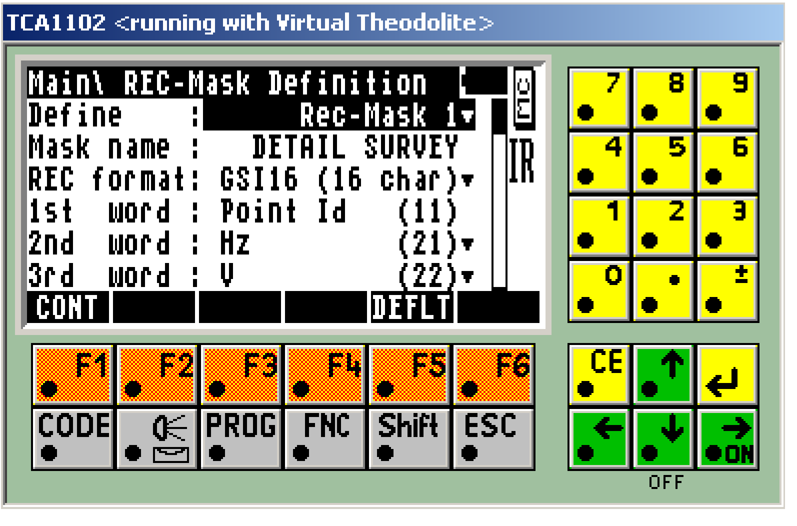


Record mask:

Press F4 to set up record mask



Type in the description DETAIL SURVEY for the Mask name



Select the following settings:

REC format….GSI16 (16 char)

1st Word…….Point Id (11)

2nd Word…….Hz (21)

3rd Word……..V (22)

4th Word…….Slope Dist (31)

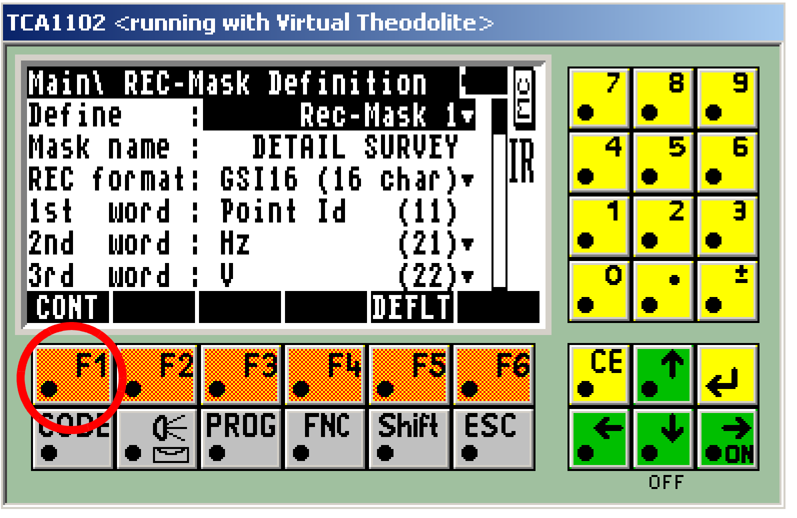
5th Word…….Ref. Ht. (87)

6th Word…….East (81)

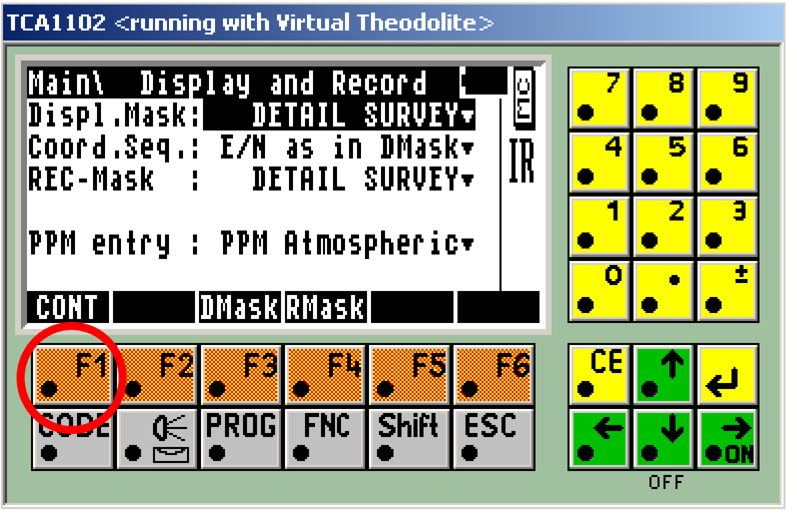
7th Word…….North (82)

8th Word…….Elev (83)

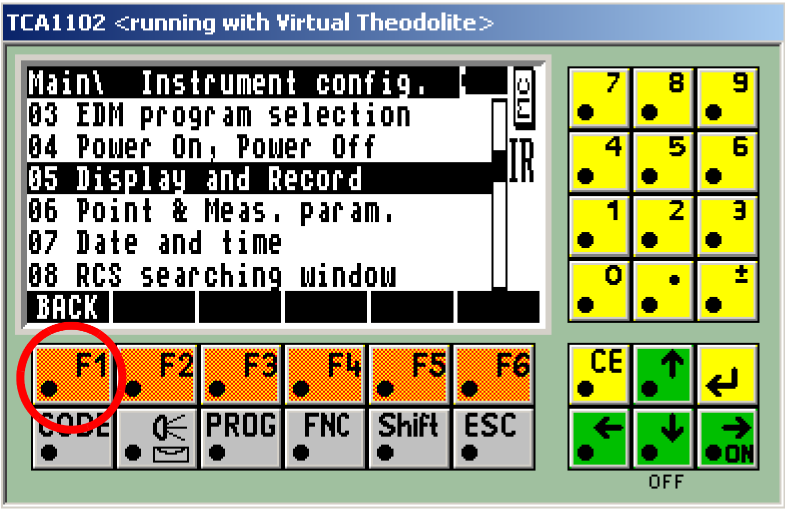
Press F1



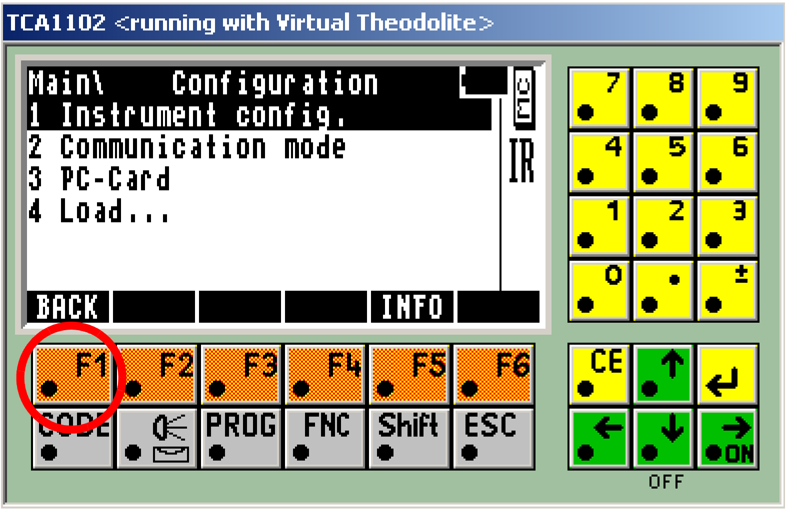
Press F1



Press F1 to exit menu



Press F1 to exit menu



37.1.6.1.3 Leica field codes

It is important to know when the code is entered into the instrument as some codes should precede a reading (BM) and some come after (AM). In this manual if a code is related to the current string then it is placed before the reading.

Below is a list of the commonly used codes to be used

.2	Directly entered coordinates
.3	New instrument station
.4	Backsight reading (BM)
.5	Height of target (BM)
.6	Check measurement (BM)
.9	Scale factor (BM)
.11	Foresight station (BM)
.14	Feature code and string number (Use for Leica quick codes only)
.15	Vertical circle correction (d.dddd) (BM)
.16	Additional code for point (AM)
.17	Arc thru last 3 points (AM)
.18	Circle (AM)
.20	Close string (AM)
.29	Note (AM)
.30	Remove height from point (AM)
.37	Rectangle by two points (AM)
.38	Make last segment non tinable (AM)
.39	Make next segment non tinable (AM)
.40	Make point non tinable (AM)
.42	Add radial offset (AM)
.43	Add tangential offset (AM)
.44	Add height offset (AM)
.45	Create parallelogram from last three points (AM)
.47	Start new string with same code and string no. as previous string (AM)
.48	End string (AM)….Not generally used

Templates

.51	Start template readings (BM)
.52	Finish template readings (AM)
.53	Pause template (AM)
.54	Continue a template (BM)
.55	Start recording template (BM)
.56	Skip points on template (BM)

Arcs

.60	Arc thru next 3 points (AM)…..See also .17
.61	Arc through sets of 3 points until .62 code entered (BM)
.62	End of arc from .61 (AM)

Pipes

.80	Reading taken to invert level of pipe (AM)
.81	Reading taken to centre of pipe (AM)
.82	Reading taken to obvert level of pipe (AM)
.95	Circular pipe diameter (AM)
.96	Box culvert dimensions (AM)

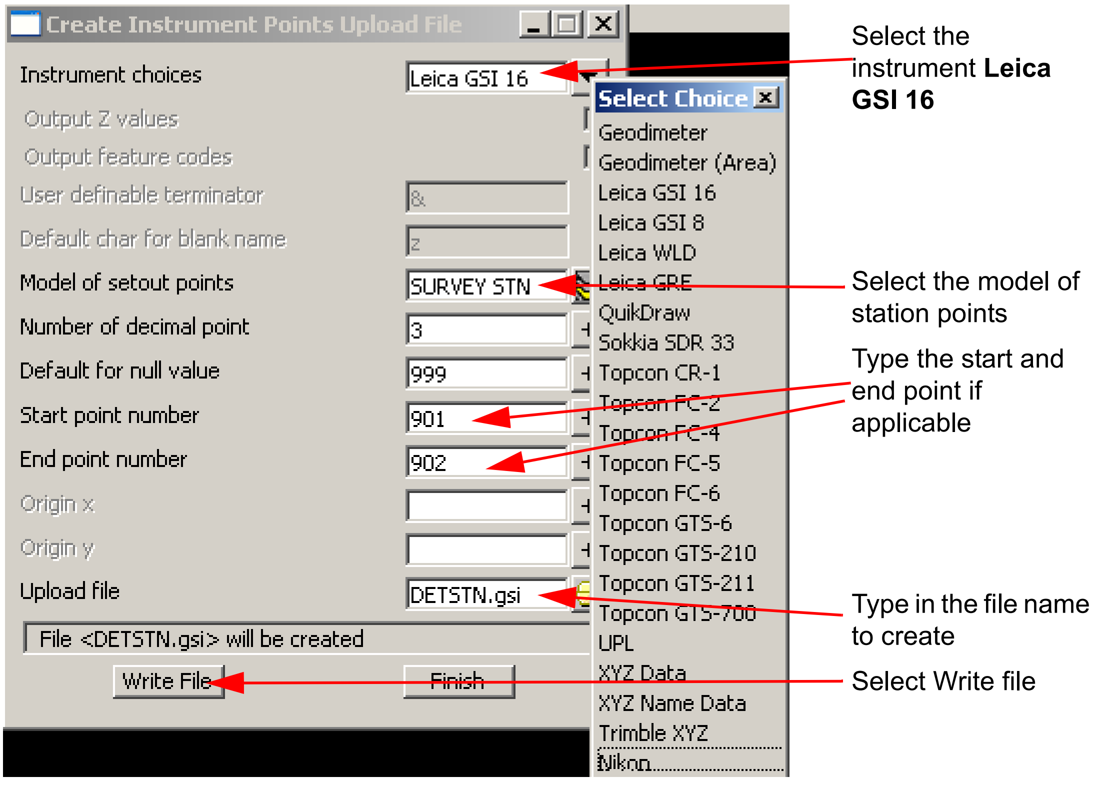
.92	Remove heights from string (AM)
.107	Make previous segment invisible (AM)
.108	Make next segment invisible (AM)

37.1.6.2 Setting up files

The existing station coordinates for a pickup can be entered into the Leica by hand or they can be uploaded using 12d. The 12d upload sequence will be described here.

37.1.6.2.1 Uploading coordinate file

Select option **Survey=>Upload=>Create points upload file**

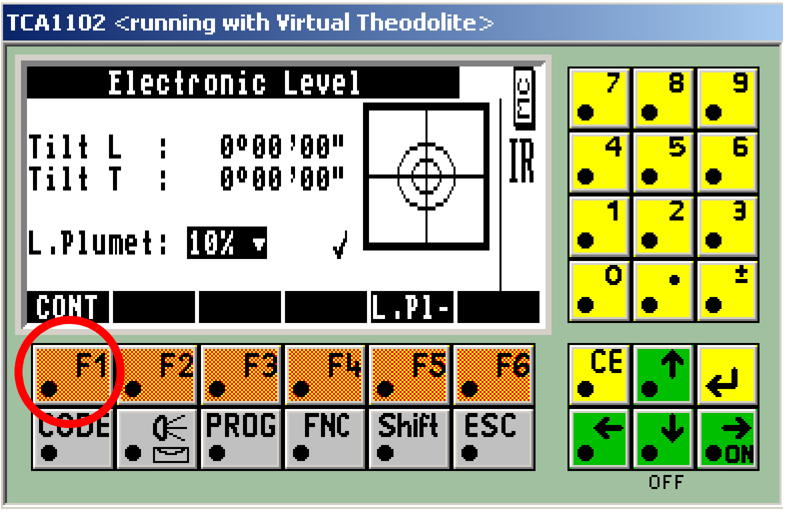


37.1.6.2.2 Copy the upload file

The file upload file should be copied to the folder “GSI” on the Leica card

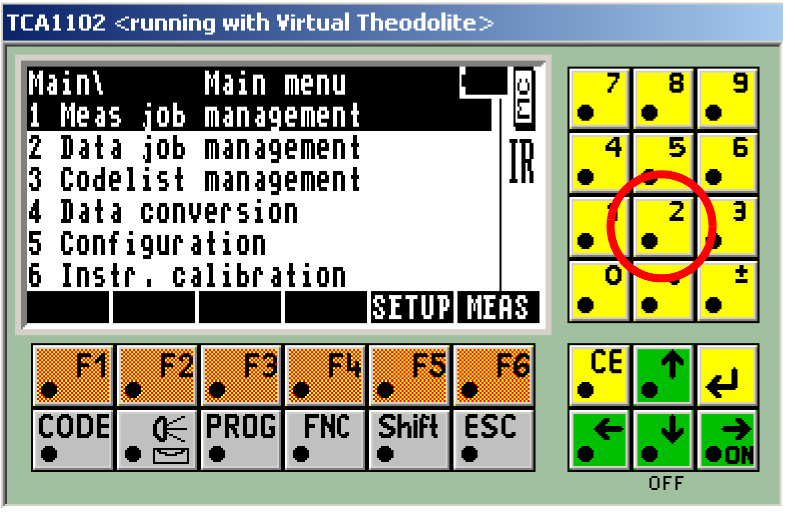
37.1.6.2.3 Data file setup

Turn on and level instrument



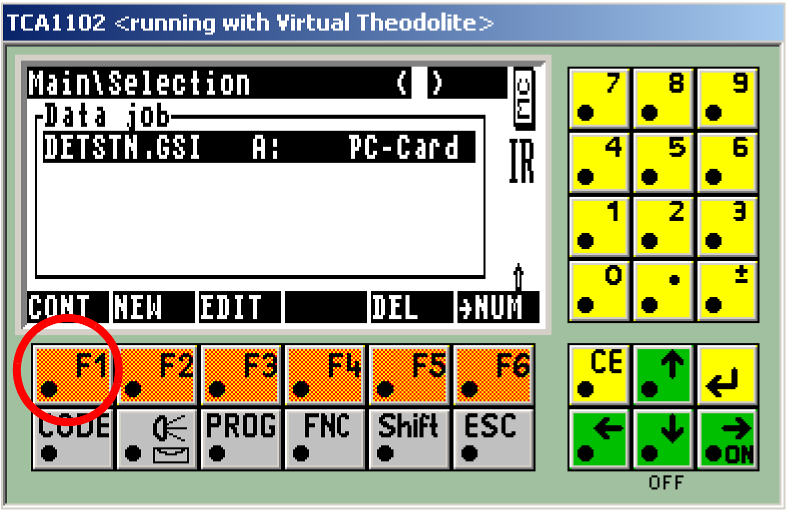
Press F1 to Continue

Press 2 to select Data job file.



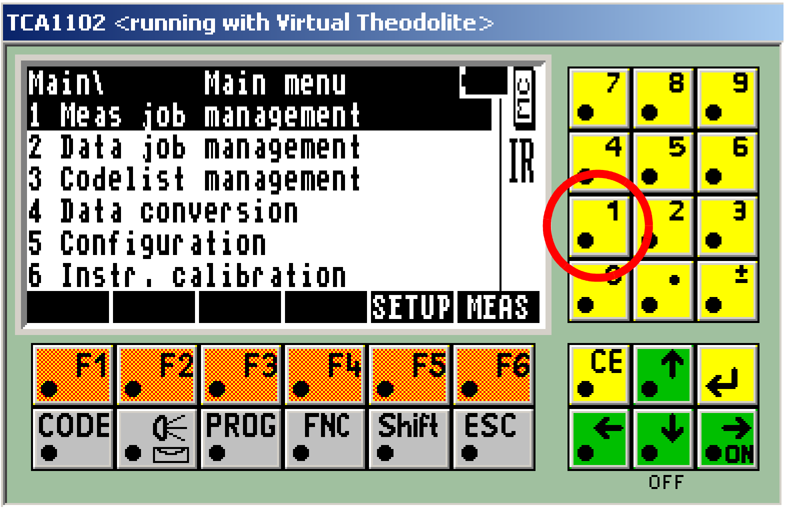
This is the file containing the control points if uploaded or if entered during the survey. Keep the file name separate from the measured data file name

Select the file to use followed by the F1 key or press F2 to create a new file



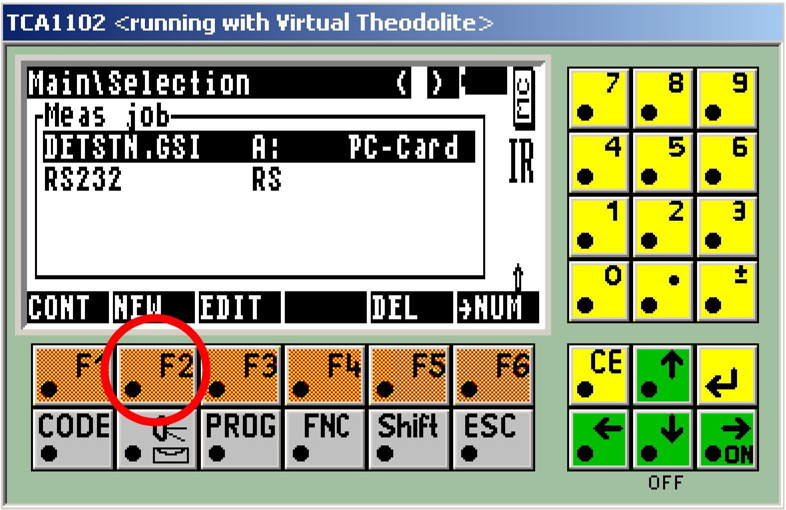
Press F1 to continue

37.1.6.3 Measured file setup

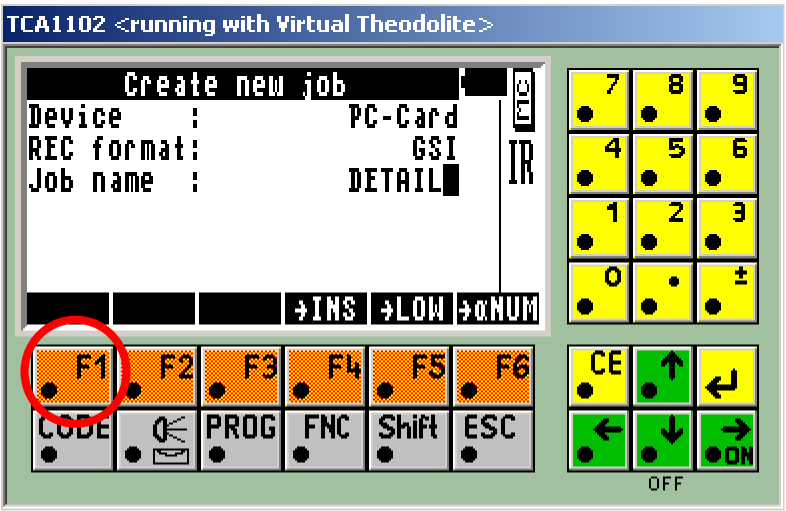


Select 1 to set up Measured job file. This is the file that will contain the detail survey readings

Select F2 to create new file

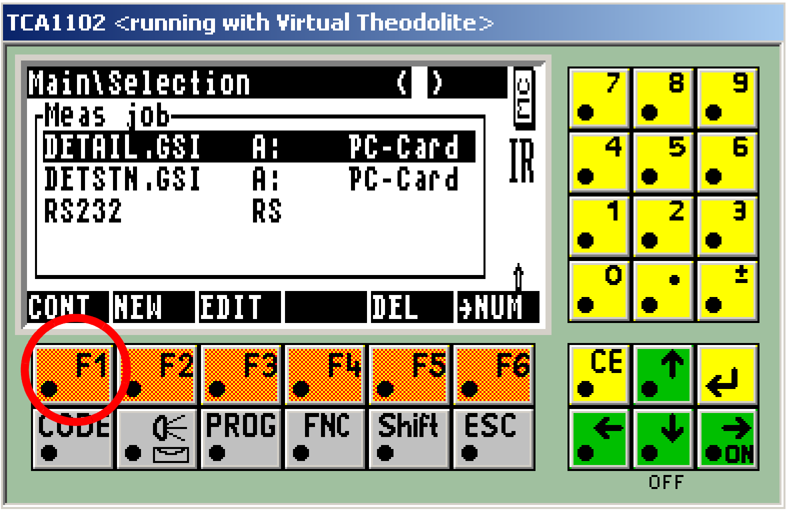


Type in new job name



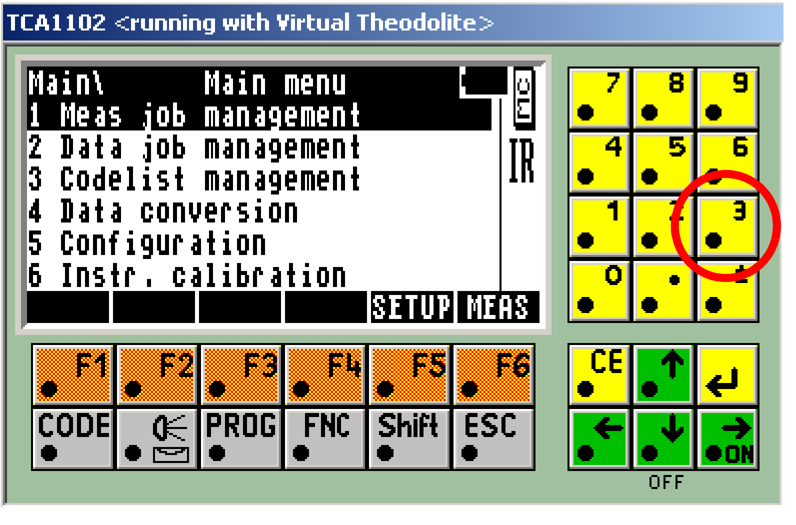
Press F1 to continue

Press F1 to continue

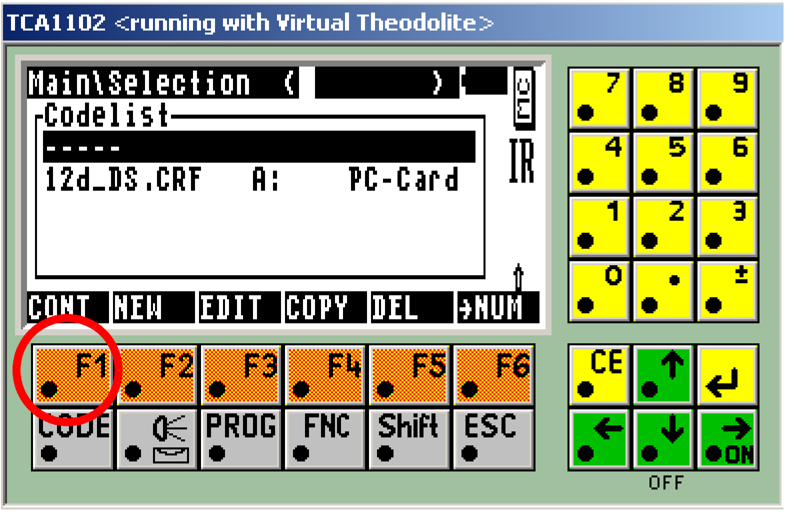


37.1.6.4 Code list selection

Press 3 to select code list



Select the code list 12D_DS.CRF



Press F1 to continue

37.1.6.5 Station setup

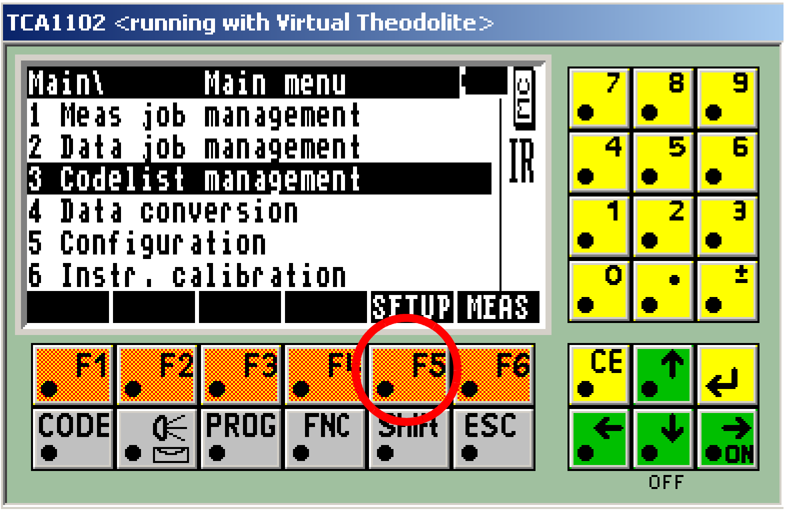
We can use Quick set (See the section37.1.6.6 Setup using Quick set (QSET)) for the station setup or manually select the Station

The following notes assume that the data file contains station coordinates

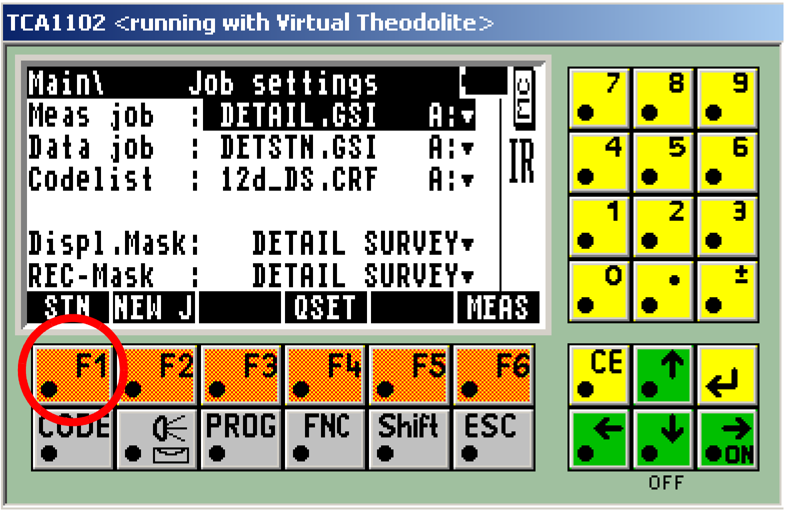
If not the user will have to follow prompts to insert the coordinates

37.1.6.5.1 Manual setup

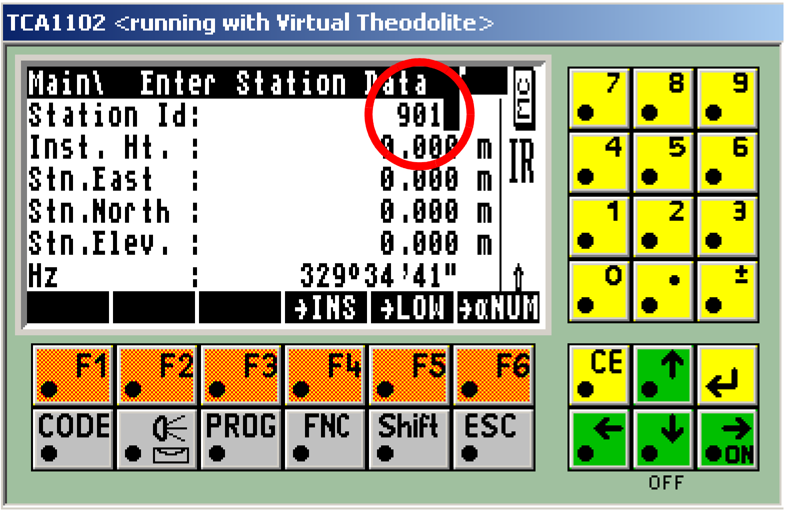
Press F5 for set up



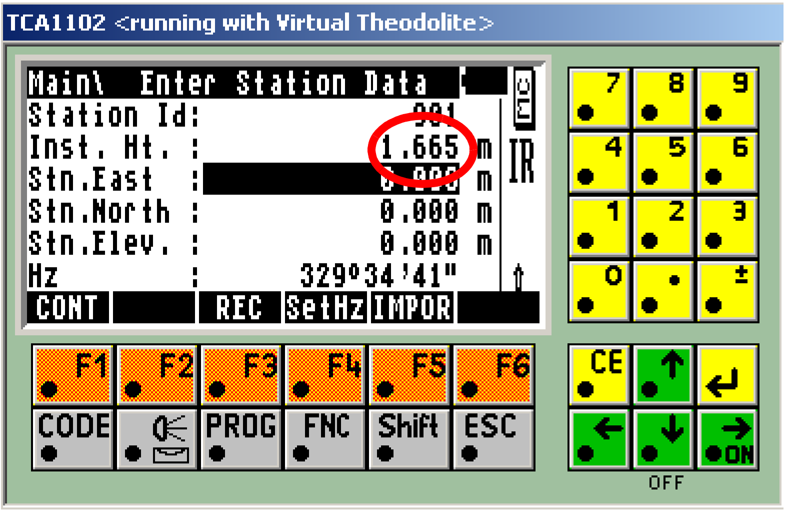
Press F1 to select station



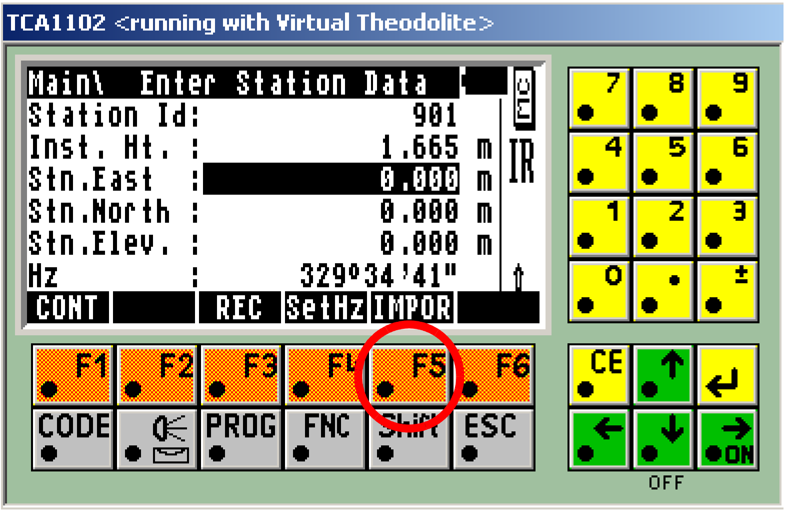
Type in setup station number



Type in the instrument height

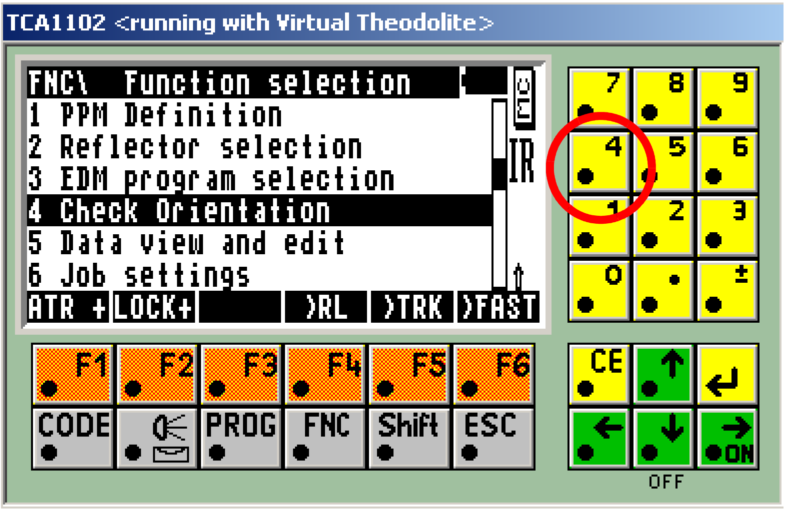


Press F5 to read the coordinates from the data file

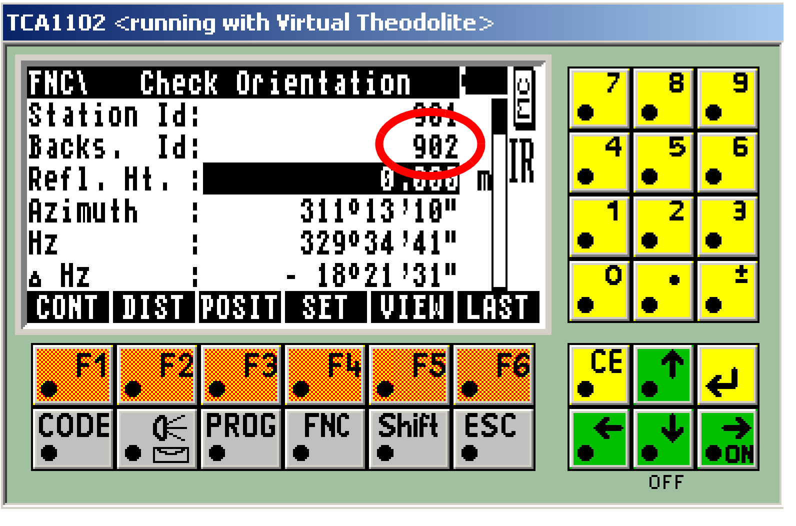


To view the bearing between the setup station and backsight station select FNC

Press 4 to check orientation



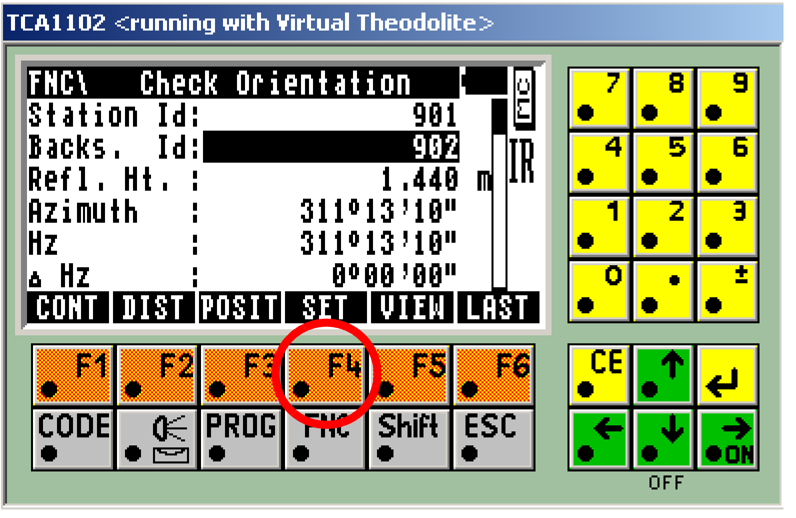
Type in the backsight station number



The Azimuth is displayed

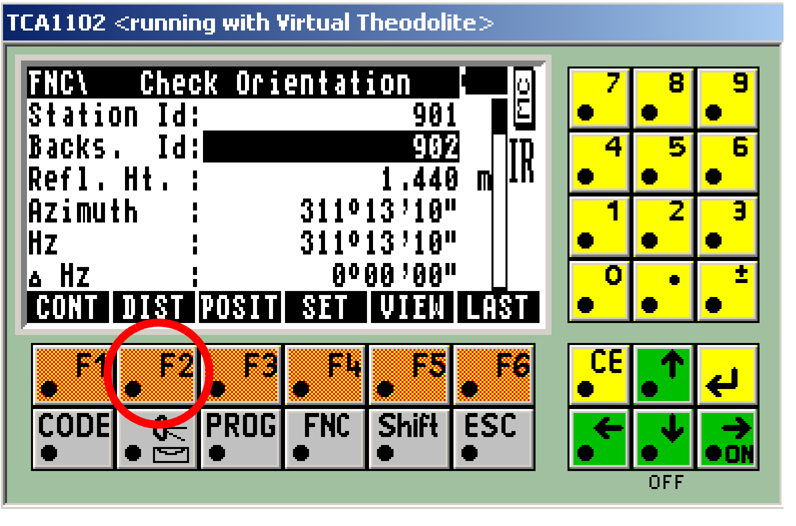
Type in the reflector height of the backsight

Sight to the backsight station and press F4 to set the bearing

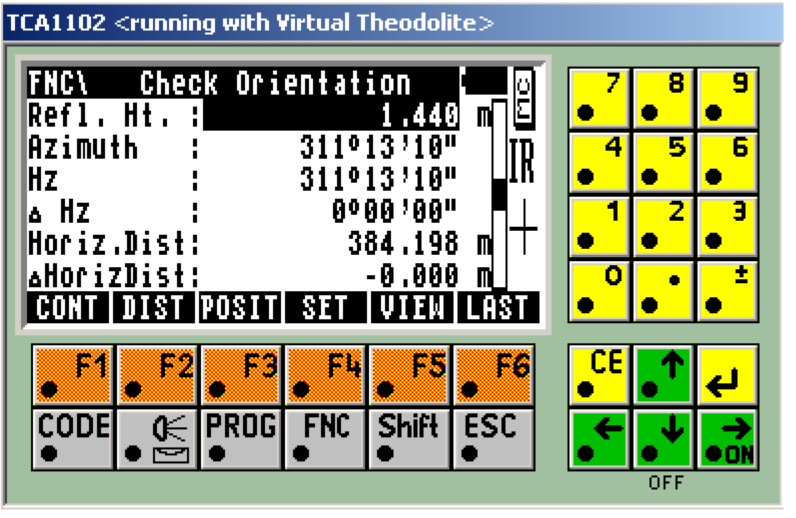


The Bearing is set. Notice that the Azimuth and HZ values are set to the same value.

Press F2 to take a distance to the backsight station

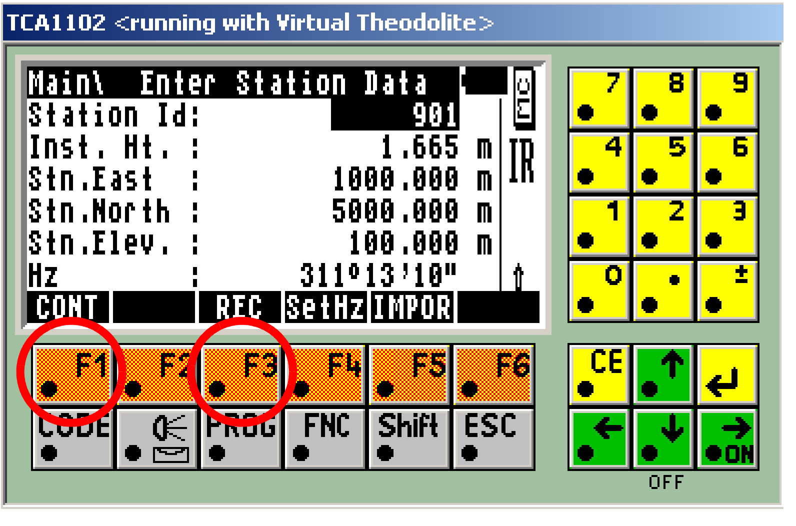


Arrow down to view the distance error



If acceptable press F1 to continue

To save the station information press F3 then F1 to continue

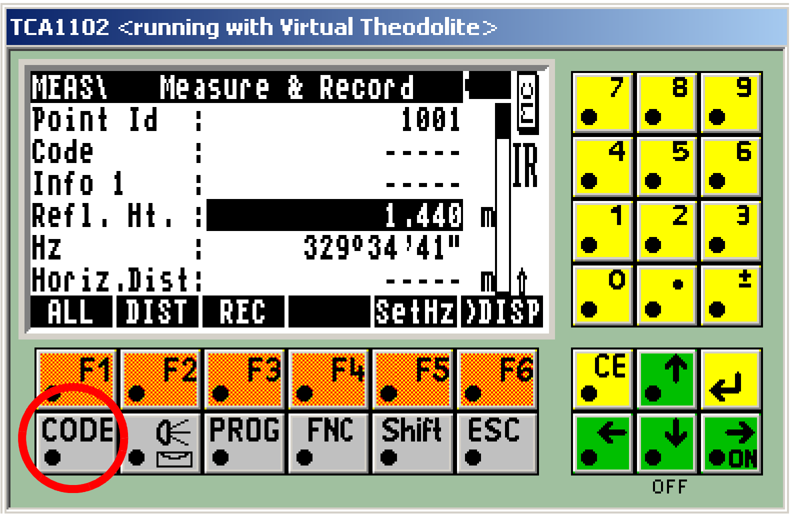


Take Backsight reading:

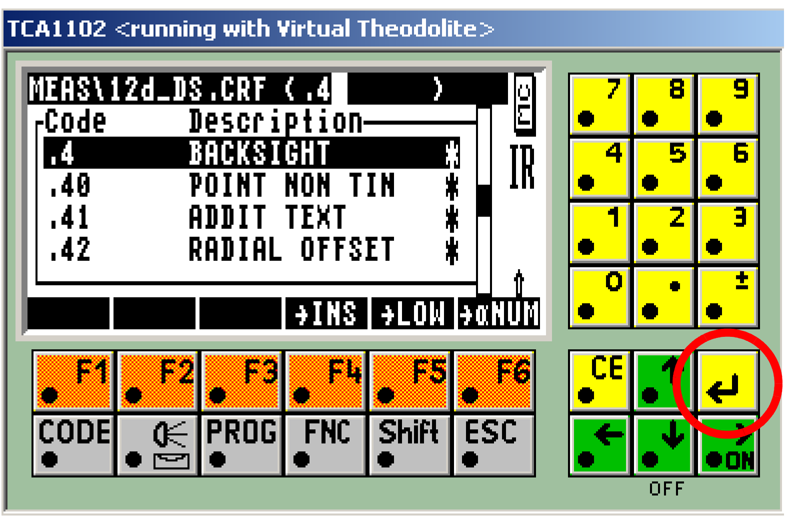
Type in the start point number of the survey

Type in the reflector height. This can also be done as part of the backsight measurement as shown below.

Select CODE

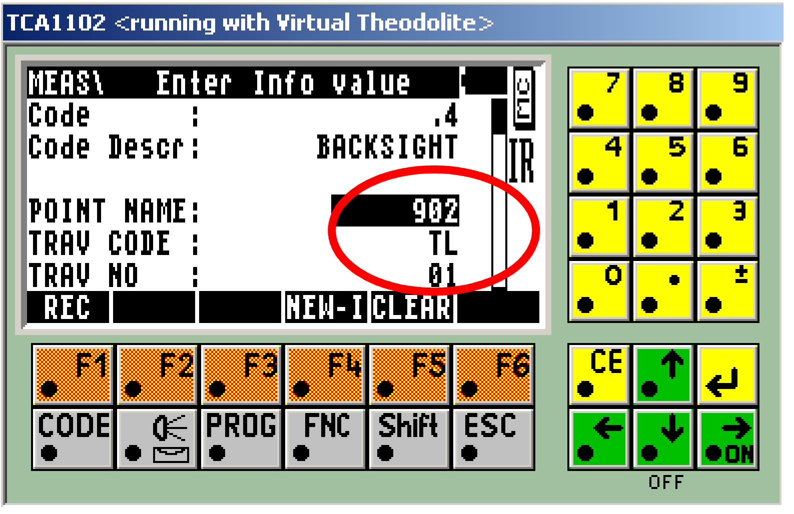


Type in .4 for backsight code followed by the enter key

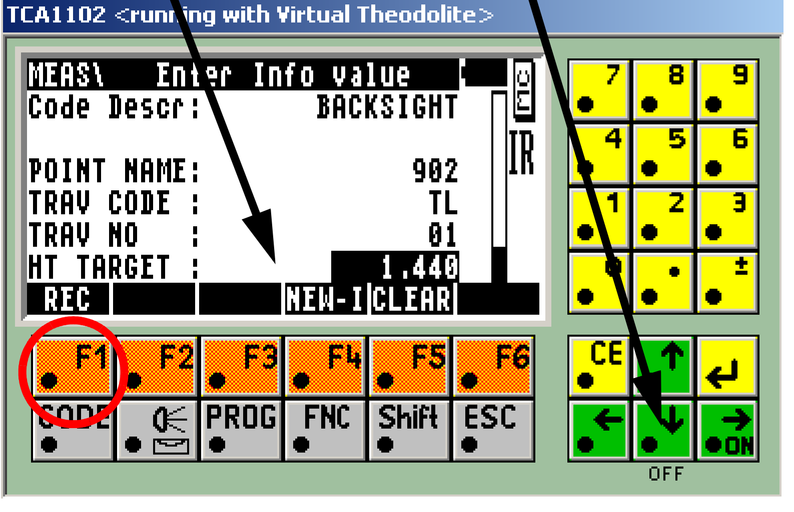


Type in backsight station number

Type in traverse code and traverse no. string number if using traverse coding. For more information about traverse coding see the section 36.6 Traverse coding.

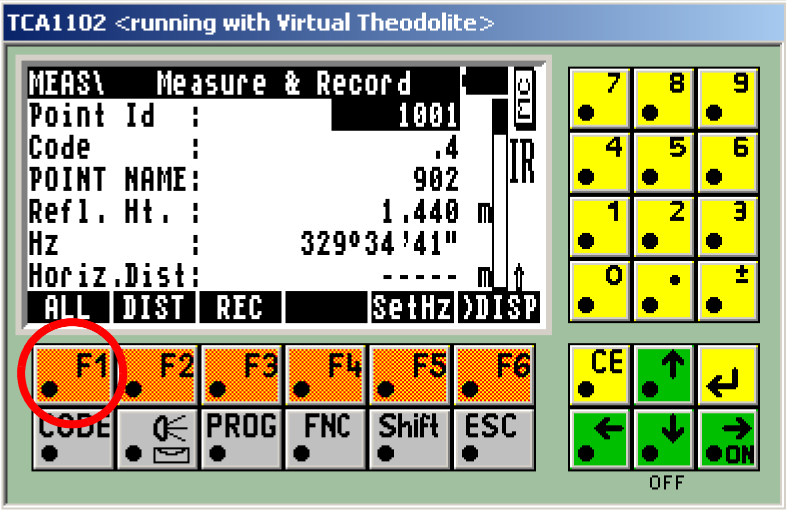


Scroll down using the arrow keys to show other parameters



Press F1 to record the code

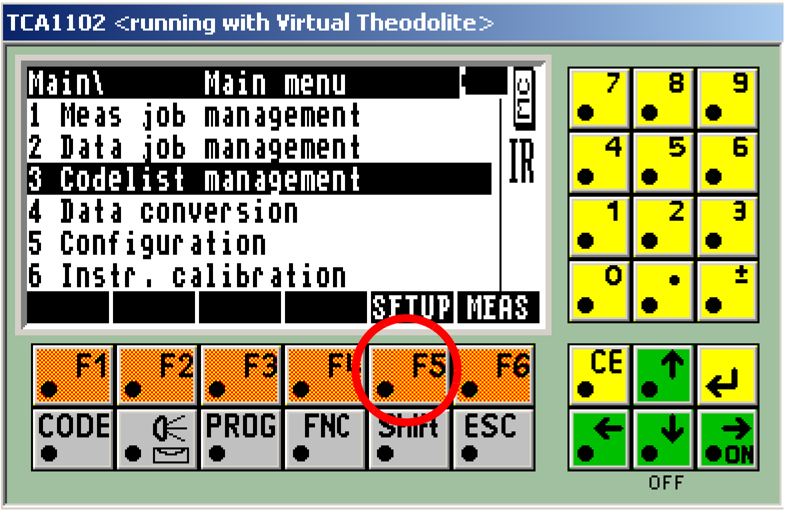
Point to backsight station and press F1 to take and record reading



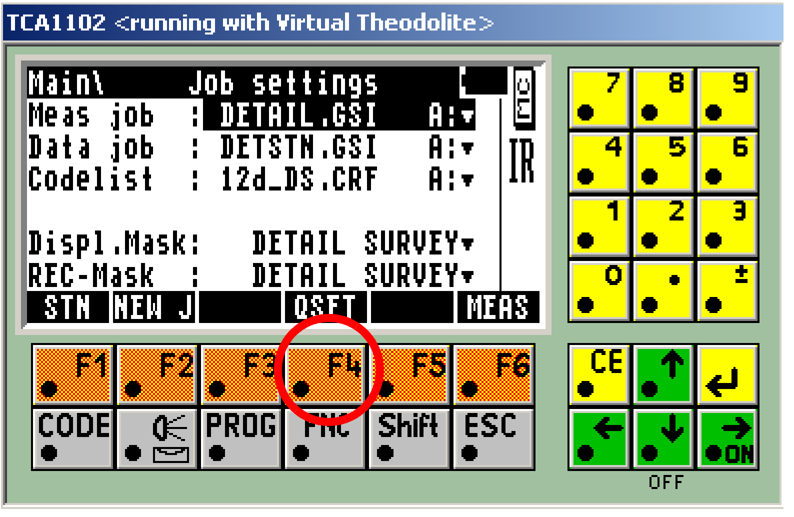
37.1.6.6 Setup using Quick set (QSET)

IMPORTANT NOTE: If using QSET, you MUST take a check reading to your backsight station as described below.

Press F5 for set up



Press F4 for Quick set



TCA1102 <running with Virtual Theodolite>
Main\ Job settings

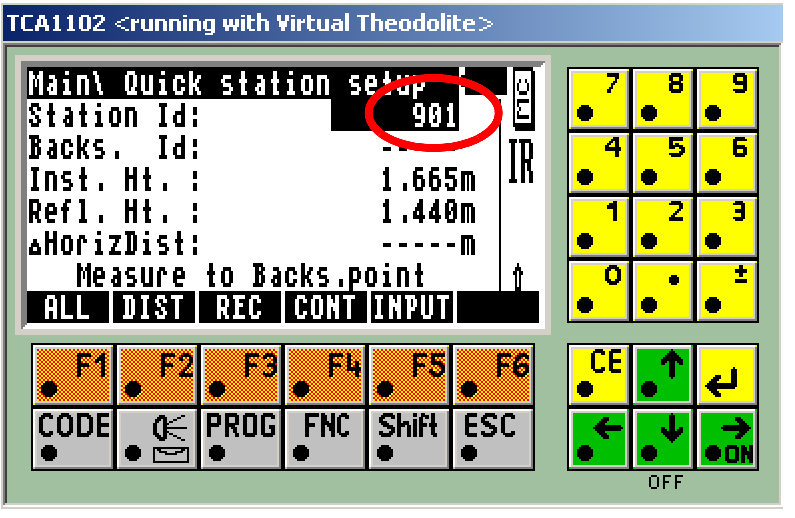
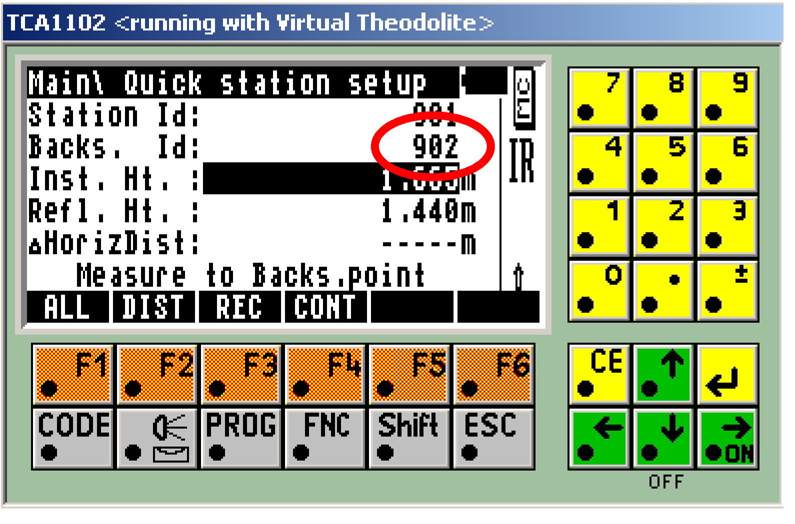
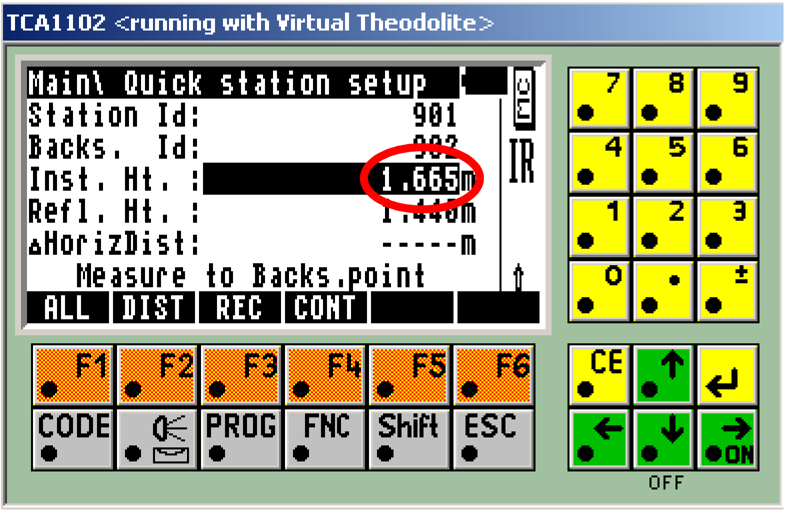
Type in setup station number



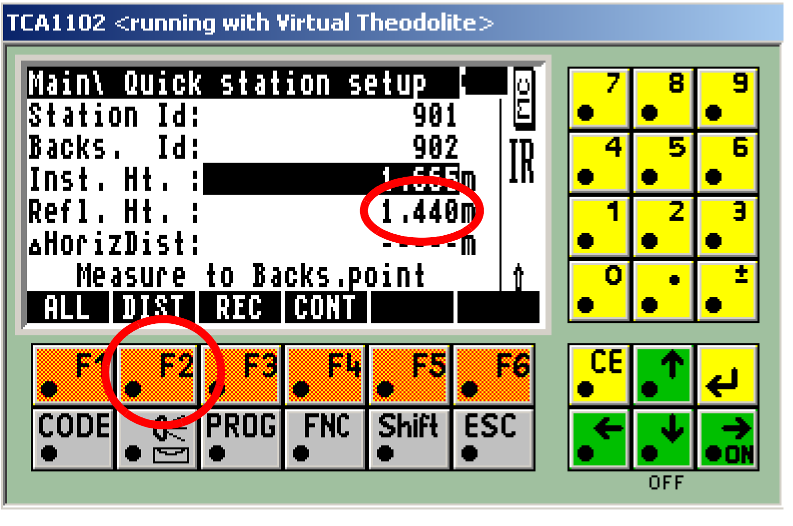
Type in the backsight station number



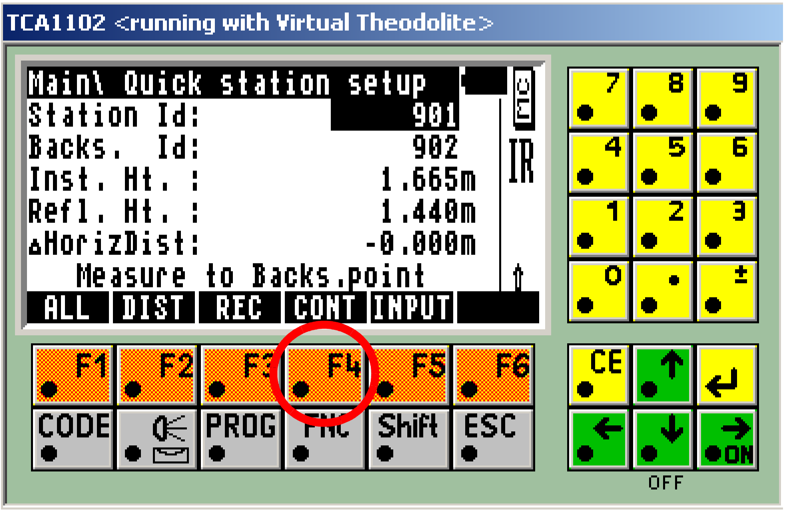
Type in instrument height



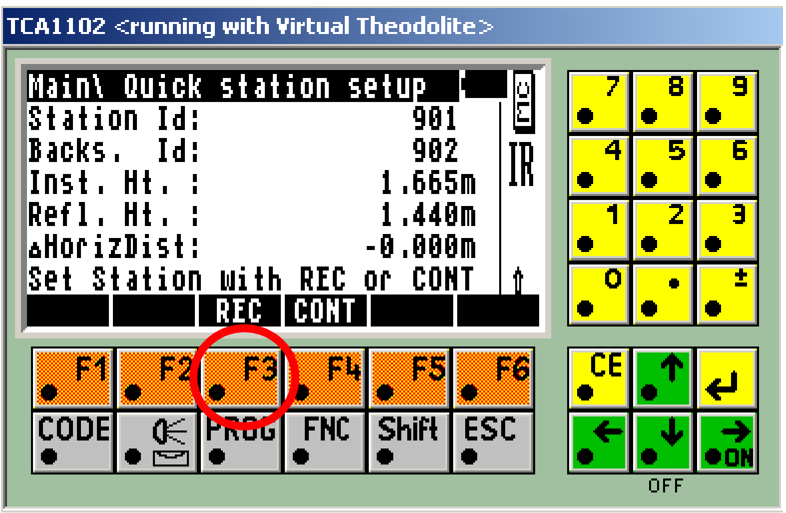
Type in height of target then Press F2 to take reading to backsight to initialise the QSET function.



Press F4 to continue



Press F3 to record the station setup information.

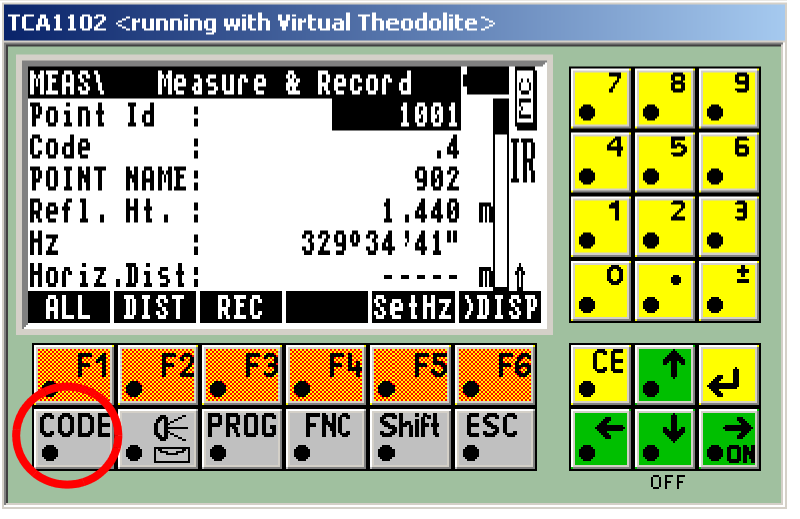


IMPORTANT NOTE: If using QSET, you MUST take a check reading to your backsight station as described below.

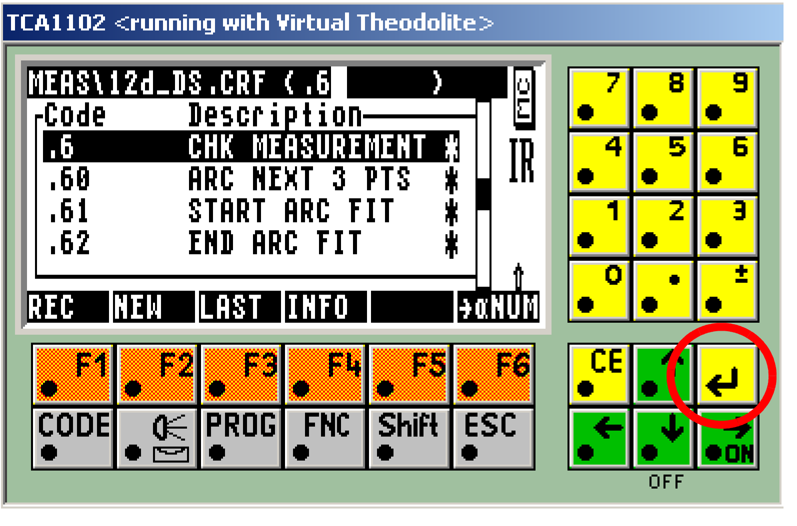
Take Check reading (Mandatory):

Type in reflector height

Select CODE

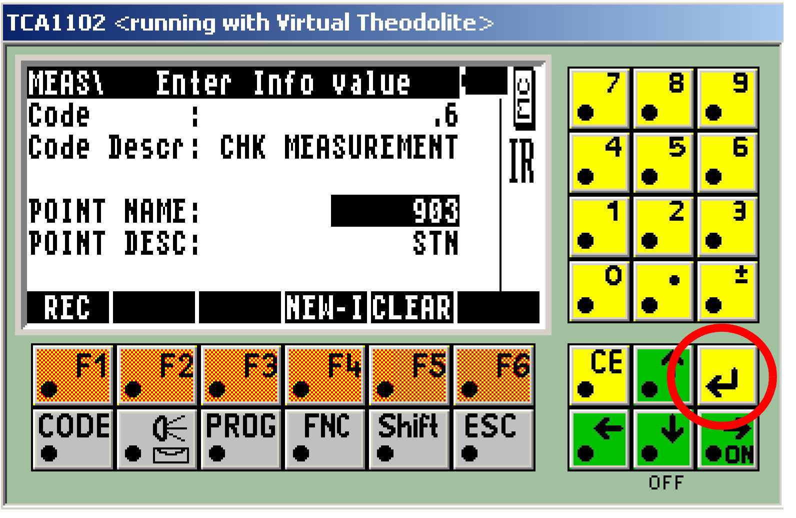


Type in .6 for check measurement code followed by the enter key

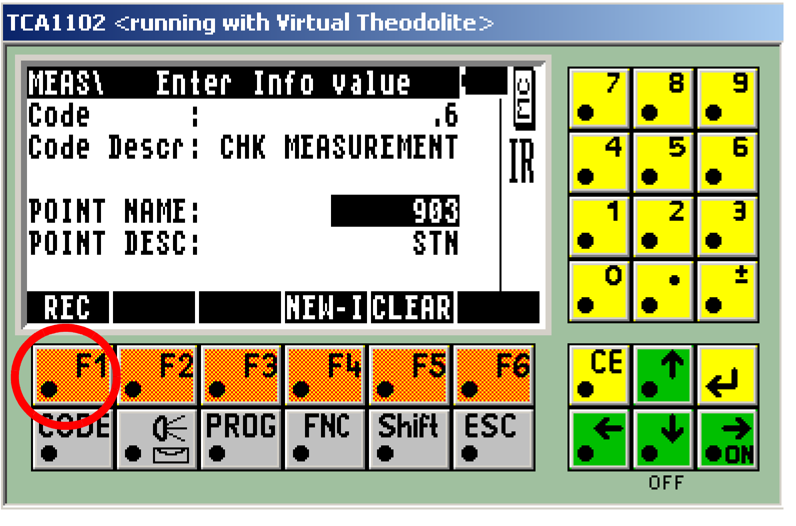


Type in the check station number

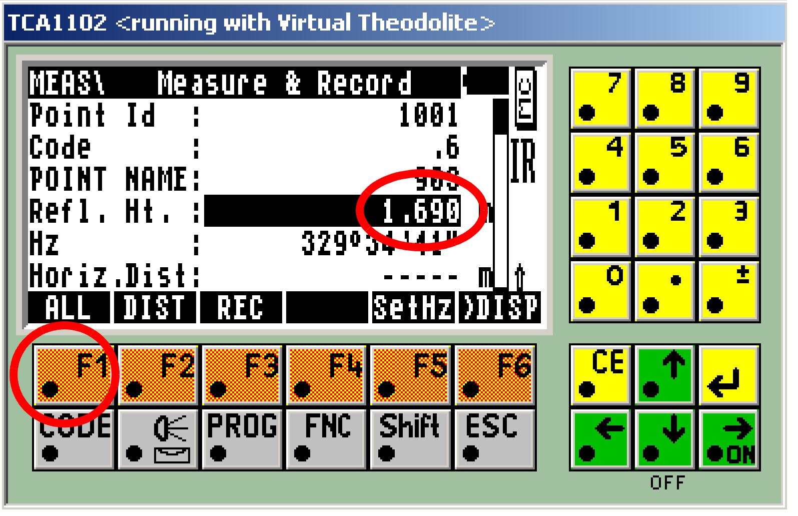
Type in the description



Press F1 to record code



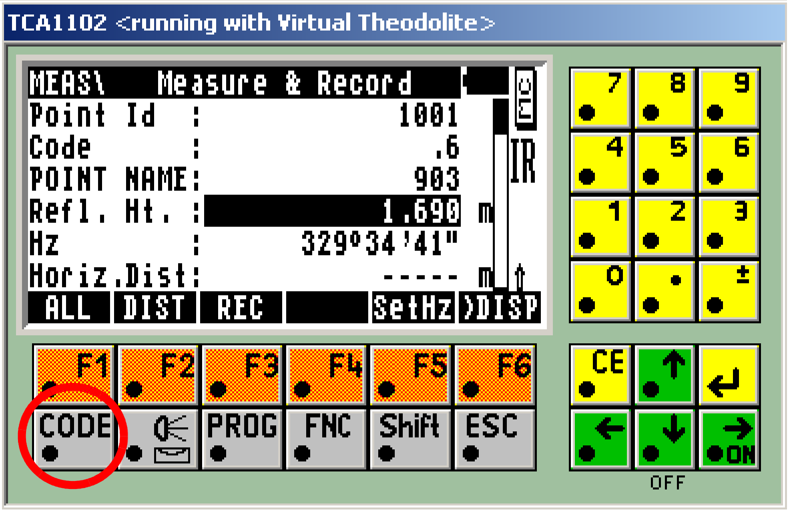
Type in the reflector height



Select F1 to take reading

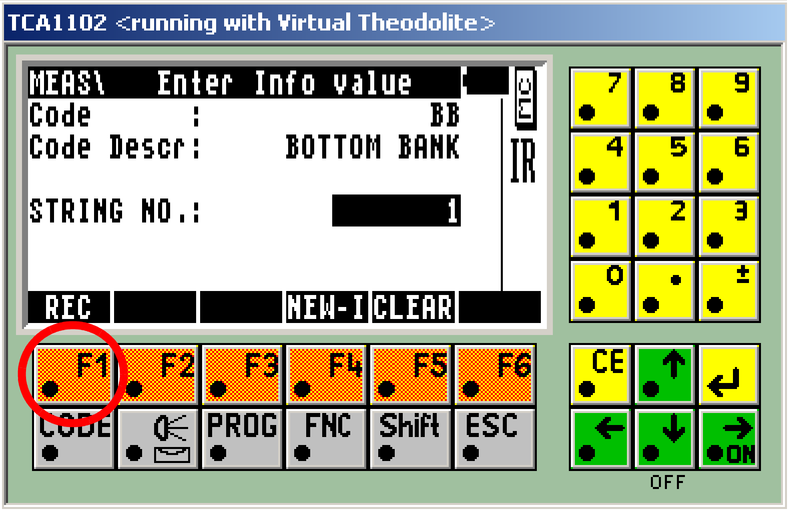
37.1.6.7 Normal readings

Always change the code prior to starting a new feature and ensure the reflector height is correct



37.1.6.7.1 Select Code

Type in the required code and string number

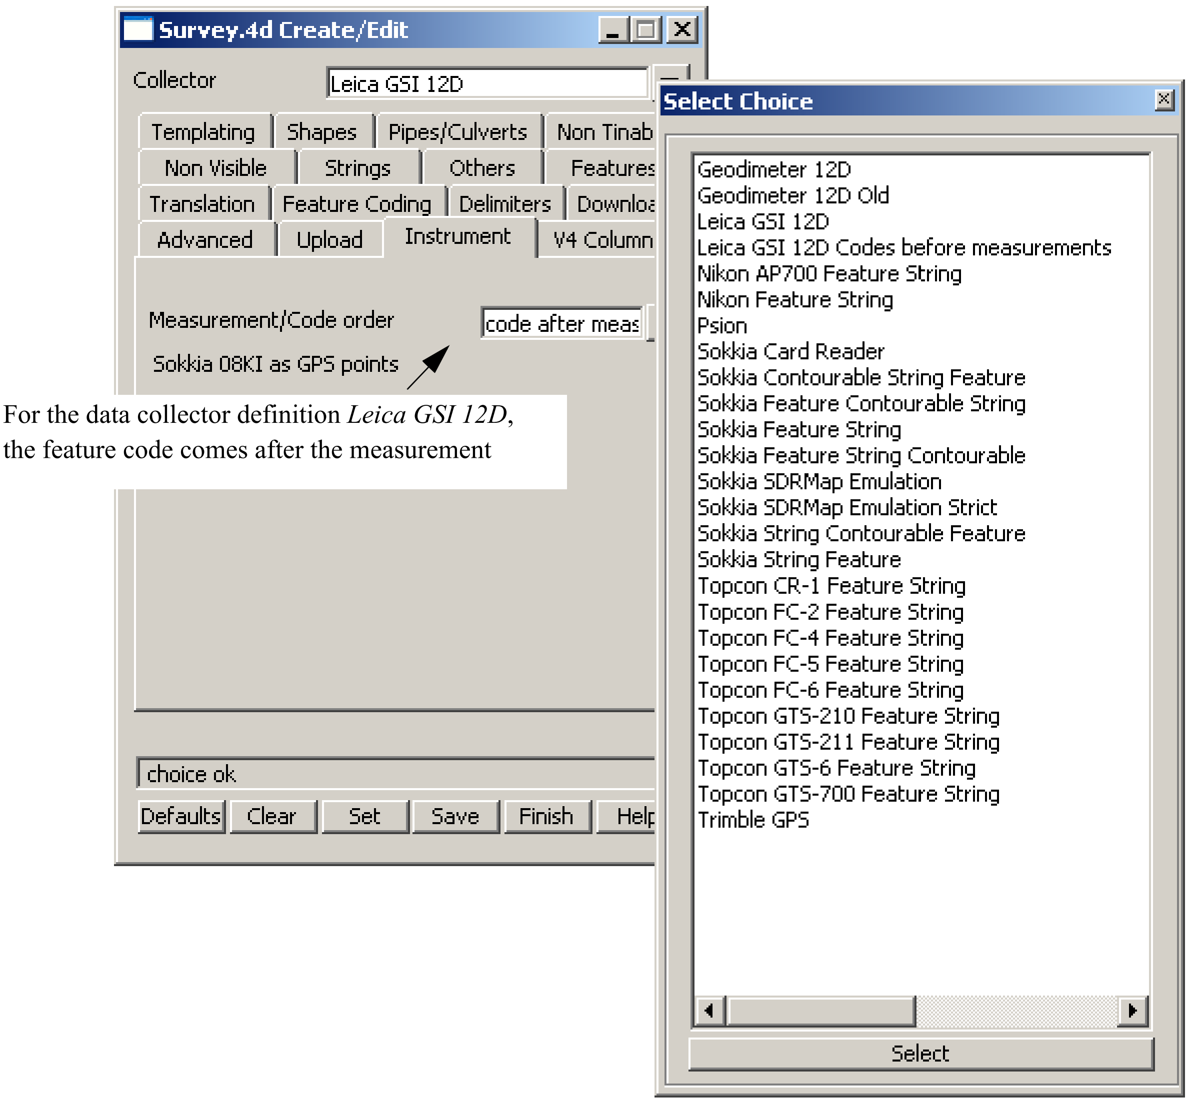


Press F1

37.1.6.7.2 Example of Leica GSI File

The following GSI file has been coded with the Feature Code being recorded after the measurement. The Feature code definition is then applied to all subsequent measurements until another measurement with a following Feature Code definition is found.

The data collector definition *Leica GSI 12D* which is shipped with ***12d Model***, is an appropriate data collector definition for converting the example GSI file to a 12d Field File ready for processing.



The data collector definition *Leica 12D* which is shipped with ***12d Model*** is selected using the option *Survey=>Setup*

37.2 Sokkia Instruments (SDR Files)

This Section deals with interfacing 12d with Sokkia SDR20/33 data formats specifically with the SDR33 electronic field book (Controller). Other controllers and instruments such as the powerset range of total stations also use these formats.

A large number of instruments support the Sokkia SDR data format including (Trimble Total Station ACU), not just those from Sokkia.

For the topic:

1. Field Coding see the section 37.2.1 Coding For SDR Files
2. Sending raw file from controller to 12d 37.2.1.1.1 Downloading SDR File To 12d
3. Converting raw data to field file see the section 37.2.1.1.2 Converting SDR Raw File To Field File
4. Creating Points upload file see the section 37.2.1.1.3 Creating SDR Point Upload File
5. Creating Road upload file see the section 37.2.1.1.4 Creating SDR Roads Upload File
6. Creating Tin upload file see the section 37.3.7 Create Tin Upload File

Also, SDRMap users should also read the section 37.2.1.1 Special Notes for SDRmap Users

37.2.1 Coding For SDR Files

The Sokkia SDR20/33 data formats are used as raw data files by 12d Model and are converted into a 12d Field File before reduction. ***12d Model*** uses the following Sokkia records:

01	Record header - SDR format
02	Station details
03	Target height
07	Back bearing details
08	Position - directly entered co-ordinates
09	Observation - measurement
13	Comment or continuation of blocks
15	RTK station details
16	RTK observation - measurement
57	RTK antenna height

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non Leica Instruments.

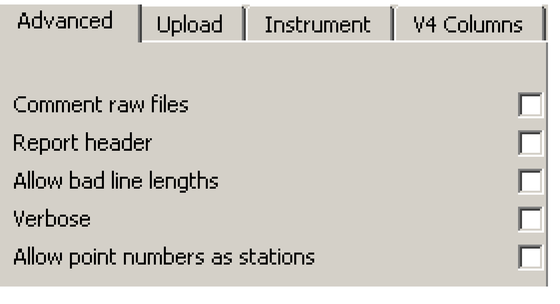
The '13' record can also be used after a measurement record to add additional information to the preceding blocks using the *extra coding* control code at the end of the previous line (see Extra Codingin the section 36.8.4 Control Code Blocks

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

'Line 248 line incorrect length. required length is 58. received length is 50.'

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

To ignore such error messages, there is a setting *Allow bad line lengths* on the *Advanced* tab of the **Survey.4d Create/Edit** panel. If this is set for a data collector, then lines of incorrect length will not be rejected.



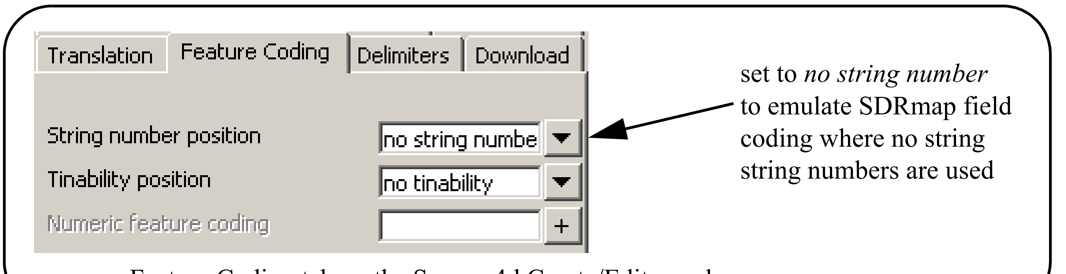
For non SDRmap users, please proceed to the section 37.2.1.1.1 Downloading SDR File To 12d.

SDRmap users, please continue to the next section 37.2.1.1 Special Notes for SDRmap Users.

37.2.1.1 Special Notes for SDRmap Users

SDRmap does not use String numbers - only Feature codes are used and a *New String* command to denote the start of a new string.

12d Model supports ***only using a Feature code*** by setting the *String number position* on the *Feature Coding* tab to ***no string number***.



Feature Coding tab on the Survey.4d Create/Edit panel

If *no string number* is set for the data collector (and so no string numbers are used in the field), then there is no way of telling from the field data whether the string is a *point* string or a *line* string (setting the pt-line type for the string).

For the *no string number* case, the method of defining the point-line type is to:

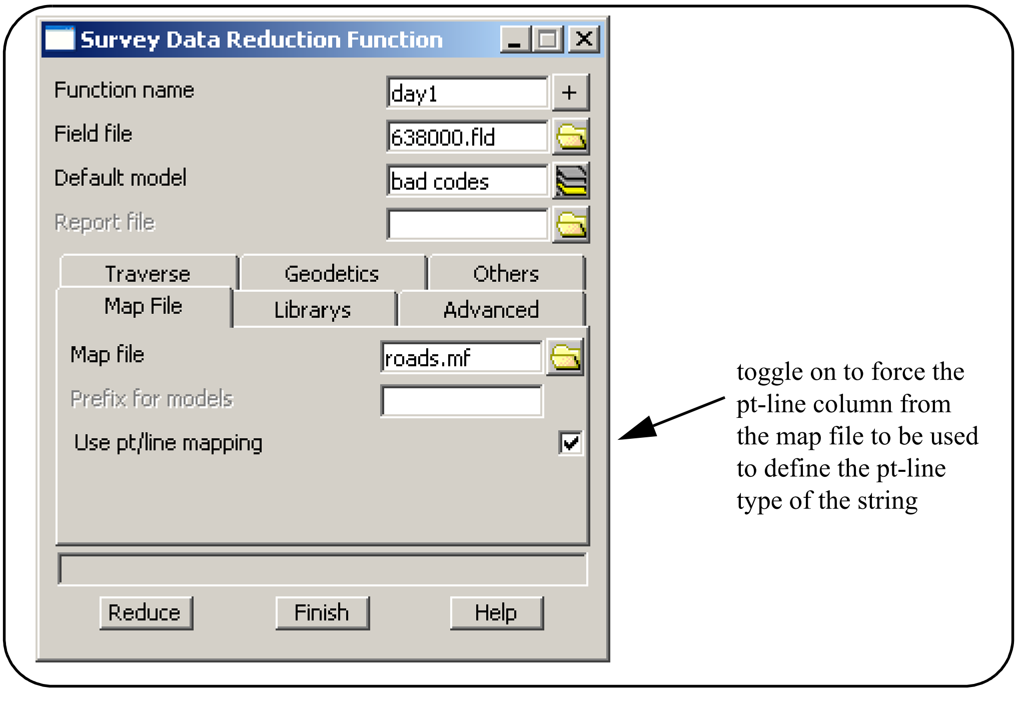
(a) use a map file during the reduction

and

(b) have a key in the map file to match the feature code *and* have the pt-line type set for that key. If the *feature code* does not match any key in the map file, the string defaults to a *point string*.

and

(c) because by default the pt-string column in the map file is *ignored* during reduction (the string number usually defines the pt-line type), the *Use pt/line mapping* tick box in the Survey Data Reduction Function panel must be set to tick to *force* the pt-line column in the mapping file to be used.



Please continue to the next section 37.2.1.1.1 Downloading SDR File To 12d.

37.2.1.1.1 Downloading SDR File To 12d

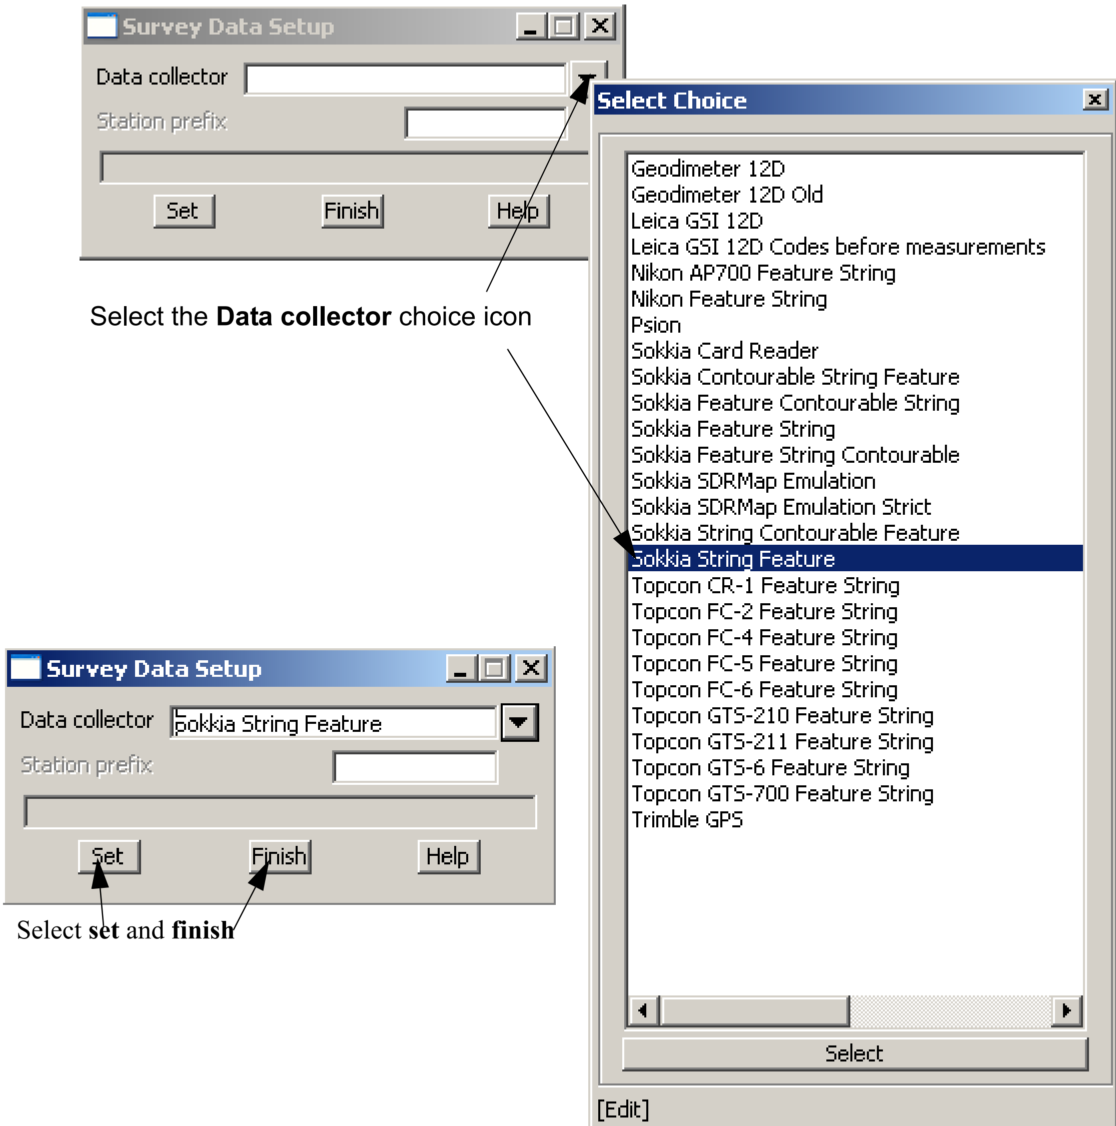
Raw SDR files can be input to 12d for reduction by two basic methods:

1. Download directly from the instrument
2. Copy the SDR file to the working folder directly from a PCMCIA card or by using a data transfer product such as "HyperTerminal" or "Wincomms". For this method, see the following section 37.2.1.1.2 Converting SDR Raw File To Field File.

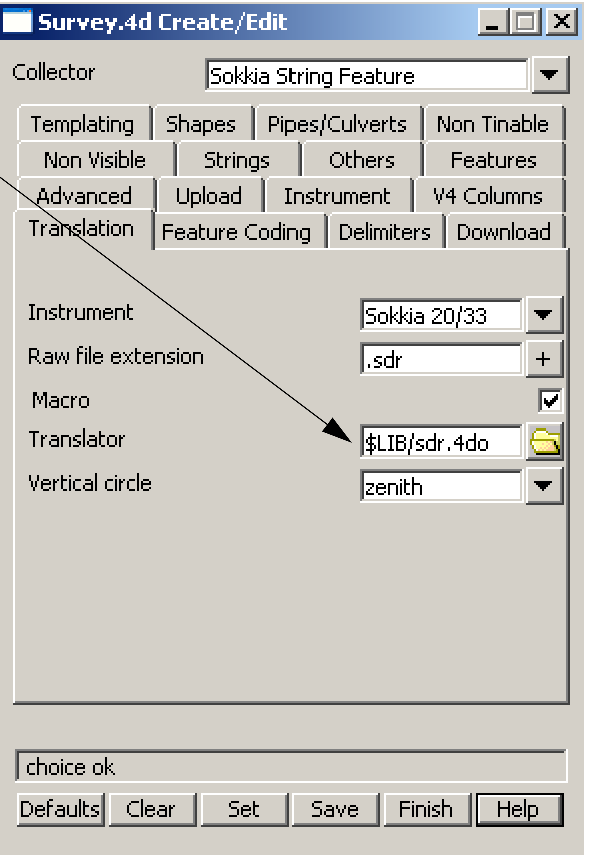
An option exists within 12d to download the raw SDR file from the instrument. This option has the added functionality that is reduces the raw propriety format (SDR file) to a 12d field file format at the same time. This conversion requires that the data collector definition be set before the download of the file is commenced.

Select the data collector type

Select option ***Survey=>Setup***



The raw file will be converted to the 12d field file format using the specified translator macro

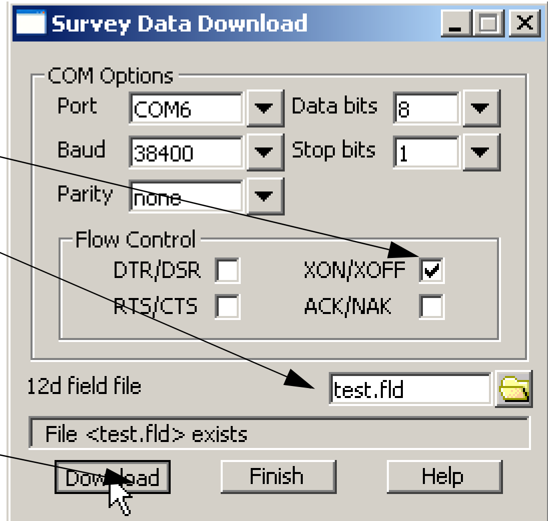


Select ***Survey=>Download***

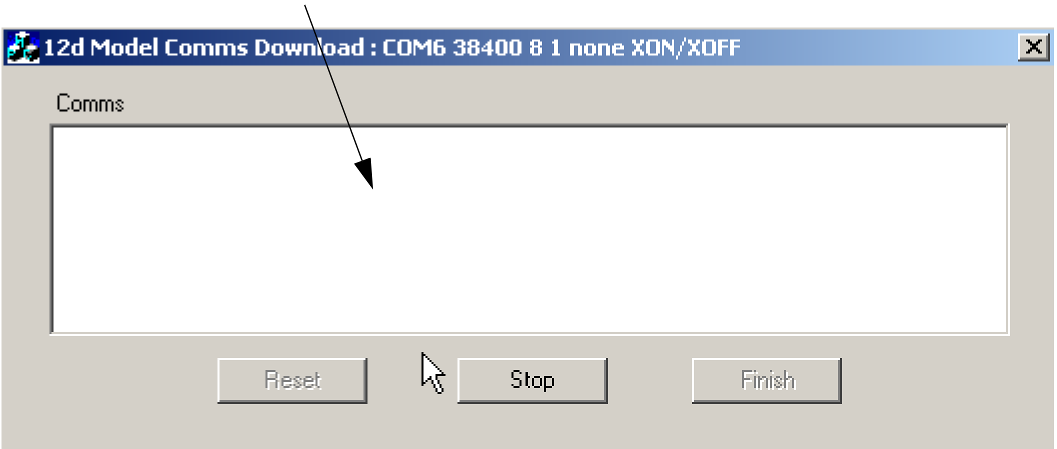
Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters

Enter a name for the field file

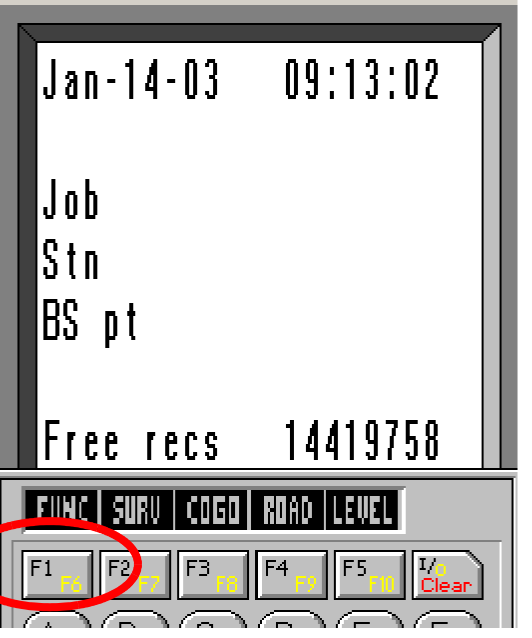
Press **download**



The 12d download window is shown.

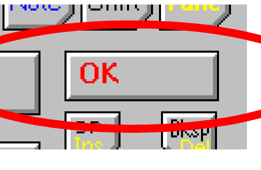


Prepare the data collector for download by connecting to appropriate port, selecting file to download etc.

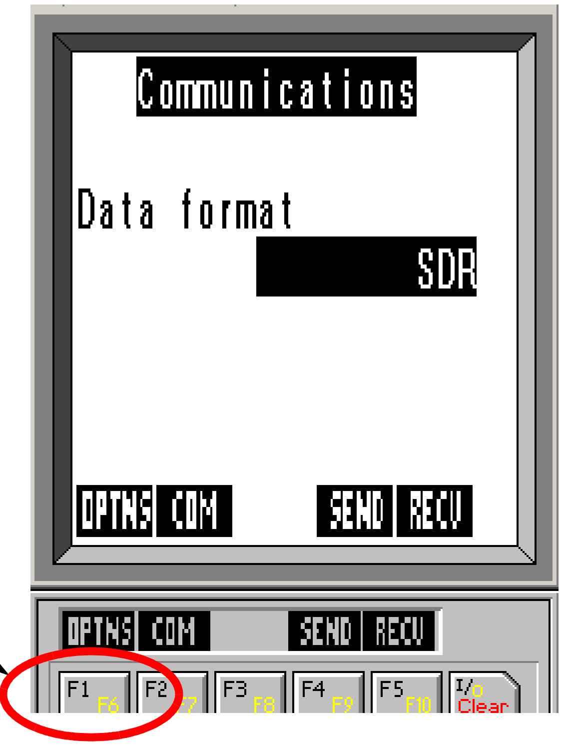


From the Data collector main menu select the **FUNC** (function) menu

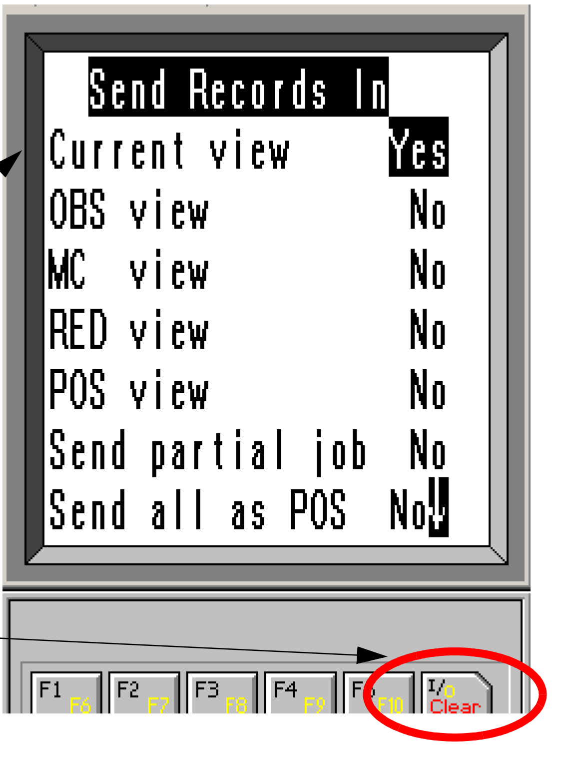
Toggle down to the **Communications** menu



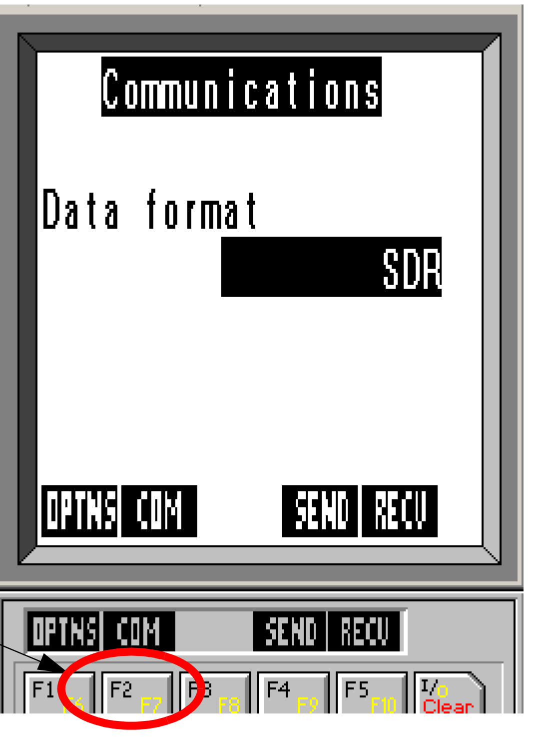
Press **OK** to select menu



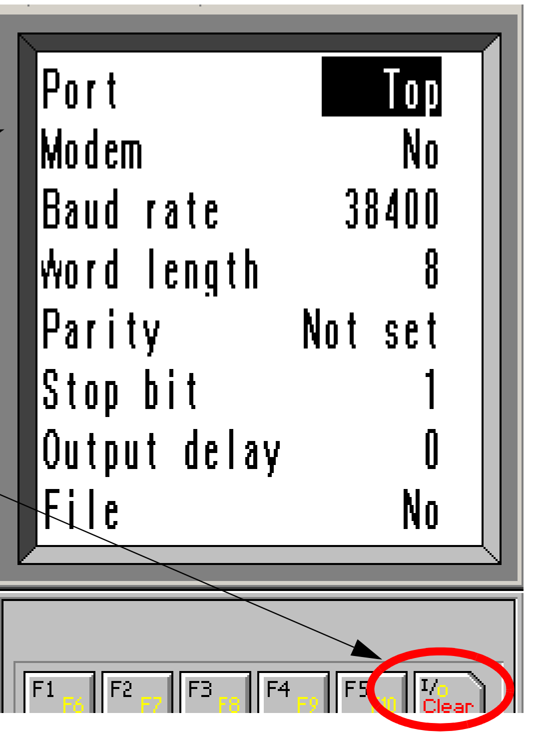
Select the **Options** menu to view the current settings



Select the **Current view** to **Yes** only. If the POS view were set to **Yes** also, the POS points would be sent also and eventually reduced twice in 12d (once from observations and the other from the POS record). Press **Clear** to leave menu



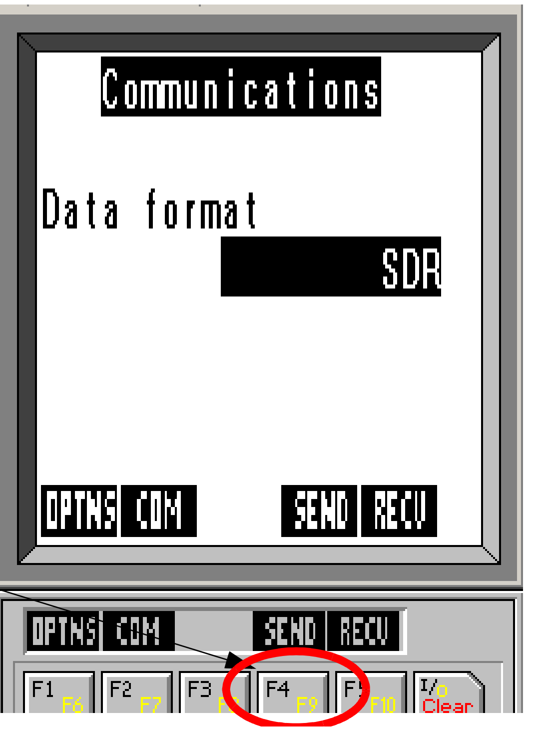
Select the **COM** menu to view the current comms settings



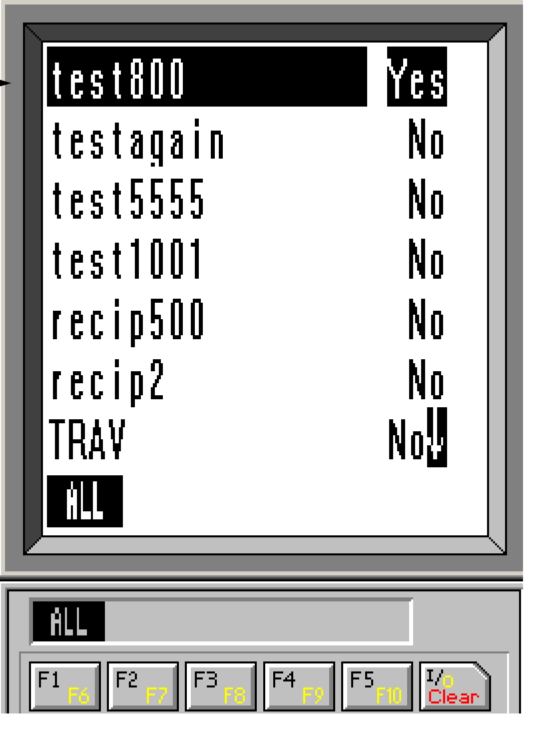
Ensure the comms settings are as per the values set in the 12d download option.

Select **Clear** to leave the menu

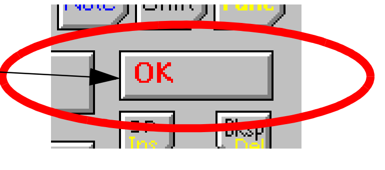
Select the **SEND** menu



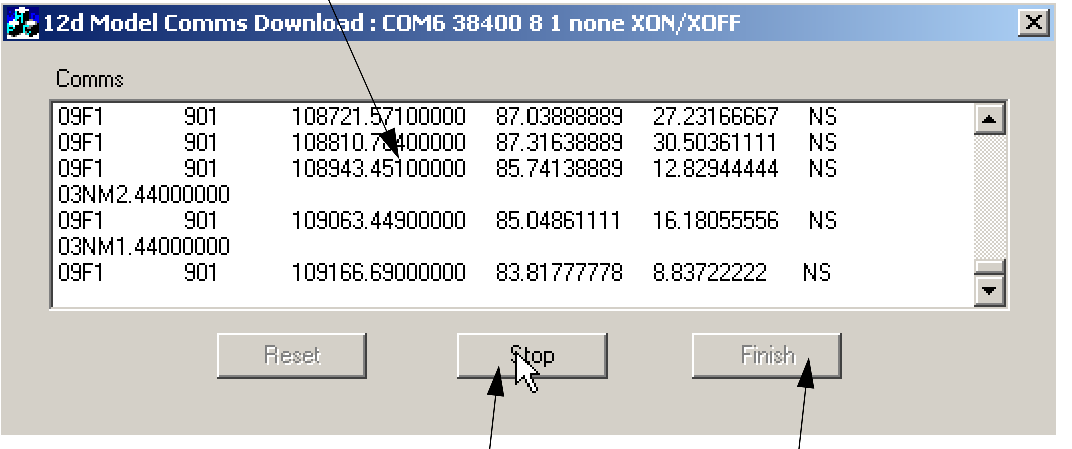
Select the file to download



Press **OK** to send



The file is shown downloading line by line in the 12d download window.



When the download is finished select the **stop** button and then **finish**

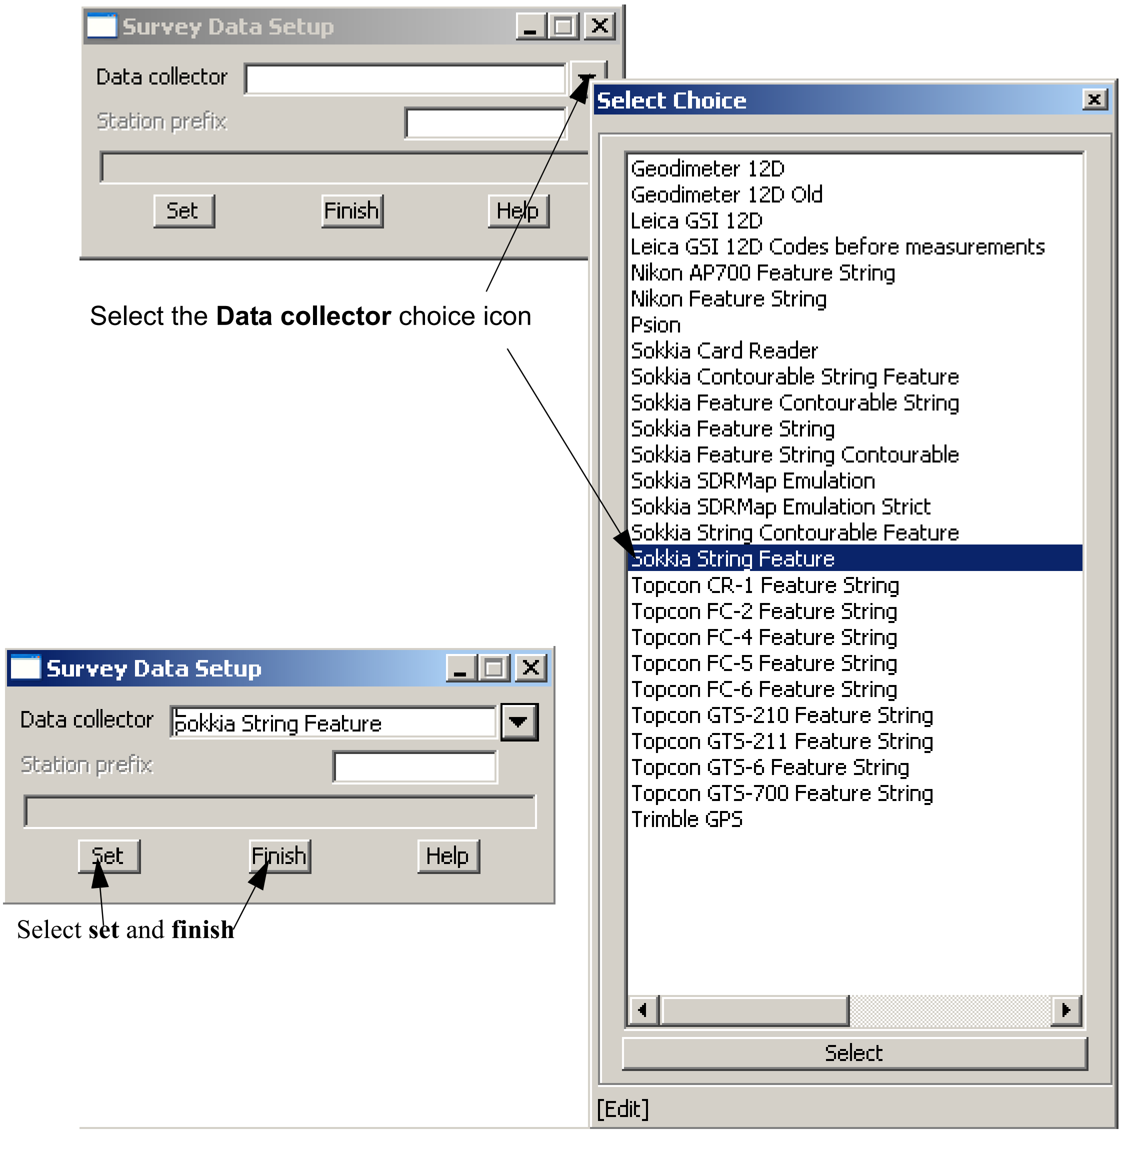
Please continue to the next section 37.2.1.1.2 Converting SDR Raw File To Field File

37.2.1.1.2 Converting SDR Raw File To Field File

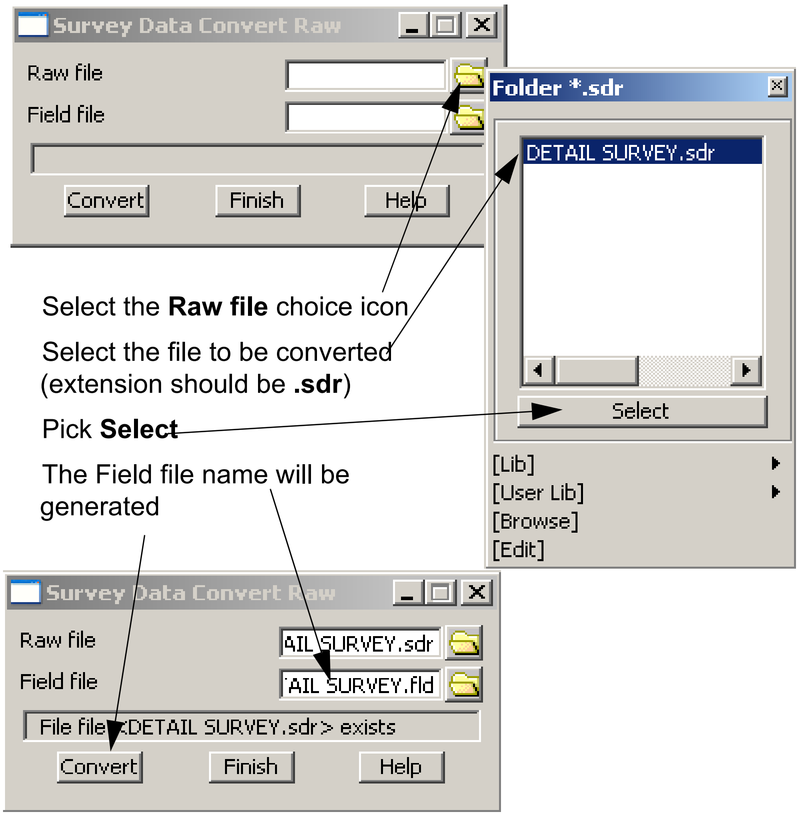
If a raw SDR file is copied to the working folder from a PCMCIA card or other means such as transferring it from a third party software package, it must be converted to a 12d field file for reduction inside 12d.

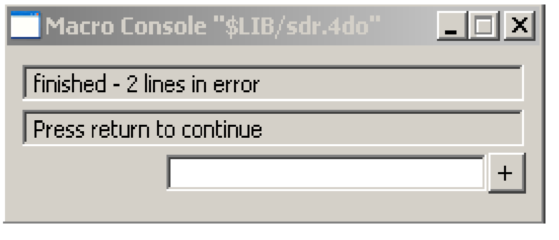
Select the data collector type

Select option ***Survey=>Setup***



Select option ***Survey=>Convert raw***





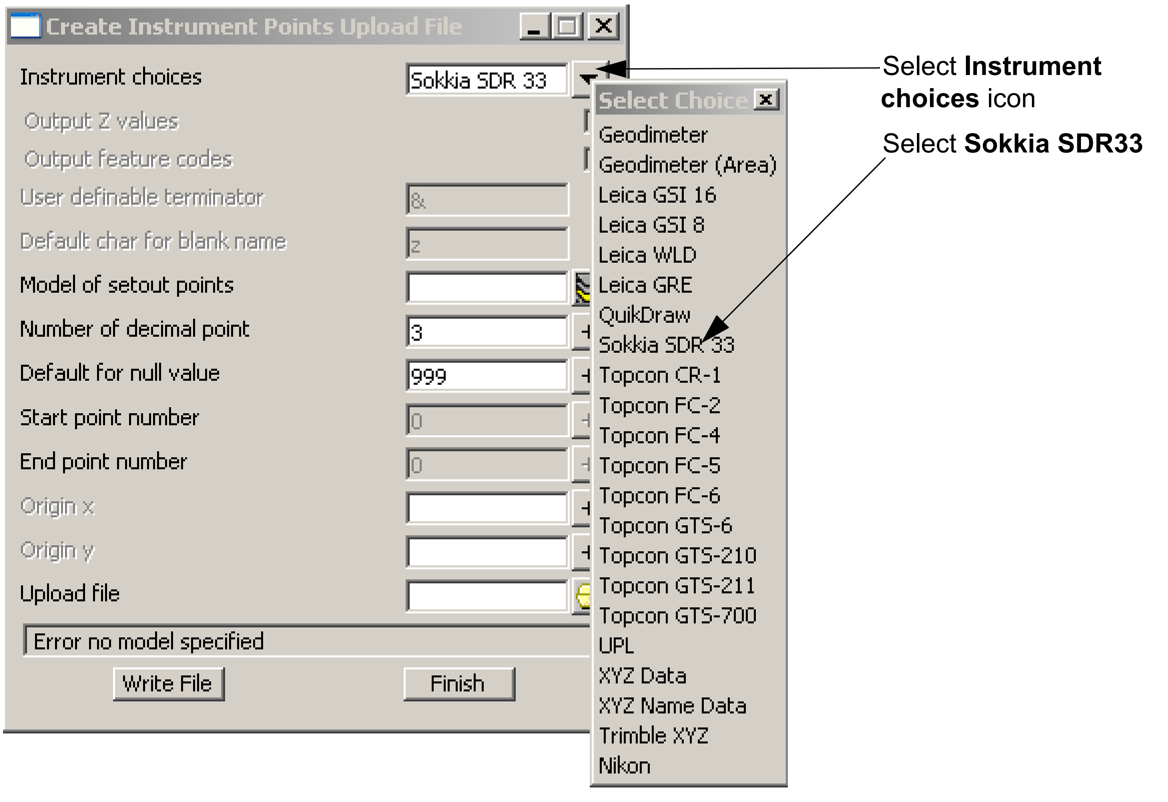
Any errors will be listed in the Output window. If the Output window is not shown, it can be opened using the option ***Window=>Output Window***

37.2.1.1.3 Creating SDR Point Upload File

Create upload file in 12d

After creating the setout points an upload file can be created for the sdr format

Select option ***Survey=>Upload=>Create points upload file***



Fill in the rest of the screen as per normal

Select **Write File**

A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc.

Loading file into controller using 12d upload facility

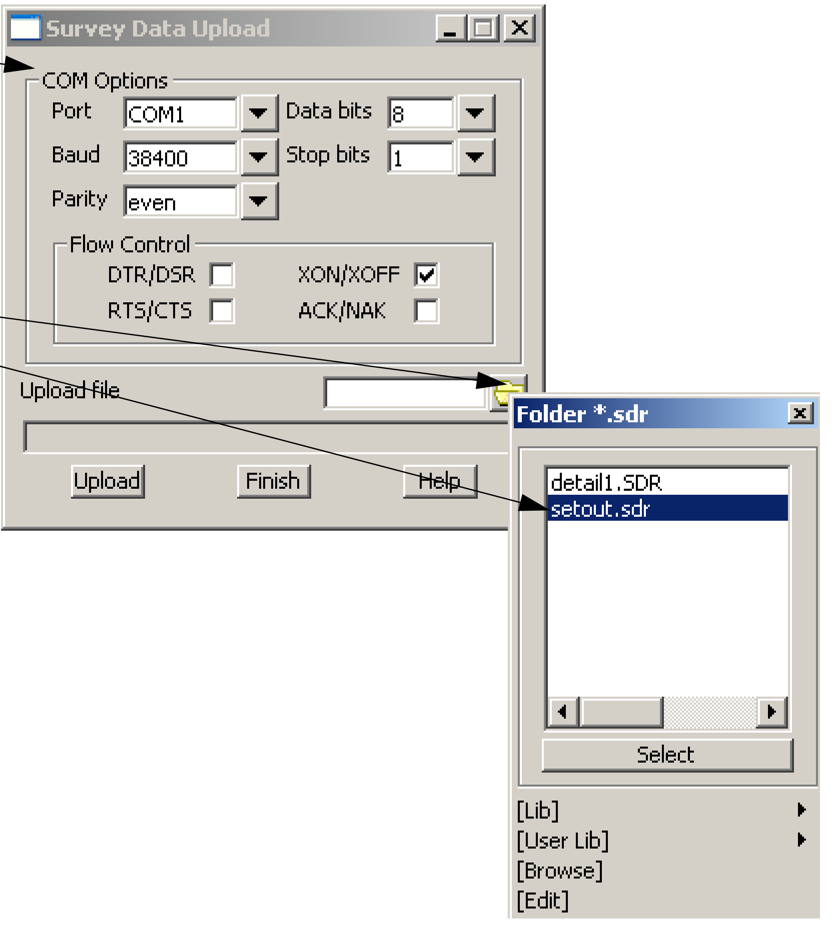
The points upload file can be transferred to the controller for setout using the upload panel.

Connect the controller to the PC

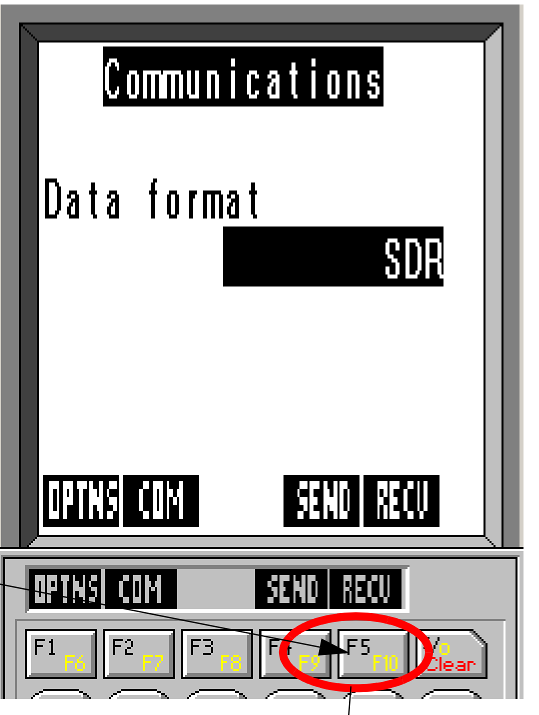
Select option ***Survey=>Upload=>Upload***

Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters

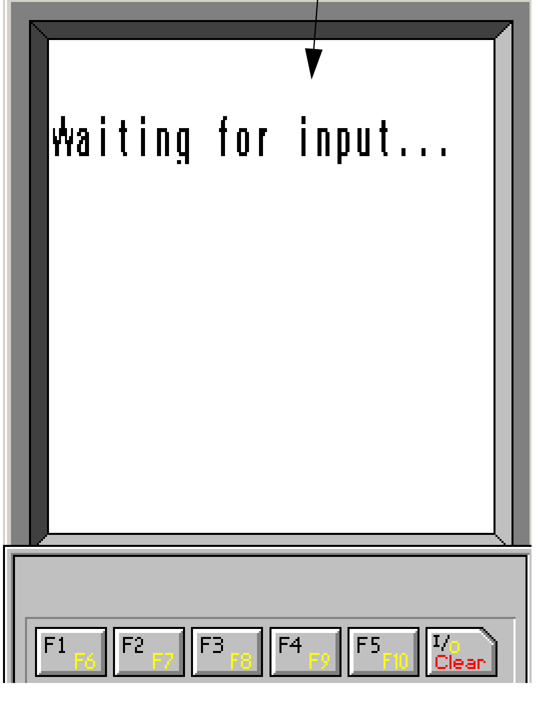
Select the upload file by selecting the folder icon and selecting the appropriate file



Prepare the data collector for uploading.

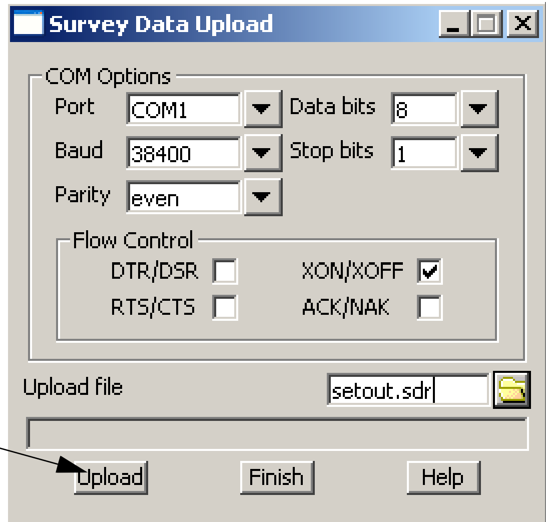


From the communication menu, select the receive button



Once the data collector is ready, the data can be sent from 12d

Select **upload** to start uploading the file



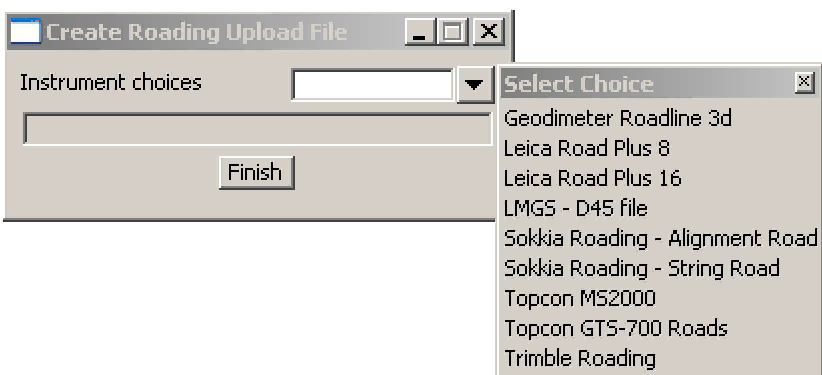
Please continue to the next section 37.2.1.1.3 Creating SDR Point Upload File

37.2.1.1.4 Creating SDR Roads Upload File

Create upload file in 12d

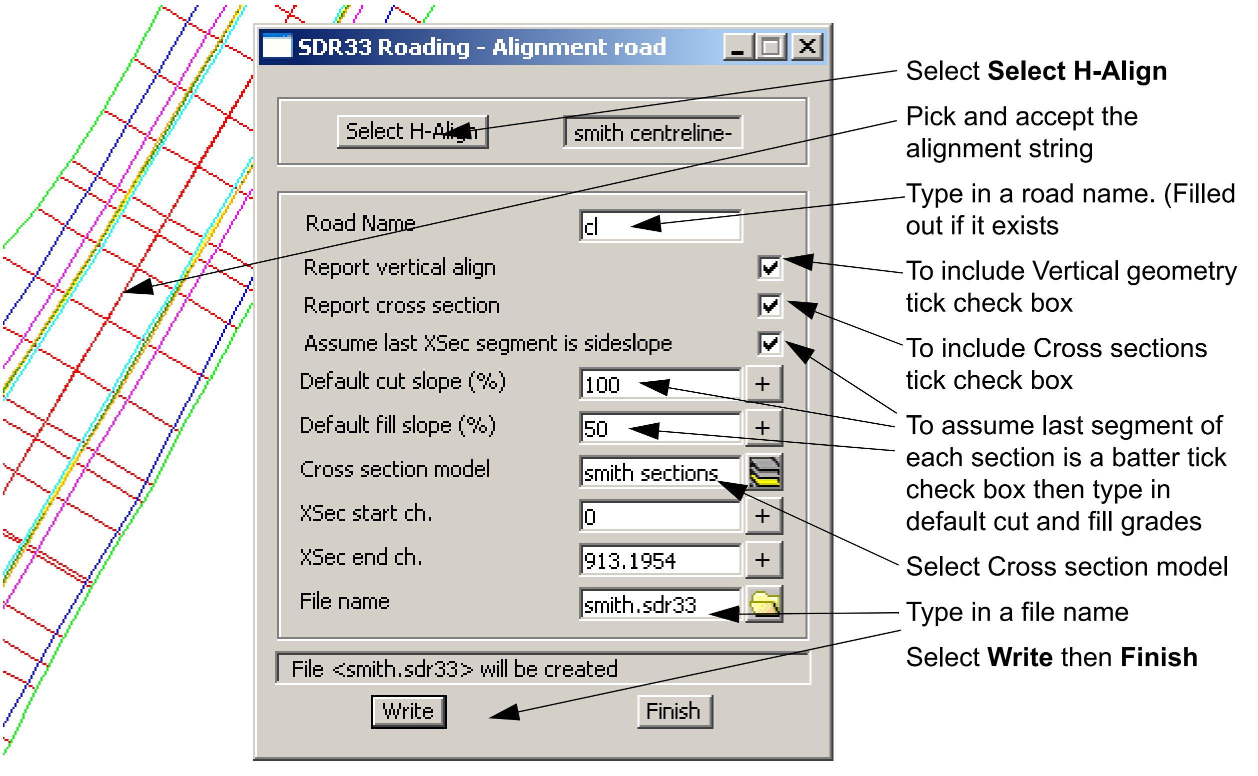
After creating the road alignment an upload file can be created for the SDR33 format

Select option ***Survey=>Upload=>Create roads upload file***



Select **Instrument** choice icon

Select **Sokkia Roading - Alignment Road**



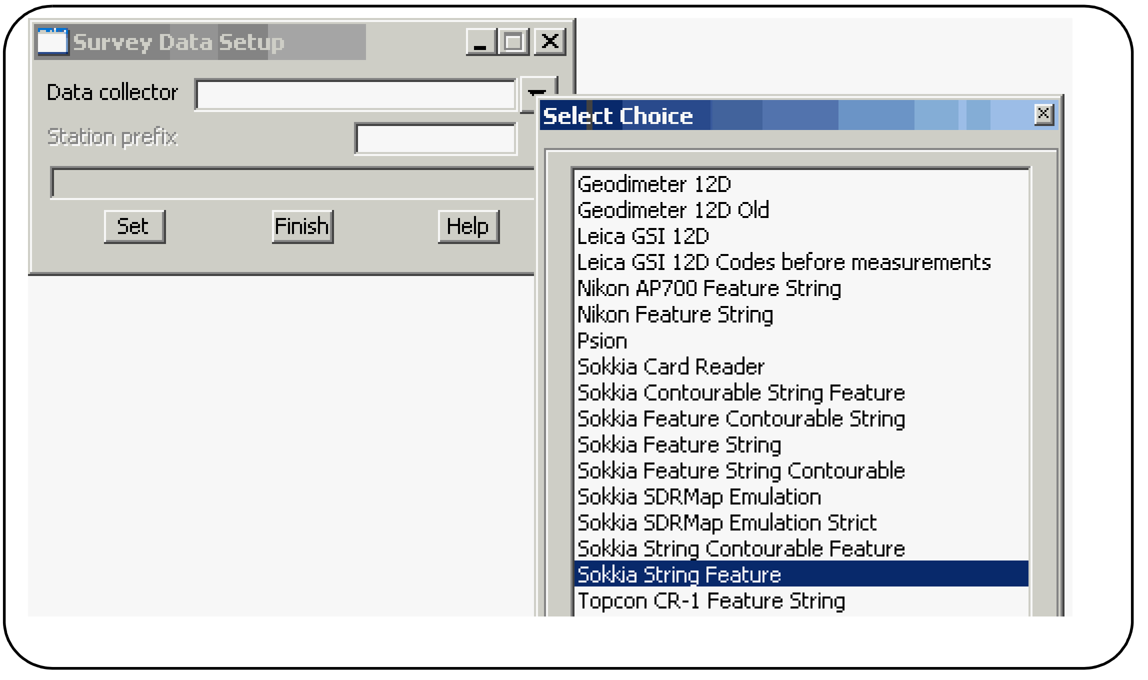
A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc. The steps involved in uploading the file to the controller using the 12d upload facility can be seen is the previous section Loading file into controller using 12d upload facility.

Please continue to the next section 37.2.1.2 Example of Sokkia SDR File

37.2.1.2 Example of Sokkia SDR File

The raw Sokkia SDR file 'detail1.sdr' has been coded in accordance with the data collector definition *Sokkia String Feature* which is shipped with ***12d Model***.

The data collector *Sokkia String Feature* is set using the option *Survey=>Setup*



Survey Data Setup

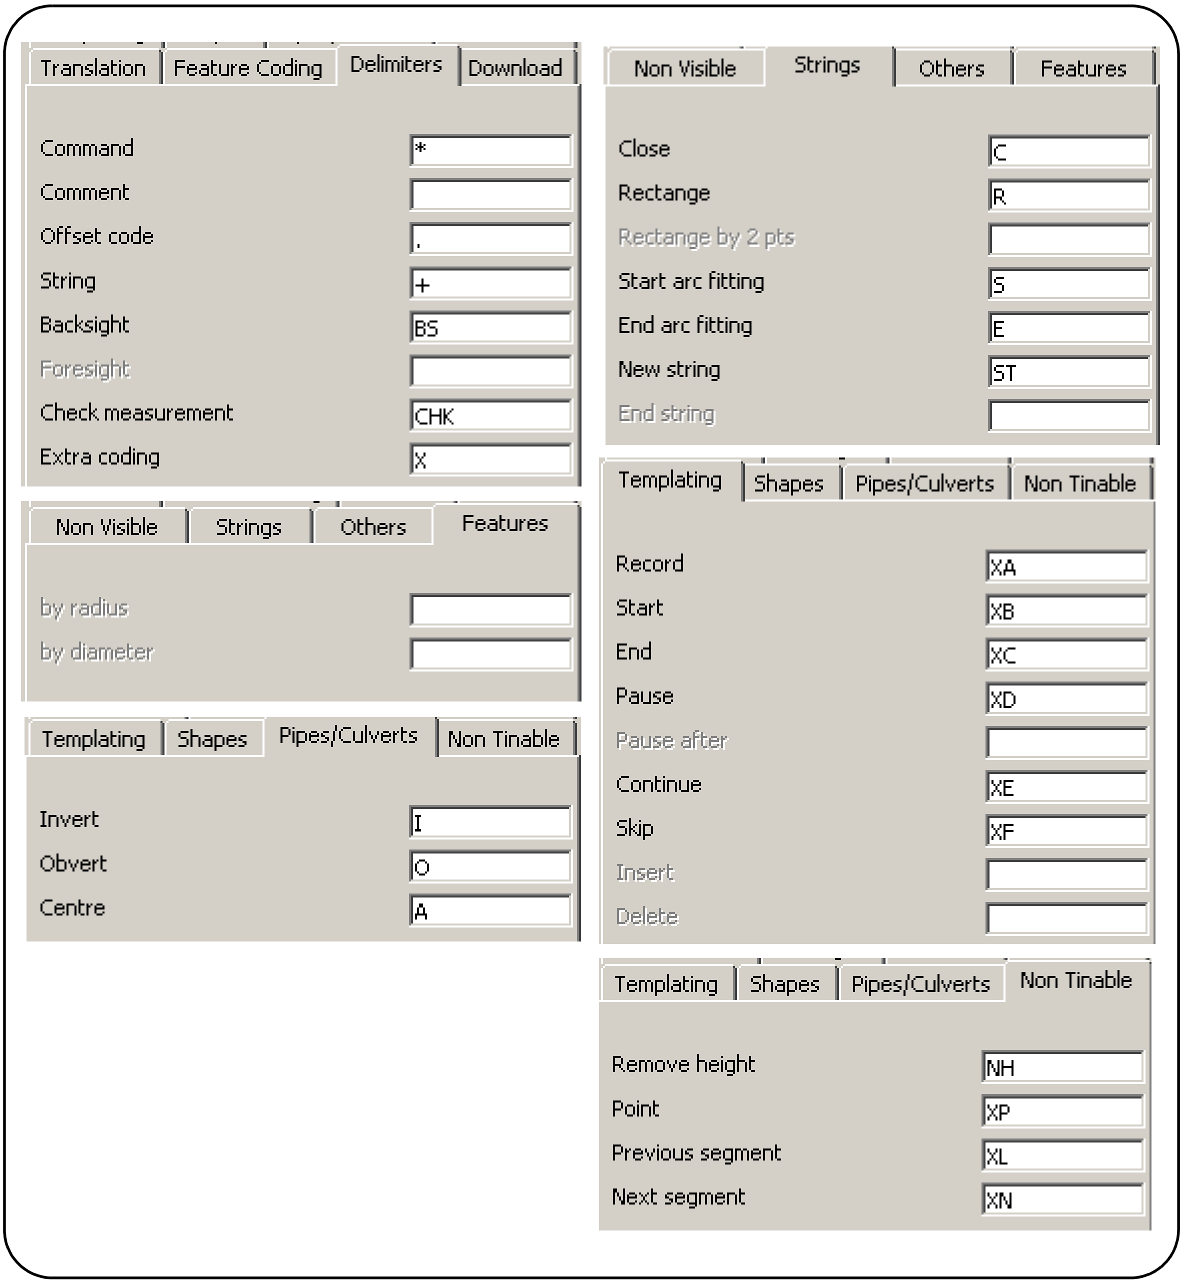
Sokkia Feature Contourable String
Sokkia Feature String
Sokkia Feature String Contourable
Sokkia SDRMap Emulation
Sokkia SDRMap Emulation Strict
Sokkia String Contourable Feature
Sokkia String Feature
Topcon CR-1 Feature String



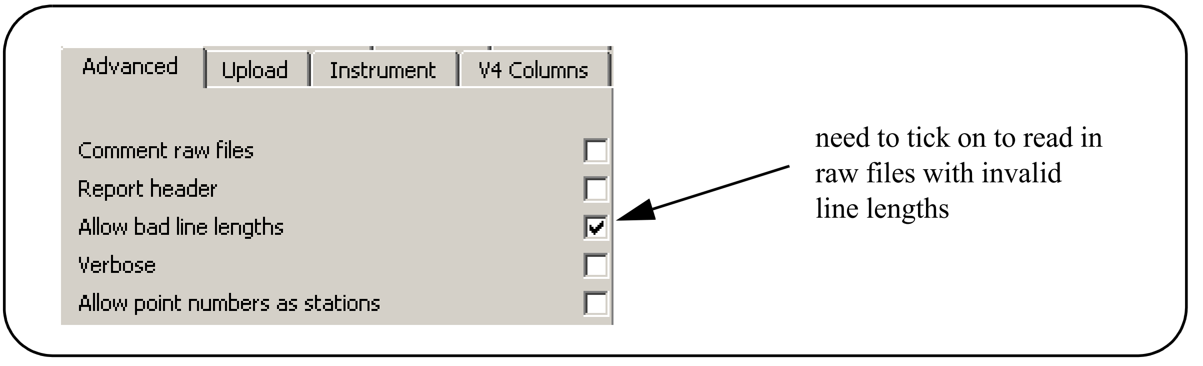
For the *Sokkia String Feature* data collector definition, the *string number* is given before the *feature code.*

Some of the control codes defined for the *Sokkia String Feature* data collector that are used in the example are:

***** is used as the Command (Block) delimiter
space is used as the comment delimiter
S and **E** are used to start arc fitting and end arc fitting respectively
R is the Rectangle (make a parallelogram) command
the template commands **XA**, **XB**, **XC** and **XD** are used
the invert **I** and obvert **O** commands are used.
XN for the next segment to be non-tinable (that is, not a breakline).

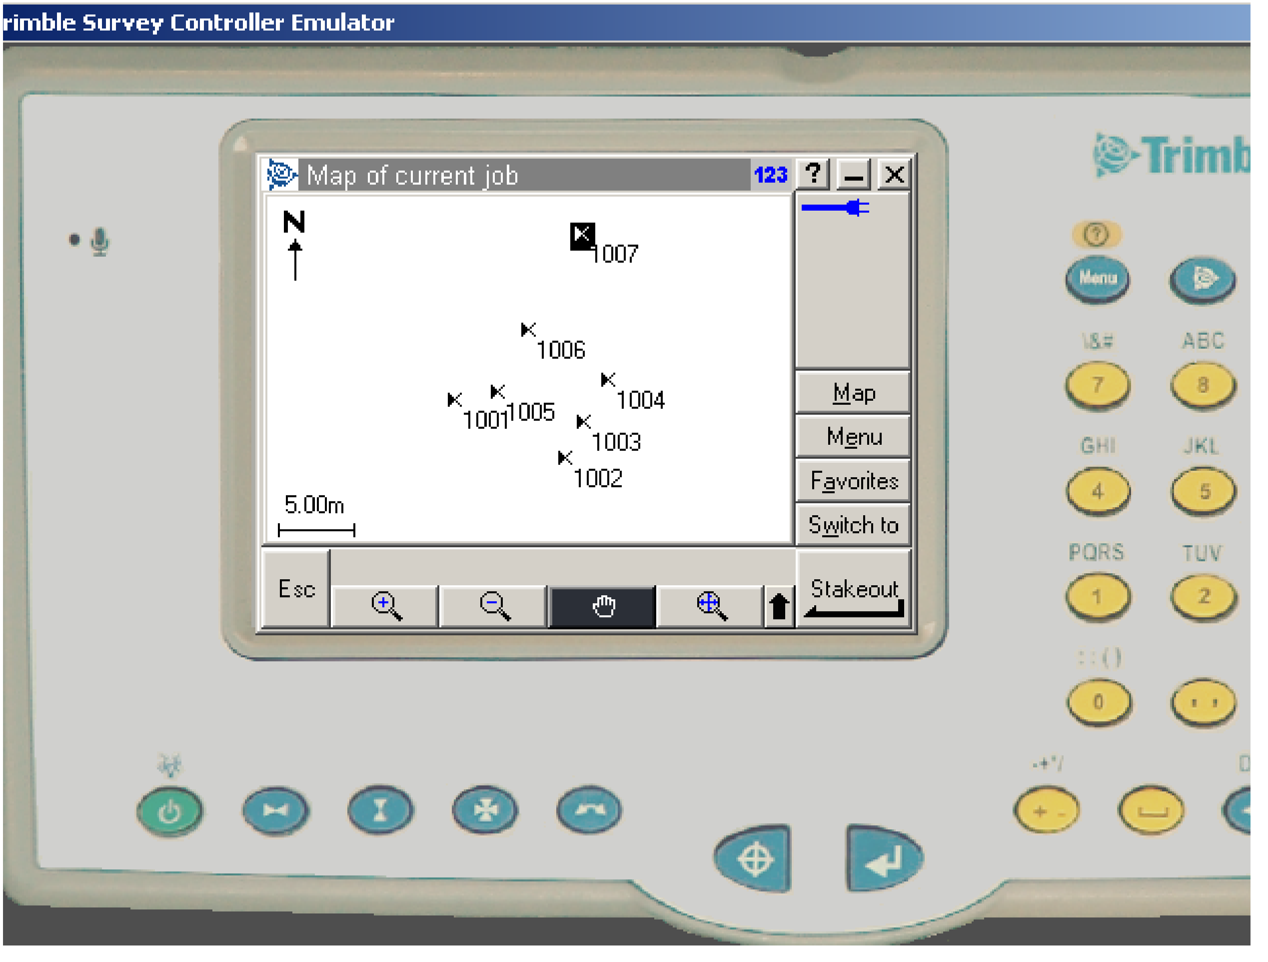
The listing of the raw file 'Detail1.sdr' is now given, followed by a dump of a ***12d Model*** view displaying the job. No Map File has been used in the reduction so no line styles appear on the view.

WARNING - The raw file 'Detail1.sdr' is in the Survey area of the training data but the file has been manually edited and if read in with the standard *Sokkia String Feature* data collector, will have bad line lengths and the data ignored. To read the file in, the *Allow bad line lengths* on the *Advanced* tab of the *Sokkia String Feature* data collector will need to be set before converting the raw file to a 12d field file.



37.3 12d and the Trimble Total Station ACU

This Section deals with interfacing 12d with the Trimble Total Station ACU unit data formats



These notes are not meant to take the place of the operations manuals for the Trimble ACU but rather to act as a guide for ensuring the correct file types are used between the two systems.

See the sections:

37.3.1 Coding

37.3.2 Sending Raw file to 12d

37.3.3 Creating and Setting Data Collector Type

37.3.4 Convert Raw File

37.3.5 Creating Point Upload File

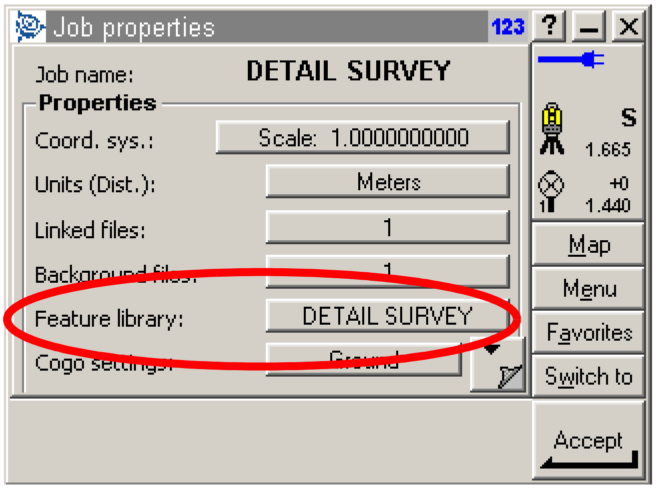
37.3.6 Create Roads Upload File

37.3.7 Create Tin Upload File

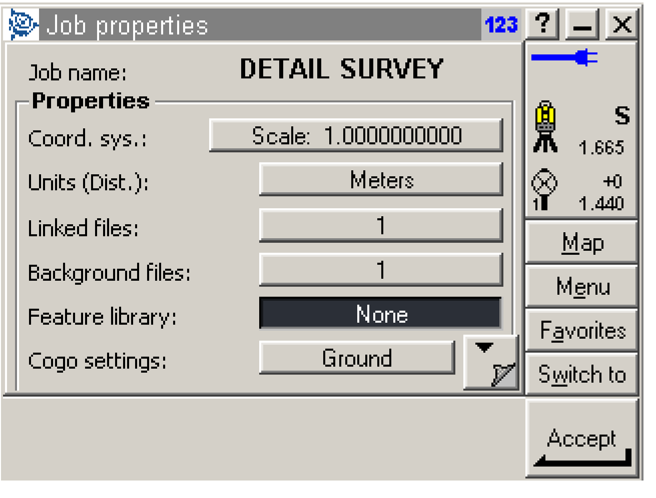
37.3.1 Coding

On the ACU the user can either manually type in a code for field readings or use a code library to pre-define codes which can then be selected from a list

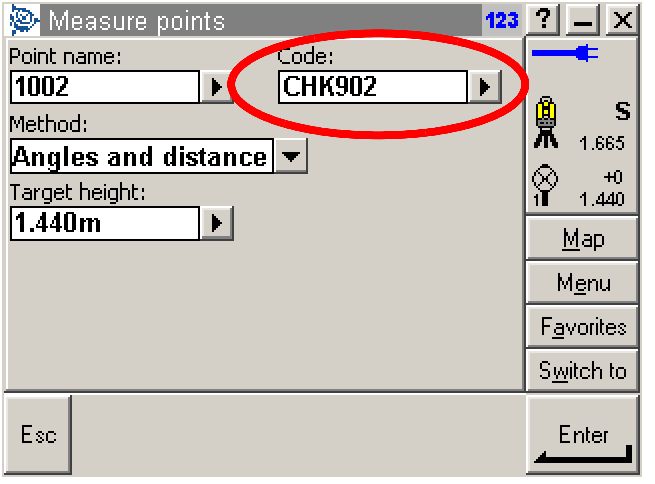
To use a code library the user should select the relevant library when creating the job

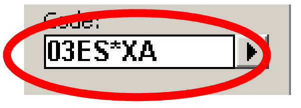


If using string numbers the Feature library can be set to ***None*** and the string number, feature code, field code and delimiters can be manually typed in



Codes are typed in to the ACU in the **MEASURE POINTS** option



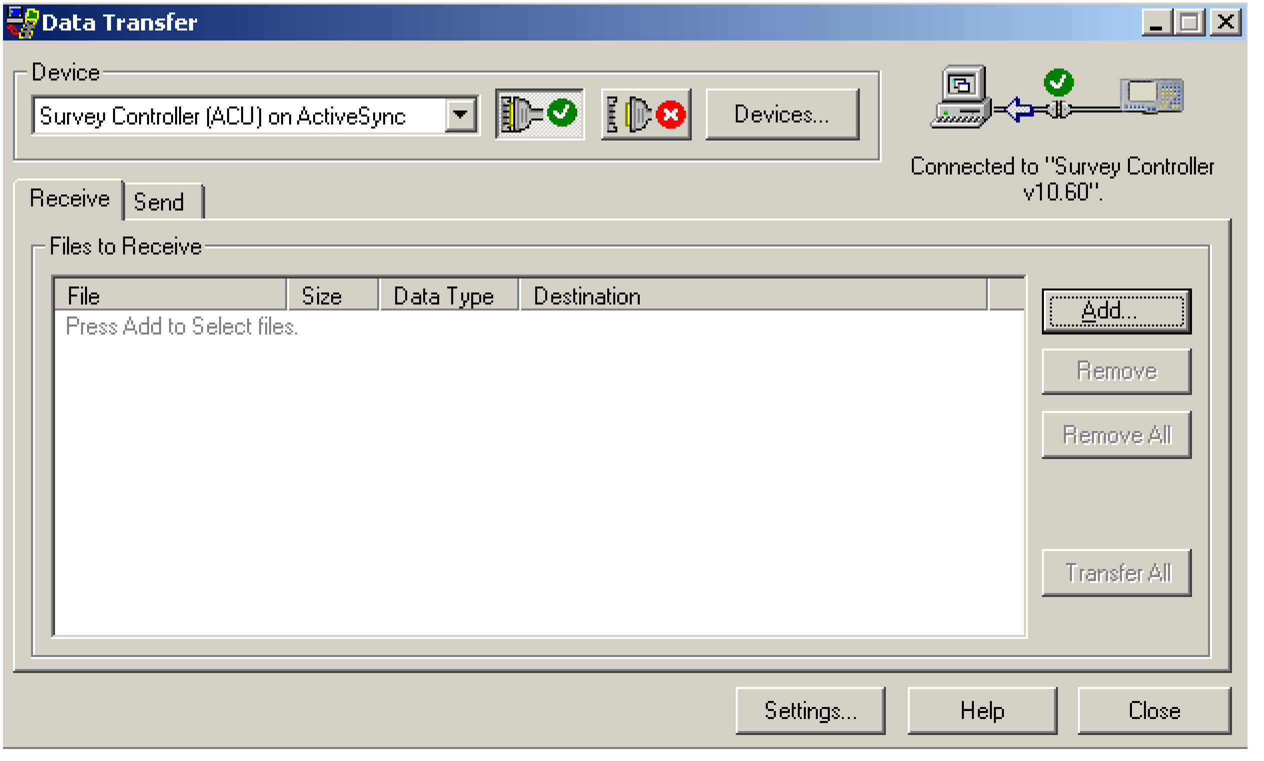


Please continue to the next section 37.3.2 Sending Raw file to 12d

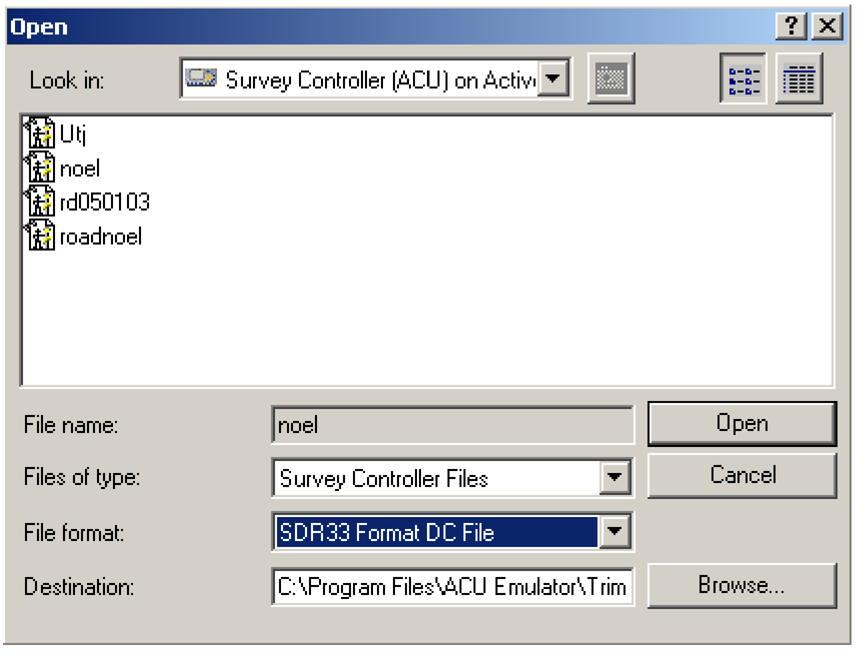
37.3.2 Sending Raw file to 12d

The raw file can be transferred from the ACU as a format similar to the SDR33. This is called the **SDR33 DC** file format.

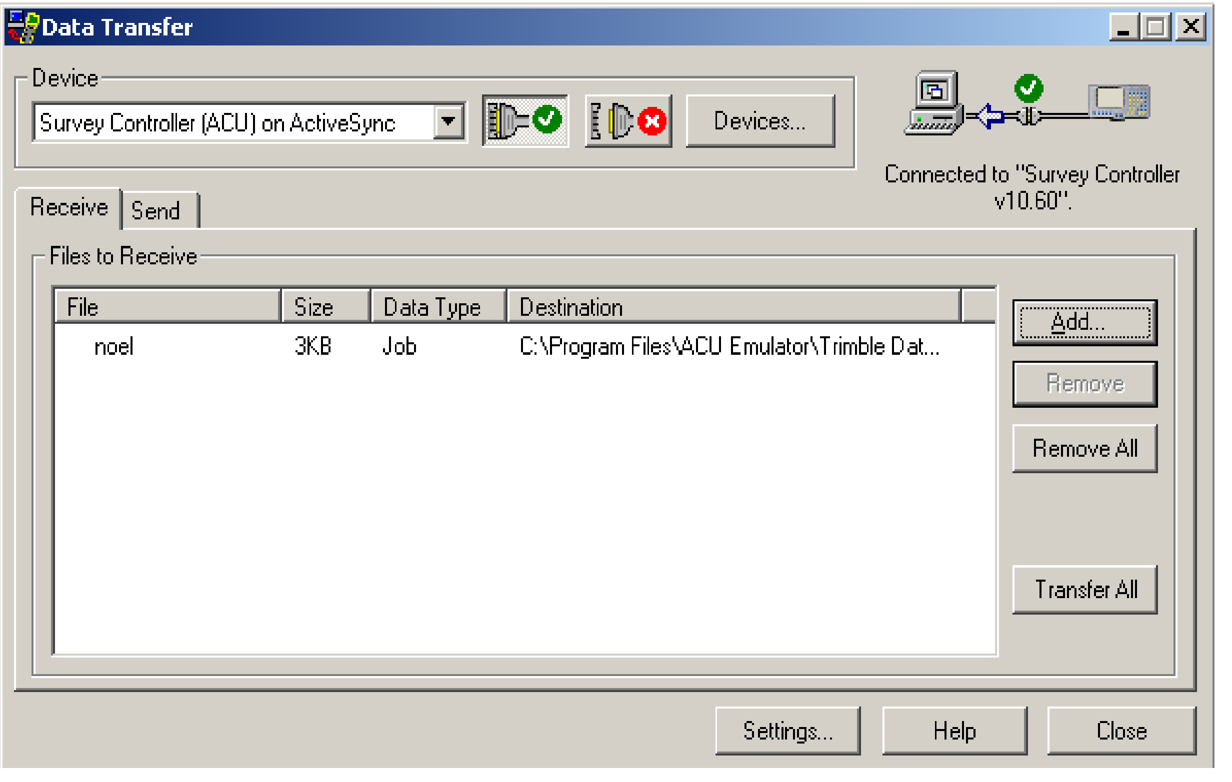
Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**



Select ***Receive*** tab then select ***Add***



Select the Job to download using the format ***SDR33 FORMAT DC FILE***



Select ***Transfer All*** to transfer the file

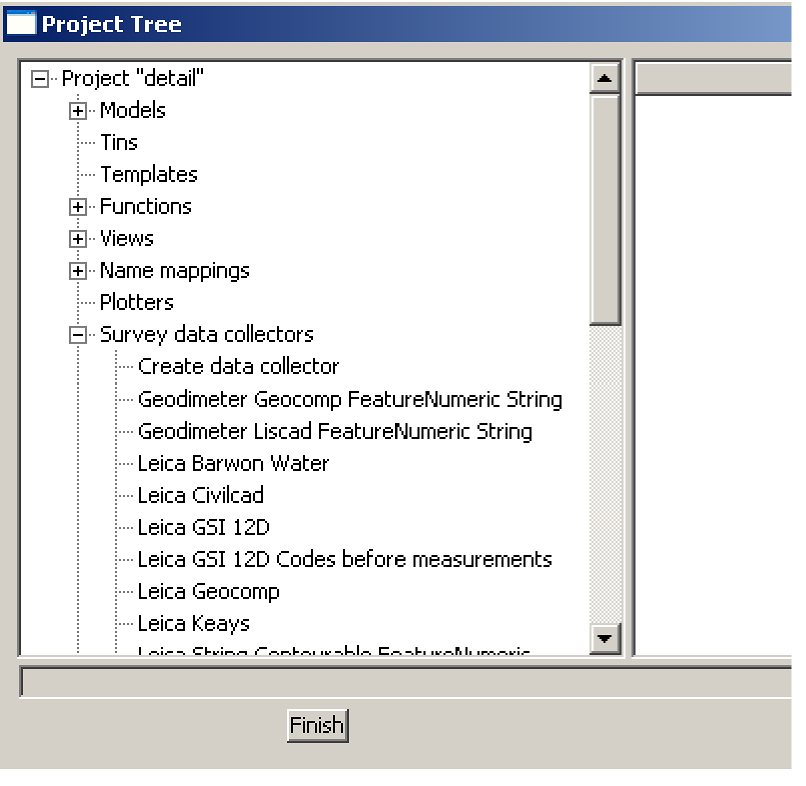
Please continue to the next section 37.3.3 Creating and Setting Data Collector Type

37.3.3 Creating and Setting Data Collector Type

Create new data collector type

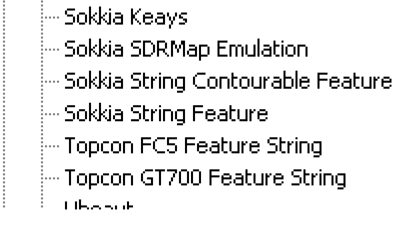
We will create a specific name for the Trimble data collector even though it is similar to the SDR33 format

Select ***Project=>Browse***



Select the Survey data collectors branch

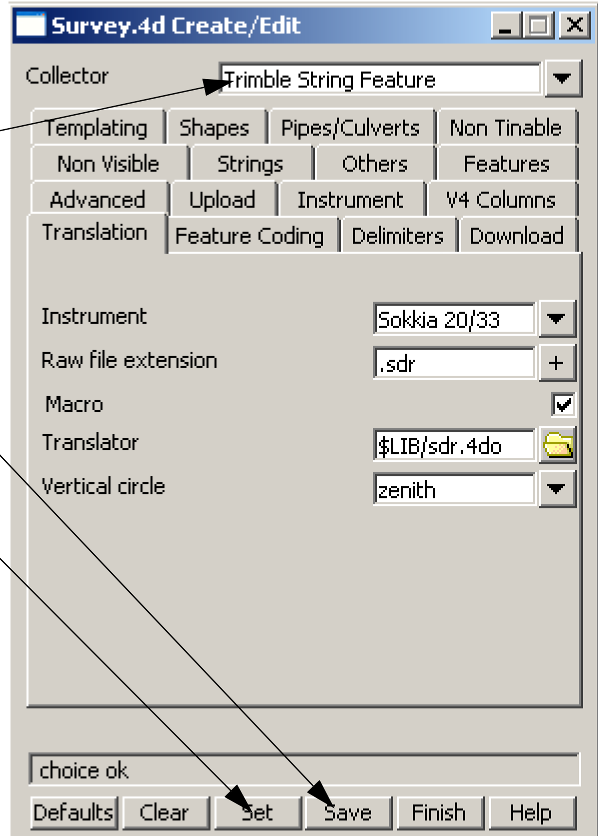
Double click on **Sokkia String Feature**



This loads up the default parameters for the SDR33 format.

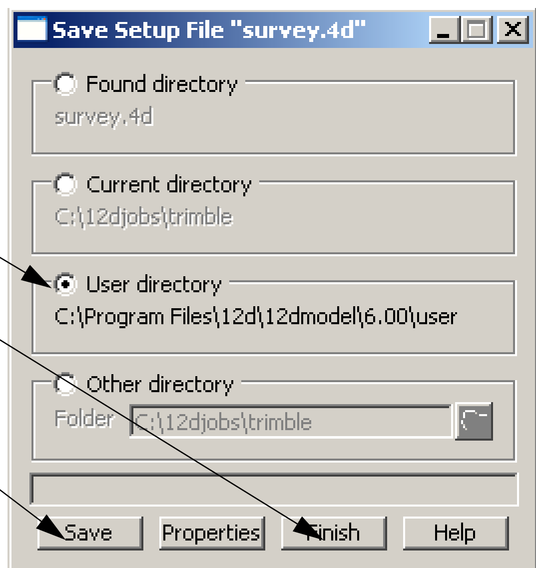
Type in the new name **Trimble String Feature**

Select **Set** then **Save**



Select **User directory**

Select **Save** then **Finish**

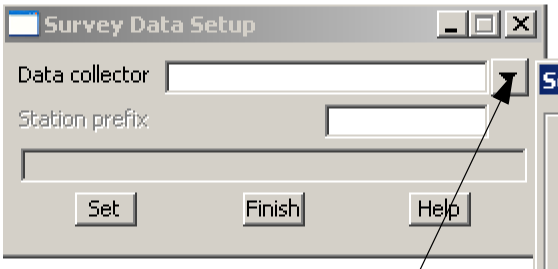


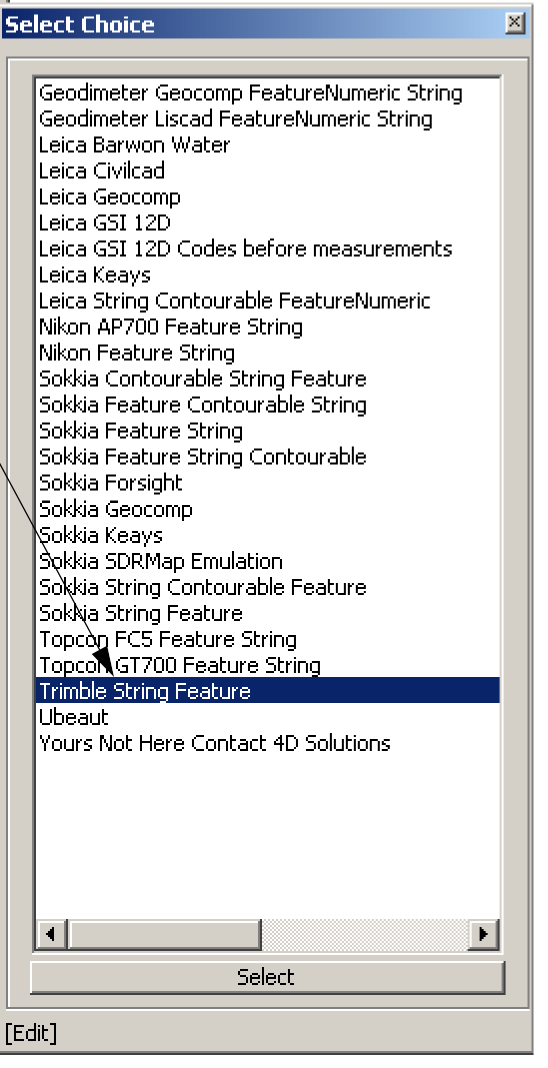
Select **Finish** back in the previous panel

To set the changes the project has to be restarted by selecting ***Project=>Restart***

Select the data collector type

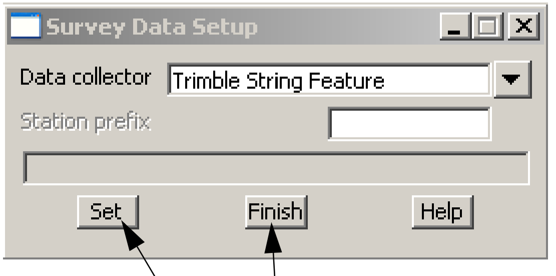
Select option ***Survey=>Setup***





Select the **Data collector** choice icon

Double click on **Trimble String Feature**

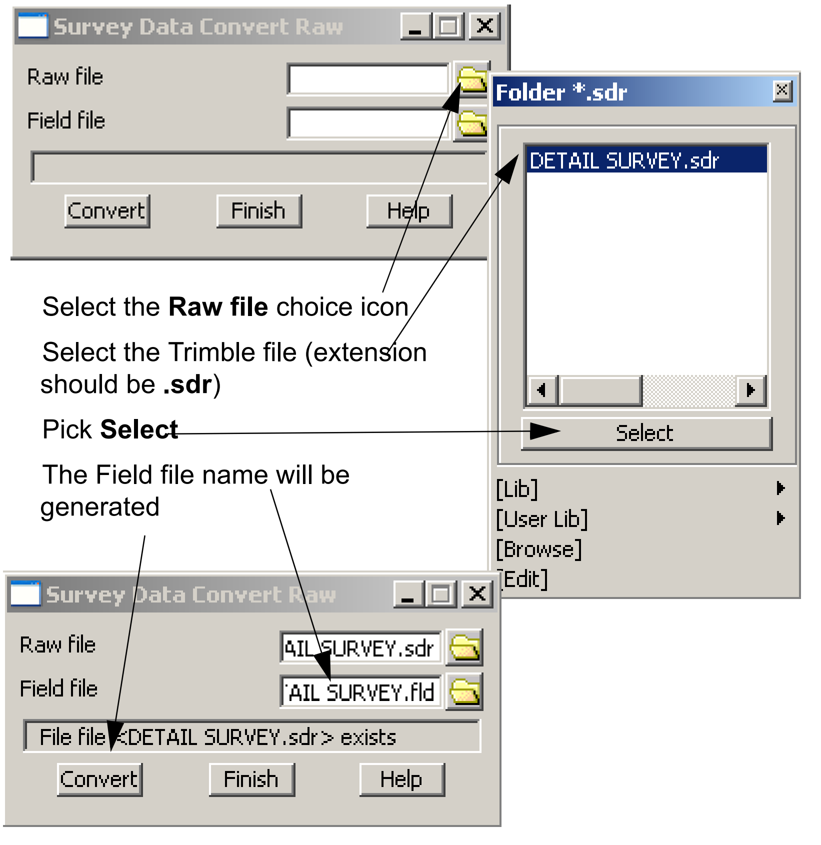


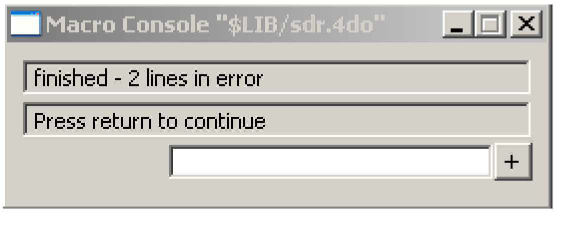
Select **Set** then **Finish**

Please continue to the next section 37.3.4 Convert Raw File

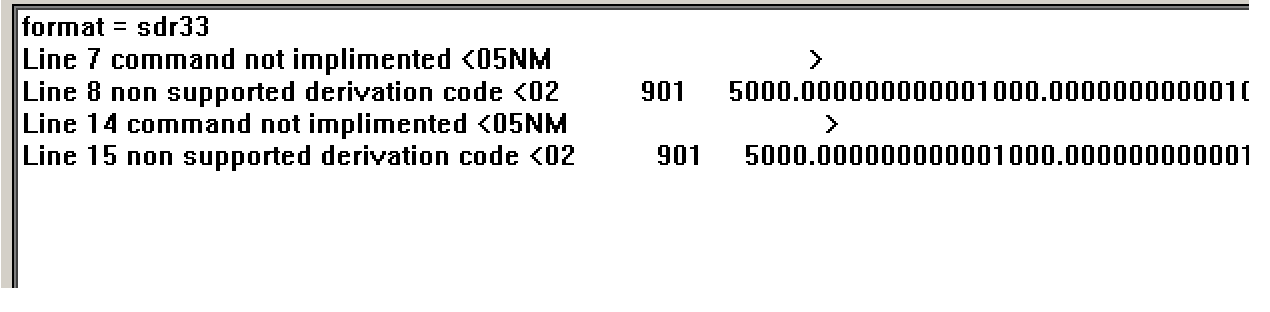
37.3.4 Convert Raw File

To convert raw file to field file select option ***Survey=>Convert raw***

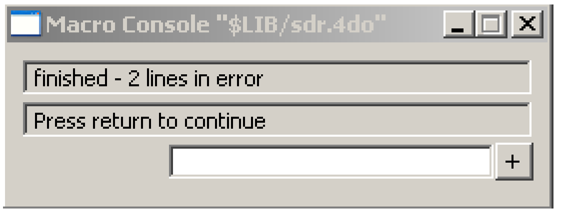




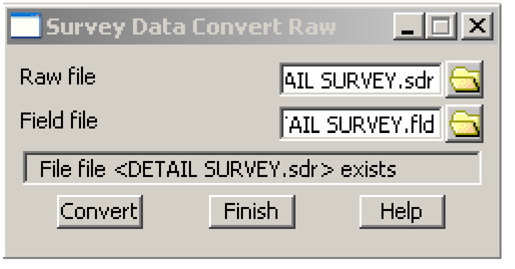
Any errors can be listed by opening the Output window using option ***Window=>Output Window***



format = sdr33
Line 7 command not implimented <05NM >
Line 8 non supported derivation code <02 901 5000.000000000001000.00000000001(
Line 14 command not implimented <05NM >
Line 15 non supported derivation code <02 901 5000.000000000001000.000000000001



Close the Error panel



Select **Finish**

The field file can now be reduced in the normal manner

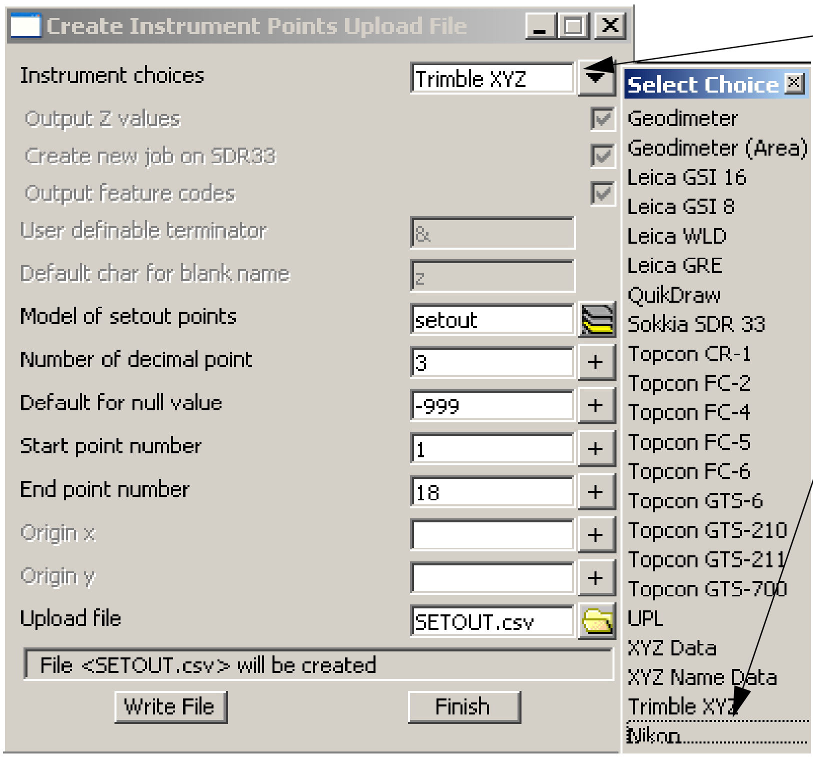
Please continue to the next section 37.3.5 Creating Point Upload File

37.3.5 Creating Point Upload File

Create upload file in 12d

After creating the setout points an upload file has to be created for the Trimble format

Select option ***Survey=>Upload=>Create points upload file***



Select **Instrument choices** icon

Select **Trimble XYZ**

Fill in the rest of the screen as per normal

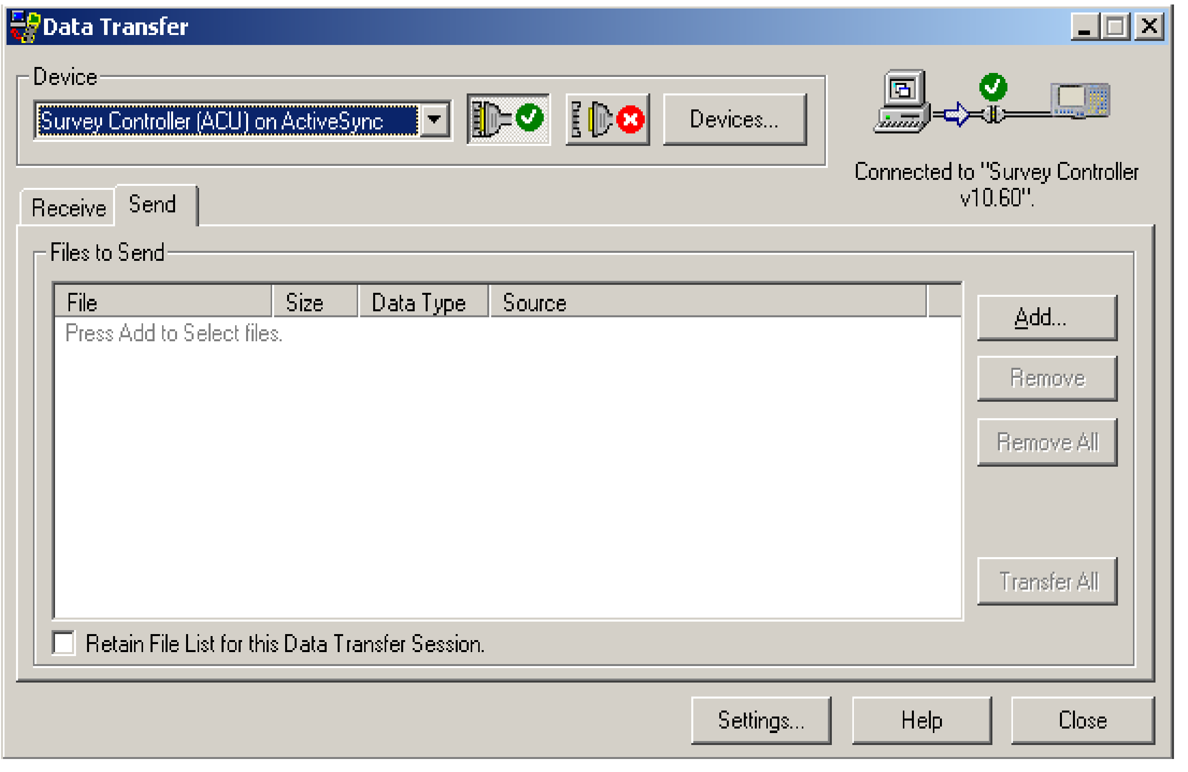
Select **Write File**

A standard comma delimited file is created ready to send to the ACU

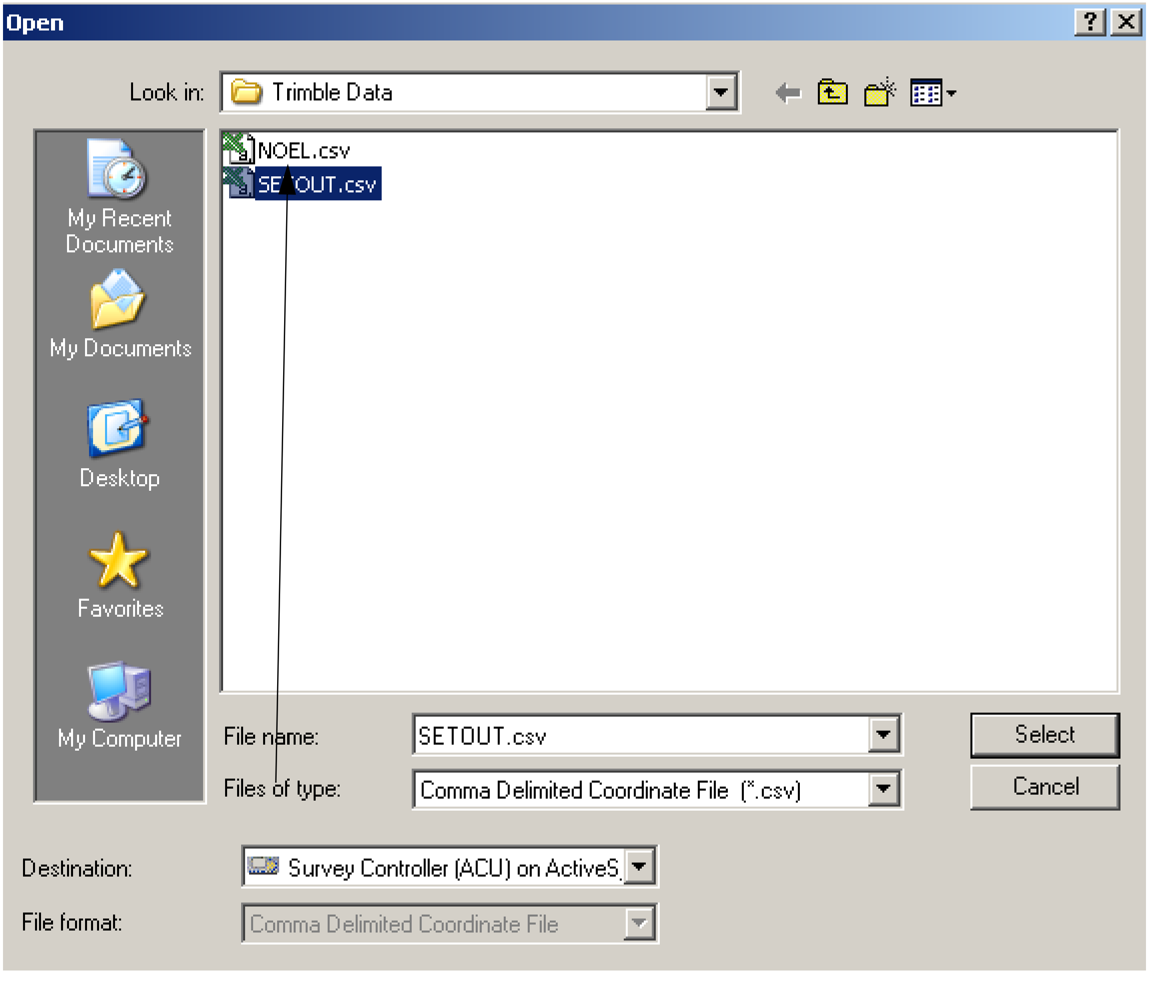
Loading file into job in ACU

The points upload file can be transferred to the ACU for setout.

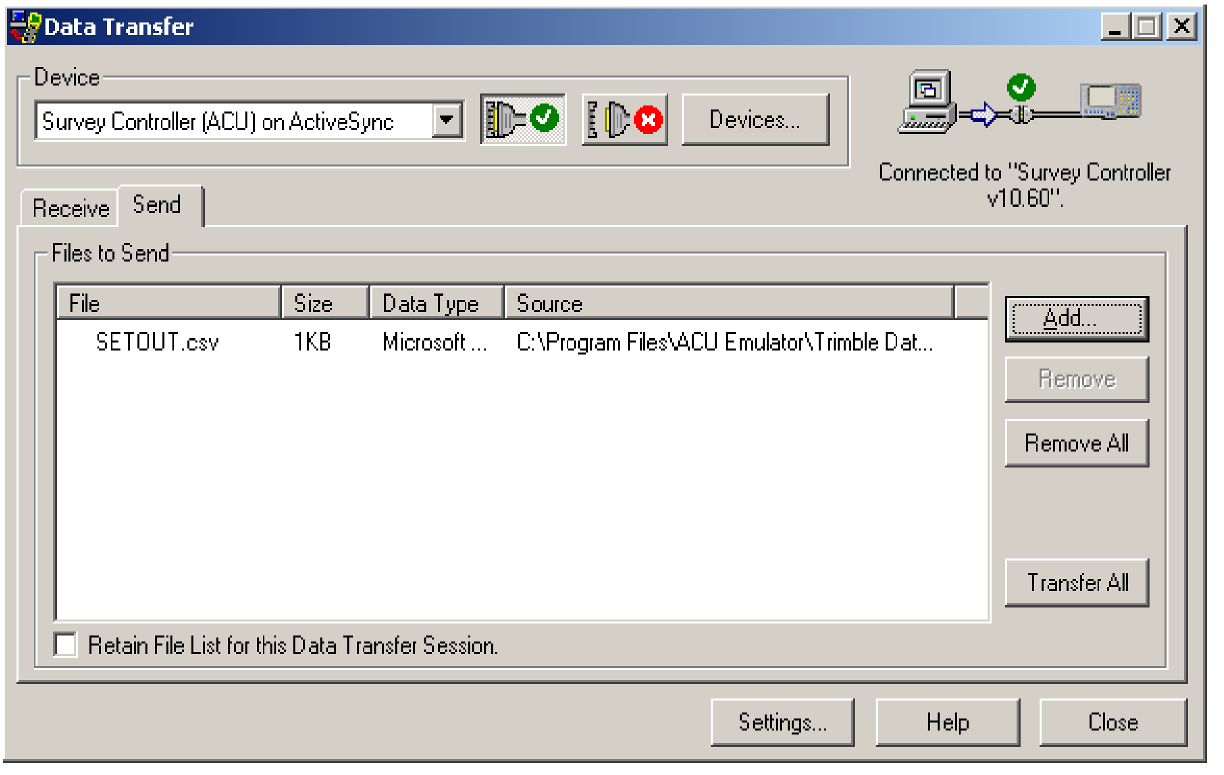
Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**



Select ***Send*** tab then select ***Add***

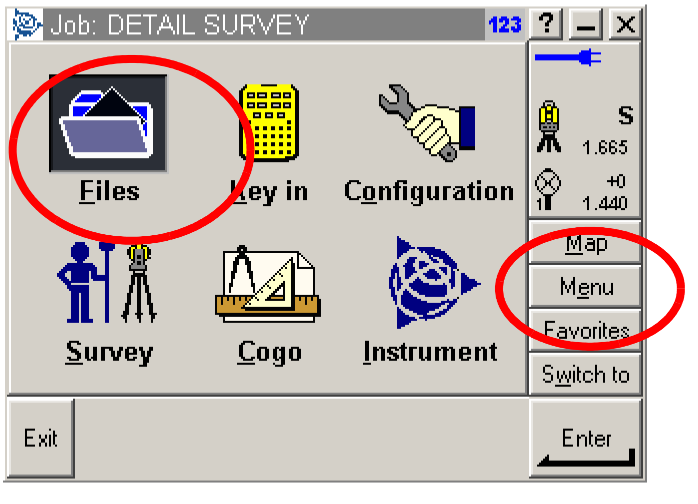


Select the file to upload using format ***Comma delimited coordinate file***

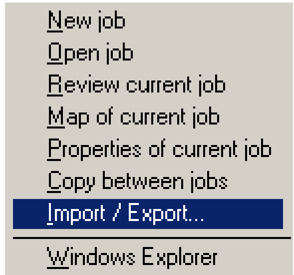


Select ***Transfer All*** to transfer the file

To load the file into the current job on the ACU select ***Menu=>Files***

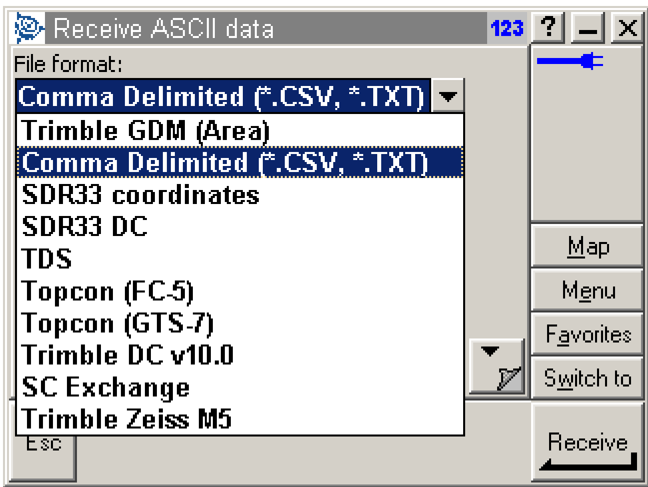


Select ***Import / Export***

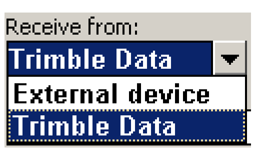


Select ***Receive ASCII data***

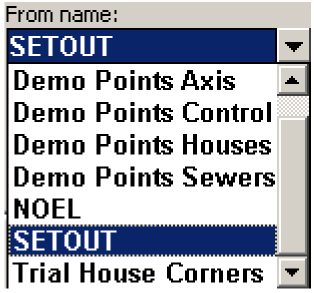
Select **File format** choice icon then pick ***Comma Delimited (*.CSV, *.TXT)***



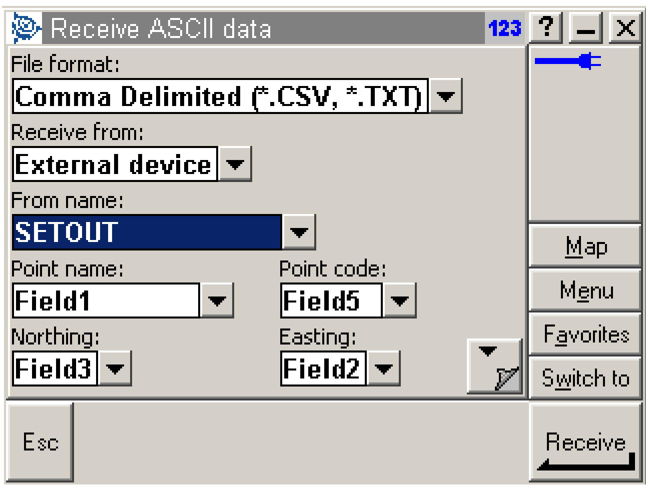
Select **Receive from** choice icon and pick ***Trimble Data***



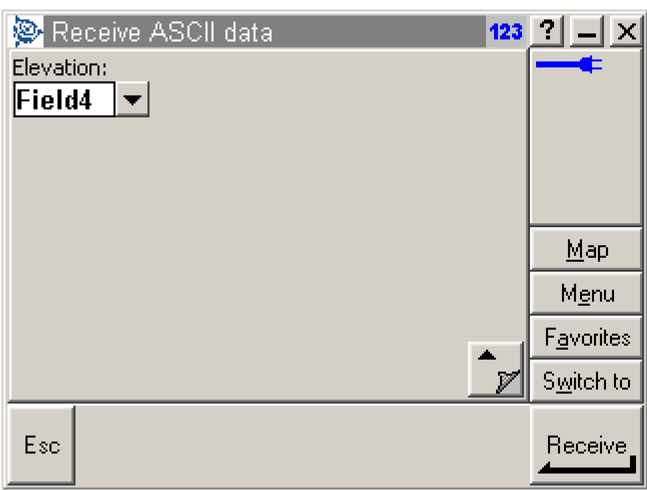
Select **From file** choice icon and select file



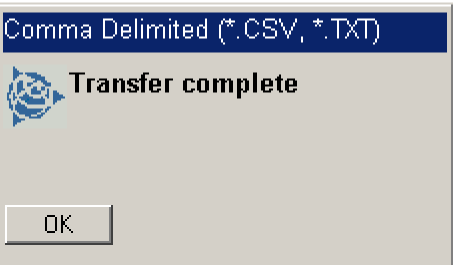
Select the field order for the file as (1) Point number, (2) Easting, (3) Northing, (4) Level and (5) Code



Select the **Next page** icon

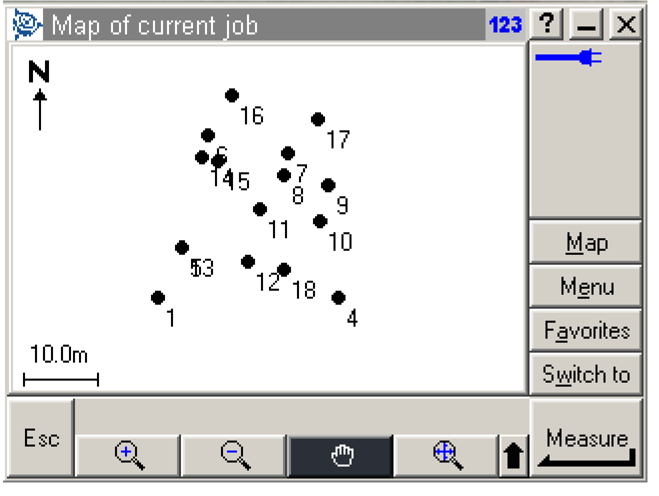


Select **Receive**



Select **OK** to finish

The points can be displayed by selecting **Map** and zooming all of the job



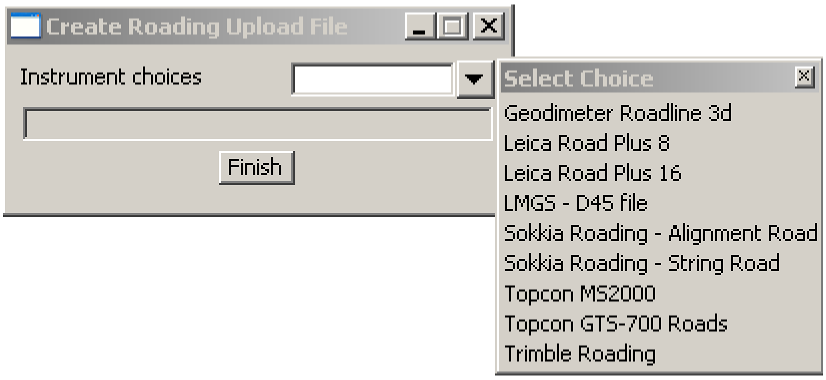
Please continue to the next section 37.3.6 Create Roads Upload File

37.3.6 Create Roads Upload File

Create upload file in 12d

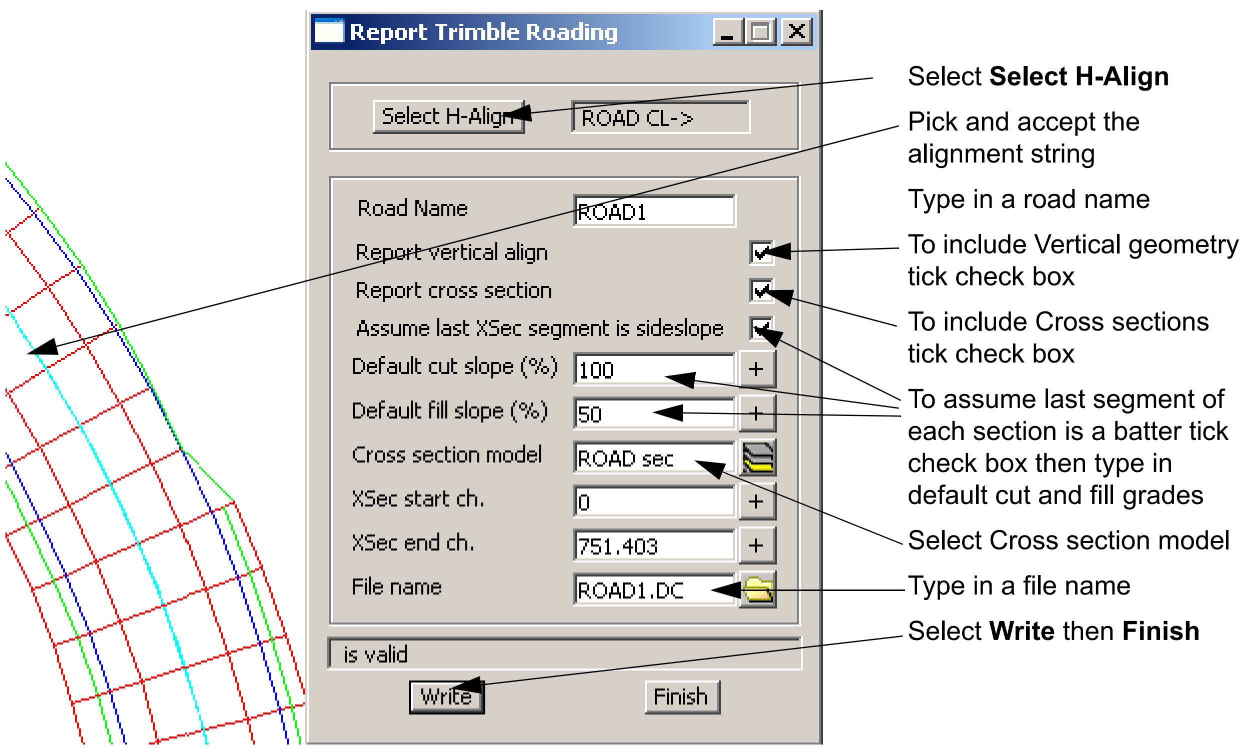
After creating the road alignment an upload file has to be created for the Trimble format

Select option ***Survey=>Upload=>Create roads upload file***



Select **Instrument** choice icon

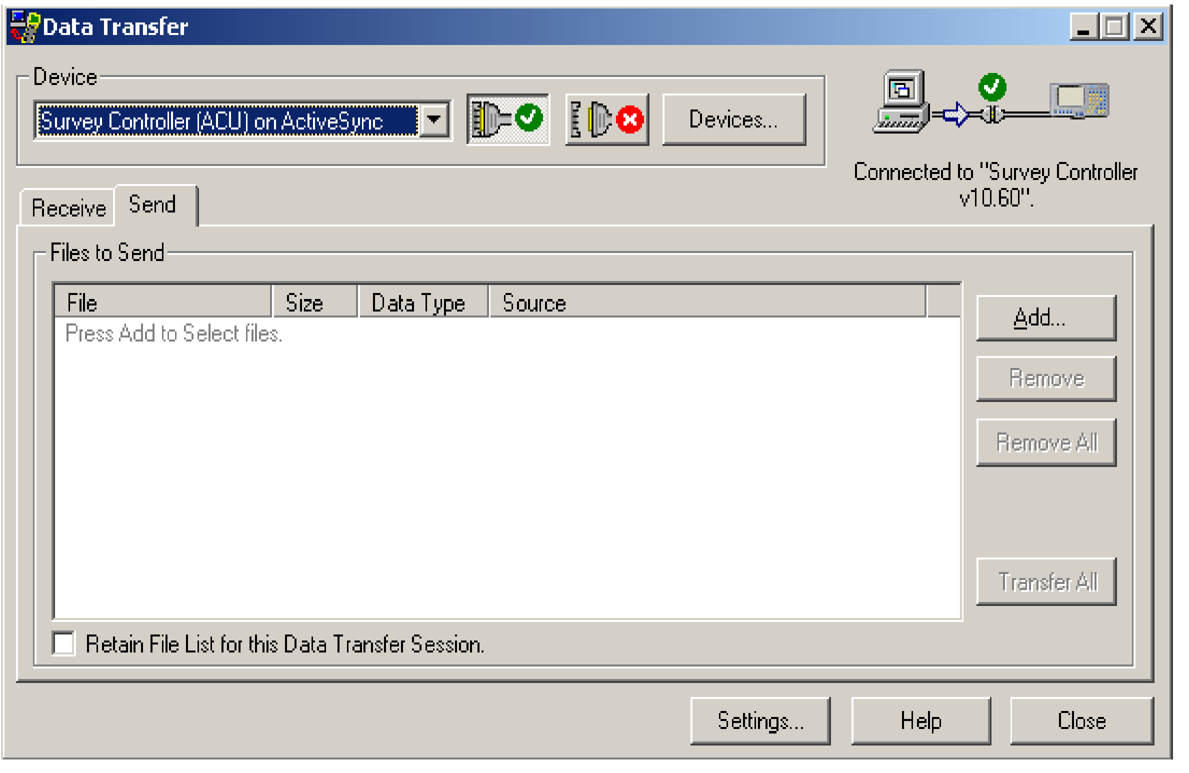
Select **Trimble Roading**



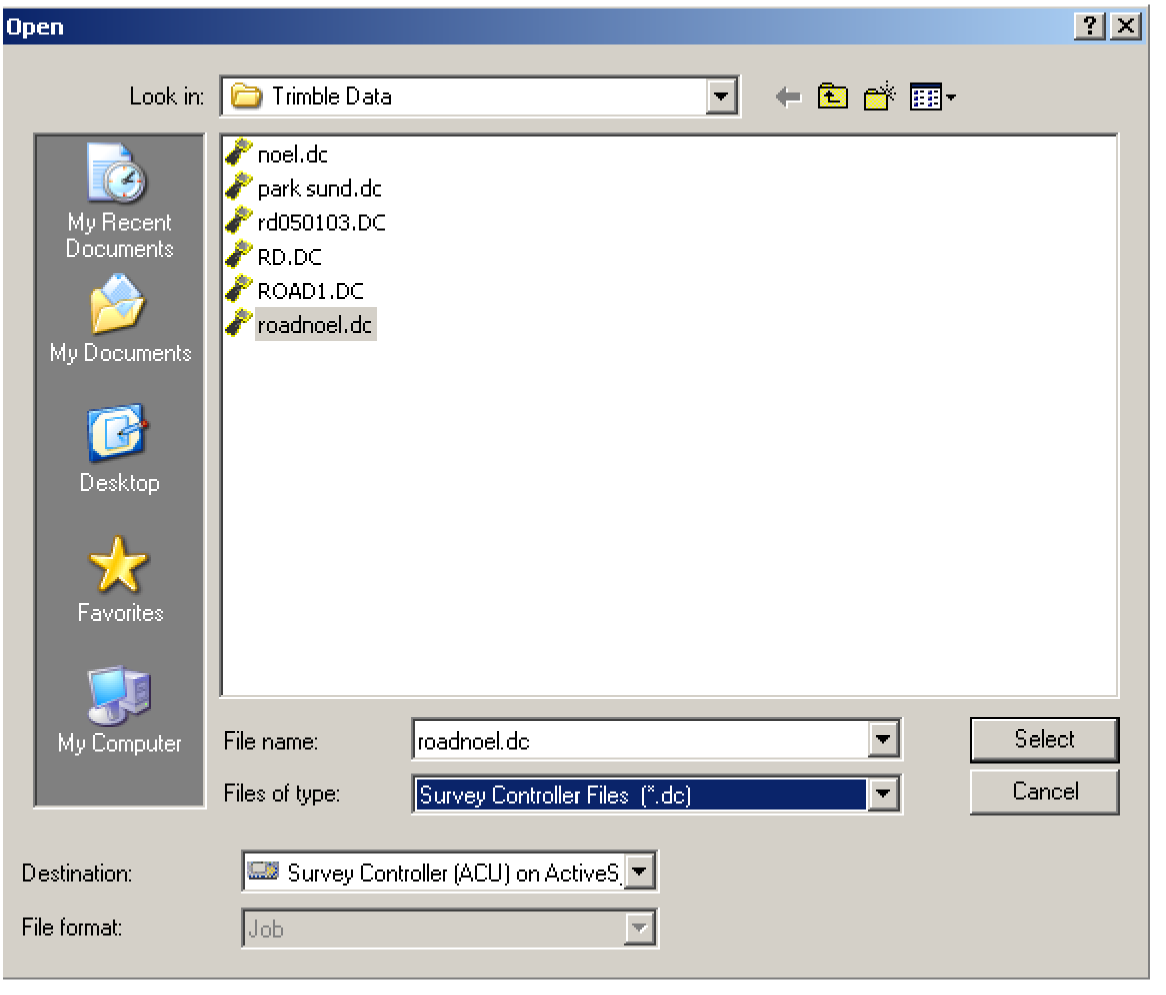
Loading file to the ACU

The road upload file can be transferred to the ACU for setout.

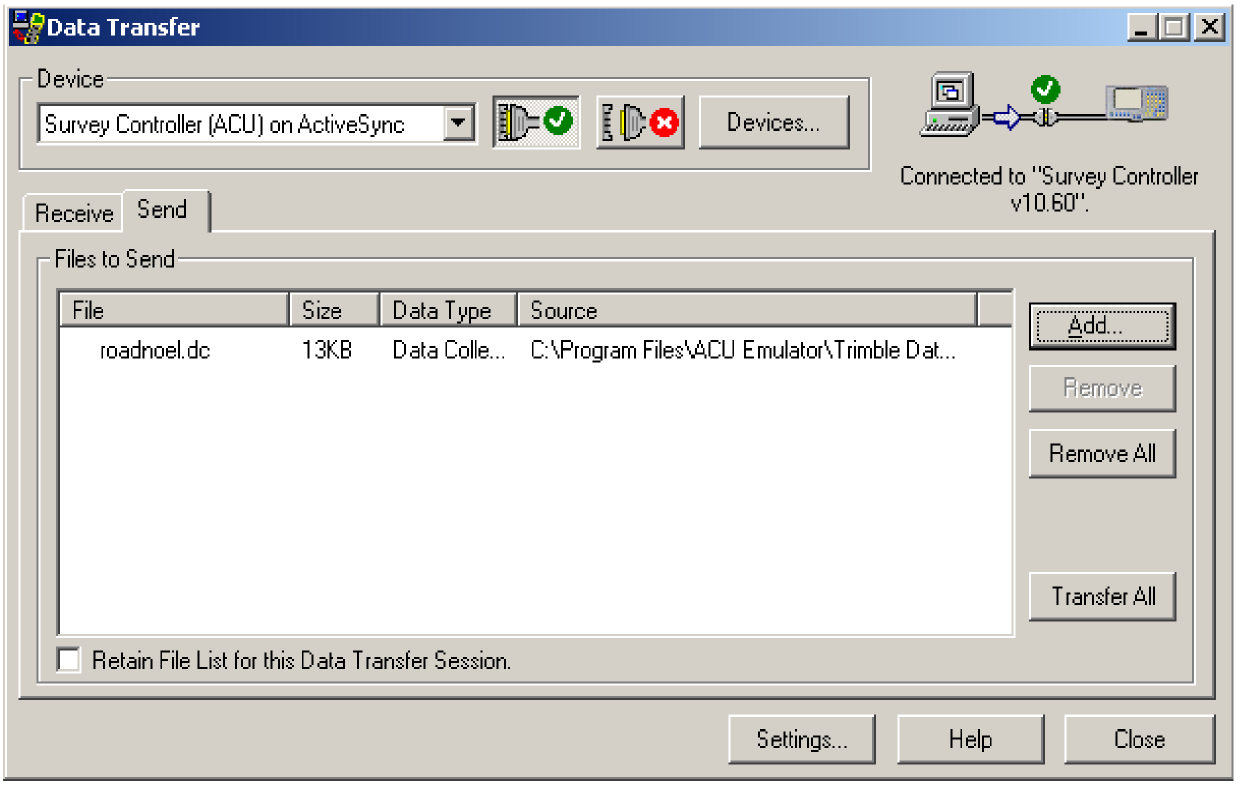
Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**



Select ***Send*** tab then select ***Add***

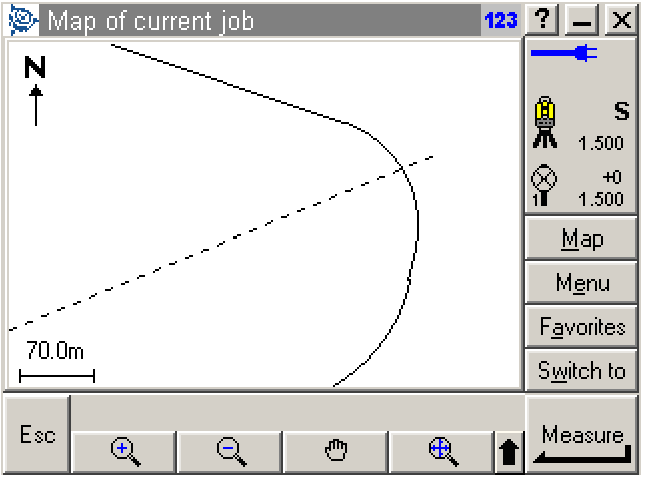


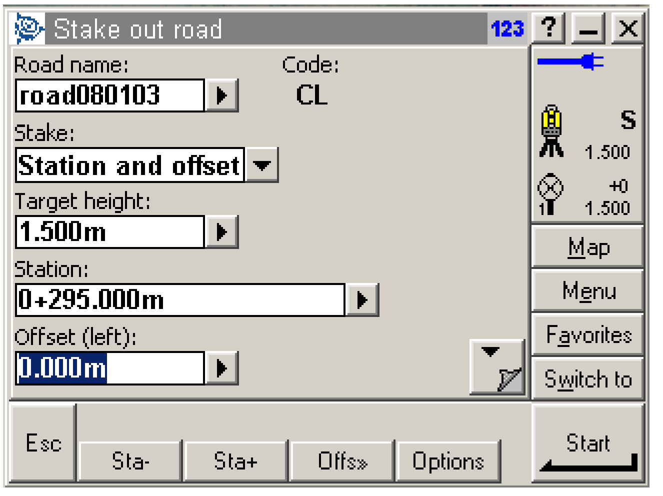
Select the road file to upload using format ***Survey Controller file***

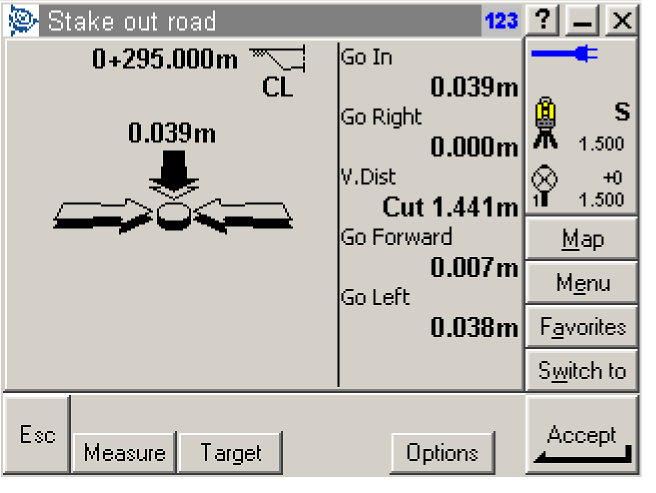


Select ***Transfer All*** to transfer the file

Once the road file has been copied into the ACU it can be setout using option ***Survey=>Stakeout=>Roads***







Please continue to the next section 37.3.7 Create Tin Upload File

37.3.7 Create Tin Upload File

Create upload file in 12d

After creating the triangulation an upload file has to be created for the Trimble format

Select option ***Survey=>Upload=>Create triangle upload file***

Select the **File Type** choice icon and select **Trimble**

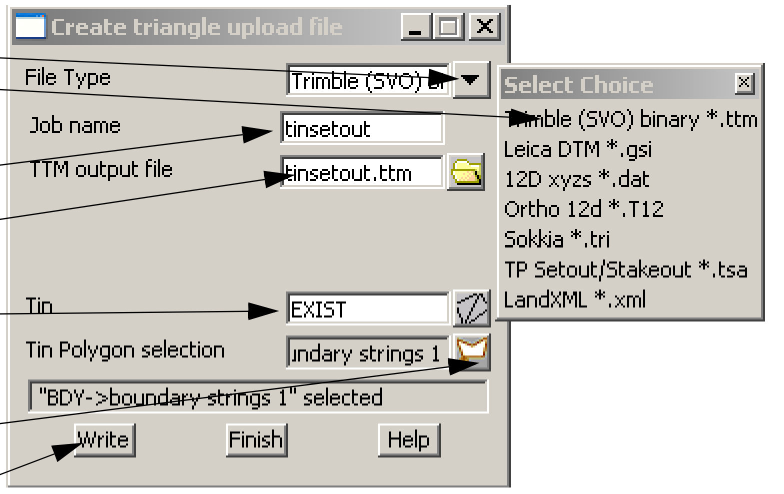
Type in Job name

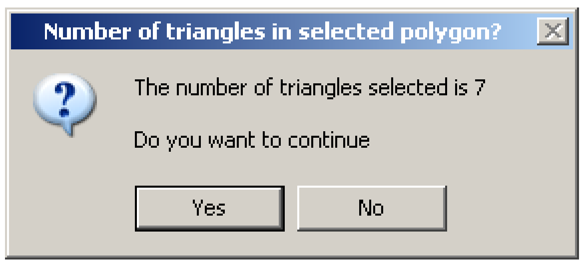
Type in output file name

Select the tin to list

Select the boundary string for the tin

Select **Write** then **Finish**



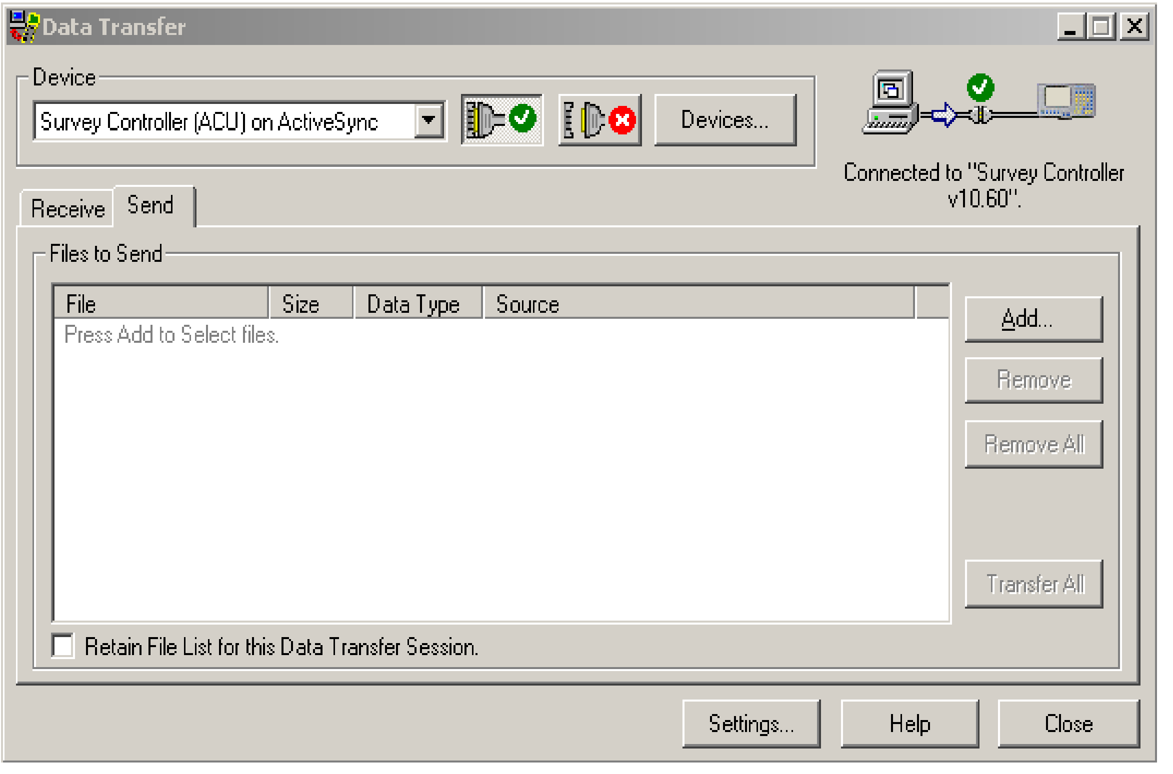


Select **Yes** to create the file

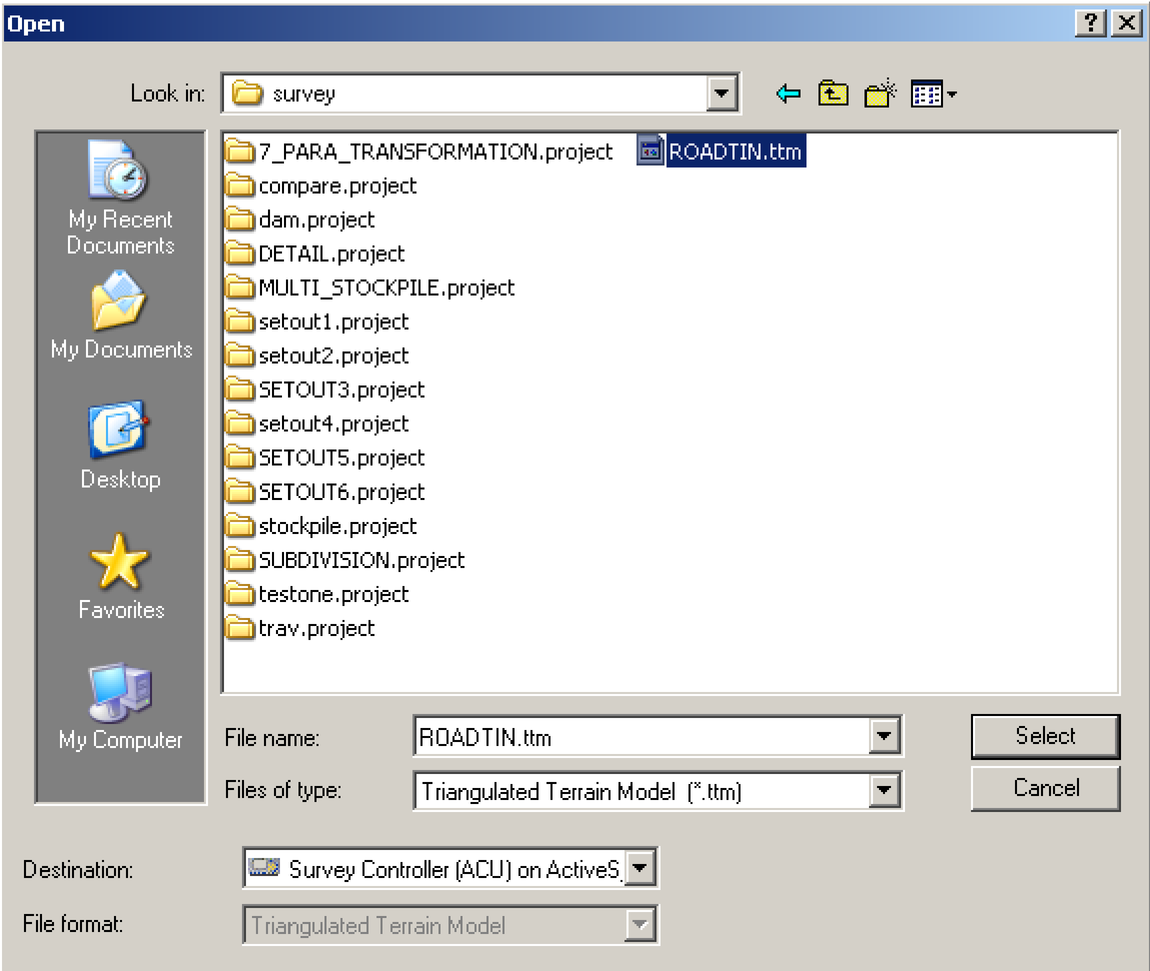
Loading and using the file in the ACU

The tin upload file can be transferred to the ACU for setout.

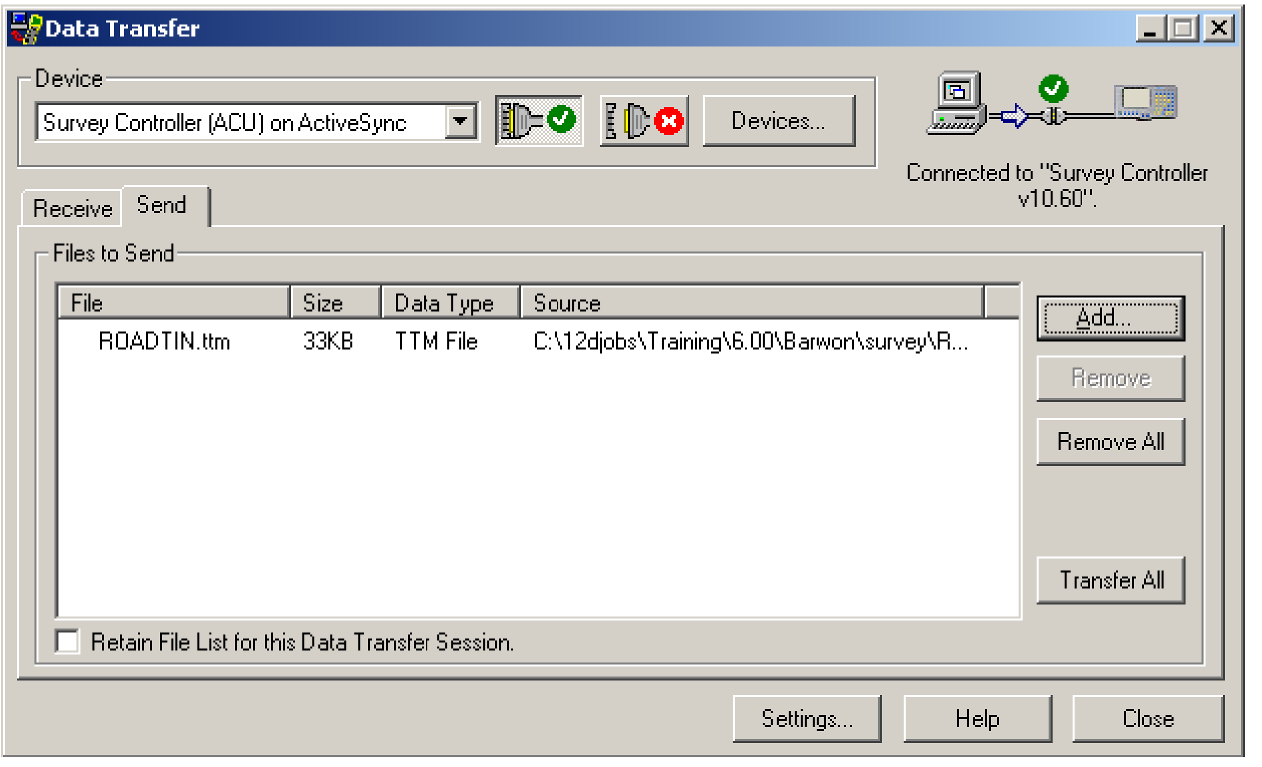
Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**



Select ***Send*** tab then select ***Add***



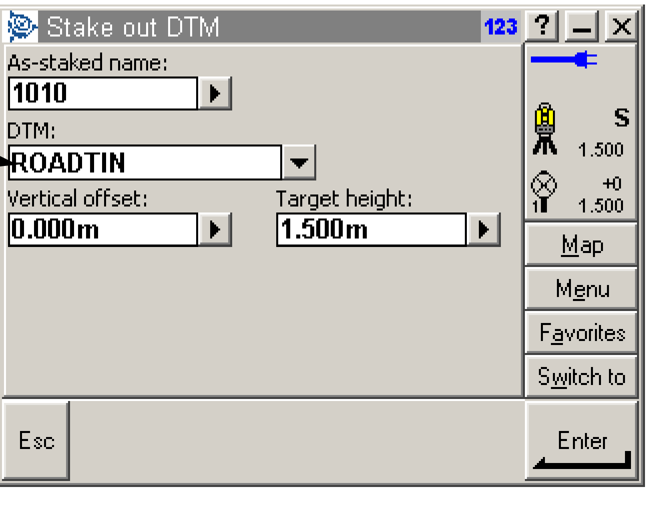
Select the tin file to upload using format ***Triangulated Terrain model***

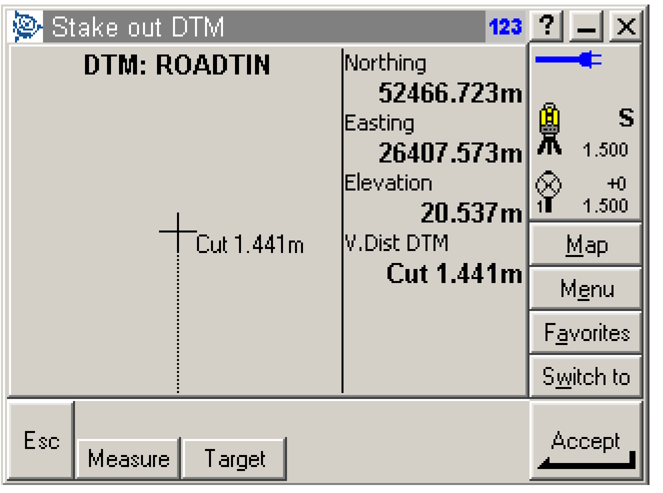


Select ***Transfer All*** to transfer the file

Once the tin has been copied into the ACU it can be called up when using the Stakeout option ***Survey=>Stakeout=>DTM***

Select the uploaded tin file to setout





The cut to the tin is calculated and displayed

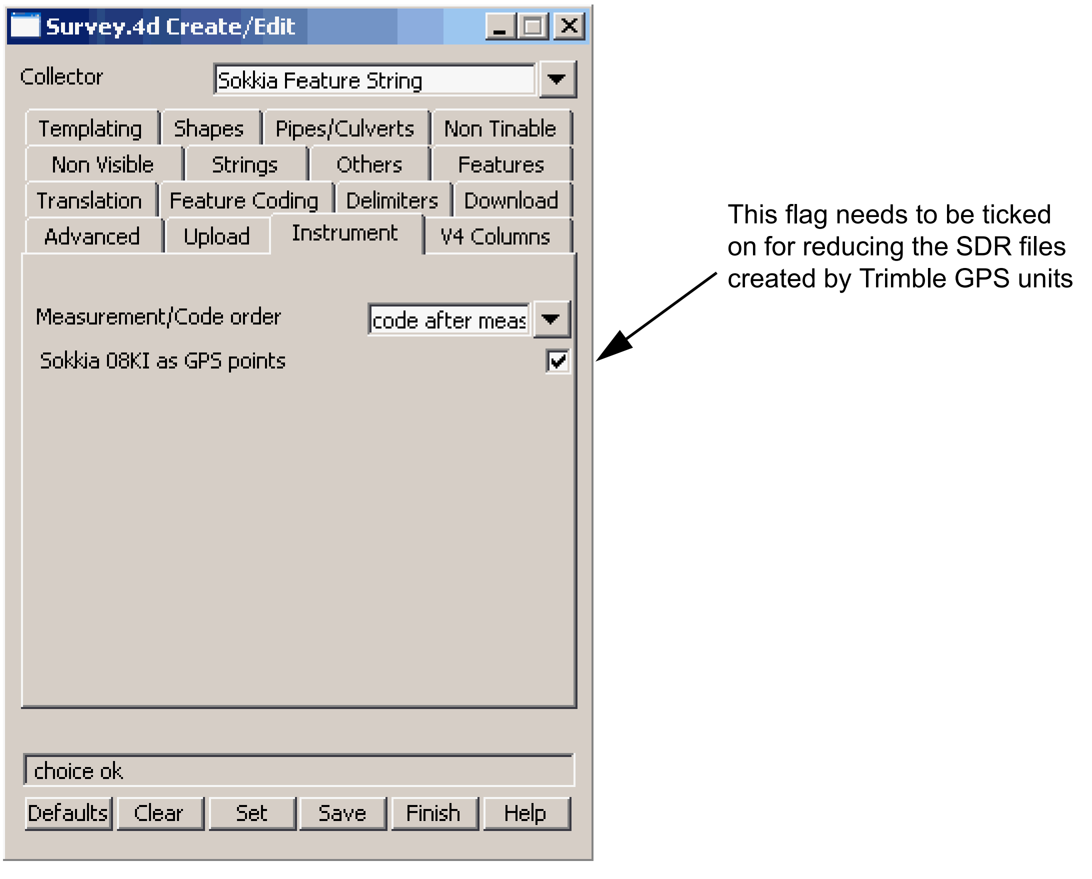
37.4 12d and Trimble GPS Controllers

The Trimble Geomatics Office software which comes with most Trimble GPS units can produce a Sokkia SDR file which is used by 12d Model as a raw data file.

However, the Trimble software writes out the (x,y,z) co-ordinates of GPS points as a "08KI" record which is normally treated by 12d Model as directly entered co-ordinates for a Station.

To overcome this problem, there is a flag in the data collector definitions to treat the Sokkia 08KI records as GPS points.

So before converting a Sokkia SDR file from a Trimble GPS unit, define a data collector which has a tick for the field *Sokkia 08KI as GPS points* on the *Instrument* tab of the **Survey.4d Create/ Edit** panel.



The code information that is entered on the Trimble in the field is appended the Sokkia 08KI record and is processed as blocks of information as given in the section 36.8 Field Coding for Non Leica Instruments and the appendix 37 12d and Survey Instruments.

37.5 12d and Geodimeter Instruments

This appendix deals with interfacing 12d with Geodimeter files.

See the sections:

37.5.1 12d UDS's

The geodimeter allows the recording of information in a format specified by the user. Data for each label can be prompted for and measurements from the instrument can be registered. The user can assign a certain series of labels to a User Defined Sequence or UDS.

For 12d to reduce files from the geodimeter instruments, the recorded information from the instrument must be in a specific format that 12d can understand. A number of Geodimeter UDS files are supplied on the ***12d Model*** Installation CD in the folder '*Other_Software\Geodimeter'.*

For uploading or direct entry of UDS's to your particular instrument see you instrument manual.

These UDS's have been set up so that 12d can convert the raw files from the instrument in a 12d field file. These UDS's should be installed ***prior*** *to undertaking surveys that are to be reduced by 12d. The standard UDS that 12d supply is as follows:*

UDS 1 - used within UDS 8 to record 12d field op codes.

UDS 2 - prompts for additional data for a 12d field op code.

UDS 5 - job administration at the start of a job

UDS 6 - station co-ordinates entry

UDS 7 - station set up - name and instrument height

UDS 8 - data pick-up

UDS 5 is run at the beginning of the job and it runs UDS 6, which runs UDS 7 which runs UDS 8.

UDS 1 can be run as required from within UDS8 to give 12d field file op codes.

UDS 1 - used within UDS 8 to record 12d field op codes

12d standard UDS's for pick-up with Geodimeter

The Geodimeter data format is used as a raw data file by 12d Model and is converted into a 12d Field File before reduction by potentially 2 different macros:

1) geodat4d.4do (default) for use with the 12d standard UDS's.

2) geodat_qmrd.4do (Specialised reduction) for use with Queensland MRD UDS's.

For the geodat4d.4do macro (default) ***12d Model*** uses the following Geodimeter labels:

0=	Information
1=	Attributes
2=	Station name or named point
3=	Instrument height
4=	Blocks
5=	Point number
6=	Target (signal) height
7=	Horizontal angle
8=	Vertical angle
9=	Slope distance
37=	Northing (X) value
38=	Easting (Y) value
39=	Height (Z) value
51=	Date
53=	Operator
90=	End of record, flush buffer
91=	***12d Model*** field file op code
92=	Parameters for the previous 12d op code
95=	

In particular, the Geodimeter PCode label block (4=) is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non Leica Instruments.

A new conversion macro for V6.0, geodat_qmrd.4do recognises geodimeter Program 22 and Program 32 commands **if the following setup/procedures are used**:

1. The geodimeter should be set to record program numbers. This is shown by the label **0=Pn** in the raw file, where **n** is the program number and is assigned by the instrument. To set this up on the instrument use MENU 6 1(Switches) and turn Prg_Num on.

2. For 12d to convert raw files using geodimeter programs such as P22 and P32 the data must contain a label **61=n** each time an UDS or onboard program is started (Where **n** is the program number). This allows 12d to be able to determine when one program is finished and another started. Queensland MRD have created there own UDS's which utilise the **61=** label so that it is prompted for within the UDS's. They have also set up a UDS (UDS 6) which is used to place the label at the commencement of an onboard program such as program 22.

Please continue to the next section 37.5.2 Using 12d Field Ops Codes on the Geodimeter.

37.5.2 Using 12d Field Ops Codes on the Geodimeter

In additional to the commands accessible from the blocks, most of the 12d field file op codes are accessible directly from the Geodimeter.

The label '91=' label is used to specify a 12d field file op code and any following '92=' labels provide any additional information required by the 12d op code.

The 12d field file ops codes apply to the measurement *before* the op code.

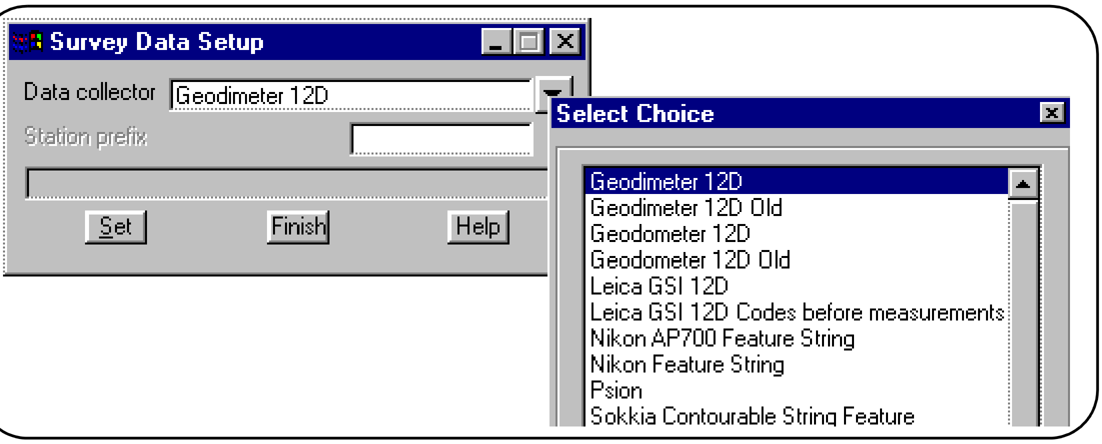
For a complete definition of the ***12d Model*** field file and the ***12d Model*** field file op codes, see the section 36.10 The 12d Field File Format

Please continue to the next section 37.5.3 Example of Geodimeter File.

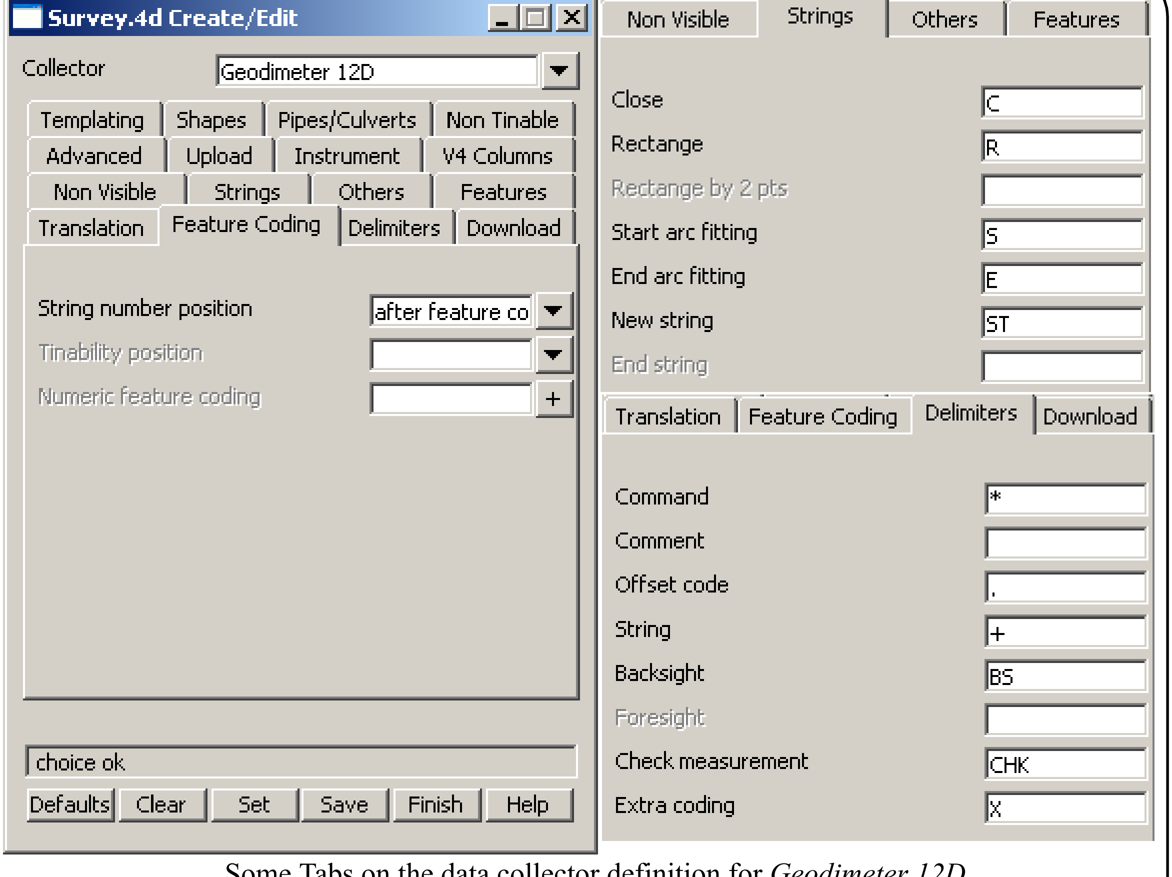
37.5.3 Example of Geodimeter File

The raw file 'Geodimeter.job' has been coded in accordance with the data collector definition *Geodimeter 12D* which is shipped with ***12d Model***. The ***12d Model*** Geodimeter UDS's were used in the field pick-up.

The data collector *Geodimeter 12D* is set using the option *Survey=>Setup*



Some of the tabs on the *Geodimeter 12D* data collection definition as show below. Note that ***** is used as the Command (Block) delimiter, the *string number* is given after the *feature code*, **S** is used to start arc fitting and **R** is the Rectangle (make a parallelogram) command.



Some Tabs on the data collector definition for *Geodimeter 12D*

The listing of the raw file is now given, followed by a dump of a ***12d Model*** view displaying the job with string names (feature codes) and point numbers toggled on. The raw file 'Geodimeter.job' is in the Survey area of the training data. It can be converted into a 12d field file by using the default conversion macro geodat4d.4do.

38 Geodetics Summary

Various options in ***12d Model*** use geodetic calculations to present and change data. These options use terminology that are common to the field of geodetics, which will be defined here.

Most of the terminology adopted follows definitions given in the Australian **GDA Technical Manual** which is published by the **Intergovernmental Committee on Surveying and Mapping** (ICSM). This publication is a valuable reference document and the reader is encouraged to obtain a copy for a full understanding of the topic. The document can be accessed on the internet at the following address http://www.icsm.gov.au/gda/tech.html

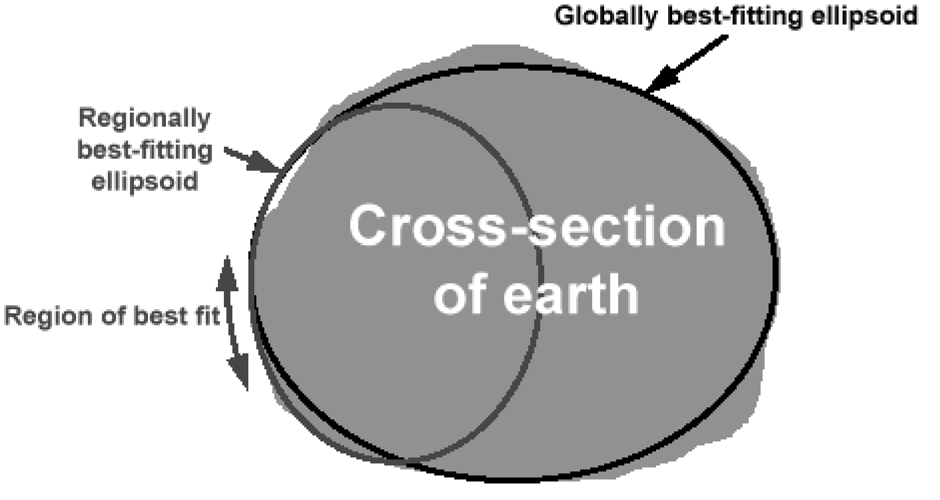
38.5 Converting Between AMG, ISG and MGA

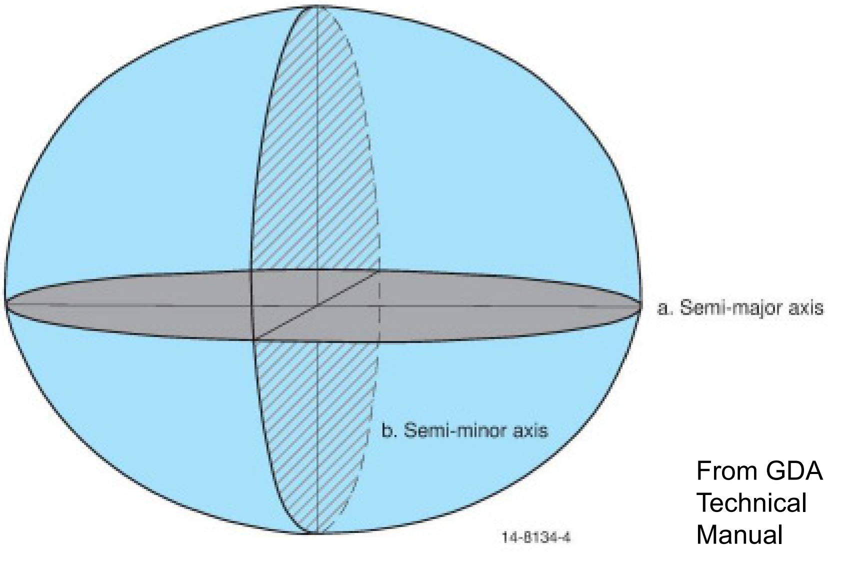
38.1 Shape Of The Earth

The determination of the Earth's shape is a science known as **Geodesy**. Today, it is widely accepted that the Earth's shape best approximates an **ellipsoid** that has been revolved around the Earth's polar axis. Put another way, the shape is a sphere that has been squashed at the north and south poles. The non-spherical shape is due to gravity.

A number of ellipsoids have been calculated to best approximate the Earth's shape at local locations and the earth as a whole. The best fit is concerned with matching the Earth's equipotential gravity field (the **Geoid** that is best approximated by Mean Sea Level), to a geometric ellipsoid shape. As such, there a wide number of definitions.



The most common way of defining an ellipsoid is by describing the **semi-major axis** value and an **inverse flattening** value (this parameter describes the "squashing" of the ellipse).



From GDA Technical Manual

Some commonly used ellipsoids are:

1. GRS80

Ellipsoid	**Semi-major axis**	**Inverse flattening**
GRS80	6,378,137.0	298.257222101

This ellipsoid is used for Australia's GDA definition (Geocentric Datum of Australia GDA 94) used for MGA (Map Grid of Australia) calculations, New Zealand's NZGD2000 datum as well as other geocentric earth model datums around the world.

2. ANS

Ellipsoid	Semi-major axis	Inverse flattening
ANS	6,378,160	298.25

This was the ellipsoid used to define the Australian Geodetic datum (AGD 84) used for AMG (Australian Map Grid) calculations and ISG (Integrated Survey Grid) co-ordinates.

3. NZ Geodetic 49

Ellipsoid	Semi-major axis	Inverse flattening
NZ Geodetic 49	6,378,399.065	297.0

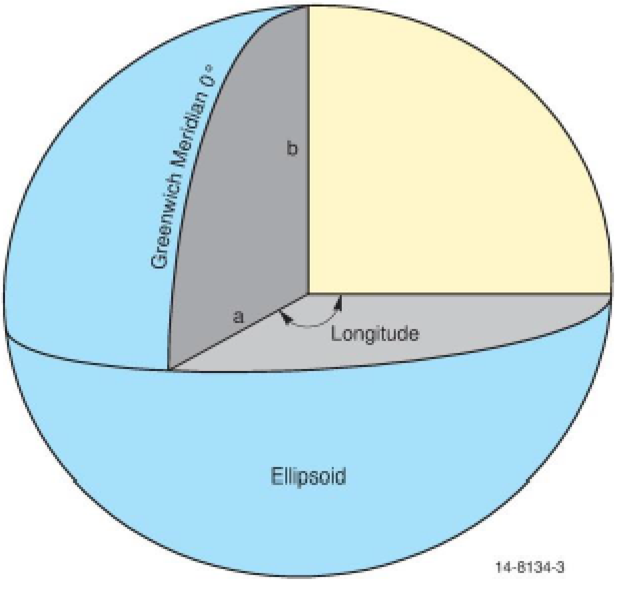
This was the ellipsoid used to define the NZ 1949 Geodetic datum. The semi-major axis given here has been adjusted to compensate for errors in units conversion from links to meters.

Continue to the next section 38.2 Geodetic Coordinates or return to 38 Geodetics Summary.

38.2 Geodetic Coordinates

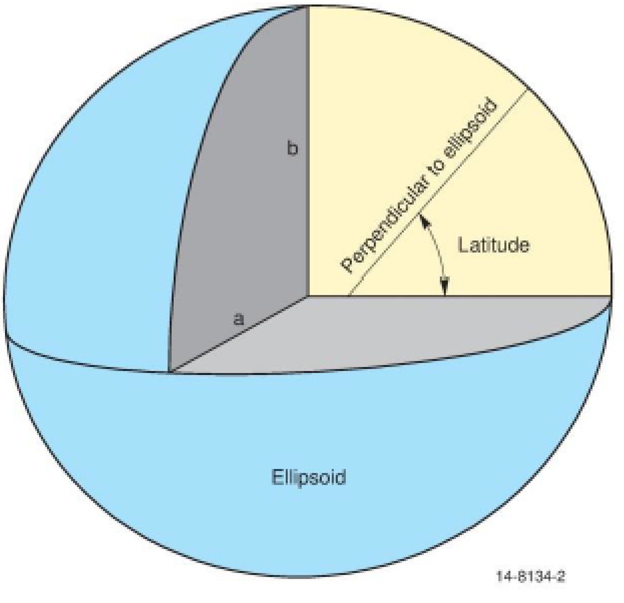
Once an ellipsoid or **Geodetic Datum** is defined, a position on the earths surface can be described in terms of Geodetic coordinates. These coordinates are **Longitude**, **Latitude** and **Ellipsoid height**.

Longitude is a angular quantity measured from the Greenwich meridian. It is most commonly described in terms of degrees, minutes, seconds East or west of the Greenwich meridian.



From GDA Technical Manual

Latitude is a angular quantity measured from the equatorial plane, to the plane defined by the point position and the plumb line to the ellipsoid surface. It is most commonly described in terms of degrees, minutes, seconds South or North to the equator.

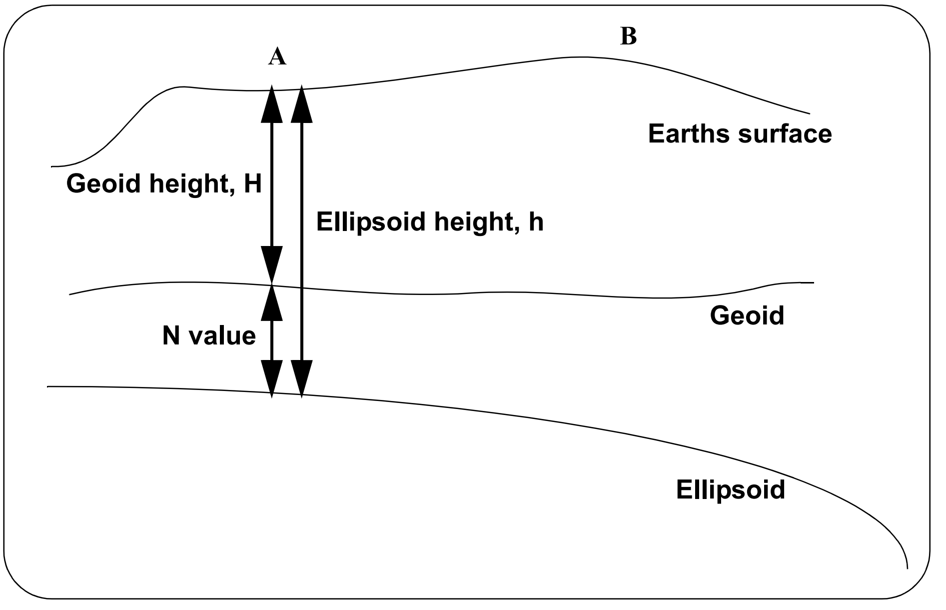


From GDA Technical Manual

The ***ellipsoid height***, h is the height above the reference ellipsoid.

Most height datums are not based on ellipsoid height but are based on the ***geoid***.e.g. **AHD** in Australia.

As such, levels from GPS observations (which are *ellipsoid* heights) need to be corrected to a **geoidal** or **orthometric height**. To do this, we require the separation or gap distance between the two different surfaces. This separation is known as the **N value**.



The **Ellipsoid height** = **Geoid height** + **N** value

or

$$h = H + N$$

N values can be defined in a geoidal model such as **Ausgeoid98** which represents grids of **N** values over all of Australia.

For a given Geodetic coordinate, an N value can be interpolated from the model and applied to the ellipsoid height to give a geoidal height. Similarly, the N value can be used to convert a geoidal height to an ellipsoid height.

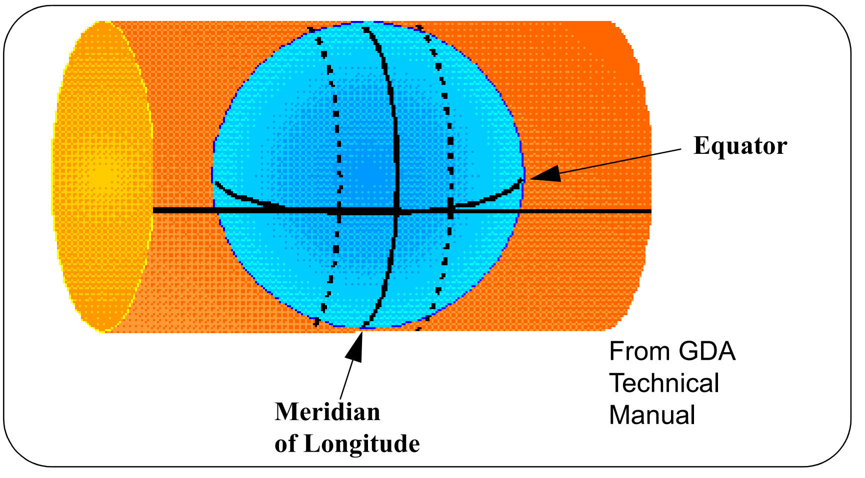
Since most geodetic calculations are made on the ellipsoid, the ***ellipsoid height*** is required for precise calculations.

Continue to the next section 38.3 Map (Cartographic) Projections or return to 38 Geodetics Summary.

38.3 Map (Cartographic) Projections

In order to represent ellipsoid data on a flat surface for mapping, it is necessary to use a projection. A projection enables points on the earths surface to be mathematically projected onto an imaginary developable surface. This surface can then be developed or “rolled flat”. Typically, this surface is a cylinder or cone.

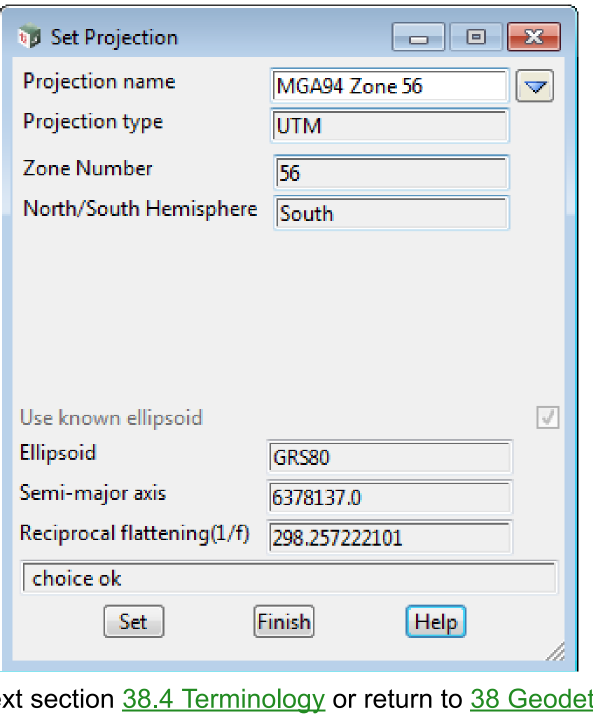
The Transverse Mercator system (TM) projects coordinates onto a cylinder that is tangent to the equator and the entire length of a meridian of Longitude.



12d Model allows a number of projections to be specified including, Universal Transverse Mercator (UTM), Transverse Mercator (TM) and Rectified Skew Orthomorphic (RSO). There are many more available using the **General** type.

Within 12d Model, a projection can be defined that specifies both the ***reference ellipsoid*** and ***projection type***. This then can be used for geodetic calculations.

A projection has various parameters that define it. These are specific to the projection and are clearly defined for major mapping systems. For example MGA94 zone 56 projection is defined as follows:



Continue to the next section 38.4 Terminology or return to 38 Geodetics Summary.

38.4 Terminology

The various geodetic options in 12d Model mostly use standard geodetic terminology as defined in the Australian GDA technical manual. For clarity, they will be defined again here. For some options it is important to note that some terminology used in Australia has quite a differing meaning in other countries.

See

38.4.1 Ellipsoid Distance

The ***ellipsoid distance*** is the reduced distance along the *surface* of the ellipsoid. Standard survey measurements are reduced to the horizontal but require a correction due to the height above the ellipsoid. This is usually done by a **height scale factor** which takes into account the ellipsoid height at each end of the measured line. i.e.

$$HeightScaleFactor = 1 - \frac{h_M}{R + h_M}$$

Where:

$\mathbf{h_M}$ = Mean terrain height (mean of the two ellipsoid heights at either end of the measured line)

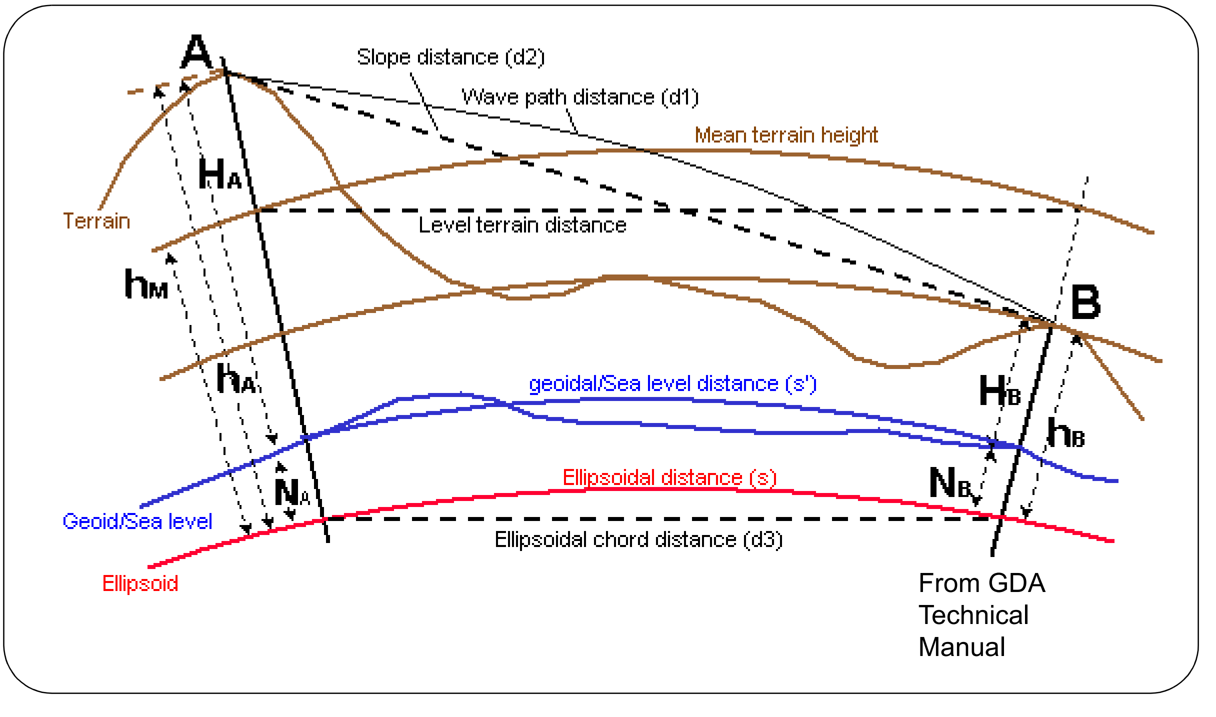
R = Radius of the earth in the azimuth of the line.

Note: An error of 60 meters in the value of $\mathbf{h_M}$ will introduce an error of 10 ppm in the reduced ellipsoid distance. With the introduction of the Australian Geocentric datums, the N values have increased markedly over Australia. So even if a survey is undertaken at sea level (Geoid height approximately 0.0), the ellipsoid heights may very well be greater than 60 meters. As The Ellipsoid height = Geoid height + N value, N values should be considered when reducing measured distances to these datums.

For older Australian ellipsoids, Mean seal level approximated the surface of the ellipsoid (i.e. N value approximately 0.0), so corrections could use geoidal heights to bring the distances down onto the reference surface.

The ellipsoid distance can be calculated using the calculated height factor:

Ellipsoid Distance = Reduced Horizontal Distance x height scale factor.



Continue to the next section 38.4.2 Bearings and Distances - Plane and Grid or return to 38.4 Terminology or 38 Geodetics Summary.

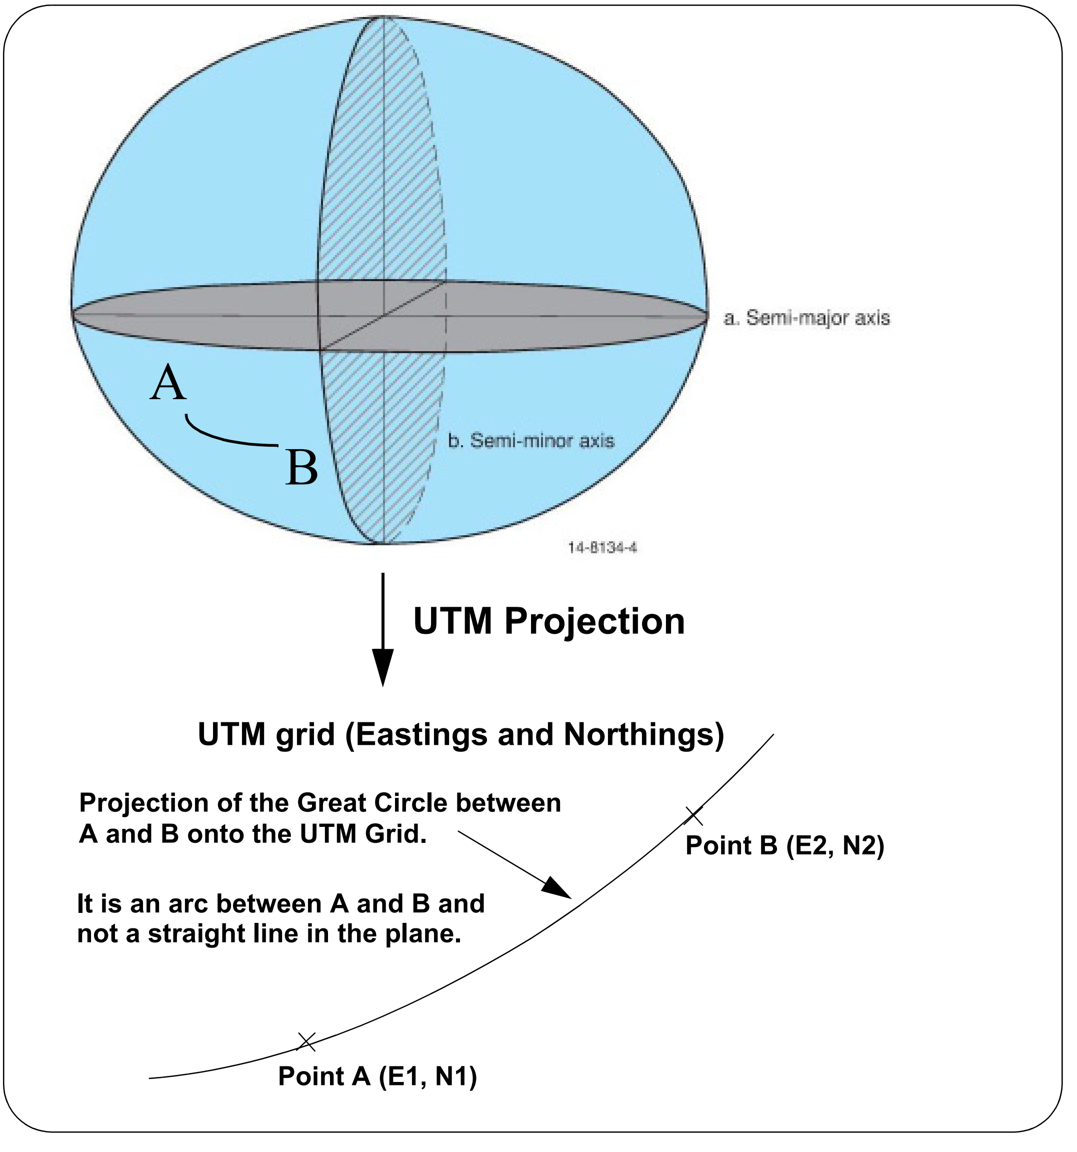
38.4.2 Bearings and Distances - Plane and Grid

If you have a point on an ellipsoid and a Transverse Mercator projection (such as UTM), the projection co-ordinates are known as the grid co-ordinates of the point (Easting and Northing).

On an *ellipsoid*, the ***straight line*** joining two points is the ***Great circle*** between the two points. If each point along the Great circle is projected onto the grid, the path that is traced out is an *arc* between the points.

That is, the *straight lines* on an ellipsoid project onto the TM grid as arcs.

In the diagram below, the Great circle arc through points A and B on the ellipse projects onto the arc shown through Points A and B in grid co-ordinates.



So the *straight line* joining the two points in the **plane** *is different* from the projection of the great circle (straight line on the ellipse) joining the two points on the ellipse.

Continue to the next section 38.4.3 Plane Bearing, Projection Bearing or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.3 Plane Bearing, Projection Bearing

If a straight line is drawn in the plane between two points on a grid, the angle between grid north and this line in equal to the ***plane bearing***.

In other words, if the two point's coordinates are known, standard plane trigonometry can be used to calculate the bearing of the line.

tan (plane bearing) = (E2 - E1) / (N2 - N1)

Projection bearing and *plane* bearing is used interchangeably in ***12d Model***.

Continue to the next section 38.4.4 Australian Grid Bearing, Ellipsoid Bearing or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.4 Australian Grid Bearing, Ellipsoid Bearing

In Australia, the ***grid bearing*** is the angle between grid north and the *tangent* to arc at a point on the arc. e.g Point A. The grid bearing at point A is **not** equal to the reverse grid bearing from point B.

This term is also known as the **ellipsoid bearing** in some countries.

Warning: In some countries, including New Zealand and the US, the term **Grid bearing** is used for the previously defined term **Plane bearing**. However, as defined in the Australian GDA technical manual, the definition of Grid bearing is different to that of a plane bearing.

To avoid confusion, we will use the term ***ellipsoid bearing***.

Continue to the next section 38.4.5 Plane Distance or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.5 Plane Distance

The ***plane distance*** is the length in the plane of the straight line joining two points on a grid - that is, the standard distance between two points in a plane

plane distance = square root [(E2 - E1)*(E2 - E1) + (N2 - N1)*(N2 - N1)]

Continue to the next section 38.4.6 Australian Grid Distance or return to 38.4 Terminology or 38 Geodetics Summary.

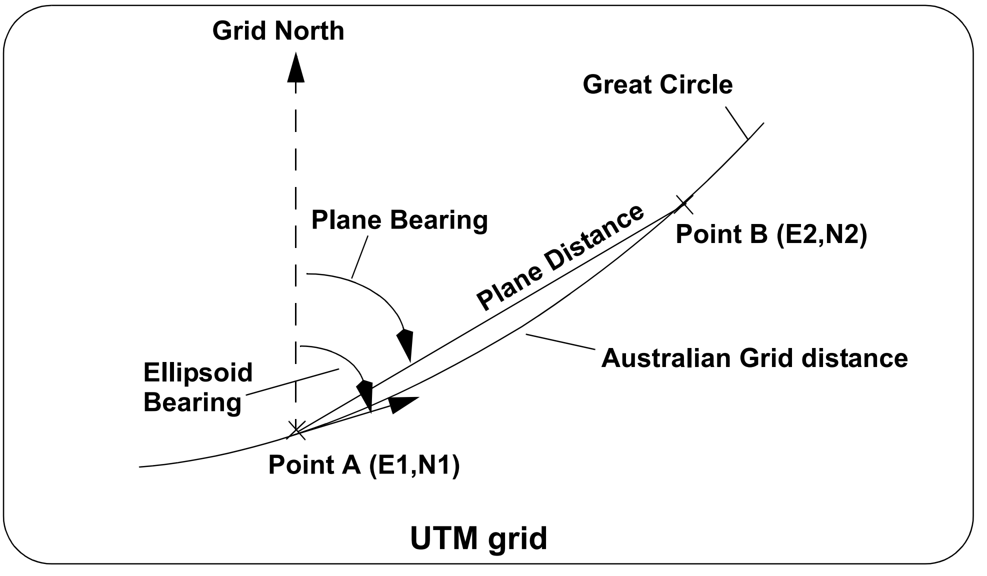
38.4.6 Australian Grid Distance

On an ellipsoid, the *straight line* joining two points on the ellipsoid is the Great circle between the two points. The *straight lines* on an ellipsoid project onto the UTM grid as arcs. In the diagram below, the arc shown through points A and B is the projection of the Great circle arc through points A and B on the ellipse.

In Australia, the ***grid distance*** is the distance on this *arc* from point A to B.

The difference between the plane distance and the grid distance is usually negligible.

Warning: In some countries, the term *grid distance* is used for the definition of plane distance here.



Continue to the next section 38.4.7 Datum or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.7 Datum

Within the Geodetic sections of 12d Model, the term ***datum*** relates to the reference ellipsoid adopted by countries/organisations for mapping projects.

For example AGD is the Australian Geodetic Datum, using the ANS ellipsoid parameters. GDA refers to the Geodetic Datum of australia, using the GRS80 ellipsoid as the basis for defining geodetic coordinates.

In New Zealand, the NZGD49 datum refers to the NZ Geodetic 49 ellipsoid. The NZGD2000 datum is the New Zealand geodetic datum which again refers to the GRS80 ellipsoid.

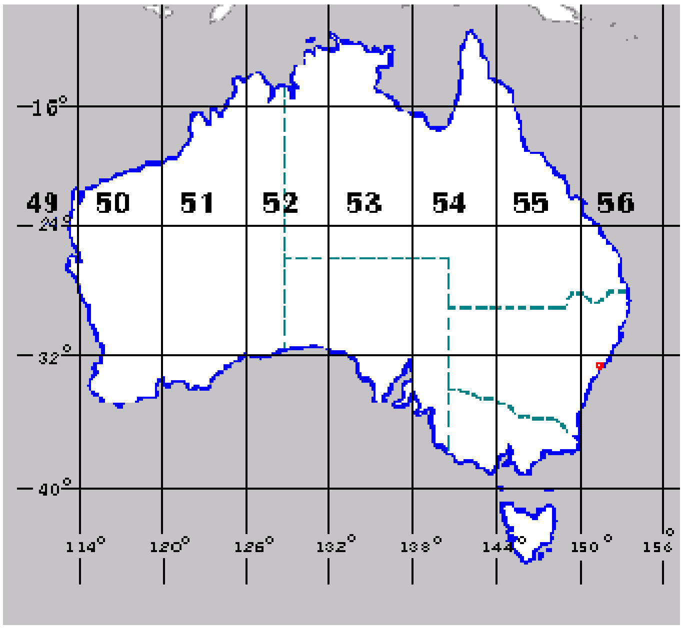
Continue to the next section 38.4.8 Zone or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.8 Zone

The meaning of ***zone*** is specific to the UTM projection type which is commonly used around the world as a mapping projection. This includes AMG and MGA in Australia.

The Universal Transverse Mercator projection splits the world into 60 zones of 6 degrees of longitude. The zone numbering starts at 180 degrees West, longitude. Each zone has a specific central meridian and range of longitude that defines it. As such, by supplying a zone number, a number of parameters about a projection can be deduced.

For example, Australia is covered by the UTM zones 49 to 56.



Continue to the next section 38.4.9 Arc-to-Chord Correction (t-T correction) or return to 38.4 Terminology or 38 Geodetics Summary.

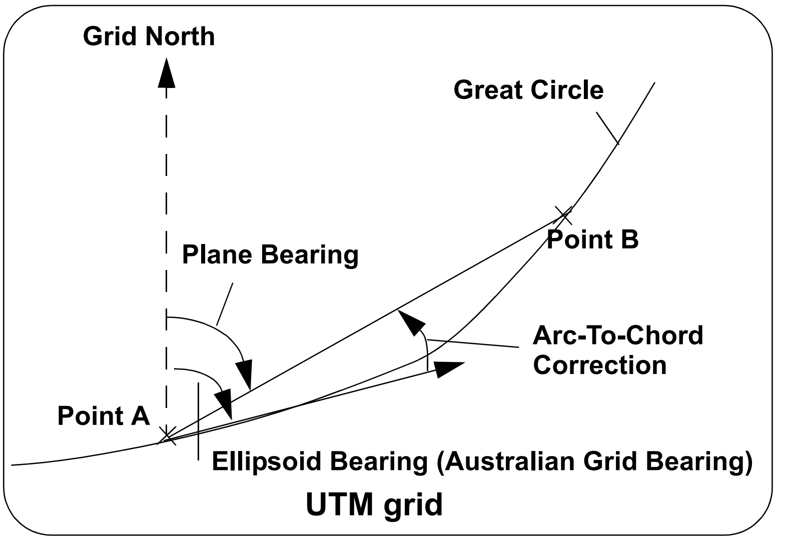
38.4.9 Arc-to-Chord Correction (t-T correction)

The ***arc-to-chord*** correction is the quantity to be added algebraically to a ellipsoid bearing (Australian grid bearing) to obtain a plane bearing.

Plane Bearing = Ellipsoid Bearing + Arc-To-Chord Correction

Plane Bearing = Australian Grid Bearing + Arc-To-Chord Correction

This correction is only really applicable for lines over 10 km but it is included in calculations for completeness. The correction shown in the example below is negative in sign but it can also be positive.



Continue to the next section 38.4.10 Point Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.10 Point Scale Factor

The ***point scale factor*** is the ratio of an infinitesimal plan distance at a point on a grid to a corresponding ellipsoid distance.

It can be used as an approximation to convert (factor) measured ellipsoid distances to plane distances.

Continue to the next section 38.4.11 Line Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.11 Line Scale Factor

The ***line scale factor*** is the ratio of the plane distance on a grid to a corresponding ellipsoid distance. i.e.

$$LineScaleFactor = \frac{PlanDist}{EllipsoidDist}$$

This factor can be used to calculate either the plane or ellipsoid distance given the Line Scale Factor and the other distance. i.e.

Plane distance = Ellipsoid distance x Line scale factor,

Similarly,

Ellipsoid distance = Plane distance / Line scale factor.

Continue to the next section 38.4.12 Combined Point Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.12 Combined Point Scale Factor

The ***combined point scale factor*** is the product of the point scale factor and the height scale factor. i.e.

Combined Scale Factor = Point Scale Factor x Height Scale Factor.

Continue to the next section 38.4.13 Azimuth and Convergence or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.13 Azimuth and Convergence

Azimuth is the horizontal angle measured from an *ellipsoidal meridian clockwise from north* and the great circle between measured points.

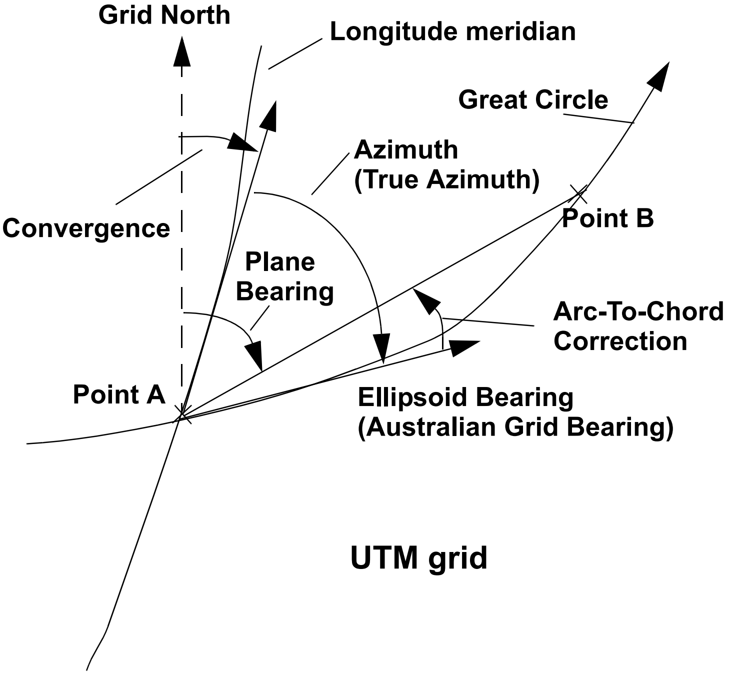
It is also known as the ***True Azimuth***. In general, this value will be calculated internally in 12d Model.

Convergence or ***Grid Convergence*** is the angular quantity to be added algebraically to an *Azimuth* to obtain an ellipsoid bearing (Australian grid bearing). i.e.

Ellipsoid Bearing = Azimuth + Grid Convergence

Australian Grid Bearing = Azimuth + Grid Convergence

Warning: In some countries, the *Grid Convergence* has the opposite sign.



Combining

Ellipsoid Bearing = Azimuth + Grid Convergence

Australian Grid Bearing = Azimuth + Grid Convergence

and

Plane Bearing = Ellipsoid Bearing + Arc-To-Chord Correction

Plane Bearing = Australian Grid Bearing + Arc-To-Chord Correction

produces the equation

Plane Bearing = Azimuth + Grid Convergence + Arc-To-Chord Correction

or

Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction

True Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction

Warning: In some countries, the *Grid Convergence* has the opposite sign.

Please continue to the next section 38.5 Converting Between AMG, ISG and MGA or return to 38.4 Terminology or 38 Geodetics Summary.

38.5 Converting Between AMG, ISG and MGA

In Australia the ellipsoid used to represent the shape of the earth used to be defined by AGD 84 but it has now has been changed to an ellipsoid that has its centre at the centre of mass of the earth (geocentric - GDA 94). See 38.1 Shape Of The Earth.

This is to fit in with GPS because satellites orbits are centred on the centre of mass.

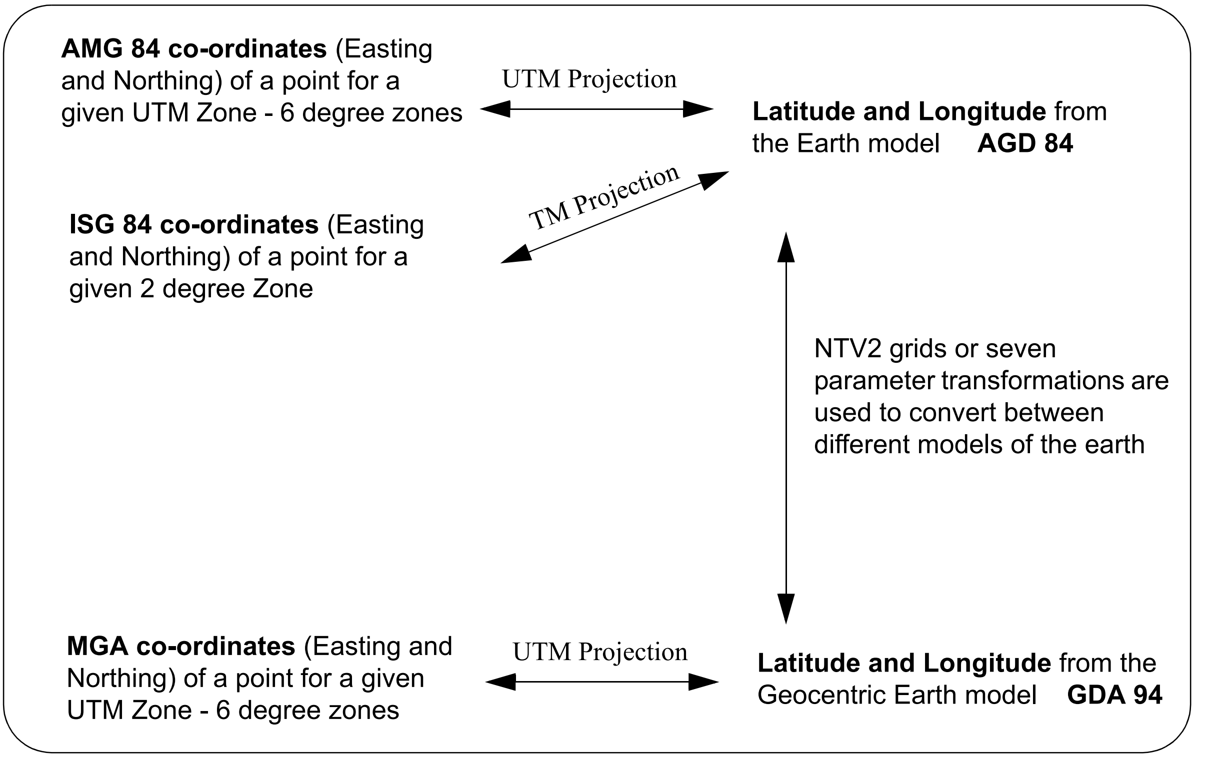
This means that the Latitude and Longitude of every point has changed.

The use of UTM projections (Universal Transverse Mercator - see 38.3 Map (Cartographic) Projections) and Zones still apply but because the latitude and longitude of each point has change, its Easting and Northing for a UTM zone has also changed.

AMG 84 Zones are the co-ordinates for the UTM Projections defined for six degree zones using the ellipsoid defined by AGD 84.

MGA 94 Zones are the co-ordinates for the UTM Projections defined for six degree zones using ellipsoid define by GDA 94.

Note - ISG 84 Zones are the co-ordinates for the TM Projections defined for two degree zones using the ellipsoid defined by AGD 84.



For converting between the ***different datums*** AGD66/84 and GDA94 (i.e. AMG, ISG, Long Lat <-> MGA, Long Lat), use the option

Survey =>Conversions =>AGD66/84 <-> GDA94 (see 17.10.4 AGD66/84 <---> GDA94

For converting between different AMG Zones (AMG <->AMG) or different MGA Zones (MGA<->MGA) use the option

Survey =>Conversions =>Australian conversions. See 17.10.1 Australian Conversions.

For converting between different ISG/AMG Zones (AMG,ISG <->AMG, ISG)

Survey =>Conversions =>Cartographic. See 17.10.2 Cartographic.

Return to38 Geodetics Summary.

39 Setting Up & Configuring 12d

This appendix contains information about files used for setting up and configuring ***12d Model***.

See

39.1 Folder Structure Installed by 12d Model

12d Model has Set Up files to define how new projects are created, define colours, linestyles, symbols etc. and control many other aspects of ***12d Model***.

12d Model comes with defaults for these things but most users wish to customise many of the settings, share them between groups of users across a network etc.

To make customisation easier, all the ***12d Model*** customisation files (called Set Up files) have default names and on installation, are stored in a folder called ***Set_ups***.

To customise ***12d Model***, users only need to which file to modify for that particular customisation.

When *12d Model 11* is installed on a *Windows* computer, the major components are installed in the Microsoft preferred installation folder **Program Files,** in the sub folders **12d\12dmodel\11.00.**

That is, the software and associated files are installed in **Program Files\12d\12dmodel\11.00**

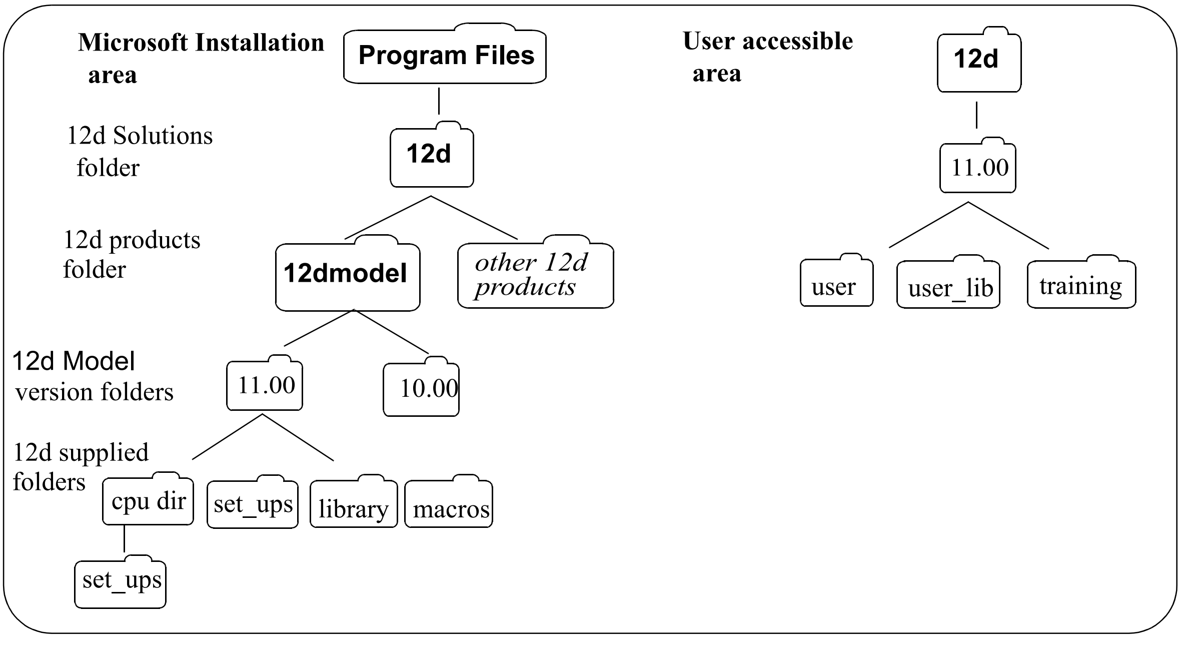
However, without *Administrator* privilege, users do no have write access to **Program Files.**

To allow non-administrator users access to Set Up areas that users can store modified files, *12d Model 11* also installs extra folders in an area that could be accessed by the user. The default folder structure for this area is **C:\12d\11.00**

So the customisation system allows the use of both the areas
Program Files\12d\12dmodel\11.00

and

C:\12d\11.00 for storing Set Up and other files necessary for the tailoring and running of ***12d Model***.



Please continue to the next section 39.2 Files for Setting Up 12d.

39.2 Files for Setting Up 12d

When ***12d Model*** fires up, it looks for special files (called ***Setting Up*** or ***Setup*** files) to define many of its features. Hence the *Setup* files can be used to customize ***12d Model*** for a site, a client or even a user.

When ***12d Model*** creates a new project, or changes to another project, then for each Setting Up file

EITHER

(a) an environment variable for the Setup file exists, and the value of the environment variable is taken as the full path name of the file to be used as that Setup file.

OR if the environment variable does not exist for the Setup file

(b) a file with the default Setup file name is searches for in specially named folders, in a fully defined order.

The search for ***each Setup file*** is independent of any other Setup file. That is, for each Setup file, the folders are searched in the specific order until that file is first found and the searching stops for that Setup file. and then the search is begun again for the next Setting Up file.

Consequently the Setup files do not all have to be in the same folder. This greatly increases the tailorability of ***12d Model***.

The description, default name and any environment variable for each Setup file are given in the sections 39.2.1 Setup Files Only Used for a New Project, 39.2.2 Setup Files Only Used for an Existing Project and 39.2.3 Setup Files Used for New and Existing Projects.

The folders searched for Setup files, and the folder search order, is described in the section 39.2.4 Folders Searched for Setup Files.

See

39.2.1 Setup Files Only Used for a New Project

The two Setup files, **setups.4d** and **defaults.4d**, are only used when creating a **NEW *12d Model*** project, and after the project is created, the information supplied in these two Setup files is ***stored within the 12d Model project*** and is then modified from within ***12d Model*** when in that project.

Similarly the file **macros.4d** is a file of macros or chains (one per line) that are only run when a **new** project is created (**project_macros.4d** is a run when an **existing** project is opened).

defaults.4d

define the defaults for a **new** project.

Modified by the **Defaults** panel from the **Projects =>Management =>Defaults** option.

Once a project is created, the defaults can be modified inside 12d Model.
The defaults are then saved with the project.

The environment variable is DEFAULTS_4D.

For more information go to the section 39.2.7.3 Defaults File (defaults.4d)

setups.4d

define the layout of views on the screen for a **new** project.

Once a project is created, the view layout can be modified inside ***12d Model***.

The view layout is then saved with the project.

The environment variable is SETUPS_FILE_4D.

For more information go to the section 39.2.7.1 Set Ups File (setups.4d)

macros.4d

a file of macros and/or chains (one per line) that are run when a **new** project is created (see 5.9 Running Macros and Chains on Start Up).

The environment variable is RUN_MACROS_FILE_4D.

39.2.2 Setup Files Only Used for an Existing Project

The file **project_macros.4d** is a file of macros or chains (one per line) that are only run when an **existing** project is opened. So project_macros.4d is modified between accesses to the project then the modified version of the file is used for the project.

project_macros.4d

a file of macros (one per line) that are run when an **existing** project is opened (see 5.9 Running Macros and Chains on Start Up).

The environment variable is RUN_PROJECT_MACROS_FILE_4D.

39.2.3 Setup Files Used for New and Existing Projects

The other *Setting Up* files are searched for ***each time a project is created or opened***. So if these files are modified between accesses to the project then the modified versions of the files are used for the project.

Some of the Setup files that ***12d Model*** searches for each time a project is opened are:

colours.4d // sets the colour names and red, green, blue mix; also defines the default pens that the colours map to (as displayed in the panel **colours to pens**). See 39.2.7.2 Colours File (colours.4d).

The environment variable is COLOURS_4D.

digitize.4d // list and defines the digitizers available in 12d Model. See 8.5.7 Digitizer Definitions File.

The environment variable is DIGITIZERS_4D.

env.4d // contains values for environment variables See 39.4 Environment Variables.

The environment variable is ENVIRONMENT_4D.

fonts.4d // defines the fonts used in text styles. See 40.3 Textstyles and Fonts.

The environment variable is FONTS_4D.

gui.4d // define the fonts and colours used in panels and menus, spacing between items in panels and menus and the maximum pop-up length. See 39.2.7.6 GUI.

The environment variable is GUI_4D.

layout.4d // a file containing the screen layout file information (slx/slf) for placing menus or panels on the screen. The layout file is used every time a project is opened. The layout file can have most menus and panels in it. See 42.2.3 Screen Layout File in the appendix 42 Special File Formats.

The environment variable is LAYOUT_FILE_4D.

linestyl.4d // defines the line styles (linestyles, worldstyles, groupstyles and twoptstyles). See 40.1 Line Styles.

The environment variable is LINESTYLES_4D.

names.4d // a special name mapping file which is used to define for given string names, information such as colours, model etc. This is used in some panels to fill out other panels fields after entering the string names in the panel.

The environment variable is NAME_MAPPINGS_4D.

plotters.4d // defines the plotters that appear in the pop-up for the plotter type panel field. See 43.2 Defining Plotters - Plotters.4d.

The environment variable is PLOTTERS_4D.

pmf.4d // plotter mapping file for defining mapping of 12d Model colours to pens with thicknesses, and the rgb for the pens See 43.3.2.1 Definition of a Plotter Mapping File

The environment variable is PLOTTER_MAPPING_4D.

sheets.4d // gives sheet sizes and names used in the pop-up for the sheet size panel field. See 39.2.7.4 Sheet Sizes File (sheets.4d)

The environment variable is SHEET_SIZES_4D.

survey.4d // lists and defines the data collectors available in 12d Model See 7.9.3 Survey Data Collectors

The environment variable is DATA_COLLECTORS_4D.

symbols.4d // defines the symbols. See 40.2 Symbols

The environment variable is SYMBOLS_4D.

textstyl.4d // defines the text styles. See 40.3 Textstyles and Fonts.

The environment variable is TEXTSTYLES_4D.

textstyle_names.4d // defines the textstyle favourites

The environment variable is TEXTSTYLE_MAPPINGS_4D.

toolbars.4d // defines the toolbars See 41.3 User Defined Toolbars

The environment variable is TOOLBARS_4D.

userkeys.4d // defines the action of function keys. See 41.1 User Defined Function Keys

The environment variable is FUNCTION_KEYS_4D.

usermenu.4d // defines the user defined walk-right menus for User on 12d Model menus. See 41.2 User Defined Menus.

The environment variable is USER_OPTIONS_4D.

xtramenu.4d // defines the 12d Solutions defined walk-right menus for User on 12d Model menus. See 41.2 User Defined Menus.

The environment variable is EXTRA_OPTIONS_4D.

The folders searched for Setting Up files, and the folder search order, is described in the next section 39.2.4 Folders Searched for Setup Files.

39.2.4 Folders Searched for Setup Files

When ***12d Model 11*** is installed on a *Windows* computer the major components installed by ***12d Solutions*** are under the Microsoft preferred installation folder **Program Files,** in the sub folders **12d\12dmodel\11.00.** That is **Program Files\12d\12dmodel\11.00.**

Without Administrator privilege, users do no have access to this area.

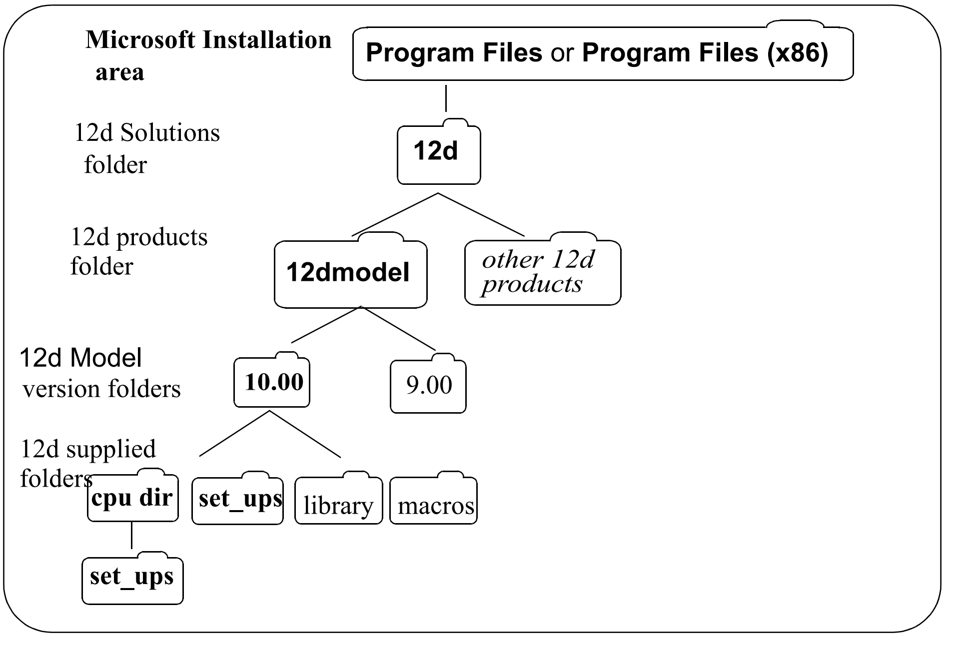
Note: these are the folders used for 32-bit ***12d Model*** on a 32-bit Windows and 64-bit ***12d Model*** on a 64-bit Windows. For a 32-bit ***12d Model*** on a 64-bit Windows, the software is installed in **Program Files (X86)\12d\12dmodel\11.00**

Other information that can be accessed and modified by the user, will be installed in the sub folders **C:\12d\11.00** in an area that the user has access to.

The structure of the folders containing Setting Ups files are **Set_ups** and **User**. How the various folders are searched for Set Up files will be described in the following sections.

set_ups

The ***12d Model*** installation creates a number of specific folders such as the operating system-cpu specific folder (for example **nt.x86** for 32-bit ***12d Model*** on Intel chips and **nt.x64** for 64-bit ***12d Model*** on Intel chips), and areas for ***set up files:*** namely an o/s-cpu specific **set_ups** under the o/s-specific folder and a **set_ups** under **Program files\12d\12dmodel\11.00** (or **Program files (X86)\12d\12dmodel\11.00** for 32-bit ***12d Model*** on 64-bit Windows).



It is also possible to move the set_ups folder **Program files\12d\12dmodel\11.00\set_ups** to another location, and even give it another name, by defining an environment variable SET_UPS_4D which gives the path of the moved folder

SET_UPS_4D folder // 12d supplied folder of Setting Up files

User and Customer_User

Users usually want to customise ***12d Model*** by modify one or more of the Setup files but most users do not have written access to the ***Program Files*** folder, and **Program files\12d\12dmodel\11.00\set_ups**. Also, any files in the **set_ups** folders may be overwritten by future *12d Model* installations.

To overcome these two problem, there are two special folders (reserved for customers) that are searched ***before*** **set_ups** for any Setting Up files.

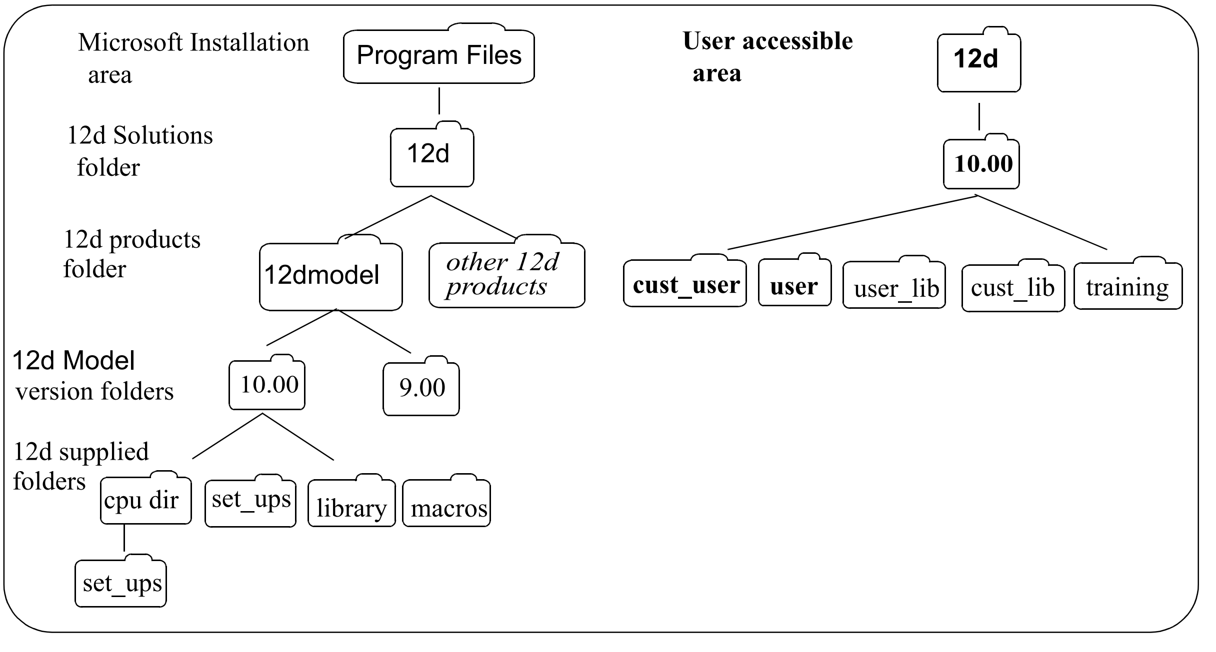
One folder is only looked for when it has been created by a user and is pointed to by the environment variable CUSTOMER_USER_4D. It has no default name but is whatever name has been set up for it. We will call it as **cust_user.**

The other folder has the default name **user**.

The folders **cust_user** and **user** should ***NOT*** be under ***Program Files*** but in **12d\11.0** which the ***12d Model*** installer usually creates in a folder that the ***12d Model*** user has read/write access to. The default folder to contain **user** and **cust_user** is **C:\12d\11.0**

During the ***12d Model*** installation, if **user** does not exist, an empty **user** folder is created.

The folder **cust_user** is not created and if required, must be created by the user and the environment variable CUSTOMER_USER_4D set up to point to it.



To find a Setting Up file, the folder **cust_user** will be searched for before **user**, and **user** is searched for before **set_Ups**.

Consequently any modified Setting Up files should be placed in **cust_user** or **user** and then they will be found before the file of the same name in **set_ups** (**user** may contain o/s-cpu specific folders).

When a new ***12d Model*** version is issued (*e.g.* 11), the contents of **cust_user** and **user** from the previous version of ***12d Model*** (*e.g.* V10) need to be copied over to the new **cust_user** and **user** area. This is **NOT** done automatically during the installation in case there are files that need to be modified for the newer version.

There is also an ***environment variable*** USER_4D which can be set to point to another user defined folder which will be searched for Setting Up files ***before*** the default **user** is searched.

USER_4D folder // users own folder for Setting Up info

This is a common method for having all users on a network share the same Setup files. The common files are placed on a disk drive accessible by all the users and the environment variable USER_4D defined to point to that folder.

Note - both **user** and the folder pointed to by USER_4D can exist.

Current and Home

The folder that a project is in (the **current** folder) and the users **home** folder are also searched for Setup files.

39.2.5 Searching Order for Setup Files

When ***12d Model*** creates a new project, or changes to another project, it searches folders for the Setup files in a well defined order.

Each Setup file has a default name, and unless there is an environment variable for that specific Setup file defining its exact name and path, folders are searched in a specific order until the file is found. The search is begun afresh for each Setup file so different Setup files may come from different folders.

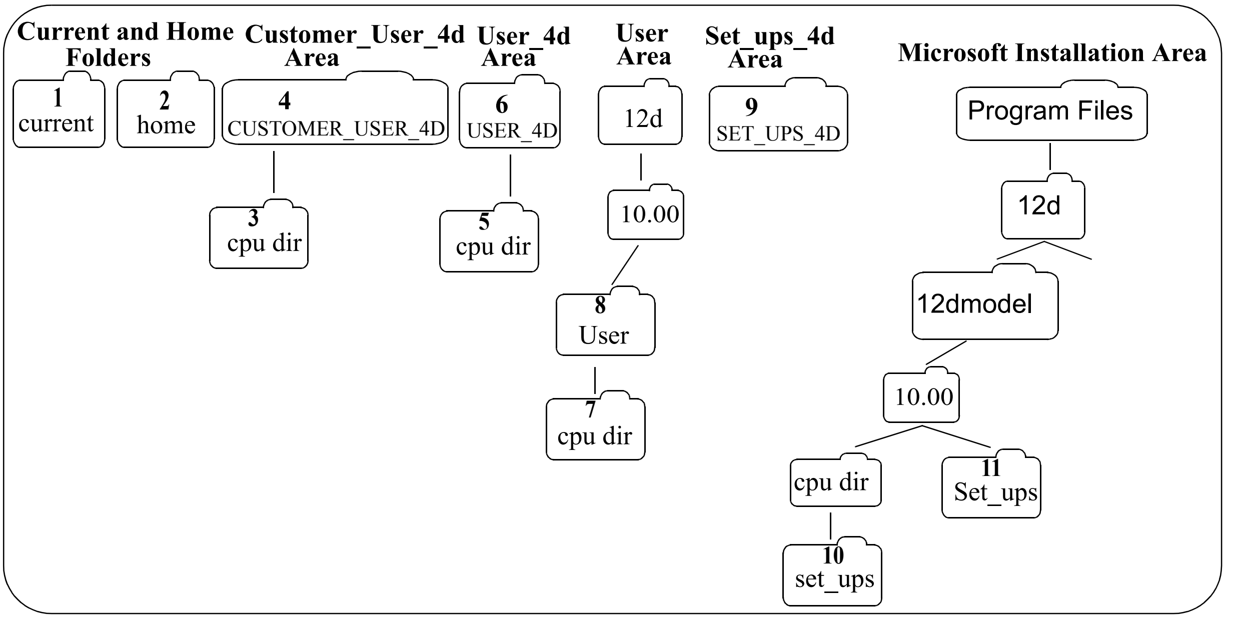
The fixed search order for any Setup files is

1. check for the appropriate environment variable defining the full path to the ***specific*** Setup file.

If the environment variable is not defined, or the file pointed to does not exist, then the folders are searched for in the following order for the specific Setting Up file with its default name (e.g. colours.4d)

2. the projects current folder
3. the users home folder
4. specific cpu folder in CUSTOMER_USER_4D
5. file folder defined by CUSTOMER_USER_4D
6. specific cpu folder in USER_4D e.g. nt.x86 for Intel
7. file folder defined by USER_4D
8. specific cpu folder in **User** under **C:\12d\11.00**
9. **User** under **C:\12d\11.00**
10. the folder defined by SET_UPS_4D
11. **set_ups** folder under the specific cpu folder under **Program Files\12d\12dmodel\11.0**
12. **set_ups** folder under **Program Files\12d\12dmodel\11.00**

Once the appropriate Setup file is found, the search is terminated and that, and only that file, is used.



Notes

(a) When an **existing** project is opened by *12d Model*, the Setting Up files ***setups.4d***,

defaults.4d and ***macros.4d*** are ***not*** used. These files are only used for defining a NEW project.

(b) **project_macros.4d** is only used when opening an EXISTING project and not a new project.

(c) A Setup file such as ***colours.4d*** may exist in one or more of the above folder. However, only the ***first*** occurrence of the file found when using the above search order, is used.

Please continue to the next section 39.2.6 Writing Out Setup Files.

39.2.6 Writing Out Setup Files

Most of the ***Setup*** files can be created and edited within ***12d Model*** using panels such as **Projects =>Management =>Defaults.**

When the **Write** button is selected on these panels, a **Write Setup File** panel comes up to specify where the file is to be written out to.

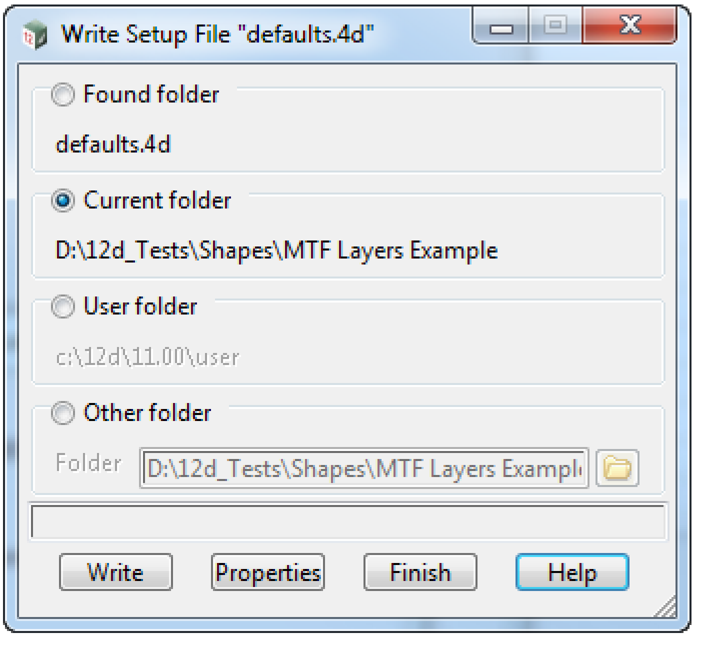
The choices on the panel allow the file to be written out to:

Found folder - the folder where the file currently being used by ***12d Model*** resides. This will be unavailable (greyed out) if the user doesn't have access to the folder.

Current folder - the folder where the project currently being used by ***12d Model*** resides. This will be unavailable (greyed out) if the user doesn't have access to the folder.

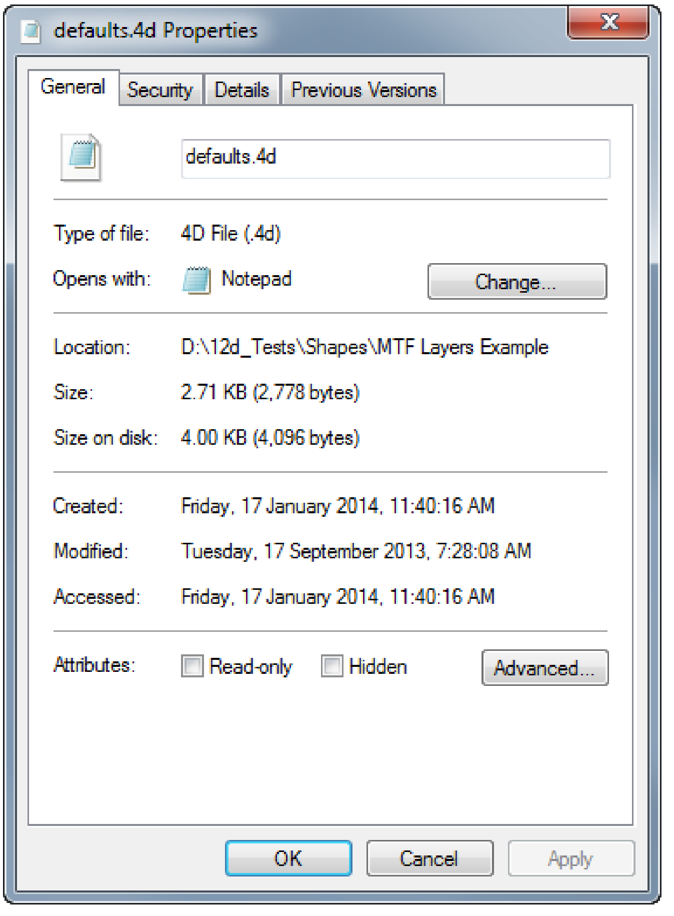
User folder - the **user** folder. This will be unavailable (greyed out) if the user doesn't have access to the folder.

Other folder - any folder can be selected.



A project restart is required for the new file to take effect

If you are having problems writing to the file, click on the **Properties** button to bring up the **Properties** panel for the selected file (if it exists) and check the *Security* for the file.



Please continue to the next section 39.3 Library, User Library, Customer Library.

39.2.7 Some Special Setup Files

See

39.2.7.1 Set Ups File (setups.4d)
39.2.7.2 Colours File (colours.4d)
39.2.7.3 Defaults File (defaults.4d)
39.2.7.4 Sheet Sizes File (sheets.4d)
39.2.7.5 Transitions and Spirals File

39.2.7.1 Set Ups File (setups.4d)

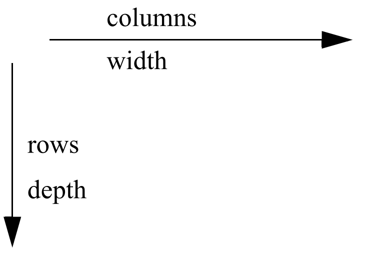
The St Up file, **setups.4d**, is used to define the initial screen set-ups. It can be used for

- the system font used for text
- the size of the initial window
- the position of the main menu, header menu, function menu, function recalc menu, snaps menu, volumes menu, geometry menu, sewer menu, pipeline menu
- the position of the screen message box, xyz message box
- the position of the **save project** panel (now redundant)
- the position, size, name and viewing parameters for the initial views

The co-ordinate system used for specifying the position of the left hand top corner of items on the screen is by column and row. For items which include an area of the screen (such as the window and views), a width and depth are also specified.

The column value is measured from the left hand size of the screen and the row value is measured from the top of the screen.

The units for row, column, width and depth are screen pixels.



Note - If any views are defined in the set_up_file, then the position of the **screen message box** must be also be defined and it must be **before** the definition of any view.

The format of the commands in the file setups.4d is

WINDOW *column_value* *row_value* *width* *depth* // main window

MAIN MENU *column_value* *row_value*

FUNCTION MENU *column_value* *row_value*
FUNCTION RECALC MENU *column_value* *row_value*
GEOMETRY MENU *column_value* *row_value*
PIPELINE MENU *column_value* *row_value*
SEWER MENU *column_value* *row_value*
SURVEY MENU *column_value* *row_value*
VOLUMES MENU *column_value* *row_value*

SNAPS MENU *column_value* *row_value*
SNAPS BUTTONS HORIZONTAL *column_value* *row_value*
SNAPS BUTTONS VERTICAL *column_value* *row_value*

PROJECT SAVE PANEL *column_value* *row_value*

// Views

PLAN VIEW *column_value* *row_value* *width* *depth* *name*

```
SECTION VIEW            column_value     row_value   width     depth   name

PERSPECTIVE VIEW        column_value     row_value   width   depth     name
  reference point       0.0         750.0       120.0       // x  y   z
  view plane normal     1.0           0.0         0.0       // dx  dy  dz
  view up vector        0.0           0.0         1.0       // dx  dy  dz
  view distance         10.0                                // distance

PERSPECTIVE OPENGL VIEW   column_value     row_value   width  depth  name
  reference point       0.0         750.0       120.0       // x  y   z
  view plane normal     1.0           0.0         0.0       // dx  dy  dz
  view up vector        0.0           0.0         1.0       // dx  dy  dz
  view distance         10.0                                // distance
```

The following parameters were used for V5.00 but are ignored for V5.0 onward:

```
SCREEN MESSAGE BOX          column_value          row_value
XYZ MESSAGE BOX             column_value          row_value
```

Continue to the next section 39.2.7.2 Colours File (colours.4d) or return to 39.2.7 Some Special Setup Files.

39.2.7.2 Colours File (colours.4d)

12d Model allows the use of up to 10,240 distinct colours for drawing in any view.

The colours are numbered from 0 to 10,239 and the user can define how the colour appears on the screen by giving the red, green and blue intensities (RGB) for each colour, and what name is used throughout the program when referring to a particular colour number.

The ***colour names*** and ***RGB*** mix associated with each colour number, pop up order etc are defined in the file **colours.4d**.

Each line of the file refers to a particular colour number.

There are nine items on each line, each separated by one of more spaces, with an optional comment at the end which is preceded by //.

The items in their order on a colour line are:

1. *red intensity value - a value between 0 and 255*
2. *green intensity value - a value between 0 and 255*
3. *blue intensity value - a value between 0 and 255*
4. *plotter pen number - 0 or a positive integer*

   When plotting, the **plotter pen number** is the default pen number that the colour is mapped to. This may be overridden by a plotter mapping file.
5. *colour name - the name that can be used instead of the colour number.*

   The **colour name** used to describe the colour is given in quotes. Colour names can be alphanumeric with a decimal point, although upper and lower case are considered the same. Each colour must have a *unique* colour name. If an underscore "_" is used in a colour name in the *colours.4d* file then a space is inserted in ***12d Model***. The colour name must be enclosed within quotes. For example, "dark red".
6. *colour number - 0 or a positive integer. the actual colour number that the line refers to.*

   The **colour number** is the actual colour number that the line refers to and what is actually stored in ***12d Model***. A colour numbers can only occur once in the *colours.4d* file but there can be gaps in the colour numbers.
7. *colour pop-up number*

   The colour pop-up number is an integer that can be negative, zero or positive. Colour pop-up numbers can only occur once in the *colours.4d* file but there can be gaps in the colour pop-up numbers.

   The *colour pop-up number* is used to decide which colours are should in the Colour box. If **Display colours** is set to ***n*** in ***Project =>Management =>Defaults***, then the colours with the *n* smallest pop-up numbers are displayed in the Colour box pop-up. So the order that the colours are chosen to appear in the colour pop-up is independent of the colour number.
8. *colour group*

   The colour group is simply text and does not have to be unique. The colour group is enclosed in quotes. For example, "vis".

   The colour group is not currently used in ***12d Model*** but in the future will be used to give a tree structure to the colours pop-up.
9. *colour legacy name*

   This is another name that the colour number could be known as. This was introduced to allow upward compatibility when going from the colours.4d supplied in v10 to that supplied in v11.
10. *// comment*

    text that is treated as a comment. It must be preceded by a //.

The *colours.4d* file is displayed and modified by using the **Edit Colours** panel brought up from the

[Edit] item on the Colours pop-up, *Select Colour.* For more information, go to the section 4.22 Colours.

Continue to the next section 39.2.7.3 Defaults File (defaults.4d) or return to 39.2.7 Some Special Setup Files.

39.2.7.3 Defaults File (defaults.4d)

The **defaults** file, **defaults.4d**, defines the initial default settings used in the ***12d Model*** **Default** and the **Systems Defaults** panels.

The **defaults** file can contain:

```
// general defaults

DEFAULT COLOUR                              red
DEFAULT POINT COLOUR                        yellow
DEFAULT TIN COLOUR                          brown
DEFAULT CONTOUR COLOUR                      cyan
DEFAULT CONTOUR INDEX COLOUR                magenta
DEFAULT TEXT SIZE                           8

// view settings

```

The information panel for each editor can be toggled on/off and the initial state when a new edit operation is begun is given by

```
DEFAULT EDIT INFORMATION     1          // show info panel on editor start-up
                             0          // don't show info panel
```

When output report are created, the scripts/programs pointed to by EDITOR_4D and PRINTER_4D will be run depending on the values of the defaults **display reports** and **print reports**.

```
DEFAULT DISPLAY REPORT FILES                1          // run EDITOR_4D
```

	0	// don't run "
DEFAULT PRINT REPORT FILES	1	// run PRINTER_4D
	0	// don't run "

Similarly when plots are created, the script/program pointed to by PLOTTER_4D and will be run depending on the value of the default **send plots**.

DEFAULT SEND PLOT FILES	1	// run PLOTTER_4D
	0	// don't run "

The number of minutes between displays of the **save project** yes-no box is given by

DEFAULT SAVE INTERVAL	minutes	// 0 for never

The file defining string colours can have up to 10,240 colours in it however this number is usually inconvenient to display in the standard colour pop-up so there is a setting to set how many colours are displayed from the list.

DEFAULT POPUP COLOURS	number_of_colours	// default 16

The precision for displaying real numbers in the information panel and in boxes and panel fields can be set.

DEFAULT PRECISION	integer	// info panel - default 3
DEFAULT BOX PRECISION	integer	// boxes & panels -default 4

The sign for cut areas and volumes can be positive or negative (fill is the opposite) and is given by

DEFAULT CUT VOLUME SIGN	-1	// negative for cut (default)
	1	// positive for cut

Text in text string, 4d strings and linestyles may be in pixels and must be given a millimetre size for plotting. Pixel text is multiplied by a factor to convert it to a millimetre size. The pixels to mm plot

DEFAULT PIXELS TO MM PLOT FACTOR	real	// default 1.0

Continue to the next section 39.2.7.4 Sheet Sizes File (sheets.4d) or return to 39.2.7 Some Special Setup Files.

39.2.7.4 Sheet Sizes File (sheets.4d)

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal Set Up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D      file        // file of plotter sheets sizes
```

The layout of the sheet sizes file is

```
// User definition file for sheets sizes in 12d Model
// Heights and widths are in mm.

//          sheet name          width       height

            A0                  1189        841
            A1                  841         594
            A2                  594         420
            A3                  420         297
            A4                  297         210

            B1                  1000        707
```

Continue to the next section 39.2.7.5 Transitions and Spirals File or return to 39.2.7 Some Special Setup Files.

39.2.7.5 Transitions and Spirals File

A transition is a means of easing from a straight to a curve (full transition) or from one radius curve to another radius curve (partial transition).

There is often confusion between the words spirals and transition curves come in a variety of formulae and spiral is just one type of transition curve.

See

39.2.7.5.1 Spirals

39.2.7.5.2 Left/Right, Leading/Trailing Transitions

39.2.7.5.3 Transitions/Spirals Supported by 12d Model

39.2.7.5.1 Spirals

A spiral curve (Euler spiral) is a special type of transition where the radius of curvature is proportional to the length along the curve.

That is

Radius of curvature at a point x length from start of spiral to that point = Constant

rl = K

Although the above definition fully defines a spiral (or Euler curve), spiral calculations are difficult by hand and so no authority uses the full definition but uses an approximation to the Euler spiral.

A Euler spiral can be uniquely defined in terms of a start tangent vector, a final radius of curvature (R) and a total spiral length (L).

The equation for this spiral can be given in terms of a local co-ordinate system where the origin is at the start of the spiral and the x-direction (abscissa) is along the tangent vector at the start of the spiral. The y-direction (ordinate) is given as the offset from the x-axis of the point on the spiral.

Formulae for the local co-ordinates of a point on the spiral can then be derived in terms of the distance of the point along the spiral (the spiral length to the point) and the given constants L (the total spiral length) and R (the final radius of curvature of the spiral).

These formulae for the local co-ordinates of a point on the spiral are **polynomial series** in terms of the spiral length to that point.

For use in calculations, the local co-ordinates can be **approximated** by restricting the polynomial series for the abscissa and the offset to a fixed number of terms.

So for example, the so called ***clothoid*** spiral used by Australian road authorities is defined as using exactly 5 terms for the abscissa (x) polynomial and exactly 4 terms of the offset (y) polynomial.

Note that a spiral is a transition but not all transitions are spirals.

Continue to the next section 39.2.7.5.2 Left/Right, Leading/Trailing Transitions or return to 39.2.7 Some Special Setup Files.

39.2.7.5.2 Left/Right, Leading/Trailing Transitions

The radius of curvature **R** (or simply the radius) of a transition is allowed to be positive or negative.
To agree convention of going to the left or right when travelling along a road and the sign of the curve radius, the radius of curvature **R** of a transition is allowed to be positive or negative.

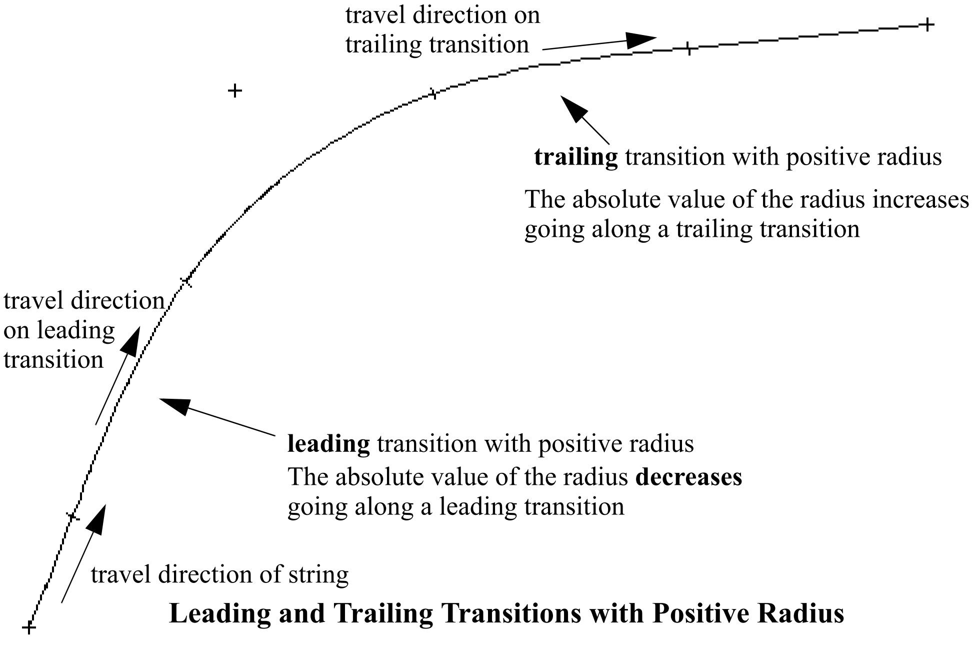
If **R** is **positive**, the transition will then curve to the **right**

If **R** is **negative**, the transition will then curve to the **left**

Also depending on the direction of travel along a transition, the absolute radius of curvature will be increasing or decreasing going along the transition.

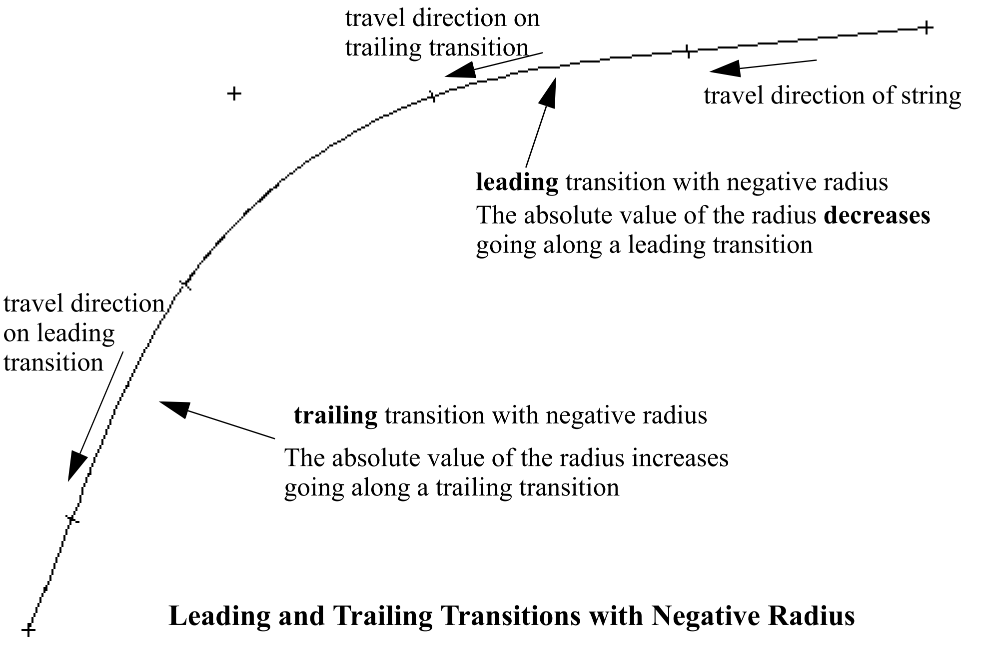
If the radius is decreasing along the transition, it is called a **leading** transition.

If the radius is increasing along the transition, it is called a **trailing** transition.



Leading and Trailing Transitions with Positive Radius

If the direction of the travel along the string is reversed, the radius of the transitions, and the arc, will be negative and the leading transition become trailing transition and the trailing transition becomes a leading transition.



Leading and Trailing Transitions with Negative Radius

Continue to the next section 39.2.7.5.3 Transitions/Spirals Supported by 12d Model or return to 39.2.7 Some Special Setup Files.

39.2.7.5.3 Transitions/Spirals Supported by 12d Model

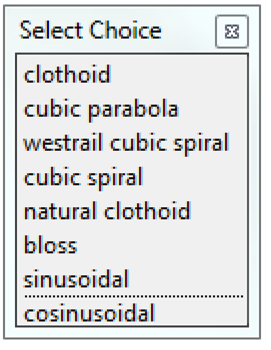
Users must be aware of the exact transition definitions that are to be used in their work.

In Australia, totally different transitions are used by NSW Rail, Queensland Rail and WA Rail.

Luckily all the road authorities in Australia use the same spiral approximation, and that is the same spiral approximation used by Queensland Rail.

So if work is being done in Western Australia or New South Wales, a different transition type is needed in the road alignments from that used in any rail alignments.

The transitions/spirals supported by ***12d Model*** are:



Clothoid - spiral approximation used by Australian road authorities and Queensland Rail.

Cubic parabola – special transition curve used by NSW railways. Not a spiral.

Westrail cubic – spiral approximating used by WA railways.

Cubic spiral – low level spiral approximation. Only ever used in surveying textbooks.

Natural Clothoid – the proper Euler spiral. Not used by any authority.

Bloss – special transition used by Deutsche Bahn. Not a spiral.

Sinusoidal - special transition. Not a spiral.

Cosinusoidal - special transition. Not a spiral.

Return to 39.2.7 Some Special Setup Files.

39.2.7.6 GUI

Note - this section is only for versions earlier than V4.0 and is here for historical reasons

The file **gui.4d**defined the colours used for screen objects (the graphical user interface objects), screen fonts, maximum pop-up length, and spacing in the menus and panels.

The gui.4d file is read every time a project (new or old) is opened.

39.2.7.6.1 GUI Colours

The colours associated with each screen object are given in terms of intensity values of red, green and blue. The intensity values are between 0 and 255, where 0 represents no colour and 255 full colour.

The layout for screen colours in the gui.4d file is:

```
//   object                            RGB values- red green blue

VIEW BACKGROUND COLOUR           0      0       0         // black
VIEW BORDER COLOUR                 255   255    0         // yellow

BUTTON HIGHLIGHT COLOUR        255     255    0           // yellow
BUTTON TEXT COLOUR                127    127    127       // grey
BUTTON BACKGROUND COLOUR         60     60    200         // dark blue

MENU BACKGROUND COLOUR         150     90     0           // brown
MENU BORDER COLOUR                 255      255   0       // yellow

PANEL BACKGROUND COLOUR        150     90     0            // brown
PANEL BORDER COLOUR                255     255   0        // yellow

FRONT SCREEN LOGO COLOUR          255      255    0       // yellow
FRONT SCREEN TEXT COLOUR           0        255     0     // green
FRONT SCREEN BACKGROUND COLOUR    60     60    200        // dark blue

WINDOW BACKGROUND COLOUR 1      64       128       0      // half green
WINDOW BACKGROUND COLOUR 2       0       128      196     // cyan
```

39.2.7.6.2 Maximum Pop-Up Length

The maximum number of items in a pop-up list before splitting into walk-right pop-ups is given by (necessary when using VGA screens on PC's)

```
POPUP LENGTH            integer        //maximum number of items in a pop-up
```

39.2.7.6.3 Fonts for Menus and Panels

A font can be defined for use in the menu and panel titles areas and a separate font for the rest of the text in the menus and panels.

The fonts are defined in the gui.4d file as:

```
SYSTEM TITLE FONT             font_name            // font for titles
SYSTEM FONT                   font_name            // font used elsewhere
```

For X-Windows, the font_name is the name of the required font from the font list given by the command xlsfonts.

For Windows NT, the font_name is made up of the Windows font name plus zero or more parameter values for the font.

The font name and parameter values are given as one text name, font_name, by concatenating the font name and values with only a minus separating them.

If the font name consists of more than one word, the font name is enclosed in double quotes(").

Hence for NT, an example of defining fonts is:

Parameter	**Possible Values**
Font	font name (less than 32 characters)
Height	number
italic	
underline	
strikeout	
Weight	thin extralight light normal medium semibold bold extrabold heavy
Quality	draft proof
Pitch	default_pitch fixed_pitch variable_pitch
Family	decorative modern roman script swiss

Defaults

Height	14
Weights	fw_dontcare (family weight don't care)
Pitch	font default pitch
Family	ff_dontcare (font family don't care)
Quality	default_quality
italic	false
underline	false
strikeout	false

For example

Arial-14-bold-italic	is the fond Arial, of height 14 and bold and italic
"Courier New"-16-italic	is the font Courier New, of height 16 and bold.

Under NT, if the font is not properly defined or doesn't exist, then the system font is used.

Under X-Windows, if the font does not exist, the font fixed is tried. If fixed does not exist, 12d Model will not start up.

39.2.7.6.4 Spacing for Borders and Panels

There are parameter to control the amount of space in border, between items etc. for menus and borders. These are normally set by 12D Solutions and should not need to be modified.

SCREEN TEXT BORDER X	pixels
SCREEN TEXT BORDER Y	pixels
SCREEN TEXT EXTRA X	pixels
SCREEN TEXT EXTRA Y	pixels
EDIT BOX BORDER X	pixels
EDIT BOX BORDER Y	pixels

PANEL BORDER X	pixels
PANEL BORDER Y	pixels
PANEL GAP Y	pixels
VERTICAL BORDER X	pixels
VERTICAL BORDER Y	pixels
VERTICAL GAP Y	pixels

HORIZONTAL BORDER X	pixels
HORIZONTAL BORDER Y	pixels
HORIZONTAL GAP Y	pixels
INPUT BOX BORDER X	pixels
INPUT BOX BORDER Y	pixels

39.3 Library, User Library, Customer Library

Apart from ***Setting Up*** files which are **only accessed** when a project is **opened** or **first created**, there are two or three special library areas that are searched for files with the appropriate file ending whenever the folder icon at the end of a panel file field is selected. For example, clicking on the folder icon for a **Map File** panel field would display a list of files ending in **.mapfile** and **.mf**.

One folder, **Library**, is supplied by *12d Solutions Pty Ltd* and is installed by ***12d Model***, and two other folders, **User_Lib** and **Customer_Lib** are not touched in an install and only contains files placed there by users.

39.3.1 Library

In a manner similar to the folder **set_ups**, the location of **Library** can be modified defining the environment variable

LIB_4D

If the environment variable LIB_4D doesn't exist, or the folder it points to doesn't exist, then the folder **Library** installed by 12d as **Program files\12d\12dmodel\11.00\Library** is used.

The files of the required ending in **library** are listed under the **[Lib]** walk right of pop-ups.

39.3.2 User Library

Because most users do not have write access to **Program files\12d\12dmodel\11.00\Library,** and the fact that any files in that area may be deleted or overwritten by future ***12d Model*** installations, there is a special user library folder called **User_lib** where user library files should be placed.

The user library, is also a folder and is pointed to by the environment variable

USER_LIB_4D

or if the environment variable USER_LIB_4D or the folder that it points to doesn't exist, in a folder called **User_lib** directly under the user accessible area **C:\12d\11.00**

The files from the User library are listed under the **[User Lib]** walk right of the pop-up.

So unlike the files in the folders *set_ups* or *user*, files in the ***12d*** supplied area **Library** and the user file in **User_lib**, are all displayed.

39.3.3 Customer Library

There is one more folder that is only looked for when it has been created by a user and is ***pointed to by the environment variable*** CUSTOMER_LIB_4D. It has no default name but is whatever name the user gave it. For convenience, we will call it **Customer_lib.**

So the customer library, is also a folder and is pointed to by the environment variable

CUSTOMER_LIB_4D

If the environment variable CUSTOMER_LIB_4D or the folder that it points to doesn't exist, then no Customer Library is used.

The files from the Customer library are listed under the **[Customer Lib]** walk right of the pop-up.

So unlike the files in the folders *set_ups* or *user*, files in the ***12d*** supplied area **Library** and the users files in **User_lib** and **Customer_lib**, are all displayed.

Notes

1. The list of special endings for files is given in the Appendix, Special File Formats.
2. A full list of environment variables is given in the later section 39.4 Environment Variables.

Please continue to the next section 39.4 Environment Variables.

39.4 Environment Variables

When ***12d Model*** is invoked for a new or existing project, it uses environment variables to tailor the system.

In Windows, environment variables can be set for each User from the Control Panel, but a much easier method to set the environment variables used by ***12d Model*** is to include them in a special file which is read in each time a project (new or existing) is opened by ***12d Model***.

The environment variables that ***12d Model*** recognises can be broken into two types

(a) mode type where the environment variable is only a flag setting a mode

and

(b) a second type which point to a file, program or folder. For the environment variables of the second type, a default file/program is often searched for if the environment variable is not defined.

The folder search order for the default files for the file group of environment variables is given in the previous sections.

The list of environment variables will be given in alphabetical order but it will be obvious from the documentation which type the environment variable is.

39.4.1 Alphabetical Environment Variables List

For environment variables that simply set a flag or value (the default value is shown in bold), the documentation will be:

Variable Name Value Description Default

For environment variables that point to a file, program or folder, and their associated default files/ programs, the documentation will be:

Environment Variable Name Type Default

Environmental Variables List

ACAD_SEEDFILES_4D

ACAD_SEEDFILES_4D folder no default

if not blank, the full path name of the folder holding Autocad template files.

ADAC_VERSION_4D

ADAC_VERSION_4D text

the ADAC Schema version, *e.g.* 4.1.0 or 4.0.0

ALIGNMENT_CORRIDOR_FIXUP_4D

ALIGNMENT_CORRIDOR_FIXUP_4D value 0 or **1** *default* 1

if not zero, alignment corridor calculations introduced in V8 are used.
If zero, the V7 alignment corridor calculations are used.

ALLOW_ANONYMOUS_FUNCTIONS_4D

ALLOW_ANONYMOUS_FUNCTIONS_4D value 0 or 1

if tick, when a file is read with a File input option, a function is automatically created and named. This function must exist to allow data to be added to a view after it is read in, to be able to delete all the data read in at a later time, and to re-run the function to reread the data file and replace the data read in last time.

ALLOW_NAMED_POINT_ATTRIBUTES_4D

ALLOW_NAMED_POINT_ATTRIBUTES_4D value 0 or 1

ALLOW_OLD_PLOTTING_4D

ALLOW_OLD_PLOTTING_4D value 0 or 1

If not zero, then a menu **Plot =>Old plotting** is included which has all the old text ppf options.

ALLOW_SUPER_TINS_EXACT_CALCS_4D

ALLOW_SUPER_TINS_EXACT_CALCS_4D value 0 or 1

Options using tins are split into two categories:

(1) options that require sections through tins
(2) options that require the triangles of the tin

if ticked, this allows super tins to be used in options where triangles are required for calculations.
if not ticked, this prevents super tins to be used in options where triangles are required for calculations.

Note: ticking this option requires super tins to be updated when a tin within the super tin changes, so

there is a time, storage, and memory cost. It was found that some projects only ever required options that used sections (not triangles), so for these type of projects, there is an efficiency gain by turning off this option.

ALWAYS_VALIDATE_PROJECT_DETAILS_4D

ALWAYS_VALIDATE_PROJECT_DETAILS_4D value 0 or 1

if ALLOW_ANONYMOUS_FUNCTIONS_4D is set to 1, then when a file is read with a File input option, a function is automatically created and named. This function can be used to delete all the data at a later time, to allow the data to be added to a view after it is read in, and to re-run the function to reread in the data file.

ASK_ON_CHAIN_COMMAND_DELETE_4D

ASK_ON_CHAIN_COMMAND_DELETE_4D

AUTHORIZATION_4D

AUTHORIZATION_4D full path name to nodes.4d

The authorization file is normally called **nodes.4d**, and is under the folder c:\12d**12d model**\version_number. However, the file name and path can be set by the user with the AUTHORIZATION_4D environment variable.

The full path-name of the file is given.

AUTO_CERTIFY_DONGLE_4D

AUTO_CERTIFY_DONGLE_4D value **0** or 1 *default* 0

if non zero, then when the warning period is active for the CodeMeter Container (dongle) being used by ***12d Model***, ***12d Model*** will automatically attempt to certify the dongle and if successful, no intervention by the user is required. See 7.6.5.4 Certify CodeMeter.

Note that the computer must have internet access for Certification to take place.

AUTO_DELETE_WALKRIGHTS_4D

AUTO_DELETE_WALKRIGHTS_4D	**0**	Use old method from V3.1	32
	pixels	Distance in pixels to move past the end of the last menu before the cascade collapses	

If not zero, the environment variable AUTO_DELETE_WALKRIGHTS_4D sets the distance in pixels that is used to collapse the cascade of walk-right menus when the cursor moves that distance past the end of the last walk-right menu.

The default value is 32.

AUTO_HIDE_PANEL_SELECTS_4D

AUTO_HIDE_PANEL_SELECTS_4D value 0 or **1** *default* 1

if non zero, when the string select icon is picked on a panel, the panel minimises until a string is selected is accepted.

This mode was introduced so that the panel was not in the way when selecting a string. It is particularly useful on tablets with limited screen area.

AUTO_MODEL_SYNC_4D

AUTO_MODEL_SYNC_4D	**0**	Don't auto sync models	*default 0*
	1	Auto sync models	

if auto-model sync is set to on, the server projects for any shared models added to this project are checked to see if they have been modified (checked every SHARE_CHECK_INTERVAL seconds). If any models have been modified, they are re-copied to this project.

AUTO_PAN_SELECT_4D

AUTO_PAN_SELECT_4D value 0 or **1** *default* 1

if non zero, if you have accepted but not accepted a string and are zoomed in on the strings and type **ch value** where the position at that chainage is off the view, the view will autopan so that the new selection point (at chainage value) is on the view. This applies for all typed selects.

AUTO_RESET_SELECT_4D

AUTO_RESET_SELECT_4D	0	Don't use auto-reset reselect
	1	Use auto-reset reselect

The reset mechanism for picking has ben modified for V5.0 and above. Reset is now done automatically if the cursor is moved a user specified distance (given by AUTO_RESET_TOLERANCE_4D) after a pick (without accepting), and a separate user specified distance (given by AUTO_RESET_DRAG_TOLERANCE_4D) after a directional pick (without accepting).

The default value is 1.

AUTO_RESET_SELECT_DRAG_TOLERANCE_4D

AUTO_RESET_SELECT_DRAG_TOLERANCE_4D *value*

Reset distance for directional picks.

If AUTO_RESET_SELECT_4D is non zero, then AUTO_RESET_SELECT_DRAG_TOLERANCE_4D is the distance in pixels to move the cursor to reset the picking rejection list for a directional pick.

The default value is 50.

AUTO_RESET_TOLERANCE_4D

AUTO_RESET_TOLERANCE_4D *value*

Reset distance for non-directional picks.

If AUTO_RESET_SELECT_4D is non zero, then AUTO_RESET_TOLERANCE_4D is the distance in pixels to move the cursor to reset the picking rejection list for a non-directional pick.

The default value is 5.

AUTO_TIN_SYNC_4D

AUTO_TIN_SYNC_4D	**0**	Don't auto sync tins	*default 0*
	1	Auto sync tins	

if auto-tin sync is set to on, the server projects for any shared tins added to this project are checked to see if they have been modified (checked every SHARE_CHECK_INTERVAL seconds). If any tins have been modified, they are re-copied to this project.

AUTOCAD_PATTERNS_4D

AUTOCAD_PATTERNS_4D folder no default

if non blank, the full path name of the AutoCAD patterns file.

BISECTORS_4D

BISECTORS_4D	**0**	Don't use bisector section use two sections instead.	*default 0*
	1	Use bisector section	

When applying templates to a horizontal intersection point with a sharp change of direction, (that is, it is not and end point and the HIP has no curve on it and there is a change of direction at the HIP), either two sections can be applied at the HIP point (applied perpendicular to the line on either side of the HIP point) or just a single bisector section applied to the bisector of the change of angle through the HIP.

The default value is 0.

BOXING_CONTINUE_ON_FAIL_4D

BOXING_CONTINUE_ON_FAILURE_4D value **0** or 1 *default* 0

if non zero, the boxing stops if there is an error such as not being able to intersect with a tin. If zero, the boxing stops when an error is found.

BOXING_RULES_COLOUR_4D

BOXING_RULES_COLOUR_4D *colour* *default blue*

the colour of the text in the Type column in the Boxing Rules panel for all Boxing command other than Comment, Decision, Goto and Labels.

BOXING_COMMENT_COLOUR_4D

BOXING_COMMENT_COLOUR_4D *colour* *default yellow*

background colour for the Comment boxing command grid row in the Boxing Rules panel. The text in the grid row is black.

BOXING_DECISION_GOTO_COLOUR_4D

BOXING_DECISION_GOTO_COLOUR_4D *colour* *default mauve*

the colour of the text in the Type column for the Decision and Goto commands in the Boxing Rules panel.

BOXING_LABEL_COLOUR_4D

BOXING_LABEL_COLOUR_4D *colour* *default light red*

the colour of the text in the Type column for the Label command in the Boxing Rules panel.

BOXING_REGION_COLOUR_4D

BOXING_REGION_COLOUR_4D *colour*

the colour of the text in the row for the Region command in the Boxing Rules panel.

BOXING_WALL_OFFSET_4D

BOXING_WALL_OFFSET_4D *real* *default 0.000001*

when boxing automatically creates a vertical wall, this is the offset distance between the top and bottom of the vertical wall.

CAD_START_IN_MULTI_PICK_4D

CAD_START_IN_MULTI_PICK_4D tick box

CHECK_FOR_UPDATES_4D

CHECK_FOR_UPDATES_4D integer

if non zero, the 12d web site is checked on startup for any newer updates to ***12d Model***.

If zero, the 12d web site is not checked.

CIVILCAD_PATH_4D

CIVILCAD_PATH_4D folder no default

if non blank, the full path name of the folder holding CivilCAD files.

There is no default.

COLOURS_4D

COLOURS_4D filename default colours.4d

file of colour rgb definitions and names. See 39.2.7.2 Colours File (colours.4d).

The default is colours.4d.

CONSTRUCTION_SNAP_MODEL_4D

CONSTRUCTION_SNAP_MODEL_4D model name

If non blank, the model to use for objects created during construction snaps.

CUBED_CHARACTER_4D

CUBED_CHARACTER_4D *integer (base 10)* *default 179*

The integer (base 10) value of the character to use as the cubed symbol.

CUSTOMER_LIB_4D

CUSTOMER_LIB_4D folder name no default name

if the environment variable exists and the folder exists, then the folder is available when selecting a library file (*see* 39.3 Library, User Library, Customer Library).

There is no default folder name.

CUSTOMER_USER_4D

CUSTOMER_USER_4D folder name no default name

if the environment variable exists and the folder exists, then the folder is part of the search for locating setup files (*see* 39.2 Files for Setting Up 12d).

There is no default folder name.

CUT_HEIGHT_ZONE_COLOUR_4D

CUT_HEIGHT_ZONE_COLOUR_4D *colour* *default dark red*

the colour of the text in the *Type* column for the *Cut* commands involving height, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

CUT_WIDTH_ZONE_COLOUR_4D

CUT_WIDTH_ZONE_COLOUR_4D *colour* *default light red*

the colour of the text in the *Type* column for the *Cut* commands involving width, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

CUT_SLOPE_ZONE_COLOUR_4D

CUT_SLOPE_ZONE_COLOUR_4D *colour* *default dark red*

the colour of the text in the *Type* column for the *Cut* commands involving slope, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

CUT_ZONE_COLOUR_4D

CUT_ZONE_COLOUR_4D *colour* *default red*

the colour of the text in the *Type* column for the *Cut* commands (other than those involving width, height or slope) in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

DATA_COLLECTOR_4D

DATA_COLLECTOR_4D data collect name

the data collector that is used if no data collector is set for a project.

There is no default.

DATA_COLLECTORS_4D

DATA_COLLECTORS_4D filename default survey.4d file of definitions of available data collectors

The default is survey.4d.

DATA_TIPS_4D

DATA_TIPS_4D	**0**	Don't show data tips
	1	Show data tips

When non zero, data tips are displayed when the cursor moves over vertices in a plan view.

The default value is 0.

DEBUG_DONGLE_ACCESS_4D

DEBUG_DONGLE_ACCESS_4D   positive integer

time between searches for a dongle

DECISION_ZONE_COLOUR_4D

DECISION_ZONE_COLOUR_4D   *colour*   *default green*

the colour of the text in the *Type* column for the *Decision* commands in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

DEFAULTS_4D

DEFAULTS_4D   filename   default defaults.4d

file of defaults - only used for new project

The default is defaults.4d. See 39.2.7.3 Defaults File (defaults.4d).

DEFAULT_PLAN_PLOT_SCALE_4D

DEFAULT_PLAN_PLOT_SCALE_4D   *value*

value is the scale (1:value) for new plan views

If a value is given, then it is used the default scale for any new plan view created in a project. Note that the scale is used in the plan view for displaying text, linestyles and symbols that have been defined in paper units.

DEFAULT_RASTER_DPI_4D

DEFAULT_RASTER_DPI_4D   *real_dots_per_inch*

default dots per inch to use for plotting rasters

The default value is 150.0

DEFAULT_TABLE_WIDTH_4D

DEFAULT_TABLE_WIDTH_4D   *number_of_characters*   *default 32*

Gives the number of characters displayed in tables such as decisionals and mtf editor.

The default value is 32.

DEFAULT_VIEW_COLOUR_4D

DEFAULT_VIEW_COLOUR_4D   *colour_number*   *default 0*

The default background colour for views.

DEGREES_CHARACTER_4D

DEGREES_CHARACTER_4D   *integer (base 10)*   *default 176*

The integer (base 10) value of the character to use as the degrees symbol.

DGN_PLOT_SEED_FILE_4D

DGN_PLOT_SEED_FILE_4D filename

if non blank, the full path name of the file to use as a seed file for Microstation plots.

DIAMETER_LARGE_CHARACTER_4D

DIAMETER_LARGE_CHARACTER_4D *integer (base 10)* *default 216*

The integer (base 10) value of the character to use as the large diameter symbol.

DIAMETER_SMALL_CHARACTER_4D

DIAMETER_SMALL_CHARACTER_4D *integer (base 10)* *default 248*

The integer (base 10) value of the character to use as the small diameter symbol.

DIGITIZERS_4D

DIGITIZERS_4D filename *default digitize.4d*

file of digitizer definitions

The default is digitize.4d. See 8.5.7 Digitizer Definitions File.

DISABLE_MTF_WARNINGS_4D

DISABLE_MTF_WARNINGS_4D	**0**	Display the mtf warnings in the text editor
	1	Write mtf warnings to the background window

Controls whether the mtf warnings go to a file or to the output window.

If non zero, write mtf warnings to the background window
If zero, display the mtf warnings in the text editor.

The default value is 0.

DONGLE_4D - no longer used

Important Note: this environment variable is not used for ***12d Model 11*** and above.

Hardlock dongles will not work for ***12d Model*** 11 and above so this environment variable is ignored by these versions of ***12d Model***.

The environment variable can have a number of parameters to control the use of Hardlock network and stand alone dongles.

(a) DONGLE_4D -local OR -no_local

usually used when there is a network dongle and need to know if any stand alone Hardlock dongle is to be looked for on the computer that the user is on.

if **-local**, then a stand alone Hardlock dongle is looked for on the computer the user is on.
If **-no local**, then no stand alone Hardlock dongle is looked for on the computer the user is on.

For example DONGLE_4D - local or -no local

(b) DONGLE_4D -no network OR -network first OR -network last

need to specify if any network Hardlock network dongle is to be looked for.

if -**no network**, then no Hardlock network dongle is looked for.
If **-network first**, then a Hardlock network dongle is looked for before a stand alone local dongle.
If **-network last**, then a Hardlock network dongle is looked for after looking for a stand alone local dongle.

For example DONGLE_4D -no_network *or* - network_first *or* -network_last

(c) DONGLE_4D -login_retries number of retries to find a Hardlock dongle

the number ***nn*** of retries to make when searching for a Hardlock dongle and it is not found.

For example DONGLE_4D -login_retries 3

(d) DONGLE_4D -login_wait ss

the number of seconds ***ss*** to wait between retries to find a network Hardlock dongle.

For example DONGLE_4D -login_wait 5

(e) DONGLE_4D -no_dongle

if the parameter -no_dongle is found, then no search is made for a Hardlock dongle.

For example DONGLE_4D -no_dongle

(f) DONGLE_4D -debug

if the parameter -debug is found, then Hardlock dongle debug information is written to the

For example DONGLE_4D -debug

See the separate notes on installing a network dongle for more details.

DONGLE_ORDER_4D - no longer used

Important Note: this environment variable is not used for ***12d Model 11*** and above.

Hardlock dongles will not work for ***12d Model*** 11 and above so this environment variable is ignored by these versions of ***12d Model***.

DONGLE_ORDER_4D choice box Hardlock/Wibu, Wibu/Hardlock

the order to search for network dongles.

If **Wibu/Hardlock**, then Wibu networks dongles are searched for before any Hardlock dongles.

If **Hardlock/Wibu**, then Hardlock networks dongles are searched for before any Wibu dongles.

All new dongles are Wibu so most ***12d Model*** sites now only have Wibu dongles.

DONGLES_4D

DONGLES_4D full path name to dongles.4d

The dongles file is normally called **dongles.4d** and is searched for as a Set Up file. However, the file name and path can be set by the user with the DONGLES_4D environment variable.

The full path-name of the file is then given.

DOUBLE_CONFIRM_DELETE_4D

DOUBLE_CONFIRM_DELETE_4D	0	Confirm deletes/cleans without undos once
	1	Confirm deletes/cleans without undos twice

Controls whether or not the user is asked once or twice to confirm that deletes and cleans that do not have undos are to be done.

If non zero, the user is asked twice to confirm for deletes and cleans.
If zero, the user is asked once to confirm for deletes and cleans.

The default value is 1.

DRAFTING_SPLIT_MESSAGE_4D

DRAFTING_SPLIT_MESSAGE_4D	**0**	Confirm deletes/cleans without undos once
	1	Confirm deletes/cleans without undos twice

if non zero, for CAD Dimensions, Leaders and Tables, long messages that are written to the screen message area are broken up into two shorter lines with the first one being displayed. Both the shorter lines have a (m)ore on them to get to the other line. However all the typed commands for the options are still recognised regardless of whether they are visible or not in the split message.

If zero, the messages are not split into two lines.

The default value is 0.

DRAINAGE_4D

DRAINAGE_4D filename default drainage.4d

file of definitions for the drainage option

The default is drainage.4d.

DRAINAGE_EDIT_GRADE_4D

DRAINAGE__EDIT_GRADE_4D tick box

DRAINAGE_PPF_4D

DRAINAGE_PPF_4D *full path name of .ppf file* no default

Points to the file used as the default plot parameter file (.ppf) for the panel **New Plot Drainage Network.**

The path name to the .ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/drainage.ppf** points to the file drainage.ppf in the area defined by $LIB_4D.

DRAINAGE_FLOW_DIR_4D

DRAINAGE_FLOW_DIR_4D **0** Flow direction is opposite to the string direction
1 Flow direction is the same as string direction

Defines the default flow direction used in the creating a drainage string.

The environment variable DRAINAGE_FLOW_DIR_4D specified whether the default flow direction that appears in the **Create Drainage String** panel is that the flow direction in the line is in the same direction as the direction of the drainage string (ascending chainage) or that the flow direction in the drainage line is in the opposite direction to the direction of the drainage string (descending chainage).

If non zero, the drainage flow direction is the same as the string direction.
If zero, the drainage flow direction is in the opposite direction to the string direction.

The default value is 0.

DWG_PLOT_SEED_FILE_4D

DWG_PLOT_SEED_FILE_4D filename

if non blank, the full path name of the file to use as a template file for AutoCAD plots.

DWG_PLOT_UNIT_4D

DWG_PLOT_UNIT_4D English OR Metric

if non blank, the units to use for AutoCAD files.

EDIT_BOX_WIDTH_IN_CHARACTERS_4D

EDIT_BOX_WIDTH_IN_CHARACTERS_4D *number* *default 10*

if non blank, the number of characters to make the width of an Edit Box on a panel.

EDITOR_4D

EDITOR_4D script/program 10.00\cpu_area\te

the script or program that is fired up when a report is created. It usually points to an editor.

If the parameter **display reports** in the panel **sys default settings** (given by the menu option **Utilities => Default=>Sys defaults**) is set to **yes**, the **editor displays** each report as it is created.

The default is **10.00\cpu_area\te**.

ENVIRONMENT_4D

ENVIRONMENT_4D *full path name of file* default env.4d

It is possible to set all the environment variables from a file normally called **env.4**d. The environment variable file is searched for in the standard Set Up areas (local, USER_4D, user, set_ups) or is set by the environment variable ENVIRONMENT_4D.

The default is env.4d.

The format of the environment variable file is given in the section 39.4.2 Setting Environment Variables.

EXTRA_OPTIONS_4D

EXTRA_OPTIONS_4D file default xtramenu.4d

If non blank, the full path name of the 12d Solutions supplied file of definitions for some extra menus.

The default is xtramenu.4d. See 41.2 User Defined Menus

EXTRA_START_END_MTF_4D

EXTRA_START_END_MTF_4D 0 extra start/end on *default **1***
1 extra start/end on

Used in the Modifiers section of the MTF.

If EXTRA_START_END_MTF_4D =1, then the **Extra start** and **Extra end** tick boxes on the MTF panels are ticked.

If EXTRA_START_END_MTF_4D =0, then the **Extra start** and **Extra start** tick boxes on the MTF panels are not ticked.

The default value is 1.

EXTRUSIONS_4D

EXTRUSIONS_4D filename default extrusions.4d

This points to the file which contains the definition of the extrusions in the Extrusions Library. Please see 12.13.6 Extrusions for more information about extrusions.

The default is extrusions.4d.

FAST_ACCEPT_4D

FAST_ACCEPT_4D **0** don't set fast accept snap to on for new projects *default 0*
1 set fast accept snap on for new projects

If non zero, the **Fast Accept** snap (**A** snap) is turned on by default for new projects.

If fast accept is turned on, then when an item is picked and there is only one item in the selection list, that item is automatically selected without clicking MB.

FAST_CONSTRUCTION_SNAPS_4D

FAST_CONSTRUCTION_SNAPS_4D **0** don't set construction snap to on for new projects
1 set construction snap to on for new projects

If non zero, the **Fast Construction** snap (**K** snap) is turned on by default for new projects.

The default value is 0.

FAST_ZOOM_PAN_4D

FAST_ZOOM_PAN_4D

FLD_IGNORE_XTRA_WORDS_4D

FLD_IGNORE_XTRA_WORDs_4D **0**,1

If non zero, trailing tabs are not considered words in a field file. Mainly for Leica when it is writing a format file which can't suppress trailing tabs when writing a 12d Field file.

The default value is 0.

FILE_READ_ADD_TO_VIEW_4D

FILE_READ_ADD_TO_VIEW_4D choice box

if anonymous function are set, the data created by the File input option can be added to a view. The choices are:

Do nothing - don't add the data read in to any view

Add to current view - add the data read in to the current view (the current view is the view that highlighted)

Add to new view - automatically create a new view and add the data read in to that view

Add to named view - add the data read in to the view given by FILE_READ_ADD_TO_VIEW_NAME_4D

FILE_READ_ADD_TO_VIEW_NAME_4D

FILE_READ_ADD_TO_VIEW_NAME_4D text box

name of the view to use if FILE_READ_ADD_TO_VIEW_4D is set to **Add to named view**.

If the view does not exist then it is created.

FILL_HEIGHT_ZONE_COLOUR_4D

FILL_HEIGHT_ZONE_COLOUR_4D *colour* *default dark green*

the colour of the text in the *Type* column for the *Fill* commands involving height, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FILL_SLOPE_ZONE_COLOUR_4D

FILL_SLOPE_ZONE_COLOUR_4D *colour* *default dark green*

the colour of the text in the *Type* column for the *Fill* commands involving slope, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FILL_WIDTH_ZONE_COLOUR_4D

FILL_WIDTH_ZONE_COLOUR_4D *colour* *default light green*

the colour of the text in the *Type* column for the *Fill* commands involving width, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FILL_ZONE_COLOUR_4D

FILL_ZONE_COLOUR_4D *colour* *default green*

the colour of the text in the *Type* column for the *Fill* commands (other than those involving width, height or slope) in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FINAL_CUT_SLOPE_ZONE_COLOUR_4D

FINAL_CUT_SLOPE_ZONE_COLOUR_4D *colour* *default black*

the colour of the text in the *Type* column for the *Final* command for Final Cut slope, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FINAL_FILL_SLOPE_ZONE_COLOUR_4D

FINAL_FILL_SLOPE_ZONE_COLOUR_4D *colour* *default black*

the colour of the text in the *Type* column for the *Final* command for Final Fill slope, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FINAL_NO_CUT_SLOPE_ZONE_COLOUR_4D

FINAL_NO_CUT_SLOPE_ZONE_COLOUR_4D *colour* *default black*

the colour of the text in the *Type* column for the *Final* command for No Cut slope, in the *Modifiers* section of the ***MTF Modifiers*** *panel*.

FINAL_NO_CUT_FILL_SLOPE_ZONE_COLOUR_4D

FINAL_NO_CUT_FILL_SLOPE_ZONE_COLOUR_4D *colour* *default dark brown*

the colour of the text in the *Type* column for the *Final* commands for No cut/fill, in the *Modifiers* section of the ***MTF Modifiers*** *panel*.

FINAL_NO_FILL_SLOPE_ZONE_COLOUR_4D

FINAL_NO_FILL_SLOPE_ZONE_COLOUR_4D *colour* *default black*

the colour of the text in the *Type* column for the *Final* command for No Fill slope, in the *Modifiers* section of the ***MTF Modifiers*** *panel*.

FINAL_WIDTH_ZONE_COLOUR_4D

FINAL_WIDTH_ZONE_COLOUR_4D *colour* *default light brown*

the colour of the text in the *Type* column for the *Final* commands involving width, in the *Modifiers* section of the ***MTF Modifiers*** *panel*.

FINAL_ZONE_COLOUR_4D

FINAL_ZONE_COLOUR_4D *colour* *default brown*

the colour of the text in the *Type* column for the *Final* commands (other than those involving width or slope) in the *Modifiers* section of the ***MTF Modifiers*** *panel*.

FIXED_DECISION_ZONE_COLOUR_4D

FIXED_DECISION_ZONE_COLOUR_4D *colour*

the colour of the text in the Type column for the Fixed Decision commands in the **Left/Right MTF Modifiers** panel.

FIXED_HEIGHT_ZONE_COLOUR_4D

FIXED_HEIGHT_ZONE_COLOUR_4D *colour* *default dark blue*

the colour of the text in the *Type* column for the *Fixed* commands involving height, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FIXED_WIDTH_ZONE_COLOUR_4D

FIXED_WIDTH_ZONE_COLOUR_4D *colour* *default light blue*

the colour of the text in the *Type* column for the *Fixed* commands involving width, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FIXED_XFALL_ZONE_COLOUR_4D

FIXED_XFALL_ZONE_COLOUR_4D *colour* *default dark blue*

the colour of the text in the *Type* column for the *Fixed* commands involving xfall, in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FIXED_ZONE_COLOUR_4D

FIXED_ZONE_COLOUR_4D *colour* *default blue*

the colour of the text in the *Type* column for the *Fixed* commands in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

FONTS_4D

FONTS_4D filename default fonts.4d

font definitions

The default is fonts.4d. See 40.3 Textstyles and Fonts

FULL_HYDRAULIC_REPORT_4D

FULL_HYDRAULIC_REPORT_4D 0, 1 default 0

The rational hydraulic report contains hydrology data.

If non zero, the hydrology calculations for each catchment set (1 to 3) are written to the hydraulic report.

FUNCTION_KEYS_4D

FUNCTION_KEYS_4D filename default userkeys.4d

function key definitions

The default is userkeys.4d. See 41.1 User Defined Function Keys

GENIO_WILDCARD_4D

GENIO_WILDCARD_4D *text* default ***.mos**

Sets the ending of the files selected for the pop-up list for the **File** field in the **Read Genio Data** panel.

The default value is "*.mos".

GIS_ARCSDE_PATH_4D

GIS_ARCSDE_PATH_4D filename

the full path name to the ArcSDE DLL. This is only required when using the ArcSDE Server.

GIS_ORACLE_PATH_4D

GIS_ORACLE_PATH_4D filename

the full path name to the Oracle DLL. This is only required when using the Oracle Server.

GUI_4D

GUI_4D **Standard** *default Standard*
Non Standard

Defines the mouse button usage within 12d Model.

The default value is *Standard*.

GUI_COLOURS_4D

GUI_COLOURS_4D filename default gui.4d

file of colour definitions used in the GUI

The default is gui.4d. See 39.2.7.6 GUI

HARDLOCK_4D

HARDLOCK_4D 1, 0

if non zero, search for 12d Hardlock dongles.
If zero, don't search for Hardlock dongles

HARDWARE_ARCS_4D

HARDWARE_ARCS_4D **1** Use hardware arcs *default 1*
0 Hardware arcs are not used

if non zero, use computer hardware to draw arcs (rather than software).
If zero, draw arcs in software

The default value is 1.

HEIGHT_MAX_DEFAULT_4D

HEIGHT_MAX_DEFAULT_4D integer (world units) default 0 set the default value to use in Plan Settings panels that have a **Height max (w)** field.

HELP_4D

HELP_4D	folder	default 11.00\help

folder containing the 12d Model help files.

The default is **11.00\help**.

HELP_BUTTONS_4D

HELP_BUTTONS_4D	**0**	Disable help buttons on panels
	1	Enable help buttons on panels.

If non zero, ***Help*** buttons are added to panels.

The default value is 0.

HIMETRIC_4D

HIMETRIC_4D	**0**	Printer resolution of 0.04 mm - for Win 95,98,ME*default 0*
	1	Printer resolution of 0.01 mm - for Win NT, 2000, XP

For Windows 95, 98 and ME, the printer resolution can only be 0.04 mm when covering an A0 sheet.

Under Windows NT, 2000 and XP, no such restriction exists and the full resolution of 0.01 mm can be used so the environment variable HIMETRIC_4D allows access to the higher resolution for Windows NT, 2000 and XP.

The default value is 0.

See also WINDOWS_PRINTERS_4D for enabling access to Windows printers.

HINGE_OFFSET_ZONE_COLOUR_4D

HINGE_OFFSET_ZONE_COLOUR_4D colour

the colour of the text in the Type column for the Hinge Offset commands in the **Hinge Modifiers** panel.

HINGE_HEIGHT_ZONE_COLOUR_4D

HINGE_HEIGHT_ZONE_COLOUR_4D colour

the colour of the text in the Type column for the Hinge Height commands in the **Hinge Modifiers** panel.

HINGE_POSITION_ZONE_COLOUR_4D

HINGE_POSITION_ZONE_COLOUR_4D colour

the colour of the text in the Type column for the Hinge Position commands in the **Hinge Modifiers** panel.

HLS_IPADDR

HLS_IPADDR	list of IP addresses and/or computer names

if **non blank**, a list of IP addresses and/or computer names to search for a 12d Hardlock network dongle. The items in the list are separated by commas

If **blank**, search the entire network for a 12d Hardlock network dongle

HOME_4D

HOME_4D	folder	three folder levels up from where 12d.exe is

12d Model home folder

INTERPRET_DMS_INPUT_OLD_4D

INTERPRET_DMS_INPUT_OLD_4D **0,** 1

if non zero, the special case of 0.mms is interpreted as mm minutes and s seconds. That is, 0.123 is interpreted as 12 minutes and 3 seconds.

If zero, the special case of 0.mms is interpreted as mm minutes and 10 x s seconds. That is, 0.123 is interpreted as 12 minutes and 30 seconds.

LABEL_PVC_150_PIPES_4D

LABEL_PVC_150_PIPES_4D 0, 1 default 1

If non zero, the 150 PVC pipes are labelled on the drainage long section.
If zero, the 150 PVC pipes are not labelled on the drainage long section.

LAYOUT_FILE_4D

LAYOUT_FILE_4D filename default layout.4d

a file containing the screen layout file information (slx/slf) for placing menus or panels on the screen. The layout file is used each time a project is opened to place the menus and panels in it on the screen. See 42.2.3 Screen Layout File in the appendix 42 Special File Formats.

The default is layout.4d.

LIB_4D

LIB_4D folder HOME_4D\11.00\library

12D Solutions library folder for input files such as mapping, template and macros (4DML's).

The default is **HOME_4D\11.00\library**.

LINESTYLE_BOX_HEIGHT_4D

LINESTYLE_BOX_HEIGHT_4D *value*

If non blank, the pixel height of the linestyle and symbol scrolling pop-ups.

The default is 512

LINESTYLE_BOX_WIDTH_4D

LINESTYLE_BOX_WIDTH_4D *value*

If non blank, the pixel width of the linestyle and symbol scrolling pop-ups.

The default is 256

LINESTYLE_DUPLICATE_MODE_4D

LINESTYLE_DUPLICATE_MODE_4D choice box

This environment variable manages what to do if symbols or linestyles with the same name are read from the symbols.4d or linstyle.4d file

Do nothing - accept all instances of symbols/linestyles of the same name
Take first - accept only the first instance of the symbol/linestyle
Take last - accept only the last instance of the symbol/linestyle

LINESTYLES_4D

LINESTYLES_4D filename default linestyl.4d

file of linestyle definitions

The default is linestyl.4d. See 40.1 Line Styles

LIST_POPUPS_4D

LIST_POPUPS_4D **1** Pop-up lists as scrolling lists

0 Pop-up lists as menus (as in versions up to V3.2)

Defines the look of pop-up lists.

If non zero, the popup lists are scrolling lists.
If zero, the pop-ups are menus which turn into walk-right menus when the list is too long.

The default value is 1.

LOOK3D_4D	1	3D look and greenish background	*default 1*
	0	Original 12d gui colours	

The default value is 1.

LOG_DIR_4D

LOG_DIR_4D folder-path-name default is local folder

An error log file is created each time 12d Model is invoked. The error log name automatically created by 12d Model and has the form:

log?????.4de

where ????? is a hashed number using your login name, process id & the current time.

The **folder** that the error log file is created in is given by the environment variable LOG_DIR_4D. The full path-name of the folder is given.

If LOG_DIR_4D is not used, 12d Model tries to create the log file in the current folder, the HOME folder, the TMP folder and the TEMP folder.

If creating an error log file fails in all these ares, 12d Model does not create an error log file.

LONG_SECTION_PPF_4D

LONG_SECTION_PPF_4D *path name to .ppf file* no default

This environment points to the file used as the default plot parameter file (.ppf) for the panel **section long plot**.

The path name to the .ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/long.ppf** points to the file long.ppf in the area defined by $LIB_4D.

MACRO_INPUT_MODE_4D

MACRO_INPUT_MODE_4D	**0**	Don’t put current value into the console	*default 0*
	1	Put current value into console.	

Controls whether or not the value passed down in the variable to receive the answer for any macro prompt, is actually placed into the console panel as the default answer so that it can be accepted by just typing <enter> into the console panel.

The default value is 0.

MAXIMUM_TRASH_SIZE_4D

MAXIMUM_TRASH_SIZE_4D positive integer default 0

the maximum number of Mb that the size of the trash file can be.

If the value is 0, the Trash Bin is **not** limited in size.

The default value is 0.

MIDDLE_DOT_CHARACTER_4D

MIDDLE_DOT_CHARACTER_4D *integer (base 10)* *default 183*

The integer (base 10) value of the character to use as the squared symbol.

MINI_DUMP_LEVEL_4D

MINI_DUMP_LEVEL_4D choice box

MODEL_FOR_TIN_PREFIX_4D

MODEL_FOR_TIN_PREFIX_4D pre*pos *default is* ***"tin "***

This environment variable is used to customize the default model for the tin in the panels for creating triangulations. Text can be defined for prepending and/or appending to tin name to create a default model name from the tin name.

The text for prefixing and postfixing is given in a special form: **pre-text*post-text**

If pretext only, just give the text. If post text is required, precede it by a "*.".

If the environment variable is not set, the default "tin " is used.

MODEL_VIEW_WALKRIGHTS_4D

MODEL_VIEW_WALKRIGHTS_4D	**0**	Use data source in options
	1	Walk-rights for model/view as in up to V3.2

Defines whether the Data source field is used instead of model/view walk-rights used in V3.2.

The default value is 0.

MOVIE_4D

MOVIE_4D executable default xanim

X-Windows only - program for running perspective movie

MS_SEEDFILES_4D

MS_SEEDFILES_4D folder no default

if non blank, the full path name of the folder of Microstation seed files.

MTF_TMP_4D

MTF_TMP_4D anything not defined

If defined, then the temporary files for mtf calculations go to the Windows temp folder. This is to get over a bug in Novell under Windows 95.

MTF_CONSTRUCTION_HINGE_NAME_4D

MTF_CONSTRUCTION_HINGE_NAME_4D text

the default name used to refer to the Hinge string as a link in a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_DESIGN_LAYER_NAME_4D

MTF_DESIGN_LAYER_NAME_4D text

the default name for the design layer in a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_EXTRA_START_END_VAL_4D

MTF_EXTRA_START_END_VAL_4D real value

the default extra start/end value for a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_NAMED_PART_HIGHLIGHT_TEXT_SIZE_4D

MTF_NAMED_PART_HIGHLIGHT_TEXT_SIZE_4D real value

the size of the text to use when the name of the named part is highlighted.

MTF_SEED_INCLUDE_MTFS_4D

MTF_SEED_INCLUDE_MTFS_4D 0 or 1

if non zero, existing MTF files are included (in addition to files of type **.MTF_Seed**) in the choices of files which can be used as a MTF Seed file.

if zero, only files of type **.MTF_Seed** are included in the choices of files which can be used as a MTF Seed file.

MTF_SNIPPET_TEMP_FILE_EXTENSION_4D

MTF_SNIPPET_TEMP_FILE_EXTENSION_4D text

if not blank, the standard **.tmp_mtf** file extension will be replaced with this value.

If blank, the standard **.tmp_mtf** file extension will be used.

For more information on snippets, see 21.5 Defining and Using Snippets.

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_4D

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_4D 0 or 1

if non zero, the temporary file created after the preprocessing occurs for the snippet is given the same name as the snippet, with the file extension **.tmp_mtf**

If zero, the MTF name is used. Note: If there is more than one snippet, this file will be overwritten.

For more information on snippets, see 21.5 Defining and Using Snippets.

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_KEEP_4D

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_KEEP_4D 0 or 1

if non zero, the temporary files created after the preprocessing occurs for the snippet are left on the hard drive.

If zero, the temporary files are deleted.

NOTE: If the snippet is compiled, the temporary files are always deleted.

For more information on snippets, see 21.5 Defining and Using Snippets.

MULTI_LINE_TEXT_4D

MULTI_LINE_TEXT_4D *value* 0 or 1 *default 0*

If non zero, a Text Edit Box is used instead of the Input Box and more than one line of text can be typed into the Text Edit Box.

NAME_MAPPINGS_4D

NAME_MAPPINGS_4D filename default names.4d

A name mapping file can be specified which is used to fill out information such as colour, model etc. for given string names.

The name mapping works in two ways. After typing part or all of a string name,

(a) if <enter> is entered, the map file is searched for a match in the first column.
If a match is found, the name, colour, model, style etc. from the other columns in the name mapping file are used to fill out the panel fields.

(b) if a <tab> is entered, the second column is searched for a list of completions (if a * is found, the first column is used for that check) which are displayed in a pop-up. When an entry is selected from the completion list, the name, colour, model, style etc. from the columns in the name mapping file are used to fill out the panel fields.

(c) name mapping file is used to fill out the panel fields.

NEVER_SNAP_ITSELF_4D

NEVER_SNAP_ITSELF_4D **1** try to stop a string snapping to itself during editing
0 let a string snap to itself - behaviour in V3.2

Tries to stop a string snapping to itself during editing.

The default value is 1.

NEW_DRAINAGE_PPF_4D

NEW_DRAINAGE_PPF_4D *full path name of binary ppf file* no default

Points to the file used as the default binary plot parameter file (.drainppf) for the long section plot produced by the panel **Drainage Plot PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/drainage_long.drainppf** points to the file drainage_long.drainppf in the area defined by $LIB_4D.

NEW_DRAINAGE_MELB_PPF_4D

NEW_DRAINAGE_MELB_PPF_4D *full path name of binary ppf file* no default

Points to the file used as the default binary plot parameter file (.melbppf) for the long section plot produced by the panel **Sewer Plot Melbourne Water PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/melb_water.melbppf** points to the file melb_water.melbppf in the area defined by $LIB_4D.

NEW_DRAINAGE_PLAN_PPF_4D

NEW_DRAINAGE_PLAN_PPF_4D *full path name of binary ppf file* no default

Points to the file used as the default binary parameter file (.drainplanppf) for the plan annotation produced by the panel **Drainage Plan Plot PPF Editor.**

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/drainage_plan.drainplanppf** points to the file drainage_plan.drainplanppf in the area defined by $LIB_4D.

NEW_LONG_SECTION_PPF_4D

NEW_LONG_SECTION_PPF_4D *full path name of binary ppf file* no default

Points to the file used as the default binary plot parameter file (.lplotppf) for the long section plot produced by the panel **Section Long Plot PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/long_section.lplotppf** points to the file long_section.lplotppf in the area defined by $LIB_4D.

NEW_MTF_EDITOR_AUTOPAN_DEFAULT_4D

NEW_MTF_EDITOR_ZOOM_BUFFER_4D 0, 1 *default 1*

if non zero, the default for Autopan is **on** for the MTF ***Left/Right MTF Modifiers*** panel.

if zero, the default for Autopan is **off** for the MTF ***Left/Right MTF Modifiers*** panel.

NEW_MTF_EDITOR_DEFAULT_HEIGHT_4D

NEW_MTF_EDITOR_DEFAULT_HEIGHT_4D *real_value*

real_value is the height in pixels of the MTF ***Left/Right MTF Modifiers*** panel.

The default value is 250

NEW_MTF_EDITOR_DEFAULT_WIDTH_4D

NEW_MTF_EDITOR_DEFAULT_WIDTH_4D *real_value*

real_value is the width in pixels of the MTF ***Left/Right MTF Modifiers*** panel.

The default value is 750

NEW_MTF_EDITOR_PASTED_MODIFIER_COLOUR_4D

NEW_MTF_EDITOR_PASTED_MODIFIER_COLOUR_4D   colour

when you cut/paste the modifiers, the background colour of the pasted rows will remain that colour until you edit them, *i.e.* this option lets you know the pasted rows until you edit them.

NEW_MTF_EDITOR_ZOOM_BUFFER_4D

NEW_MTF_EDITOR_ZOOM_BUFFER_4D   *real_value*

real_value is a percentage.

if *Autopan* is on for the ***Left/Right MTF Modifiers*** panel, then when a command is clicked on in the panel and the region to pan into is not displayed on the view, then the extent displayed it the required amount increased by the *real_value* percentage.

The default value is 5

NEW_PIPELINE_PPF_4D

NEW_PIPELINE_PPF_4D *full path name of binary ppf file*   no default

Points to the file used as the default binary pipeline plot parameter file (.pipelineppf) for the long section plot produced by the panel **Pipeline Plot PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/pipeline_long_section.pipelineppf** points to the file pipeline_long_section.pipelineppf in the area defined by $LIB_4D.

NEW_PLOT_FRAME_PPF_4D

NEW_PLOT_FRAME_PPF_4D *full path name of binary ppf file*   no default

Points to the file used as the default binary parameter file (.plotframeppf) for the plan plot produced by the panel **Plot Frame PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/plot_frame.plotframeppf** points to the file plot_frame.plotframeppf in the area defined by $LIB_4D.

NEW_STRING_CREATES_4D

NEW_STRING_CREATES_4D

NEW_TOOLBARS_VISIBLE_4D

NEW_TOOLBARS_VISIBLE_4D   1, 0   *default*

if non zero, when a project starts up, all the toolbars are checked to see if they are listed in the workspace (visible or invisible) and if the toolbar does not exist, then the toolbar will be displayed.

This is to allow any new toolbars added to toolbars.4d to be automatically displayed so that the user knows that it exists.

if zero, then new toolbars are not displayed. That is, only toolbars listed in the workspace (visible are displayed.

NEW_X_SECTION_PPF_4D

NEW_X_SECTION_PPF_4D *full path name of binary ppf file*   *no default*

Points to the file used as the default binary plot parameter file (.xplotppf) for the cross section plots produced by the panel **Section X Plot PPF Editor**.

The path name to the binary ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/cross_section.xplotppf** points to the file cross_section.xplotppf in the area defined by $LIB_4D.

NOP_ZONE_COLOUR_4D

NOP_ZONE_COLOUR_4D *colour*

the colour of the text in the Type column for the commands that aren't in the Fixed, Cut, Fill or Final sections of the modifiers in the **Left/Right MTF Modifiers** panel, *e.g.* Interval commands.

NVALUES_4D

NVALUES_4D filename default nvalues.4d

This points to the file which is used as the file of n value definitions. These are described in 7.6.7 N values and the editing of the n values file is documented in 7.6.7.2 Create/Edit N-Values.

The default is nvalues.4d.

OPENGL_CACHE_4D

OPENGL_CACHE_4D *value* 0 or 1 *default 1*

If non zero, rasters and textures are cached in the graphics card memory for potential speed ups. More memory in the graphics card allows more caching and usually more performance gains.

OPENGL_CACHE_TINS_4D

OPENGL_CACHE_TINS_4D *value* 0 or 1 *default 0*

If non zero, tins are cached in the graphics card memory for potential speed ups. More memory in the graphics card allows more caching and usually more performance gains.

OPENGL_MIPMAP_4D

OPENGL_MIPMAP_4D value 0 or **1**

If ticked, the graphics card down samples for rasters when the image is further away.

Default value is 1.

OPENGL_MIPMAP_BILLBOARDS_4D

OPENGL_MIPMAP_BILLBOARDS_4D value 0 or 1

If ticked, the graphics card down samples for billboards when the image is further away.

OPENGL_MIPMAP_PLAN_IMAGES_4D

OPENGL_MIPMAP_PLAN_IMAGES_4D value 0 or 1 default 1

If ticked, the graphics card down samples plan images when draped onto a tin.

OPENGL_MIPMAP_PROJECTOR_IMAGES_4D

OPENGL_MIPMAP_PROJECTOR_IMAGES_4D value 0 or 1 default 1

If ticked, the graphics card down samples projector images (a projector is for the "hidden" perspective image data object of a super string).

OPENGL_OFFSET_4D

OPENGL_OFFSET_4D value 0 or 1 default 1

If non zero, the coordinates are localised for OpenGL calls. This is to work around problems with some graphics cards that can't handle large coordinates.

OPENGL_VIEW_BACKING_STORE_4D

OPENGL_VIEW_BACKING_STORE_4D value 0 or 1

if 1, a backing store is used.

if 0, a backing store is not used.

For Window Vista/Windows 7, the default is 1. Otherwise the default is 0.

ONSCREEN_KEYBOARD_4D

ONSCREEN_KEYBOARD_4D value 0, 1 or 2

if 0, then no onscreen keyboard comes up when you double click in a panel field.
if 1, when you double click in a panel field that takes typed input, then a dockable onscreen keyboard come up for the user to type the data for the panel field into.
if 2, when you double click in a panel field that takes typed input, then a full screen onscreen keyboard come up for the user to type the data for the panel field into.

The default is 0.

ONSCREEN_KEYBOARD_FONT_SIZE_4D

ONSCREEN_KEYBOARD_FONT_SIZE_4D *number*

if non blank, the pixel size of the font for the onscreen keyboard.
If blank, it defaults to the normal system font size.

The default is the normal system font size.

ONSCREEN_KEYBOARD_LAYOUT_4D

ONSCREEN_KEYBOARD_LAYOUT_4D value 0, or 1

if 0, then when there is an onscreen keyboard, it comes up with a full keyboard.
if 1, then when there is an onscreen keyboard, it comes up with just a numeric keyboard.

The default is 0.

OVERFLOWING_TRASH_MODE_4D

OVERFLOWING_TRASH_MODE_4D choice box *default* Auto manage

the action to take when the trash bin exceeds the maximum trash bin size.

If **Auto manage,** the oldest files in the trash bin are deleted until the new item can fit in the trash bin.

if **Auto empty,** files in the trash bin are deleted.

Note - if a large model or tin is deleted and it is bigger than the maximum trash bin size, the user is alerted and asked to decide if they want the element to go in the trash bin anyway, or if they want to permanently delete it.

The default value is Auto manage.

PAN_MODE_4D

PAN_MODE_4D	**0**	Use standard pan for pan, pans on views
	1	Use pan deltas for pan, pans on views

Sets whether pan or pan delta is used for the pan and pans buttons on views.

The default value is **0**.

PATTERNS_4D

PATTERNS_4D filename default patterns.4d

Points to the file used to define the patterns used for super string fills.

The default is patterns.4d.

PDF995_TIME_LIMIT_4D

PDF995_TIME_LIMIT_4D *number*

the number of seconds to wait for PDF995 to finish producing the current PDF file.

PICK_ONLY_ON_SELECTS_4D

PICK_ONLY_ON_SELECTS_4D

PLAN_TABLE_SETTINGS_4D

PLAN_TABLE_SETTINGS_4D	**0**	Don't allow setting by model*default 0*
	1	Allow setting by model

Trial only - allow the drawing of z-values, vertices etc. on the plan view to be set by individual models rather than for all models on the view.

The default value is 0.

PLOTTER_4D

PLOTTER_4D script/program no default

This environment variable points to a script/program which can be fired up whenever a plot is generated. The name of the plot is given as the first script parameter of the script.

If the parameter **Send plots** on the 'System Settings' tab of the menu option **Utilities** => **Defaults** is set to **yes**, the plotter script is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the script is called separately for each of the plots.

An example of a script to send the plot to port lpt1 for Windows NT would be

```
@echo off
copy %1  lpt1
```

An example for Windows NT which looks for hp files is

```
@echo off
echo.
echo --------------------------------------------------
:next_file
if "%1" == "" goto done
echo %1 | find /I ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
echo Plotting file %1
shift
goto next_file
:hp_plotter
echo Plotting %1 to HP plotter
shift
goto next_file
:done
echo --------------------------------------------------
```

PLOTTER_MAPPING_4D

PLOTTER_MAPPING_4D filename default pmf.4d

This points to the file which is used as the default plotter mapping file. The format for the plotter mapping file is described in the section 43.3 Mapping 12d Colours to Pens and RGBs in the Appendix 39 Setting Up & Configuring 12d.

The default is pmf.4d.

PLOTTERS_4D

PLOTTERS_4D filename default plotters.4d

This points to the file which contains user defined plotters. The format for the file of user defined plotters is described in the section 43.2 Defining Plotters - Plotters.4din the Appendix 39 Setting Up & Configuring 12d.

The default is plotters.4d.

PLOT_SYMBOLS_4D

PLOT_SYMBOLS_4D filename default plotsymb.4d

Points to the file used to define the symbols used in long and cross section plots.

The default is plotsymb.4d.

POLYPOLYLINES_4D

POLYPOLYLINES_4D	**0**	Don't use speed ups	*default 2*
	1	Intermediate speed ups	
	2	Faster speed ups.	

A few experimental techniques are available for speeding up the drawing on the screen.

For some specific things such as fast contours, fast mesh and point crosses, the techniques can result in some redraws being up to three times faster.

The default env.4d shipped with ***12d Model*** has this set to 2.

PREVIEW_VIEW_4D

PREVIEW_VIEW_4D *text*

if non blank, the name of the view whose image is dumped on exiting the project. The image is used as the project preview.
If blank then the last active view is used.

PRINTER_4D

PRINTER_4D script/program no default

Points to a script or program which can be fired up whenever a report is generated. The name of the report is given as the first parameter of the script.

If the parameter **Print reports** on the 'System Settings' tab on the menu option **Utilities => Defaults** is set to **yes**, the printer script is run as each report is created.

PROCESSOR_AFFINITY_4D

PROCESSOR_AFFINITY_4D

PROJECT_DETAILS_4D

PROJECT_DETAILS_4D file name

If non blank, the full path name of the file of project details file to use for new projects.

PROJECT_NAMES_4D

PROJECT_NAMES_4D	**0**	Use long filenames for internal files	*default*
	1	Use short names (8.3 format)	

The use of long or short extension names for internal 12d Model files for items such as models, tins, templates etc. is controlled by the environment variable PROJECT_NAMES_4D.

Opening a new project with the short name format, project-name.4dp, will automatically create a short name project (i.e. a project using the short extension names - 3 characters after the **.**).

The default value is 0.

PROJECTIONS_4D

PROJECTIONS_4D filename default carto.4d

This points to the file which is used as the file of projections. These are described in 7.6.6 Projections and the editing of the projections file is documented in 7.6.6.2 Create/Edit Projection.

The default is carto.4d.

PROMPT_ON_VIEW_CLOSE_4D

PROMPT_ON_VIEW_CLOSE_4D **0**, 1

If non zero, when a view is closed/deleted, a prompt asks for a confirmation of deleting/closing. If zero, no confirmation is requested when a view is closed/deleted.

The default is 0.

PURGE_TRASH_DAYS_4D

PURGE_TRASH_DAYS_4D *number_of_days* *default 0*

number_of_days is a positive integer and is the number of days before the Trash Bin is automatically purged of tins and models.

If *number_of_days* is zero, the Trash Bin is **not** purged.

The default value is 0.

RECENT_PROJECTS_4D

RECENT_PROJECTS_4D positive integer default 20

The maximum number of accessed projects displayed in the Projects list when ***12d Model*** starts up.

REMEMBER_MTF_PANEL_SIZE_4D

REMEMBER_MTF_PANEL_SIZE_4D 0 or 1

if non zero, when a MTF panel is placed on the screen and closed with Finish, its final position and size are recorded and used when the panel is opened again.

REPORT_HEADER_4D

REPORT_HEADER_4D	0	Report files have no header page
	1	Some header information is used
	2	A full header page is produced.*default 2*

Controls the amount of header information in reports.

For the cases 1 and 2, the header information includes

(a) the 12d Model Project

(b) the name of the user

(c) the organization

(d) the current date

(e) the current report file name

The default value is 2.

RUN_MACROS_FILE_4D

RUN_MACROS_FILE_4D filename default macros.4d

if non blank, the full pathname of the file of macros (one per line) that are run when a new project is created.

Note: This is only run for new projects. RUN_PROJECT_MACROS_FILE_4D is run when opening an existing project.

The default is macros.4d

RUN_PROJECT_MACROS_FILE_4D

RUN_PROJECT_MACROS_FILE_4D filename default project_macros.4d

if non blank, the full path name of the file of macros (one per line) that are run when an existing project is opened.

Note: This is only run when opening existing projects. RUN_MACROS_FILE_4D is run when creating a new project.

The default is project_macros.4d

SDR_DISPLAY_V8_FORMAT_4D

SDR_DISPLAY_V8_FORMAT_4D

SETUPS_FILE_4D

SETUPS_FILE_4D filename default setups.4d

file setting up the initial screen layout for new projects. This is not to be confused with SET_UPS_4D which is where the standard Set Up files are installed. See SETUPS_FILE_4D.

The default is setups.4d. See 39.2.7.1 Set Ups File (setups.4d).

SET_UPS_4D

SET_UPS_4D folder HOME_4D\11.00\set_ups

folder for storing the standard Set Up files installed by 12D Solutions.

The default is **HOME_4D\11.00\set_ups**.

SEWER_PPF_4D

SEWER_PPF_4D path name to .ppf file no default

points to the file used as the default plot parameter file (.ppf) for the panel **new plot sewer network**.

SHARE_CHECK_INTERVAL_4D

SHARE_CHECK_INTERVAL_4D positive integer *default 0*

if non zero, the number of seconds between checks to see if any of the shared tins or models added to the project have been modified.

SHARE_LOCKS_FOLDER_4D

SHARE_LOCKS_FOLDER_4D folder default no folder

if non blank, the full path name of the folder used to keep lock files for shares.

If no folder is given, the locking files are stored inside the project.

SHARE_MAP_FILE_4D

SHARE_MAP_FILE_4D filename default blank

if non blank, the full path name of the map file to be applied to shared models.

SHARED_ELEMENT_COLOUR_4D

SHARED_ELEMENT_COLOUR_4D colour default blue

the colour to use in a list of tins/models for showing shared tins/models. That is, the tins/models that have been added to the project as shared tins/models are shown in this colour.

Setting the colour to black will disable this feature.

SHARING_CACHE_4D

SHARING_CACHE_4D folder default no folder

if non blank, the full path name of the folder that is used to store the models and tins and tins that are shared into the project. Each time the project is started, each model and tin that is shared into the project is checked to see if has changed since the last time it was used in the project, and if has not changed then the copy in the **Sharing Cache Folder** is used. This can greatly improve performance when the models and tins are being shared into your project from across the network.

If no folder is given, no chacing of models or tins is done.

SHARING_ELEMENT_COLOUR_4D

SHARING_ELEMENT_COLOUR_4D colour default rgb 255,165,0

the colour to use in a list of tins/models for showing the tins/models in the project that you are allowing to be shared. That is, those tins/models in the project that the user has allowed others to share are shown in this colour.

Setting the colour to black will disable this feature.

SHEET_SIZES_4D

SHEET_SIZES_4D filename default sheets.4d

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal Set Up areas, or is pointed to by the environment variable SHEET_SIZES_4D.

The default is sheets.4d. See 39.2.7.4 Sheet Sizes File (sheets.4d).

SHOW_OPTION_EXECUTION_TIME_4D

SHOW_OPTION_EXECUTION_TIME_4D integer 0

if non zero, the time taken for an option to run is written to the output window.

If zero, the information is not written to the output window.

SHOW_PATHS_4D

SHOW_PATHS_4D anything

If non blank, then when 12d Model fires up the actual file names defined by any environment variables are written to the output window. This is useful for debugging.

SHOW_PROJECT_DETAILS_4D

SHOW_PROJECT_DETAILS_4D 0, **1** default 1

If non zero, *the* Edit Project Details *panel is displayed when a new project is created.*

SHOW_TITLE_VARIABLES_4D

SHOW_TITLE_VARIABLES_4D	**0**	any $variable not used is left as blank
	1	any $variable not used is shown as $variable
	2	all $variable's are plotted with no substitution

This is used for debugging the title block file.

If 0, any $variable not used in the title blank file is left as blank.
If 1, any $variable not used is shown as $variable.
If 2, all $variable are plotted with no substitution.

The default value is 0.

SHOW_VISTA_VIRTUAL_STORE_PATHS_4D

SHOW_VISTA_VIRTUAL_STORE_PATHS_4D tick box

if ticked, then for Microsoft Vista, when 12d Model fires up, the actual file names defined by any environment variables are written to the output window. This is useful for debugging due to the fact that Vista may put file sin strange places.

SNIPPET_ZONE_COLOUR_4D

SNIPPET_ZONE_COLOUR_4D *colour* *default light grey (RGB(155, 140, 150)*

the colour of the text in the *Type* column for the *Snippet* command in the *Modifiers* section of the ***Left/Right MTF Modifiers*** *panel*.

SORT_COLOURS_BY_POPUP_NUM_4D

SORT_COLOURS_BY_POPUP_NUM_4D 0,**1** default 1

Controls the display order of the colours in the **Select Colour** popup that you get when you click on a **Colour** icon.

If **SORT_COLOURS_BY_POPUP_NUM_4D** is **1,** the colours in the **Select Colour** popup are sorted by the Pop-up Number given for the colours in the **Colours.4d** file.

If **SORT_COLOURS_BY_POPUP_NUM_4D** is **0,** the colours in the **Select Colour** popup are sorted alphabetically.

The default value is **1**.

SPECIAL_OFFSET_CHAINAGES_4D

SPECIAL_OFFSET_CHAINAGES_4D

SPEED_TABLES_4D

SPEED_TABLES_4D

SQUARE_CHARACTER_4D

SQUARE_CHARACTER_4D *integer (base 10)* *default 178*

The integer (base 10) value of the character to use as the squared symbol.

STATION_PREFIX_4D

STATION_PREFIX_4D *text* There is no default.

The default prefix to use in the Survey Data Setup panel or to use if no prefix has been set for the project.

There is no default value.

SUPER_ADVANCED_MODE_4D

SUPER_ADVANCED_MODE_4D

SUPER_ALIGNMENT_STYLE_4D

SUPER_ALIGNMENT_STYLE_4D filename default astyles.4d

Points to the file used to define the symbology used for super alignments.

The default is astyles.4d.

SUPER_STRINGS_4D

SUPER_STRINGS_4D	**1**	Use the super string
	0	Don’t use the super string.

Controls whether the super string is accessible or not.

The default value is 1.

SYMBOLS_4D

SYMBOLS_4D filename default symbols.4d

Points to the file used to define the symbols used for super strings.

The default is symbols.4d.

SYSTEM_NAMES_4D

SYSTEM_NAMES_4D	1	Only use the longer names
	2	Only use the 8.3 file names
	3	Use short names first then look for a long name.

For file name compatibility with DOS 8.3 format, the default names for all Set Up files can be restricted to just short names (8.3), long names, or short and then long.

The default value is 3.

TRANSFORMATIONS_4D

TRANSFORMATIONS_4D   filename   default 7params.4d

This points to the file which is used as the file of seven parameter transformations. These are described in 7.6.8 7 Parameters and the editing of the transformations file is documented in 7.6.8.1 Create/Edit 7 Parameters.

The default is 7params.4d.

TEXTSTYLE_MAPPINGS_4D

TEXTSTYLE_MAPPINGS_4D   filename   default textstyle_names.4d

file of textstyles favourites definitions

The default is textstyle_names.4d

TEXTSTYLES_4D

TEXTSTYLES_4D   filename   default textstyl.4d

file of textstyles definitions

The default is textstyl.4d. See 40.3 Textstyles and Fonts.

TEXTURE_MAP_4D

TEXTURE_MAP_4D   filename   default texture_map.4d

This points to the file which defines the tables of texture mappings. These are described in 12.13.4 Texture Map Edit.

The default is texture_map.4d.

TICK_DRAW_CROSS_4D

TICK_DRAW_CROSS_4D	**0**	Nothing for off
	1	Cross for off

The default value is 0.

TIN_VIEWPORT_CLIP_4D

TIN_VIEWPORT_CLIP_4D	**0**	Drawing tins, fast contours as per V3.1
	1	A speed up for drawing tins, fast contours

Use some experimental techniques for speeding up the drawing of tins, fast contours.

The env.4d file shipped with ***12d Model*** has this set to 1.

TOOLBAR_DUPLICATE_MODE_4D

TOOLBAR_DUPLICATE_MODE_4D   choice box

This environment variable manages what to do if toolbars with the same name are read from a *toolbars.4d* file. The choices are

Do nothing - accept all toolbars of the same name
Take first - accept only the first instance of the toolbar
Take last - accept only the last instance of the toolbar

TOOLBARS_4D

TOOLBARS_4D   filename   default toolbars.4d

file of toolbar definitions and names

The default is toolbars.4d. See 41.3 User Defined Toolbars

TP_STAKEOUT_PATH_4D

TP_STAKEOUT_PATH_4D folder no default

if non blank, the full path name of the folder of TP Stakeout files.

TRIMESH_TO_DWG_MODE_4D

TRIMESH_TO_DWG_MODE_4D Do not write OR Faces OR Polyface mesh

if **Do not write**, trimeshes are not written out to a DWG file.

If **Faces**, a trimesh is written out to DWG file as individual 3DFaces.

If **Polyface mesh**, a trimesh is written out to a DWG file as a Polyface mesh.
Note that a Polyface mesh has only one colour.

TYPED_UNITS_MODE_4D

TYPED_UNITS_MODE_4D **0** International units only e.g. f and F are both International fee
1 USA units only e.g. f and F are both US feet
2 Mixed e.g. f is International feet and F is US feet.

Controls the typed input units for feet - international and/or US

The default value is 0.

UNDO_4D

UNDO_4D 0 Don't allow undo's
1 Allow undo/redos *default 1*

Undo and Redo is available for most operations from ***12d Model*** V3.1 onwards. The availability of Undo/Redo facility is controlled by the environment variable:

The default value is 1.

USAGE_LOG_4D

USAGE_LOG_4D folder *no default*

when set, log files of the form

<log file folder>\(<dongle> <user> <computer> <time stamp> <process ID>.log)

will be created in the given folder.

That is, the log files will all be in the one folder.

USAGE_LOGS_4D

USAGE_LOGS_4D folder *no default*

when set, log files of the form

<log file folder>\<dongle>\<user>\<computer>\(<time stamp> <process ID>.log)

will be created in the given folder.

That is, the log files will be in subfolders \dongle\<user>\computer>.

USE_ALL_USERS_PROFILE_4D

USE_ALL_USERS_PROFILE_4D 0, 1

If no-zero then the file env.4d and the folders user and user_lib are looked for in ***\Documents and Setting\All Users***.

USE_BACKUPS_4D_FOLDER_4D

USE_BACKUPS_4D_FOLDER_4D 0, **1** default 1

If non-zero: in the places where ***12d Model*** creates a backup file when a new file is created (using the file endings 1, 2, ... for the old file) then the backup file is placed in the folder backups.4d.

Backups are created for options such as env.4d editor, mtf editor, boxing editor, survey.4d editor, whenever the "Write Setup File(s)" is displayed, plus the macro calls Backup_version_file and Restore_version_file.

The backups.4d folder is created in the project working folder (that is, in the folder containing the .project folder).

USE_DENSITY_CHECKS_4D

USE_DENSITY_CHECKS_4D	0	Don't do density checks	
	1	Do density checks	*default 1*

If non zero then for a new project, the default for **Use density drawing** in the **Defaults** panel is ***tick***.

If zero then for a new project, the default for **Use density drawing** in the **Defaults** panel is ***no tick***.

For more information on ***density drawing***, see Use density drawing tick box.

Note: This setting is only applicable to the 250M version of ***12d Model.***

USE_DISPLAY_MANY_SNAP_4D

USE_DISPLAY_MANY_SNAP_4D

USE_ECW_SERVER_4D

USE_ECW_SERVER_4D

USE_IMAGE_SERVER_4D

USE_IMAGE_SERVER_4D

USE_NAMES_COMMENT_4D

USE_NAMES_COMMENT_4D

USE_NEW_LINESTYLE_LIST_BOX_4D

USE_NEW_LINESTYLE_LIST_BOX_4D value 0, 1

If non zero, the linestyle and symbol pop-up lists are in scrolling boxes so they don't run over the bottom of the screen. The list of linestyles/symbols is displayed in a tree structure with the Groups as the nodes of the tree.

If zero, the linestyle and symbols lists are one long list with each Groups being an item in the list. The list may get too long to fit on the screen.

The default value is 1.

USE_NEW_SELECT_4D

USE_NEW_SELECT_4D

USE_SUPER_STRINGS_4D

USE_SUPER_STRINGS_4D

USE_TRASH_BIN_4D

USE_TRASH_BIN_4D	0	Don't use the Trash Bin	*default 1*
	1	Use the Trash Bin	

The Trash Bin is used to store copies of deleted tins and models, and cleaned models.The items can be retrieved from the Trash Bin. The Trash Bin is automatically purged of contents after PURGE_TRASH_DAYS_4D.

The default value is 1.

USE_VALIDATION_COLOURS_4D

USE_VALIDATION_COLOURS_4D *value* 0 or 1 default 1

If 1, when a panel field fails to validate, the panel field is filled with the colour given by

USER_4D

USER_4D folder HOME_4D\11.00\user

user folder containing Set Up files

The default is **HOME_4D\11.00\user**.

USER_LIB_4D

USER_LIB_4D folder HOME_4D\11.00\user_lib

user library folder for input files such as mapping, template and macros (4DML's).

The default is **HOME_4D\11.00\user_lib**.

USER_OPTIONS_4D

USER_OPTIONS_4D file default usermenu.4d

To help customise 12d Model, the walk-right menu **User** on the main 12d Model menu, can be user defined. The text for each button of **User**, plus the action taken when the button is selected is user specified. Any of the buttons can include further walk-right menus.

The definitions for the menus on **User**'s is given in the file *usermenu.4d* which is searched for in the standard Set Up areas (local, USER_4D, user, set_ups) or set by the environment variable USER_OPTIONS_4D.

if USER_OPTIONS_4D is blank, usermenu.4d is searched for in the standard search path for *User* files.

if USER_OPTIONS_4D is not blank, then it is used as the full path name of the user supplied file of definitions for user defined menus.

The default is usermenu.4d. See 41.2 User Defined Menus

V7_TITLE_BLOCKS_4D

V7_TITLE_BLOCKS_4D value 0 or **1** *default* 1

if non zero, the title block file is in 12da format.
If zero, the title block is in the pre V7 title block .tf format

VALIDATION_FAIL_COLOUR_4D

VALIDATION_FAIL_COLOUR_4D *text*

If not blank, the colour to fill the panel field with when there is a validation error for the field. The *text* is either a colour name, a colour number or RGB(x,y,z).

This is only used if USE_VALIDATION_COLOURS_4D is non zero (or at least not set to zero since the default is one).

If blank, the default colour is RGB(255,72,72),

VEHICLE_PATH_4D

VEHICLE_PATH_4D folder no default

The DOS Version of Vpath is no longer supported.

The environment variable VEHICLE_PATH_4D points to the folder where the Dos version of the Vpath executable is located. Note that WINDOWS_VEHICLE_PATH_4D points to the Windows version.

VIEW_BITMAP_BUTTONS_4D

VIEW_BITMAP_BUTTONS_4D	0	User text for view buttons
	1	Use icons for view buttons

The default value is 1

VIEW_BUTTONS_4D

VIEW_BUTTONS_4D	0	No view buttons are displayed
	1	The view buttons are displayed

If non zero, then menu items (view buttons) are displayed on the views (as icons or text).
If zero, menu items (view buttons) are not displayed on the views.

The default value is 1

Note: displaying *view buttons* as icons or text is controlled by VIEW_BITMAP_BUTTONS_4D

WARP_CURSOR_HIDE_4D

WARP_CURSOR_HIDE_4D	**0**	Don’t hide the cursor before moving it
	1	Hides the cursor before moving it

Controls whether the cursor is hidden before moving - only needed on some computers.

If non zero, don’t hide the cursor before moving it.
If zero, hides the cursor before moving it.

The default value is 0.

WEB_SEARCH_4D

WEB_SEARCH_4D	search engine web address	www.google.com

web address of the search engine that is fired up from the 12d option

Help =>12d on the Web =>Search the web.

WEED_TOLERANCE_4D

WEED_TOLERANCE_4D	0	Don’t weed
	real	Weed tolerance

used in Alignment and Super strings so that when arcs have been chord-to-arc’d, the resulting points are weeded so that no point is closer than the weed tolerance. Is is also used in Apply and Apply MTF so that no cross sections are closer than the weed tolerance.

WIBU_4D

WIBU_4D 1, 0

if non zero, search for 12d Wibu dongles.
If zero, don’t search for Wibu dongles

WIBU_DONGLE_4D

The environment variable can have a number of parameters to control the use of Wibu network and stand alone dongles.

(a) WIBU_DONGLE_4D -local OR -no_local

usually used when there is a network dongle and need to know if any stand alone Wibu dongle is to be looked for on the computer that the user is on.

if **-local**, then a stand alone Wibu dongle is looked for on the computer the user is on.
If **-no local**, then no stand alone Wibu dongle is looked for on the computer the user is on.

For example WIBU_DONGLE_4D - local or -no local

(b) WIBU_DONGLE_4D -no network OR -network first OR -network last

need to specify if any network Wibu network dongle is to be looked for.

if -**no network**, then no Wibu network dongle is looked for.
If **-network first**, then a Wibu network dongle is looked for before a stand alone local dongle.
If **-network last**, then a Wibu network dongle is looked for after looking for a stand alone local dongle.

For example WIBU_DONGLE_4D -no_network *or* - network_first *or* -network_last

(c) WIBU_DONGLE_4D -login_retries number of retries to find a Wibu dongle

the number ***nn*** of retries to make when searching for a Wibu dongle and it is not found.

For example WIBU_DONGLE_4D -login_retries 3

(d) WIBU_DONGLE_4D -login_wait ss

the number of seconds ***ss*** to wait between retries to find a network Wibu dongle.

For example WIBU_DONGLE_4D -login_wait 5

(e) WIBU_DONGLE_4D -no_dongle

if the parameter -no_dongle is found, then no search is made for a Wibu dongle.

For example WIBU_DONGLE_4D -no_dongle

(f) WIBU_DONGLE_4D -debug

if the parameter -debug is found, then Wibu dongle debug information is written to the

For example WIBU_DONGLE_4D -debug

See the separate notes on installing a network dongle for more details.

WIBU_IPADDR

WIBU_IPADDR list of IP addresses and/or computer names

if **non blank**, a list of IP addresses and/or computer names to search for a 12d Wibu network dongle. The items in the list are separated by commas

If **blank**, search the entire network for a 12d Wibu network dongle

WINDOWS_PRINT_MODE_4D

WINDOWS_PRINT_MODE_4D *value*

value is an integer representing "bit mask".

If **bit 1** set (contributes 1 to *value*): Windows 2000/XP print dialog means PrintDlgEx otherwise if bit 1 is not set, then PrintDlg.
if **bit 2** set (contributes 2 to *value*): Use exclusive access to the printer to force direct printing to the printer (may need Printer admin access)
if **bit 3** set (contributes 4 to *value*): Use an intermediate print file so that printing is first done to a file and then that file is submitted to the printer

So the legal values are from 0 to 7

WINDOWS_PRINTER_SET_DOCUMENT_PROPERTIES_4D

WINDOWS_PRINTER_SET_DOCUMENT_PROPERTIES_4D

WINDOWS_PRINTERS_4D

WINDOWS_PRINTERS_4D	0	Don’t allow Windows printers
	1	Enable Windows printers

The default value is 1.

WINDOWS_VEHICLE_PATH_4D

WINDOWS_VEHICLE_PATH_4D folder no default

if non blank, the full path name of the folder where the Windows program Vpath is located.

Note - Vpath is the Vehicle Turning Path program written by Queensland Department of Transport and Main Roads that is provided free of charge.

WINTER_4D

WINTER_4D path name to WINTER program

12d Model no longer uses the external Winter program and so this environment variable is no longer used.

Points to the WINTER program for calculation N-values for Australia.

WINTER_DATA_4D

WINTER_DATA_4D folder no default

Folder containing the Winter data of N-values for Australia.

WINTER_USE_NEW_METHOD_4D

WINTER_USE_NEW_METHOD_4D value 0, 1 default 1

if tick, re-reading the Winter data is avoided and this speeds up the calculation for the Winter interpolations.

WORKSPACE_FILE_4D

WORKSPACE_FILE_4D path name

if non blank, the full path name of the workspace file for new projects.

WRITE_ALL_PLOT_PARAMETERS_4D

WRITE_ALL_PLOT_PARAMETERS_4D 0 Only write out the plot parameters that are used in the ppf.
1 Write out all plot parameters to a ppf file

Controls whether all plot parameters are written out to a ppf file or just those that have been used in the ppf file.

The default value is 1.

X_SECTION_PPF_4D

X_SECTION_PPF_4D *path name to .ppf file* no default

points to the file used as the default plot parameter file (.ppf) for the panel **section X plot**.

The path name to the .ppf file can contain $LIB which expands out to the path of the library area. For example, **$LIB/cross.ppf** points to the file cross.ppf in the area defined by $LIB_4D.

ZOOM_ORIGIN_DYNAMIC_4D

ZOOM_ORIGIN_DYNAMIC_4D **0** The centre of the view is the zoom centre point
1 The point you pick is the zoom centre point

Controls the origin of the dynamic zoom.

If non zero then the point selected in the view to indicate which view to dynamically zoom (and to be the zoom-in, zoom-out definition point) becomes the point to dynamically zoom about. Whilst the dynamic zoom is running, another point can be selected to become the new zoom origin.

The default value is 0.

ZOOM_PAN_DYNAMIC_4D

ZOOM_PAN_DYNAMIC_4D **0** Dynamic pan is not the default
1 Dynamic pan is the default for pan

If non zero then ***dynamic pan*** is the default for the pan options. The middle mouse button (or 'd') is not required to place the pan option in dynamic mode. In fact, it would then toggle it off.

The default value is 0.

Notes

(a) If any of the environment variables (pointing to files) are not set, or the file pointed to does not exist, then 12d Model searches for the default files in a number of locations. The search order is given at the beginning of this Appendix.

(b) The eagle pen mapping file, **eagleplt.emf** is also searched for in the same order as the default files.

(c) When an **existing** project is opened by 12d Model, the setups.4d and defaults.4d are not used.

Please continue to the next section 39.4.2 Setting Environment Variables.

39.4.2 Setting Environment Variables

The simplest method for setting the required environment used in 12d Model is to place then into a file, called the environmental file (default name env.4d).

Environment Variables File

It is possible to define a file which sets the value for one or more environment variables.

The file format consists of one line for each environment variable being set and each line contains the environment variable name, followed by one or more spaces and then the value for the environment variable:

environment_variable_name *value*

The value of any environment variable given in the environment variable file **overrides** any other definition for that environment variable.

The file used as the environmental variable file is checked for in the following order - as soon as a file is found, the search terminates and that file is used:

1. as a command line argument when 12d Model is fired up. The syntax is

   12d -env path_name

   where path_name is the full path name of the file
2. pointed to by the environment variable ENVIRONMENT_4D

   ```
   ENVIRONMENT_4D    file    // file of environment variables
                             // default env.4d
   ```
3. a file called **env.4**d which is searched for in the standard Set Up areas (local, USER_4D, user, set_ups).

An example of an environment variable file is

```
EDITOR_4D         te                   // set the text editor used
SHOW_PATHS_4D     1      // show file names set by environment variables
SHEET_SIZES_4D    c:\standards\shfile
```

Setting Environment Variables not in a File

Environment variables can be set in **Windows NT** for a user from the *Environment* tab on the *System Properties* panel brought up by clicking on the *System* icon in the *Control Panel* of Windows.

To bring up the *Control Panel*, click on *Start* in the Windows Task bar, walk right on *Settings* and then click on *Control Panel*.

Please continue to the next section 39.2.7.1 Set Ups File (setups.4d).

39.5 12d Model Options Map

The ***12d Model*** menu map shows the menu structure for all the sub-menus on the main ***12d Model*** menu and the menus on the views.

The map is designed to be printed out for users who wish to affix it to a wall.

The PDF file of the menu map on the ***12d Model*** Installation CD in the folder

Documentation***12d Model*** menu map

Or in the *Updates* section of the web site www.12d.com.

Please continue to the next section 39.6 Monitoring 12d Model Usage.

39.6 Monitoring 12d Model Usage

39.6.1 Overview of 12d Usage

12d Model usage can be monitored for single-user and network licenses (or a mix of both), whether installed on a single computer, a local-area network, or a wide-area network across different time zones.

Monitoring the usage is a 3 stage procedure:

1. Generating individual .log files for each ***12d Model*** session run.
2. Consolidating all the completed .log files into a CSV file.
3. Reporting the usage details, using the CSV file as input.

The 1st stage is achieved by setting an environment variable in your env.4d file(s).

The last 2 stages are achieved by running the supplied program: 12d_usage.exe.

Continue to the next section 39.6.2 Generating the .log files or return to 39.6 Monitoring 12d Model Usage.

39.6.2 Generating the .log files

By setting one of two possible environment variables in the env.4d file(s) used for your ***12d Model*** sessions, uniquely named .log files can be generated in a specified folder on your network.

For example, by adding the lines:

usage_log_4d   F:\12d model usage

or

usage_logs_4d   F:\12d model usage

to your env.4d file(s), then each time a ***12d Model*** session is run, a .log file will be created in the "F:\12d model usage" folder. This folder, referred to as the <log file folder>, can be anywhere on your network and can have any name, ***but it must be created beforehand***, and all 12d Model users must have write-access to it.

In the first case, using variable "usage_log_4d", log files will be generated in the form:

<log file folder>\(<dongle> <user> <computer> <time stamp> <process ID>.log)

In the second case, using variable "usage_logs_4d", log files will be generated within sub-folders of the form:

<log file folder>\<dongle>\<user>\<computer>\(<time stamp> <process ID>.log)

Note that the <time stamp> represents the start time of the ***12d Model*** session in GMT (also known as UTC or Zulu Time).

It does not matter which variable you decide to use, and you can even use a mix of the variables, if you have more than one env.4d file. However, regardless of which variable you use, it is recommended that the <log file folder> is the same for all ***12d Model*** users on your network so that all ***12d Model*** sessions can be easily included in the reports.

The **.log** file generated in the <log file folder> for each individual ***12d Model*** session run on your network, contains all the information required about that session. While the session is still running, the log file will be updated at a minimum of every 75 seconds, with the time that the session has been active. At the close of the ***12d Model*** session, the log file is again updated and is set as "completed".

Continue to the next section 39.6.3 Installing 12d_usage.exe or return to 39.6 Monitoring 12d Model Usage.

39.6.3 Installing 12d_usage.exe

You can put the 12d_usage.exe program wherever you like on your network. Then, simply create a shortcut to the program on your desktop, making sure the shortcut properties are set as follows:

Target:	<path to program location>\12d_usage.exe
Start in:	<path to Working Folder>

The Working Folder is the folder that you run the 12d_usage.exe program from (it does not have to be the same as the location of the 12d_usage.exe file). After running the program for the first time, a file named 12d_usage.defaults will be created in the Working Folder. This file is used to save your settings from the last run of the program and to load your settings for the next run of the program. In addition, you might also wish to use the Working Folder to store your ***12d Model*** Usage report files (although you are free to store them elsewhere).

Continue to the next section 39.6.4 Running 12d_usage.exe or return to 39.6 Monitoring 12d Model Usage.

39.6.4 Running 12d_usage.exe

To run the 12d_usage program, simply double-click on the shortcut icon you created at install time. This will open up a DOS window from where the program's keyboard-driven menu system can be run.

From the Main menu within the 12d_usage program, your keyboard-driven menu options are:

C	Bring up the Consolidate menu
R	Bring up the Report menu
Q	Exit (quit) the 12d_usage program

Continue to the next section 39.6.5 Consolidating the .log files or return to 39.6 Monitoring 12d Model Usage.

39.6.5 Consolidating the .log files

After a while, you should notice that a lot of .log files are being generated in your specified <log file folder>. To consolidate all these .log files into a single Comma-Separated-Variable (CSV) file, you will need to run the 12d_usage.exe program, and press the “C” key to bring up the Consolidate menu.

From the Consolidate menu, your keyboard-driven menu options are:

F	Specify the <log file folder>
O	Specify the output CSV file name
T	Toggle whether to delete or rename consolidated log files
C	**Consolidate 12d Model session log files**
Q	Exit the Consolidate menu and return to the Main menu

When specifying the name of the CSV file you wish to consolidate your log files to (using the “O” key), if you want a **.csv** file extension (to allow the file to be easily loaded into MS?Excel for your own custom reports, for example), you must include the .csv in the file name. It is recommended that all users of the 12d_usage program consolidate log files to the same CSV file every time. Newly consolidated logs are always appended to an existing CSV file. If there is to be more than one user of the 12d_usage program, it might be a good idea to specify the CSV file to be in the <log file folder> or the Working Folder (or at least, some folder that all 12d_usage users can access).

You also need to specify how to tidy up the log files, after they have been consolidated, so that they are not consolidated more than once. Your options here are to rename or to delete the log files (the “T” key toggles between rename and delete). If you choose to rename them, they will be renamed with a .logc extension. If you choose to delete them, they will be lost forever, and the only record you will have of your consolidated sessions will be contained in the CSV file. As such, you should be very careful not to delete your CSV file.

Pressing the “C” key will then go ahead and consolidate the log files. Note that consolidation will only take place on “completed” log files (or on log files that have not been updated for more than 24 hours - to handle the case of a power failure, for instance).

Continue to the next section 39.6.6 Reporting on 12d Model Usage or return to 39.6 Monitoring 12d Model Usage.

39.6.6 Reporting on 12d Model Usage

After creating or adding to your consolidated CSV file, you can press the “R” key from the Main menu, in order to bring up the Report menu.

From the Report menu, your keyboard-driven menu options are:

I	Specify the input CSV file name (generated from the Consolidate menu)
O	Specify the output report file name
M	Toggle whether to overwrite or append to existing report file
D	Add/Remove Dongle constraints
C	Add/Remove Computer constraints
U	Add/Remove User constraints
F	Add/Remove Folder constraints
P	Add/Remove Project constraints
E	Add/Remove Program constraints
V	Add/Remove Version constraints
T	Specify Start and End times for report (in Local Time of 12d_usage User*)
S	Specify which summary tables you want in the report
R	Generate the 12d Model Usage report
Q	Exit the Report menu and return to the Main menu

After generating the report (using the “R” key), you will be asked if you want to view the report file. If you answer yes (using the “Y” key), the report file will be opened using Notepad.exe as the default file editor. If you would prefer to use a different file editor, you can specify it by manually editing the 12d_usage.defaults file (see Installing 12d_usage.exe), and replacing the word “notepad” (last line of the file), with the command to start your preferred editor.

Note:** In general, if reporting on ***12d Model sessions running on a WAN across different time zones, *Local Time of 12d Model User* and *Local Time of 12d_usage User* may be different.

Return to 39.6 Monitoring 12d Model Usage.

Or continue to the non related next section 39.7 Running Macros and Chains on Start Up.

39.7 Running Macros and Chains on Start Up

To allow for tailoring ***12d Model*** when a new project is created or an existing project opened, ***12d Model*** runs user supplied files of macros and/or chains.

For ***new*** projects, the default name of the file is

macros.4d

This can be changed to a different file by setting the environment variable

RUN_MACROS_FILE_4D *file_of_macros_to_run_for_new_projects*

For ***existing*** projects, the default name of the file is

project_macros.4d

This can be changed to a different file by setting the environment variable

RUN_PROJECT_MACROS_FILE_4D *file_of_macros_to_run_for_existing_projects*

(the environment variables can be set on the ***Extra A*** tab of the env.4d editor - see 7.6.3 env.4d)

The files consist of macros and/or chains, one per line, where

for macros, just the ***name of the macro*** is needed on the line

and for chains, the command **run_chain** *name_of_the_chain* is needed on the line.

The macros and chains are run in the order that they occur in the file.

Please continue to the next section 39.8 Arguments When Starting 12d Model.

39.8 Arguments When Starting 12d Model

12d Model can be started from an icon, or it can be started from a command line in a batch file by pointing to the ***12d Model*** executable, ***12d.exe***. For example,

"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe"

fires up the 64-bit ***12d.exe***.

Note This is what is used in the **Target:** field for a 12d icon. See 5.6 Project Shortcuts.

For a command line and the **Target:** field, new projects can be created and opened, existing projects can be opened, and/or a user specified ***env.4d*** file used.

39.8.1 Creating a New Project

The command

path_to_12d.exe **-create** *full_path_name_to_12d_project_to_create*

creates a ***new*** project of the given name, and ***12d Model*** starts up and opens up the new project.

If any of the path names contain spaces, then they must be enclosed in double quotes (**"**).

39.8.2 Opening an Existing Project

If the full pathname to an existing project is given after the *12d.exe* command, ***12d Model*** starts up and opens the existing project.

path_to_12d.exe *full_path_name_to_existing_12d_project*

For example

"C:\Program Files\12d\12dmodel\11.00\nt.x86\12d.exe" "C:\12d jobs\airport\airport.project"

If any of the path names contain spaces, then they must be enclosed in double quotes (**"**).

39.8.3 Environment Variables Shortcut

If a file of ***12d Model*** environment variables has been set up by the user (see section 39.4 Environment Variables in Appendix 39 Setting Up & Configuring 12d), then instead of setting the environment variable ENVIRONMENT_4D to point to the file or setting it up with the default name, env.4d, the environment file can be passed to ***12d.exe*** using the ***-env*** command.

For example

"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe" **-env** F:\12d\env.4d

would fire up the 64-bit ***12d.exe*** using the file of environment variables called F:\12d\env.4d

The command

"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe" -env F:\12d\env.4d "C:\12d jobs\airport\airport.project"

would fire up the 64-bit ***12d.exe*** using the file of environment variables called F:\12d\env.4d **and** also automatically open the project "C:\12d jobs\airport\airport.project".

If any of the path names contain spaces, then they must be enclosed in double quotes (**"**).

To return to the beginning of this appendix, click on 39 Setting Up & Configuring 12d.

40 Linestyles, Symbols, Textstyles &Patterns

This appendix contains information about how linestyles, symbols and text is defined and used in ***12d Model***.

See

40.1 Line Styles

40.2 Symbols

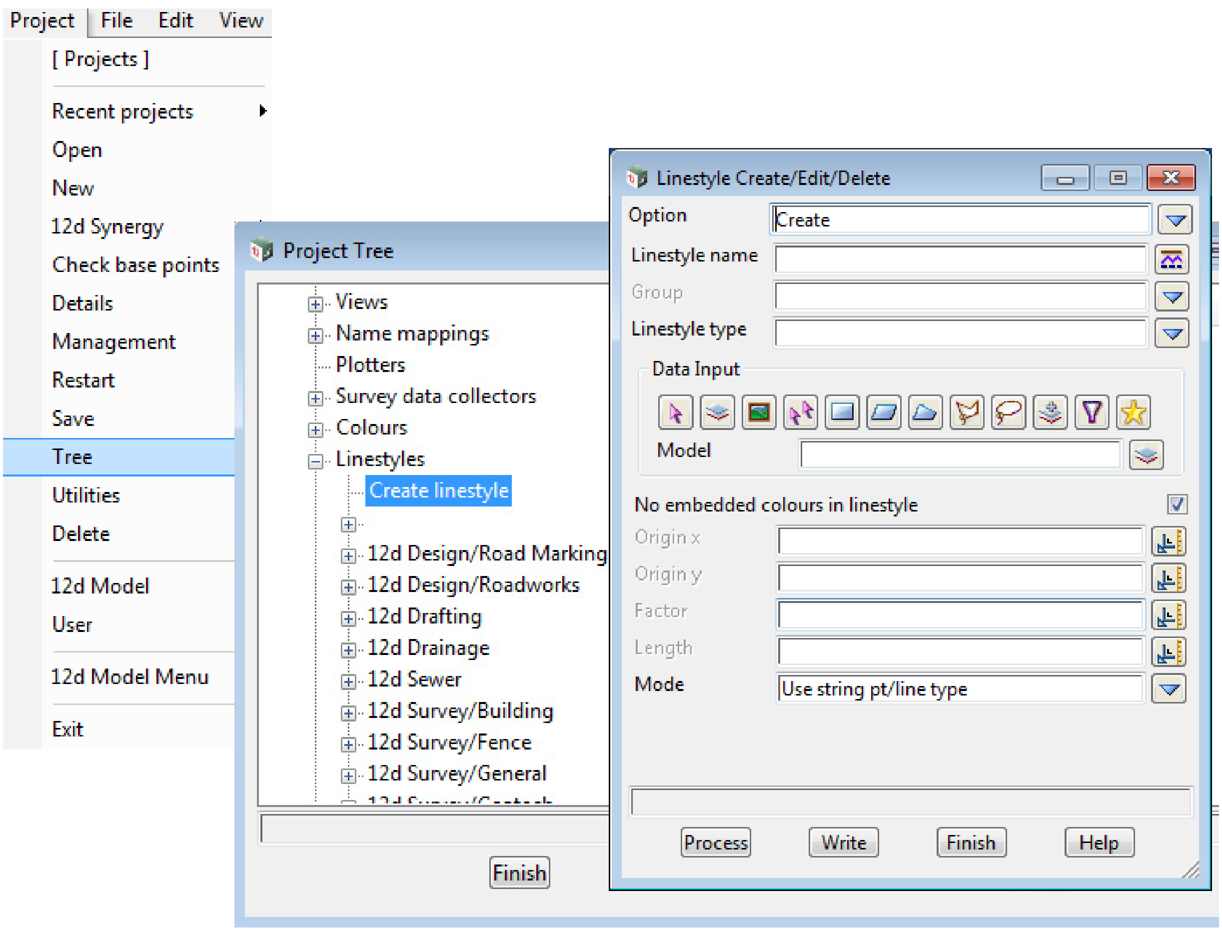
40.3 Textstyles and Fonts

40.4 Patterns

40.1 Line Styles

Users can define their own lines styles to use when drawing 12d Model strings. The definition of linestyles are stored in a file called **linestyl.4d**. (note that there is no **e** at the end of **linestyl**).

Line styles in the file can be created/edited/deleted using the **Linestyle Create/Edit/Delete** panel which is brought up by double clicking on *Create linestyle* in the *Linestyles* expansion of the *Project Tree* (see 7.9.4 Linestyles) brought up by the **Project =>Tree** option.



The **Linestyle Create/Edit/Delete** panel acts as an interactive editor to a text file which contains the linestyle definitions.

The user defined line styles can be broken into three types depending on how many origin points the line style has, plus a group style.

(a) **one origin** line styles - linestyle, paperstyle, worldstyle

These can be repeated along the string (continuous mode) or just be applied at each vertex of the string (vertex mode).

The units for the one origin line style can be in pixels, millimetres or world units and the line styles are given specific names depending on the units. The one origin line styles are called

linestyle if the definition of the one origin style is given in **pixel** units
paperstyle if the definition of the on origin style is given in **paper** units
worldstyle if the definition of the one origin style is given in **world** units

The line styles *linestyle*, *paperstyle*, *worldstyle* can be made up of lines, arcs, circles and text.

continuous mode **vertex mode**

the one origin line styles linestyle, worldstyle or paperstyle can be repeated along the string or just drawn at each point.

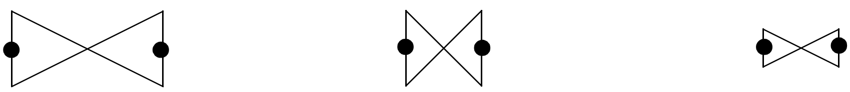
Note - to provide more flexibility, for most applications **vertex mode** has been replaced by **symbols** on **super strings**. Unlike vertex mode, symbols can be independently scaled and rotated.

(b) **two origins** line style - twoptstyle

The line style that can be is stretched between two adjacent vertices is called a **twoptstyle** style and has **two origins**.

Because the size is determine by two vertices which are only in world units, the twoptstyle is always in world units.

The line style *twoptstyle* can be made up of lines, arcs, circles and text.



A twoptstyle stretches between two points in one or both directions.

(c) **three origins** line style

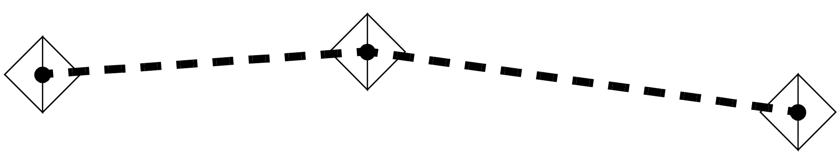
The line style that can be is stretched in two directions using three adjacent vertices is called a **threeptstyle** style and has **three origins**.

Because the size is determine by three vertices which are only in world units, the threeptstyle is always in world units.

The line style *threeptstyle* can only be made up of lines.

(d) **group** line style

The final type of line style is called a **groupstyle** and is a combined style made up of one or more *linestyles*, *paperstyles*, *worldstyles* or *twoptstyles*.



A groupstyle made up of a vertex and a continuous line style.

Warning

The words **line style** have been used to cover all the different types *linestyle*, *paperstyle*, *worldstyle*, *twoptstyle*, *threeptstyle* or *groupstyle* but for historical reasons, the word linestyle has also been used for all the different types although it also refers to a particular line style.

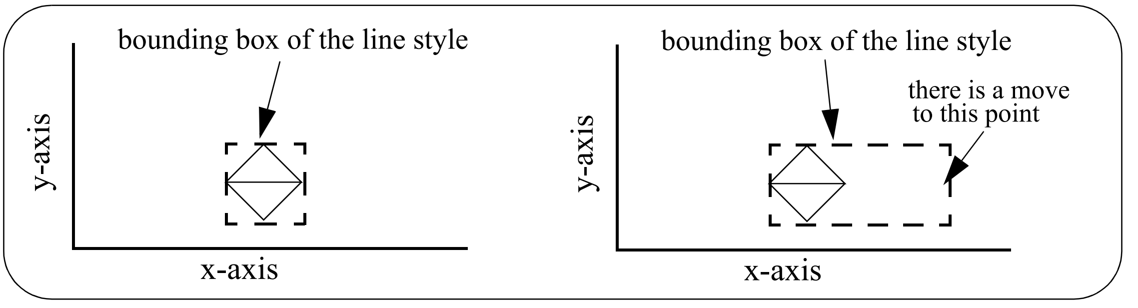
For further information about line styles, see

[40.1.1 Defining Line Styles]
[40.1.2 Linestyl.4d]
[40.1.3 Line Style Definitions]
Or return to [40.1 Line Styles]

40.1.1 Defining Line Styles

A *line style* is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.

The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn't drawn to the point.



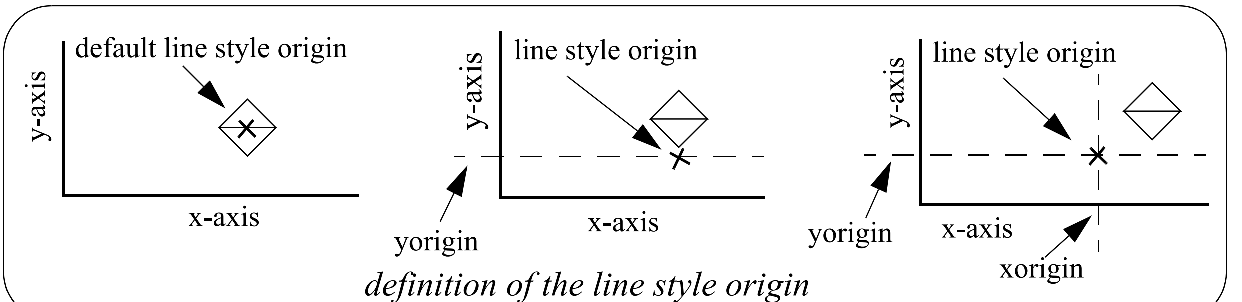
The default **origin of the line style** is defined to be the midpoint of the bounding box surrounding the line style. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are **xorigin** and **yorigin** commands to override the default origin of the line style.

If a **yorigin** is set, then it is used as the y-coordinate of the line style. If the *xorigin* isn't given, then the *xorigin* is the midpoint of the x-extent of the bounding box of the line style.

Similarly, if a **xorigin** is set, then it is used as the x-coordinate of the line style.

If the *yorigin* isn't given, then the *yorigin* is the midpoint of the y-extent of the bounding box of the line style.

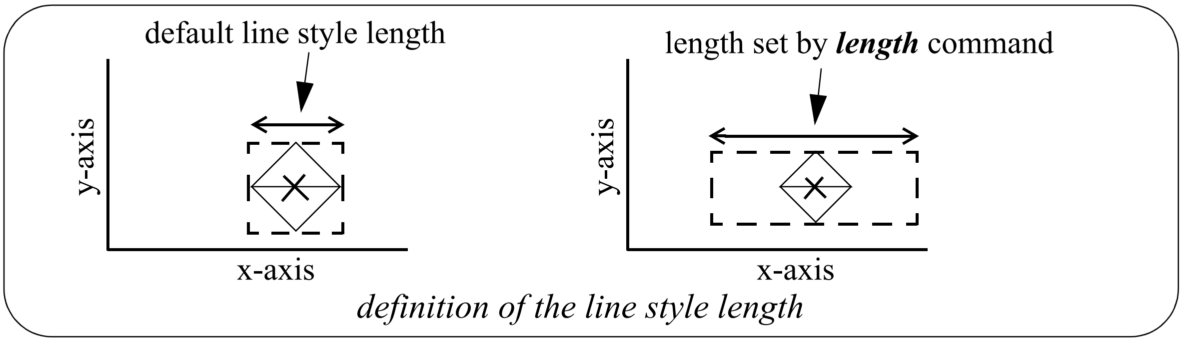


definition of the line style origin

The default **length** of the line style is the *horizontal size* of the bounding box.

There is a **length** commands to override the default length of the line style.

The *length* must always be positive but it can be larger or smaller than the line styles's calculated horizontal length.

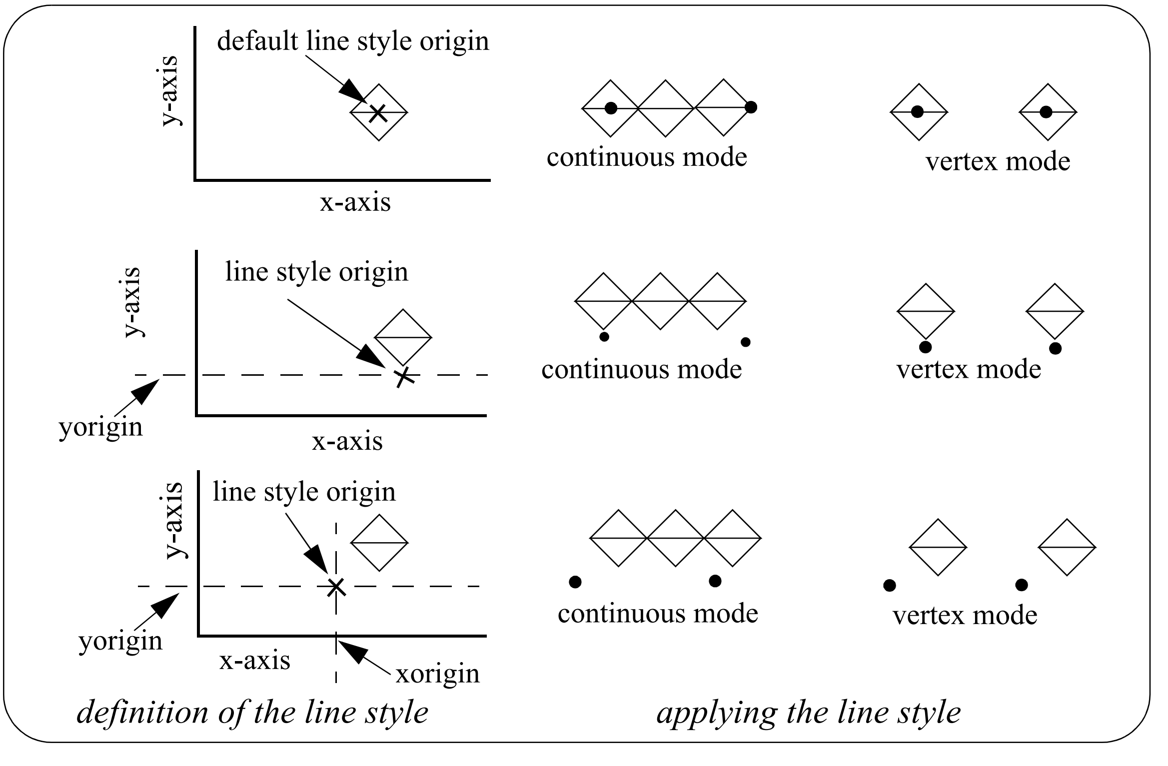


The ***origin*** and the ***length*** of the line style are both used in **positioning** and **redrawing** the line style.

For *continuous mode*, the ***origin*** of the line style is initially placed at a distance of half of the ***length*** of the line style along the first link in the string, and then moved the distance ***length*** along the string and redrawn.This is repeated along the string until the end of the string is reached.

Hence for *continuous mode*, the style is continually repeated along the string.

For *vertex mode*, the ***origin*** of the line style is placed at each point of the string and the line style drawn around the ***origin***.



Continue to 40.1.2 Linestyl.4d or return to 40.1 Line Styles.

40.1.2 Linestyl.4d

The definitions for the available linestyles are normally stored in a file called **linestyl.4d** which is read in each time ***12d Model*** opens an existing project or creates a new project. *Linestyl.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

LINESTYLES_4D *filename*

The definition of the line styles will be given in the following section 40.1.3 Line Style Definitions.

Continue to 40.1.3 Line Style Definitions or return to 40.1 Line Styles.

40.1.3 Line Style Definitions

See

40.1.3.1 Linestyles, Paperstyles and Worldstyles

40.1.3.2 Twoptstyles

40.1.3.3 Threeptstyles

40.1.3.4 Groupstyles

40.1.3.5 Description of the draw_commands for Linestyles

40.1.3.1 Linestyles, Paperstyles and Worldstyles

The line style with **one origin** is called a

linestyle if the definition of the style is given in *pixel* units

paperstyle if the definition of the style is given in *paper* units

worldstyle if the definition of the style is given in *world* units.

Aside:

A line style with two origins is called a **twoptstyle,** and a line style with three origins is called a **threeptstyle**. These behave differently to linestyles, paperstyles and worldstyles and will be documented separately.

The one origin style can be drawn at each point of a string (**vertex mode**) or redrawn regularly along the lines joining string vertices (**continuous mode**).

The definition of a **linestyle** of a given name *name* is

linestyle name {

set_up_commands

draw_commands

}

a **paperstyle** is

paperstyle name {

set_up_commands

draw_commands

}

and a **worldstyle** is

worldstyle name {

set_up_commands

draw_commands

}

where the set_up_commands **must** be before the draw_commands.

The linestyle/paper/worldstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes **"**.

The line style itself is defined inside the braces where there can be zero or more set_up_commands from the list

`length` *value*
`group` *name*
`mode` *value*

```
factor    value
xorigin   value
yorigin   value
```

followed by zero or more **draw_commands** from the list

```
move      x-value      y-value
draw      x-value      y-value
rmove     dx-value     dy-value
rdraw     dx-value     dy-value
colour    colour_name
circle    radius
arc       radius       start-angle   end-angle
text      "text"       angle     height     "justification"
text      "text"       angle     height     "justification"   "textstyle"
text  "text"  angle  height  "justification"  "textstyle"  xfactor  slant  offset _width  offset_height
repeat  num_repeats{    repeat_commands  repeat_draw_commands}
```

The **repeat** command is a positive integer *num_repeats*

and zero or more repeat_commands from the list

```
xpos      x-value
ypos      y-value
rfactor   value
```

and zero or more repeat_draw_commands where repeat_draw_commands include all the draw_commands except **repeat**.

The **set_up** commands for linestyles, paperstyles and worldstyles will now be described. The **draw_commands** will be described after the definition of a groupstyle since they are the same for linestyles, paperstyles, worldstyles and twoptstyles.

set_up_commands for Linestyles, Paperstyles and Worldstyles

group

The **group** is used to associate line styles in pop-up menus.

If the group is not defined, the style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes **"**.

mode

mode specifies whether the linestyle, paperstyle or worldstyle is drawn at the individual vertices on a string (vertex mode) or it is to be redrawn regularly along the lines joining the vertices on the string (continuous mode).

If the **mode** is not specified, the mode used for a string depends on the breakline type of the string and the number of vertices on the string.

Breakline Type	Number of Vertices	mode: vertex	mode: continuous	mode: not-given
point	1	vertex	cross	vertex
	>1	vertex	continuous	vertex
line	1	vertex	cross	vertex
	>1	vertex	continuous	continuous

NOTE: in early versions of ***12d Model***, **mode** was known as **pointline** and had the values **point** instead of *vertex*, and **line** instead of *continuous*.

factor

This command factors up/down the drawing co-ordinates, heights and radii.

xorigin, yorigin

The default **origin of the line style** is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The **xorigin** and **yorigin** commands are used to override the default origin of the line style.

length

If length is omitted, then **length** is taken to be the horizontal size of the calculated bounding box of the style.

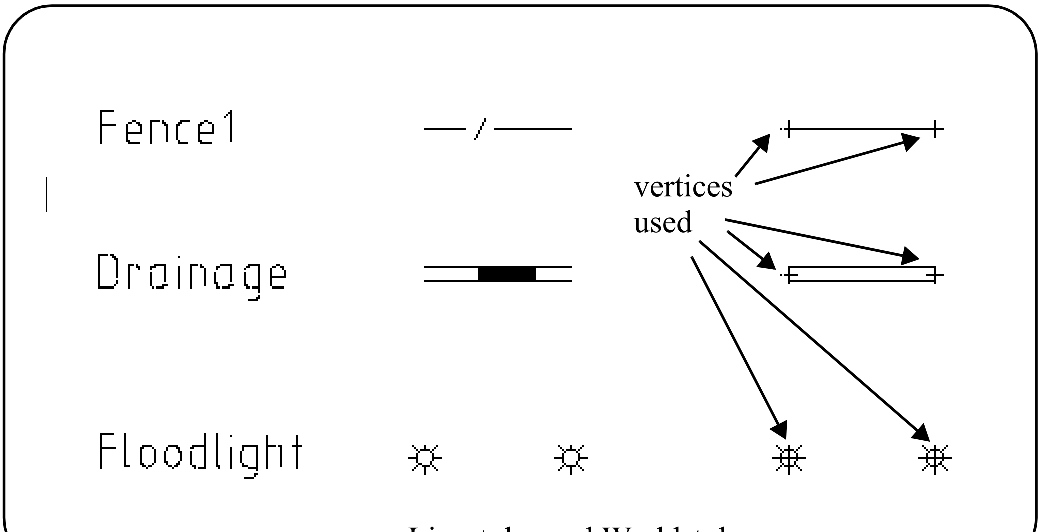
The **length** must always be positive but it can be larger or smaller than the line style's calculated horizontal size.

The origin of the line style and the length are both used in positioning and redrawing the line style.

In **vertex** mode, the origin of the line style is placed at the string points.

In **continuous** mode, the origin is initially placed at a distance of half of **length** along the first line in the string, and then moved the distance **length** along the string for each redraw.

Examples



Linestyles and Worldstyles

```
// Fence1
worldstyle "FENCE1"{
  group SWCS
  factor 20
  move 0 0
  rdraw 1 0
  rmove 0.25 -0.25
  rdraw 0.25 0.50
  rmove 0.25 -0.25
  rdraw 1 0
}
```

```
// Drainage

worldstyle drainage {
  group "4d"
  factor 0.1
  colour green

  move 0.0 -2.0  draw 30 -2.0

  move 30 -1.5  draw 15 -1.5
  move 15 -1.0  draw 30 -1.0
  move 30 -0.5  draw 15 -0.5

  move 15 0.0  draw 30 0.0

  move 30  0.5  draw 15  0.5
  move 15  1.0  draw 30  1.0
  move 30  1.5  draw 15  1.5

  move 30  2.0  draw  0  2.0
}
// Floodlight
worldstyle FLOODLIGHT {
 group "Energex"
 mode vertex
 xorigin 0
 yorigin 0
 colour "yellow"
 circle 0.225
 move -.45 0
 draw -0.225 0
 move 0.45 0
 draw 0.225 0
 move 0 -.45
 draw 0 -0.225
 move 0 0.45
 draw 0 0.225
 move -.159 0.159
 draw -0.318 0.318
 move 0.159 0.159
 draw 0.318 0.318
 move 0.159 -0.159
 draw 0.318 -0.318
 move -0.159 -0.159
 draw -0.318 -0.318
 move 0 0.8
 text "FL" 0 0.5 "centre-middle"
}
```

Continue to 40.1.3.2 Twoptstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.

40.1.3.2 Twoptstyles

A **twoptstyle** is a line style which is stretched so that one cycle fits between consecutive vertices on a string (line or arc segments). This is achieved by defining **two origins** for the twoptstyle and the first and second origins are mapped to the consecutive vertices on the string.

Hence the mapping of the two origins defines the final size of the size in world units.

The *twoptstyle* can stretch in just the direction along the string, or both along and perpendicular to the direction of the string.

Also the *twoptstyle* can be drawn for each line/arc on the string, or for every second line/arc of the string.

For a feature/circle string, the first origin is placed at the centre of the feature/circle and the second origin is placed on the circumference of the feature/circle. Hence the size of the *twoptstyle* is determined by the radius of the feature/circle string.

The definition of a **twoptstyle** of a given name is

```
twoptstyle   name {
    set_up_commands
    draw_commands
}
```

where the set_up_commands **must** be before the draw_commands.

The *twoptstyle* must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes **“**.

The *twoptstyle* itself is defined inside the braces where there can be zero or more set_up_commands from the list

```
group          name
stretch_mode   value
cycle_mode     value
xorigin1       value
yorigin1       value
xorigin2       value
yorigin2       value
```

followed by zero or more draw_commands from the list

```
move     x-value       y-value
draw     x-value       y-value
rmove    dx-value      dy-value
rdraw    dx-value      dy-value
colour   colour_name
circle   radius
arc      radius        start-angle   end-angle
text     "text"        angle     height     "justification"
text     "text"        angle     height     "justification"   "textstyle"
text  "text"  angle  height  "justification"  "textstyle"  xfactor  slant  offset  width  offset_height
repeat  num_repeats{    repeat_commands  repeat_draw_commands}
```

The **repeat** command is a positive integer *num_repeats* and zero or more *repeat_commands* from the list

```
xpos      x-value
ypos      y-value
rfactor   value
```

and zero or more *repeat_draw_commands* where *repeat_draw_commands* include all the *draw_commands* except **repeat**.

The *set_up* commands for a twoptstyle will now be described. The *draw_commands* will be described after the definition of a ***groupstyle*** since they are the same for linestyles, paperstyles, worldstyles and twoptstyles.

set_up_commands for Twoptstyles

group

The **group** is used to associate line styles in pop-up menus.

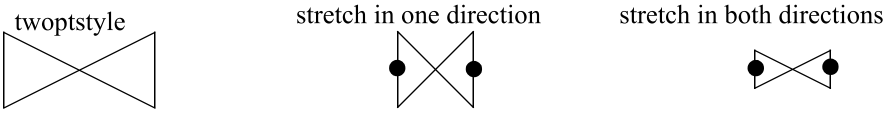
If the group is not defined, the line style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes **"**.

stretch_mode

stretch_mode controls whether the symbol stretches in just the direction along the string, or both along and perpendicular to the direction of the string

stretch_mode	1	// stretch in one direction only (default)
	2	// stretch in both directions



A twoptstyle stretches between two vertices in one or both directions.

cycle_mode

cycle_mode controls whether the symbol is drawn for each line/arc on the string, or for every second line/arc of the string.

cycle_mode	1	// draws on every line/arc (default)
	2	// draws every second line/arc

A twoptstyle draws on each line/arc or every second line/arc

xorigin1, yorigin1

The point (xorigin1, yorigin1) is mapped to the first vertex that the *twoptstyle* is being applied to.

The default **first point of origin of the twoptstyle** is defined to be the minimum x value and the average of the minimum and maximum y values (x_min,(y_min+y_max)/2).

The **xorigin1** and **yorigin1** commands are used to override the default first origin of the *twoptstyle*.

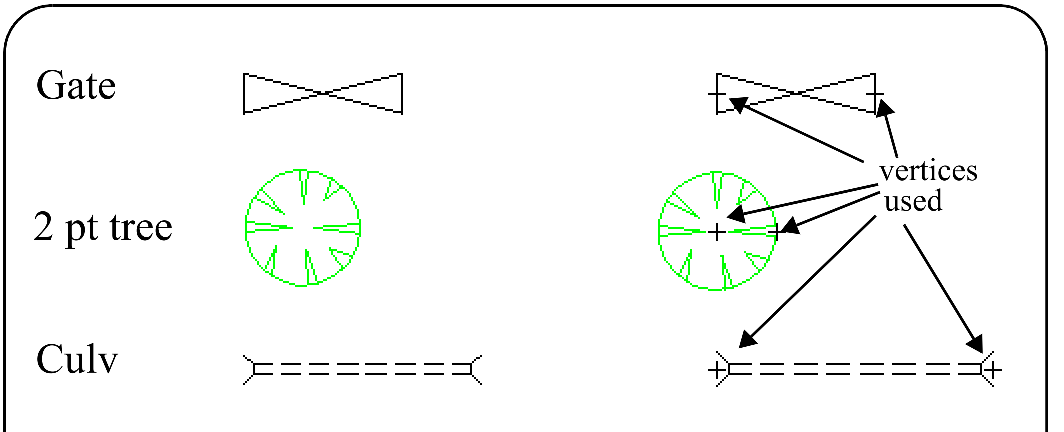
xorigin2, yorigin2

The point (xorigin2, yorigin2) is mapped to the second vertex that the *twoptstyle* is being applied to.

The default **second point of origin of the twoptstyle** is defined to be the maximum x value and the average of the minimum and maximum y values (x_max,(y_min+y_max)/2).

The **xorigin2** and **yorigin2** commands are used to override the default second origin of the *twoptstyle*.

Examples



Two Point Styles

```
// Gate
twoptstyle GATE {
  group "Two Points"
  stretch_mode 2
  cycle_mode   2
  colour red
  move 100   105
  draw 140    95
  draw 140   105
  draw 100    95
  draw 100   105
}
// two point tree
twoptstyle 2PT_TREE {
 group     "4d_standards"
 stretch_mode 2
 cycle_mode   2
 xorigin10
 yorigin10
// xorigin22.5
// yorigin2 1.25

 colour "green"
 move 0 0
 circle 2.5
 move 2.48 0.2
 draw 0.5 0
 draw 2.48 -0.2
 move 2.2 -1.2
 draw 1.2 -0.9
 draw 1.8 -1.7
 move 0.7 -2.4
```

```
 draw 0.2 -1
 draw 0.3 -2.45
 move -0.2 2.45
 draw 0 1
 draw 0.2 2.45
 move 1.2 2.2
 draw 0.9 1.2
 draw 1.7 1.8

  draw 26     8
  move 28     8
  draw 32     8
  move 34     8
  draw 38     8
```

```
move 40     8
draw 44     8
move 46     8
draw 50     8
move 52     8
draw 56     8
}
```

Continue to 40.1.3.3 Threeptstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.

40.1.3.3 Threeptstyles

A **threeptstyle** is a line style that one cycle fits between groups of three consecutive vertices on a string (line or arc segments).This is achieved by defining **three origins** for the threeptstyle.

The threeptstyle is fitted to three consecutive vertices by stretching the threeptstyle differently in two perpendicular directions.

The **first** and **second origins** are **mapped** to the **first two consecutive vertices** of the groups of three vertices on the string and that defines a stretching in the direction from vertex one to vertex two.

The second stretching is perpendicular to the line joining the first two origins and is in the direction of the third origin. When fitting the threeptstyle to the three points, the threeptstyle is stretched in the direction **perpendicular** by the factor equal to:

(perpendicular distance of the third point from the line joining the first two vertices) **/**

(per pedicular distance of the third origin from the line joining the first two origins).

So the **third origin** is usually **not mapped** to the **third vertex**. But the third origin will be on the line through the third vertex and parallel to the line through the first two vertices.

Hence the mapping of the three origins defines the final size of the size in world units.

Important Note - because of the stretching in tow independent directions, the threeptstyle can only be made up of straight lines.

The definition of a **threeptstyle** of a given name is

```
threeptstyle   name {
   set_up_commands
   draw_commands
}
```

where the set_up_commands **must** be before the draw_commands.

The *threeptstyle* must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes **"**.

The *threeptstyle* itself is defined inside the braces where there can be zero or more set_up_commands from the list

```
group          name
xorigin1       value
yorigin1       value
xorigin2       value
yorigin2       value
xorigin3       value
yorigin3       value
```

followed by zero or more draw_commands from the list

```
move     x-value    y-value
draw     x-value    y-value
rmove    dx-value   dy-value
rdraw    dx-value   dy-value
colour   colour_name
repeat num_repeats{   repeat_commands  repeat_draw_commands}
```

The **repeat** command is a positive integer *num_repeats* and zero or more *repeat_commands* from the list

```
xpos     x-value
```

```
ypos        y-value
rfactor     value
```

and zero or more *repeat_draw_commands* where *repeat_draw_commands* include all the *draw_commands* except **repeat**.

The *set_up* commands for a threeptstyle will now be described. The *draw_commands* will be described after the definition of a ***groupstyle*** since they are the same for linestyles, paperstyles, worldstyles and twoptstyles.

set_up_commands for Threeptstyles

group

The **group** is used to associate line styles in pop-up menus.

If the group is not defined, the line style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes **"**.

xorigin1, yorigin1

The point (xorigin1, yorigin1) is mapped to the first vertex that the *threeptstyle* is being applied to.

The default **first point of origin of the threeptstyle** is defined to be the minimum x value and the average of the minimum and maximum y values (x_min,(y_min+y_max)/2).

The **xorigin1** and **yorigin1** commands are used to override the default first origin of the *threeptstyle*.

xorigin2, yorigin2

The point (xorigin2, yorigin2) is mapped to the second vertex that the *threeptstyle* is being applied to.

The default **second point of origin of the threeptstyle** is defined to be the maximum x value and the average of the minimum and maximum y values (x_max,(y_min+y_max)/2).

The **xorigin2** and **yorigin2** commands are used to override the default second origin of the *threeptstyle*.

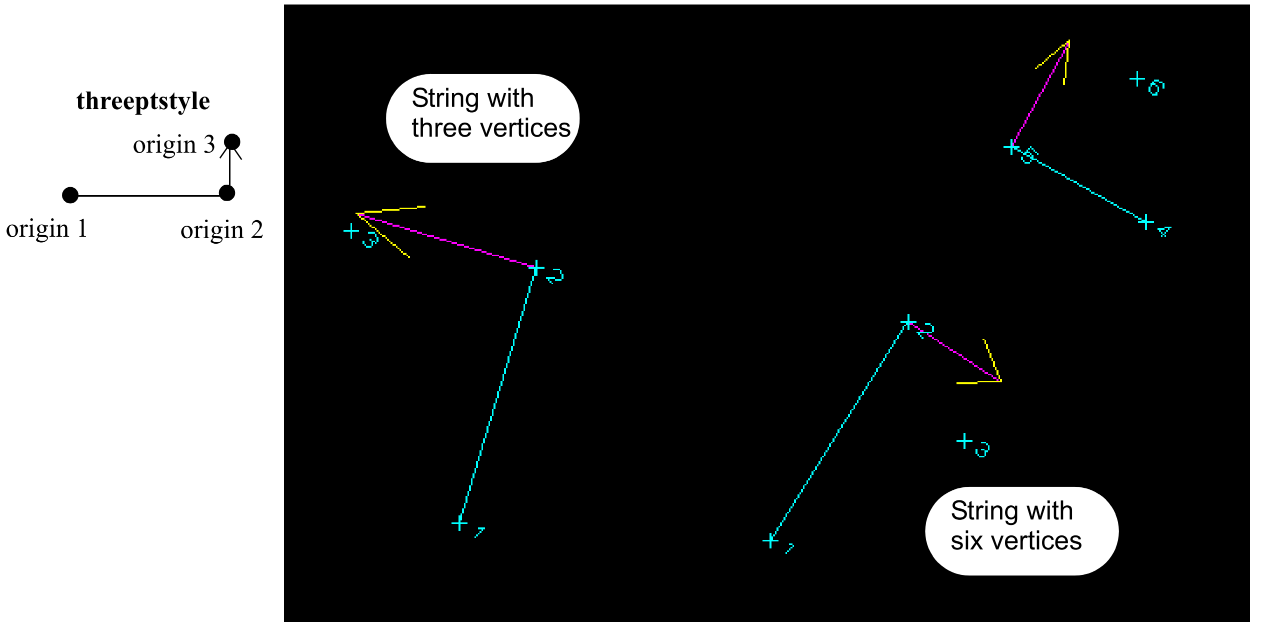
xorigin3, yorigin3

The point (xorigin3, yorigin3) is mapped to the a point on the line parallel to the line through the first two vertices and going through the third vertex of the three vertices that the threeptstyle is being applied to.

The default **third point of origin of the threeptstyle** is defined to be the maximum x value and the maximum y value (x_max,y_max).

The **xorigin3** and **yorigin3** commands are used to override the default third origin of the *threeptstyle*.

Examples



A threeptstyle stretches between two vertices in one direction and has a different stretch in the perpendicular direction.

```
threeptstyle "simple turn arrow" {
  group "3 pts"
  xorigin1  0
  yorigin1  0
  xorigin2  10
  yorigin2  0
  xorigin3  10
  yorigin3  3

  colour   cyan
  move      0.0   0.0
  draw      10.0  0.0

  colour magenta
  move     10.0 0.0
  draw     10.0 3.0

  colour   yellow
  move      10.0   3.0
  draw       9.0   2.0
  move      10.0   3.0
  draw      11.0   2.0
}
```

Continue to 40.1.3.4 Groupstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.

40.1.3.4 Groupstyles

A **groupstyle** is a combined line style which is made up of one or more *linestyles*, *paperstyles*, *worldstyles* and/or *twoptstyles*.

The definition of a **groupstyle** is simply an optional **group** for the line style to belong to, and a list of linestyle, paperstyles, worldstyle and twoptstyle names which must have already been defined in the file.

```
groupstyle   name {

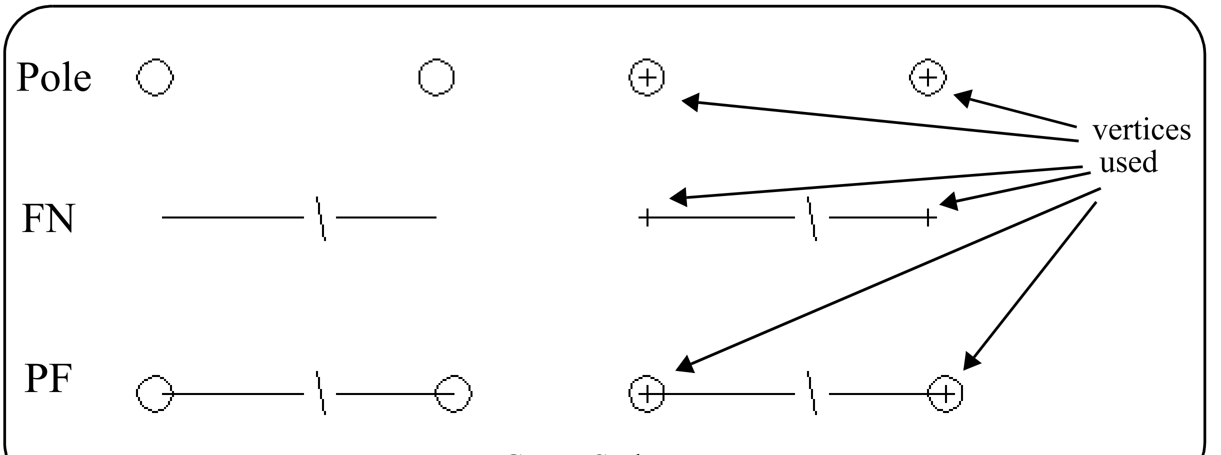
    group      name

    style_name_1
    style_name_2
      ...

}
```

If the *groupstyle* name contains spaces, then it must be enclosed in double quotes **"**. For example, "style 1".

Example



Group Style

```
// POLE
worldstyle POLE {
  group "Electricity"
  mode vertex
  circle 0.5
}
// FN
worldstyle FN {
  group "Fences"
  length 5
  draw 4 0
  move 4.4 0.6
  draw 4.6 -0.6
}
// PF
}groupstyle "PF" {
  group "Miscellaneous"
  "POLE"
  "FN"
}
```

40.1.3.5 Description of the draw_commands for Linestyles

move *x-value* *y-value*

move the pen from the current pen position to the new position (x-value, y-value).

draw *x-value* *y-value*

draw from the current pen position to the new position (x- value, y-value)

rmove *dx-value* *dy-value*

move relative from the current pen position through the distance (dx-value, dy-value)

rdraw *dx-value* *dy-value*

draw relative from the current pen position through the distance (dx-value, dy-value)

colour *colour-name*

change colour (line styles can contains more than one colour).

If colour is not defined, the line style is drawn in the colour of the string that the line style is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes **"**.

circle *radius*

draw a circle of the given radius at the current pen position.

After drawing a circle, the current pen position is left at the centre of the circle.

arc *radius* *start-angle* *end-angle*

draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.

After drawing an arc, the current pen position is left at the centre of the arc.

text *text* *angle* *height* **"***justification***"**

text *text* *angle* *height* **"***justification***"** textstyle

or

text *text* *angle* *height* **"***justification***"** textstyle xfactor slant offset_width offset_height

the characters *text* are drawn at the current pen position with the given angle, height, justification and possibly textstyle, xfactor, slant, offset_width and offset_height. Angle and slant are given in degrees, minutes and seconds in the ddd.mmssfff format. Slant is between -45 and 45 degrees.

The allowed justifications are

top-left	top-centre	top-right
middle-left	middle-centre	middle-right
bottom-left	bottom-centre	bottom-right

and the value is enclosed inside double quotes (").

After drawing text, the current pen position is left where it was before the text was drawn.

repeat num_repeats { *repeat_commands* *repeat_draw_commands* }

The **repeat** command allows the set of repeat_draw_commands inside the braces (the repeat-style) to be re-drawn a number of times (num_repeats), and with each redraw, the size of the repeat-style is modified.

In the definition of repeat, there can be zero or more *repeat_commands* from the list

xpos *x-value*

ypos *y-value*

rfactor *value*

and zero or repeat_draw_commands where repeat_draw_commands include all draw_commands except **repeat**.

Unlike style, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is actually drawn with this origin at the position given by the values of **xpos** and **ypos**.

The repeat-style is drawn *num_repeats* times and on each redraw, the distances, heights and radii are factored by the amount

repeat_factor = (1 - i*rfactor)

where i = 0,1,...num_repeats-1

If rfactor is not specified, it is given the default value of 1/num_repeats. The factor is then

repeat_factor = (num_repeats - i)/num_repeats

where i = 0,1,...num_repeats-1

Examples of the Repeat Command

1. To produce circles of radius 10,9,8,...1 about the origin.

```
repeat 10 { circle 10}
```

2. To produce circles of radius 10,9.5,9,...5.5 about the origin

```
repeat 10 { rfactor 0.05 circle 10}
```

More Examples of Line, Paper and World Styles

1. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {
  move 0 0
  circle 20
}
```

2. draw a circle of radius 20. The origin of the style is (100,100)

```
paperstyle "circle" {
  move 100 100
  circle 20
}
```

3. draw a circle of radius 20. The origin of the style is (0,0)

```
linestyle "circle" {
  xorigin 0
  yorigin 0
  move 100 100
  circle 20
}
```

4. draw a gate symbol as a twoptstyle.

```
worldstyle "circle" {
  group "fences"
  stretch_mode  1            // one direction stretch
  cycle_mode  2              // draw every second line

  move   0  0
```

```
    draw   0  0.1
    draw   1  0
    draw   1  0.1
    draw   0  0
  }
```

5. draw concentric circles of centre (0,0) inside a box

```
linestyle "dot"  {
  xorigin 0
  yorigin 0
  move -5 -5
  draw -5 25
  draw 25 25
  draw 25 -5
  draw -5 -5
  repeat 10 {
    move 0 0
    circle 10
  }
}
```

6. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

```
linestyle "arc" {
  move 0 0
  arc 10 45 -45
}
```

7. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

```
worldstyle "arc 1" {
   move 0 0
  arc -10 45 -45
}
```

8. top-left justified text with a circle centred on the actual text position

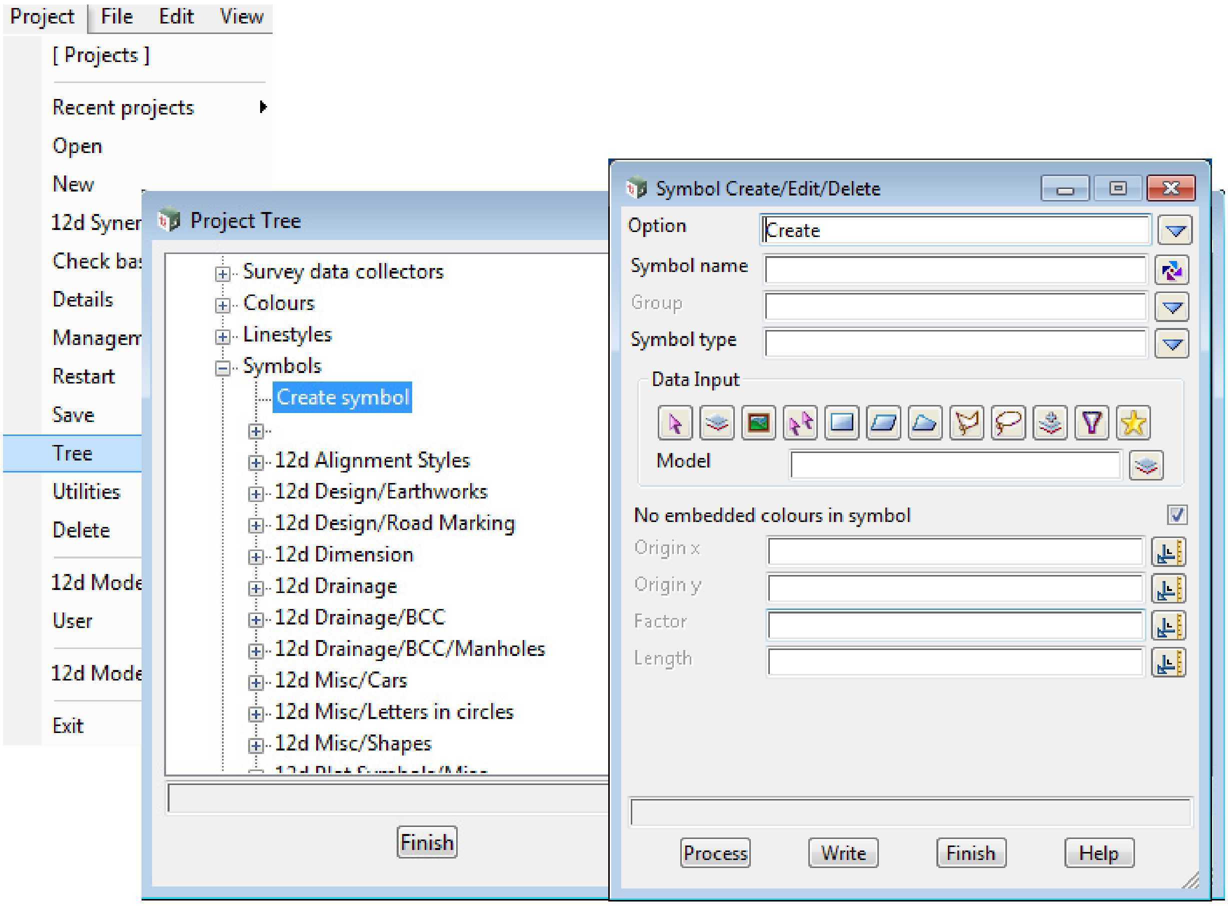
```
linestyle "top-left"  {
  group text
  move 0 0
  circle 4
  text   "<top left>" 0 10 "top-left"
}
```

Return to 40.1.3 Line Style Definitions or 40.1 Line Styles.

40.2 Symbols

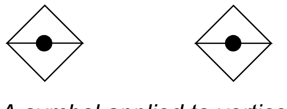
Users can define their own symbols to draw at vertices of ***12d Model*** strings. The definition of symbols are stored in a file called **symbols.4d**.

Symbols in the file can be created/edited using the **Symbols Create/Edit/Delete** panel which is brought up by double clicking on *Create symbol* in the *Symbols* expansion of the *Project Tree* (see 7.9.5 Symbols) brought up by the **Project** =>**Tree** option.



The **Symbol Create/Edit/Delete** panel acts as an interactive editor to a text file which contains the symbol definitions.

The user defined symbols can be applied to each vertex of a string. Each symbol can be made up of lines, arcs, circles and text.



A symbol applied to vertices.

The units for the symbol can be in pixels, millimetres or world units. The symbol is called a

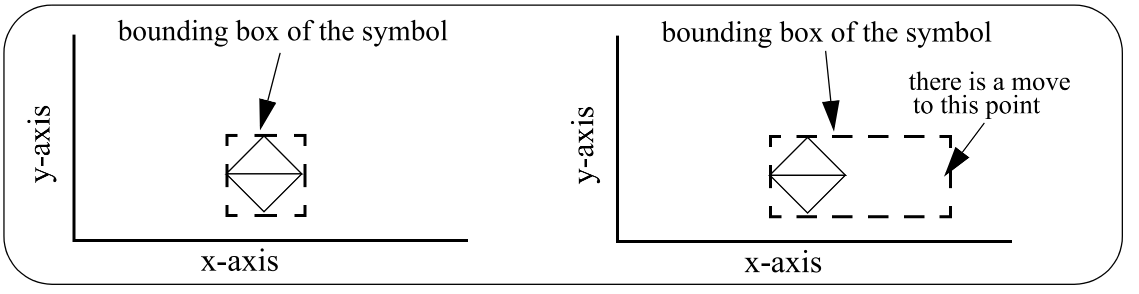
paperstyle if the definition of the symbol is given in paper units
worldstyle if the definition of the symbol is given in world units

For further information about **Symbols**, see

Or return to 40.2 Symbols

40.2.1 Defining Symbols

A *symbol* is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.
The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn't drawn to the point.

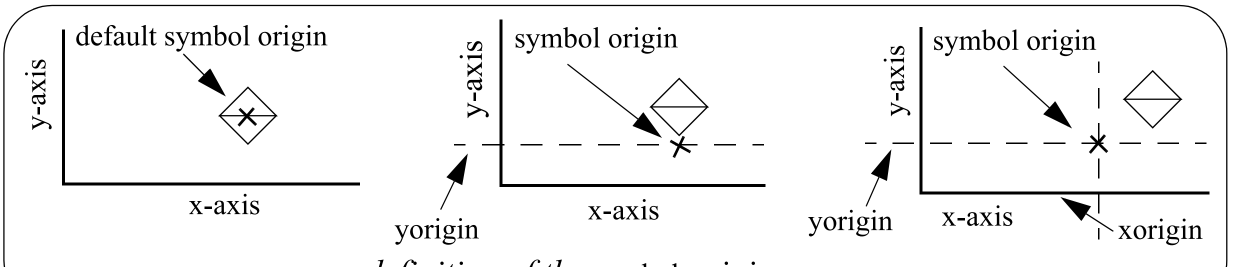


The default **origin of the symbol** is defined to be the midpoint of the bounding box surrounding the symbol. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are **xorigin** and **yorigin** commands to override the default origin of the symbol.

If a **yorigin** is set, then it is used as the y-coordinate of the symbol. If the *xorigin* isn't given, then the *xorigin* is the midpoint of the x-extent of the bounding box of the symbol.

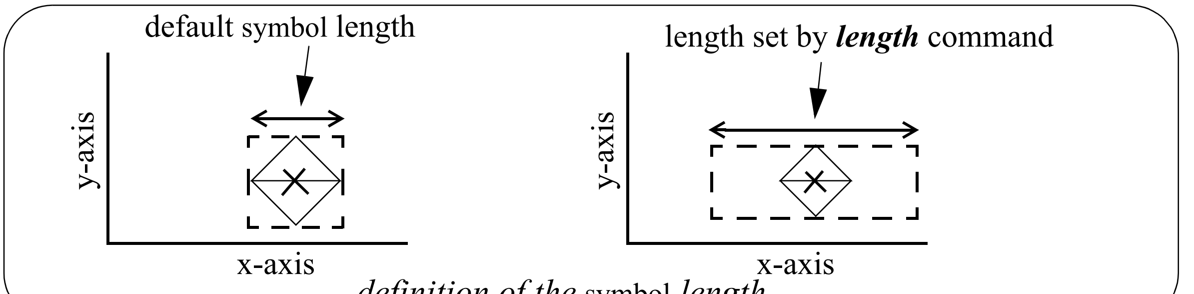
Similarly, if a **xorigin** is set, then it is used as the x-coordinate of the symbol. If the *yorigin* isn't given, then the *yorigin* is the midpoint of the y-extent of the bounding box of the symbol.



definition of the symbol *origin*

The default **length** of the line style is the *horizontal size* of the bounding box.

There is a **length** commands to override the default length of the symbol. The *length* must always be positive but it can be larger or smaller than the symbols calculated horizontal length.



definition of the symbol *length*

The *origin* and the *length* of the symbol are both used in positioning and sizing the symbol.

Continue to 40.2.2 Symbol.4d or return to 40.2 Symbols.

40.2.2 Symbol.4d

The definitions for the available symbols are normally stored in a file called **symbols.4d** which is read in each time ***12d Model*** opens an existing project or creates a new project. *Symbol.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

SYMBOLS_4D *filename*

The definition of the symbols will be given in the following section 40.2.3 Symbol Definition.

Continue to 40.2.3 Symbol Definition or return to 40.2 Symbols.

40.2.3 Symbol Definition

The definition of a worldstyle **symbol** of a given name *name* is

worldstyle name {

set_up_commands

draw_commands

}

where the set_up_commands **must** be before the draw_commands.

The linestyle/paper/worldstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes **"**.

The symbol itself is defined inside the braces where there can be zero or more set_up_commands from the list

```
length    value
group     name
factor    value
xorigin   value
yorigin   value
```

followed by zero or more **draw_commands** from the list

```
move      x-value     y-value
draw      x-value     y-value
rmove     dx-value    dy-value
rdraw     dx-value    dy-value
colour    colour_name
circle    radius
arc       radius      start-angle    end-angle
text      "text"      angle     height     "justification"
text      "text"      angle     height     "justification"   "textstyle"
text  "text"  angle  height  "justification"  "textstyle"  xfactor  slant  offset _width  offset_height
repeat  num_repeats {   repeat_commands  repeat_draw_commands }
```

The **repeat** command is a positive integer *num_repeats*

and zero or more repeat_commands from the list

```
xpos      x-value
ypos      y-value
rfactor   value
```

and zero or more repeat_draw_commands where repeat_draw_commands include all the draw_commands except **repeat**.

The **set_up** commands for symbols will now be described followed by the **draw_commands.**

See

40.2.3.1 set_up_commands for symbols

40.2.3.2 Description of the draw_commands for Symbols

Or return to 40.2 Symbols

40.2.3.1 set_up_commands for symbols

group

The **group** is used to associate symbols in pop-up menus.

If the group is not defined, the symbol is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes **"**.

factor

This command factors up/down the drawing co-ordinates, heights and radii.

xorigin, yorigin

The default **origin of the symbol** is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The **xorigin** and **yorigin** commands are used to override the default origin of the symbol.

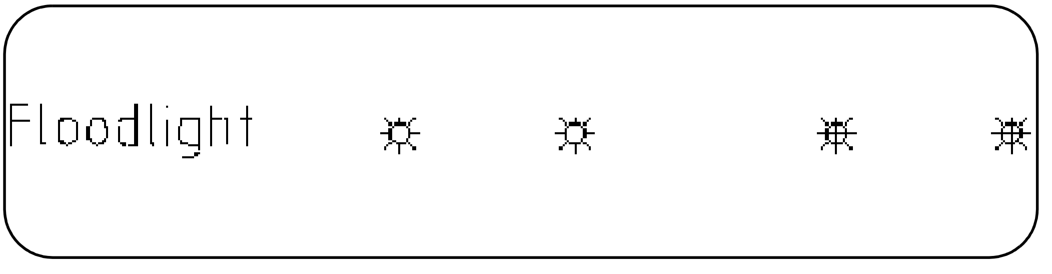
length

If length is omitted, then **length** is taken to be the horizontal size of the calculated bounding box of the symbol.

The **length** must always be positive but it can be larger or smaller than the symbols calculated horizontal size.

The origin of the symbol and the length are both used in positioning and sizing of the symbol.

Examples



```
// Floodlight
worldstyle FLOODLIGHT {
 group "Energex"
 mode vertex
 xorigin 0
 yorigin 0
 colour "yellow"
 circle 0.225
 move -.45 0
 draw -0.225 0
 move 0.45 0
 draw 0.225 0
 move 0 -.45
 draw   -0.225
 move 0 0.45
 draw 0 0.225
 move -.159 0.159
 draw -0.318 0.318
 move 0.159 0.159
 draw 0.318 0.318
```

```
 move 0.159 -0.159
 draw 0.318 -0.318
 move -0.159 -0.159
 draw -0.318 -0.318
 move 0 0.8
 text "FL" 0 0.5 "centre-middle"
}
```

Continue to 40.2.3.2 Description of the draw_commands for Symbols or return to 40.2.3 Symbol Definition or 40.2 Symbols.

40.2.3.2 Description of the draw_commands for Symbols

move *x-value* *y-value*

move the pen from the current pen position to the new position (x-value, y-value).

draw *x-value* *y-value*

draw from the current pen position to the new position (x- value, y-value)

rmove *dx-value* *dy-value*

move relative from the current pen position through the distance (dx-value, dy-value)

rdraw *dx-value* *dy-value*

draw relative from the current pen position through the distance (dx-value, dy-value)

colour *colour-name*

change colour (line styles can contains more than one colour).

If colour is not defined, the symbol is drawn in the colour of the string that the symbol is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes **"**.

circle *radius*

draw a circle of the given radius at the current pen position.

After drawing a circle, the current pen position is left at the centre of the circle.

arc *radius* *start-angle* *end-angle*

draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.

After drawing an arc, the current pen position is left at the centre of the arc.

text *text* *angle* *height* **"***justification***"**
text *text* *angle* *height* **"***justification***"** textstyle
or
text *text* *angle* *height* **"***justification***"** textstyle xfactor slant offset_width offset_height

the characters *text* are drawn at the current pen position with the given angle, height, justification and possibly textstyle, xfactor, slant, offset_width and offset_height. Angle and slant are given in degrees, minutes and seconds in the ddd.mmssfff format. Slant is between -45 and 45 degrees.

The allowed justifications are

top-left	top-centre	top-right
middle-left	middle-centre	middle-right
bottom-left	bottom-centre	bottom-right

and the value is enclosed inside double quotes (").

After drawing text, the current pen position is left where it was before the text was drawn.

repeat num_repeats { *repeat_commands* *repeat_draw_commands* }

The **repeat** command allows the set of repeat_draw_commands inside the braces (the repeat-style) to be re-drawn a number of times (num_repeats), and with each redraw, the size of the repeat-style is modified.

In the definition of repeat, there can be zero or more *repeat_commands* from the list

xpos *x-value*

ypos *y-value*

rfactor *value*

and zero or repeat_draw_commands where repeat_draw_commands include all draw_commands except **repeat**.

Unlike symbol, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is actually drawn with this origin at the position given by the values of **xpos** and **ypos**.

The repeat-style is drawn *num_repeats* times and on each redraw, the distances, heights and radii are factored by the amount

repeat_factor = (1 - i*rfactor)

where i = 0,1,...num_repeats-1

If rfactor is not specified, it is given the default value of 1/num_repeats. The factor is then

repeat_factor = (num_repeats - i)/num_repeats

where i = 0,1,...num_repeats-1

Examples of the Repeat Command

1. To produce circles of radius 10,9,8,...1 about the origin.

```
repeat 10 { circle 10}
```

2. To produce circles of radius 10,9.5,9,...5.5 about the origin

```
repeat 10 { rfactor 0.05 circle 10}
```

More Examples of World Styles

1. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {
  move 0 0
  circle 20
}
```

2. draw a circle of radius 20. The origin of the style is (100,100)

```
worldstyle "circle" {
  move 100 100
  circle 20
}
```

3. draw a circle of radius 20. The origin of the style is (0,0)

```
worldstyle "circle" {
  xorigin 0
  yorigin 0
  move 100 100
  circle 20
}
```

4. draw concentric circles of centre (0,0) inside a box

```
worldstyle "dot"  {
  xorigin 0
  yorigin 0
  move -5 -5
  draw -5 25
  draw 25 25
```

```
  draw 25 -5
  draw -5 -5
  repeat 10 {
    move 0 0
    circle 10
  }
}
```

5. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

```
worldstyle "arc" {
  move 0 0
  arc 10 45 -45
}
```

6. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

```
worldstyle "arc 1" {
   move 0 0
  arc -10 45 -45
}
```

7. top-left justified text with a circle centred on the actual text position

```
worldstyle "top-left"  {
  group text
  move 0 0
  circle 4
  text   "<top left>" 0 10 "top-left"
}
```

Return to 40.2.3 Symbol Definition or 40.2 Symbols.

40.3 Textstyles and Fonts

Users can define any number of textstyles and specify how they are mapped to AutoCAD style names or Microstation (DGN, Intergraph) font numbers.

There is one fixed spaced textstyle called "**1**" (the default) which is identical to the textstyle used in earlier versions of 12d Model.

Each textstyle has a font definition (or font **1** as the default) which defines the stroking for each character in the font. True Type fonts are supported and most AutoCAD SHP files can be used to define the fonts.

Textstyles using True Type fonts or shape file which do not use arcs in their font definition, can also have a slant and a x_factor.

Textstyles can be used in text strings, 4d strings, super strings, linestyles, plots and user defined title blocks.

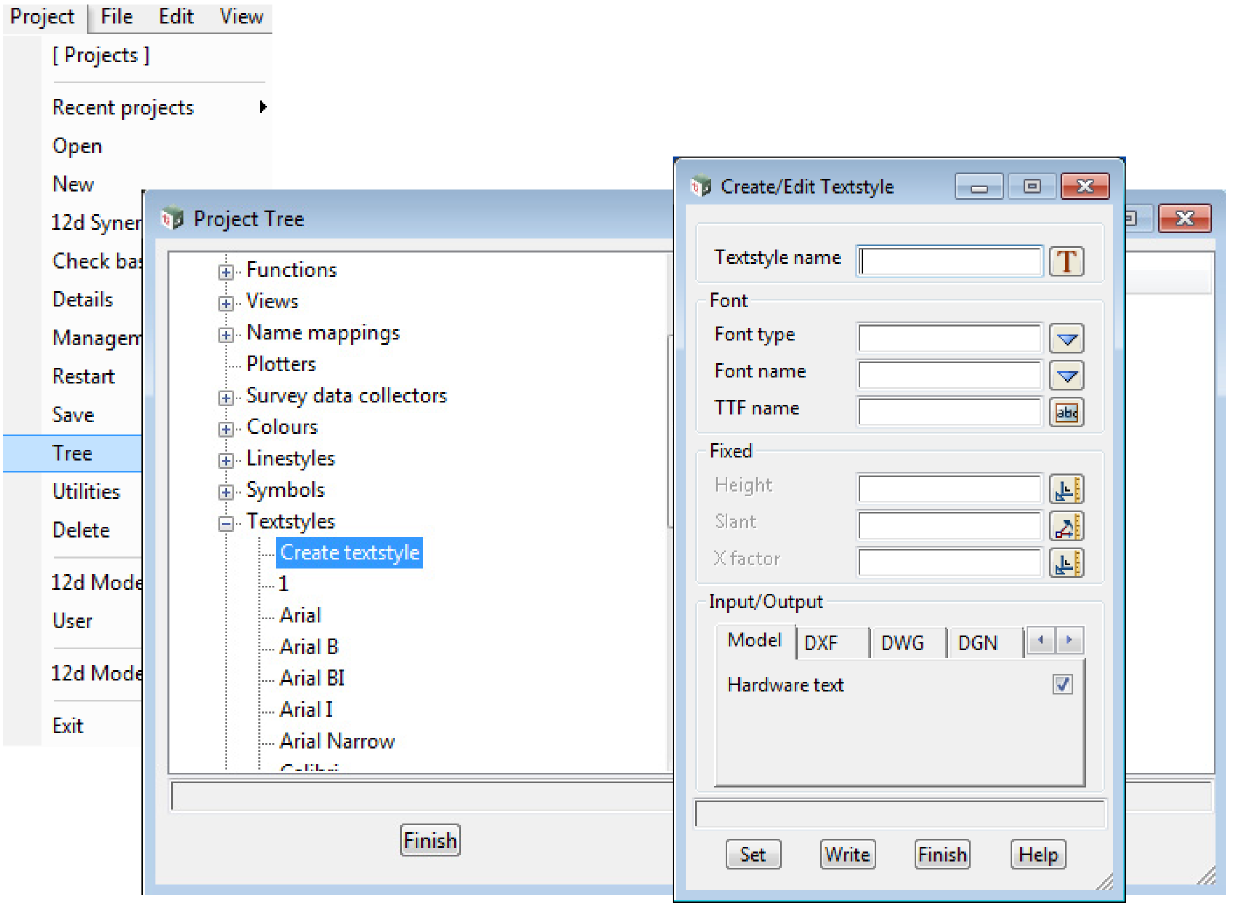
For further information about Textstyles and Fonts, see

40.3.1 Textstyles Definitions File

40.3.2 Fonts Definitions File

40.3.1 Textstyles Definitions File

Textstyles can be created/edited using the **Create/Edit Textstyle** panel which is brought up by double clicking on *Create textstyle* in the *Textstyles* expansion of the *Project Tree* (see 7.9.6 Textstyles) brought up by the **Project** =>**Tree** option.



The **Create/Edit Textstyle** panel acts as an interactive editor to a text file which contains the textstyle definitions. The full description of the text file will now be given.

The definitions for the available textstyles are normally stored in a file called **textstyl.4d** which is read in each time ***12d Model*** opens an existing project or created a new project. *Textstyl.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

TEXTSTYLES_4D   filename

Inside textstyl.4d, a textstyle of a given name is defined by

```
textstyle   textstyle_name   {
        textstyle commands
}
```

Each textstyle must have a **name** and if the name includes imbedded spaces, it must be enclosed in double quotes **"**.

The textstyle itself is defined inside the braces where there can be zero or textstyle commands from the list

font_name   text

hardware_text_dxf
or   stroked_text_dxf

	output_name_dxf	text
	input_name_dxf	text
	hardware_text_dgn	
or	stroked_text_dgn	
	output_name_dgn	integer
	input_name_dgn	integer
	hardware_text_model	
or	stroked_text_model	
	stroked_text	
or	hardware_text	
	fixed_height	value
	variable_height	
	fixed_slant	value
	variable_slant	
	fixed_xfactor	value
	variable_xfactor	

The description of each command is

font_name text

Name of the font to be used to draw the characters of the textstyle. The stroking of the font characters can be defined in the file fonts.4d. If no font_name is given, or the stroking is not given in the font file, then the standard ***12d Model*** font is used ("1").

hardware_text_dxf or **stroked_text_dxf**

If stroked_text_dxf appears, then any text in this textstyle written out to dxf will be stroked - that is, broken into straights, lines and curves.

If hardware_text_dxf is in the file, then any text in this textstyle sent to dxf will be given as actual dxf text (not stroked).

output_name_dxf dxf_style_name

If text is sent to dxf as hardware text, the dxf style of the text will be dxf_style_name.

input_name_dxf dxf_style_name

When reading in dxf files, any text of style dxf_style_name will be given the 12d Model textstyle name textstyle_name.

The commands for reading and writing dgn files are similar to those for dxf except that dgn has font numbers.

hardware_text_dgn or **software_text_dgn**

output_name_dgn dgn_font_number
input_name_dgn dgn_font_number

hardware_text_model or **stroked_text_model**

Similarly, when writing out to a 12d Model model. For hardware_text_model, text will be sent to text with the same textstyle.

stroked_text or **hardware_text**

If stroked_text appears in the definition and there is no other hardware_text flag set, then the text will be stroked - that is, broken into straights, lines and curves.

If hardware_text appears in the definition, then the text is written out as hardware text.

By default, the height, slant and xfactor for the text can be set when text is defined however it is possible to set each of height, slant and xfactor to a fixed value.

	fixed_height	value
or	**variable_height**	

If fixed_height and a value are specified, then all text in this textstyle is drawn at a fixed height. If fixed_height is missing or variable_height (the default) appears, then each text string in the textstyle has its own height.

	fixed_slant	value
or	**variable_slant**	

If fixed_slant and a value are specified, then all text in this textstyle is drawn at a fixed slant. If fixed_slant is missing or variable_slant (the default) appears, then each text string in the textstyle has its own slant. Slant is given in degrees, minutes and seconds in the ddd.mmssfff format and must be between -45 and 45 degrees.

	fixed_xfactor	value
or	**variable_xfactor**	

If fixed_xfactor and a value are specified, then all text in this textstyle is drawn at a fixed xfactor. If fixed_xfactor is missing or variable_xfactor (the default) appears, then each text string in the textstyle has its own xfactor.

Example of a Textstyle File

```
textstyle  "1" {              // DGN FONT 0          ACAD FONT STANDARD

           output_name_dxf        STANDARD
           input_name_dxf         STANDARD
           input_name_dgn         "0"
           output_name_dgn        "0"
           stroked_text
           hardware_text_model
           hardware_text_dgn
           hardware_text_dxf
}
textstyle  ISO {              // DGN FONT 1          ACAD FONT ISO

           font_name              ISO
           input_name_dxf         ISO
           output_name_dxf        ISO
           input_name_dgn         "1"
           output_name_dgn        "1"
           stroked_text
           hardware_text_model
           hardware_text_dgn
           hardware_text_dxf
}
textstyle  MONO {             // DGN FONT 2          ACAD FONT MONO

           font_name       MONO
           output_name_dxf   MONOTXT
           input_name_dxf    MONOTXT

           output_name_dgn   "2"
           stroked_text
           hardware_text_model
           hardware_text_dgn
```

```
                    hardware_text_dxf
}
textstyle  SCRIPT {             // DGN FONT 3              ACAD FONT SCRIPTC

                    font_name         SCRIPT
                    output_name_dxf   SCRIPTC
                    input_name_dxf    SRCIPTC
                    input_name_dgn    "3"
                    output_name_dgn   "3"
                    stroked_text
                    hardware_text_model
                    hardware_text_dgn
                    hardware_text_dxf
}
```

Continue to the next section 40.3.2 Fonts Definitions File for a description of the fonts file, or return to 40.3 Textstyles and Fonts.

40.3.2 Fonts Definitions File

The definition of any fonts referred to in the **textstyl.4d** file are given in the **fonts.4d** file which is searched for in the standard 12d Model set up paths, or is pointed to by the environment variable

FONTS_4D filename

The stroking for each character in the font (which is used when drawing the text on the screen and when required, stroking the text for outputs and plots) can be given in a separate file in the Autocad shape file format.

Inside **fonts.4d**, a font of a given name is defined by

```
font    font_name {
            font commands
}
```

Each font must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes **"**.

The font itself is defined inside the braces where there can be zero or more font commands from the list

```
            stroke_file         filename
            proportional
or          fixed
```

The description of each command is

stroke_file stroke_file_name

The name of the file containing the stroking for each character in the font in AutoCAD ascii shape file format (.shp). The stroke_file_name is searched for in the standard ***12d Model*** set up paths.

If the stroking for a character is not defined, the standard ***12d Model*** character is used instead.

proportional or **fixed**

If a stroke file is not given, then the font could be a fixed (mono) or proportional font.

Example of a Font File

```
font    ISO {

            proportional
            stroke_file "ISO"
}
font    GOTHIC {

            proportional
            stroke_file "GOTHICE.SHP"
}
font    MONO {

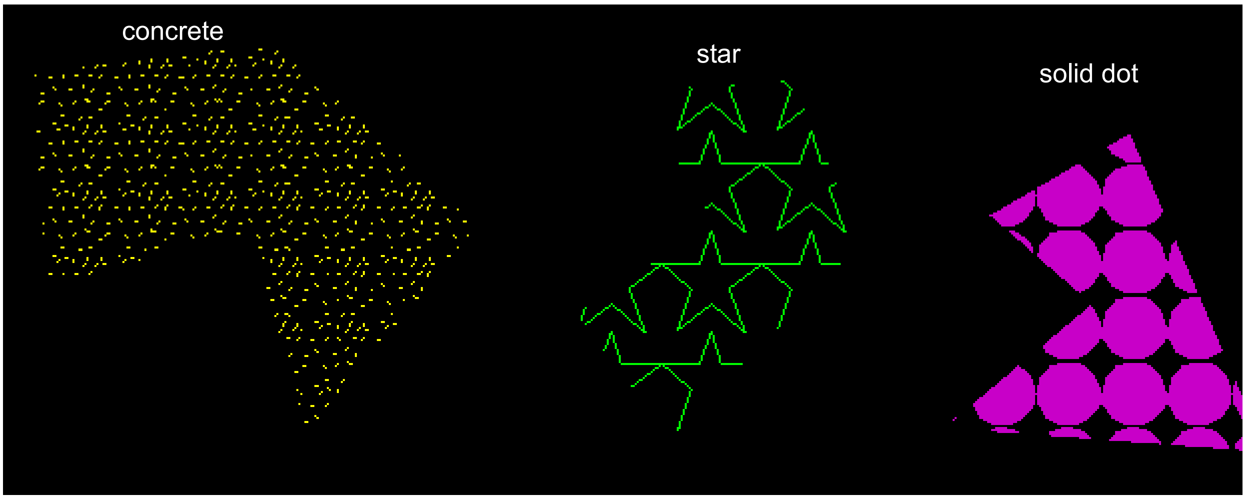
            proportional
            stroke_file "MONOTXT.SHP"
}
```

Continue to the next section 40.3.2 Fonts Definitions File for a description of the fonts file, or return to 40.3 Textstyles and Fonts.

Return to 40.3 Textstyles and Fonts or 40 Linestyles, Symbols, Textstyles &Patterns.

40.4 Patterns

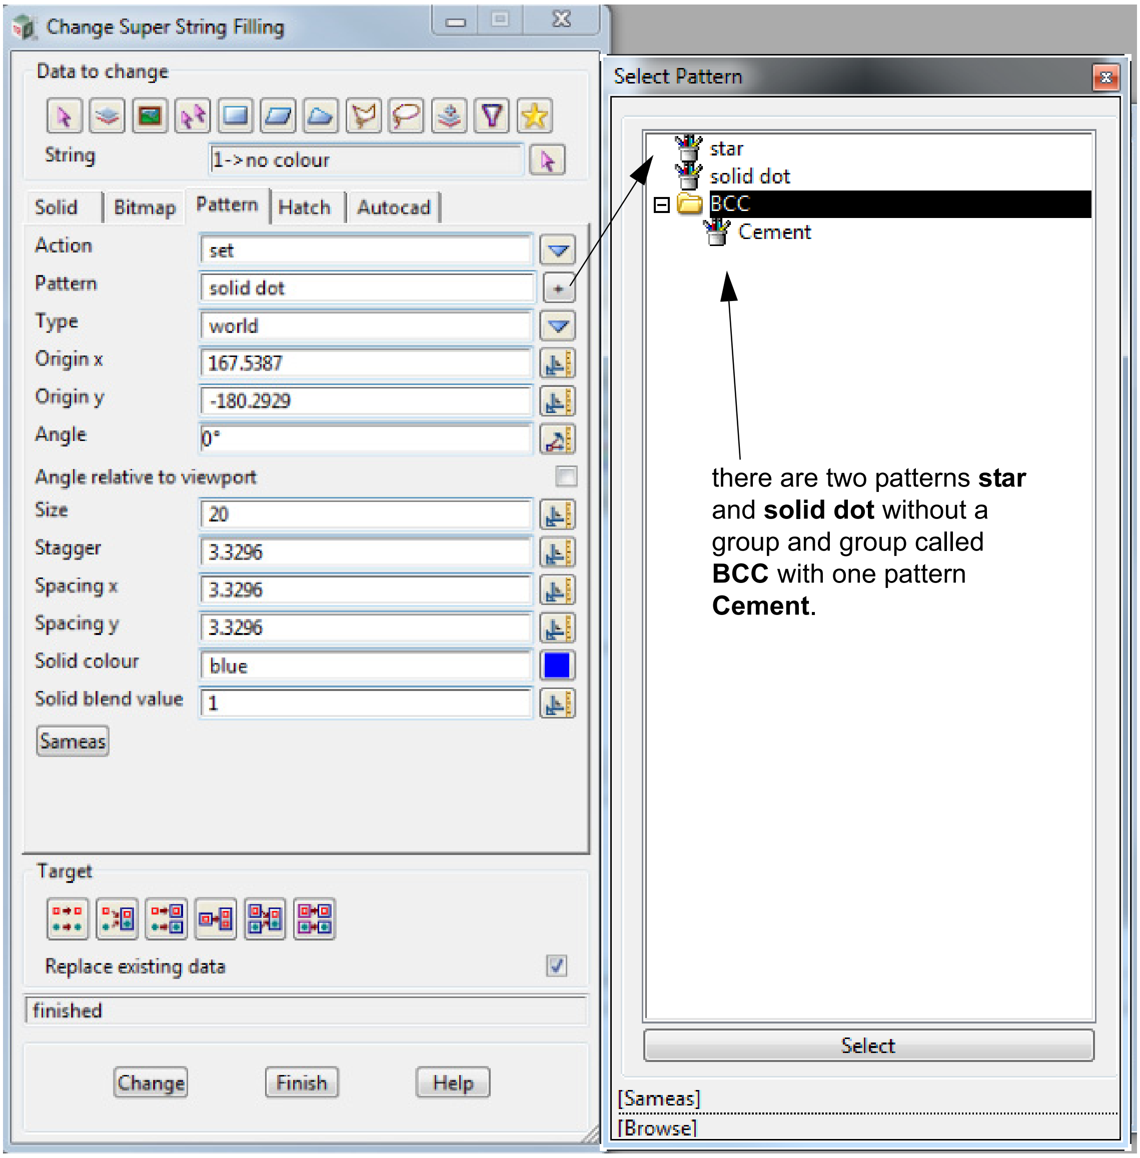
12d Pattern Fills provide the definitions of the patterns used for filling Super Strings.



The definitions of patterns are stored in a file called **patterns.4d** and users can add their own patterns to this file. See 40.4.1 Patterns.4d.

If a patterns file has been read, the pop-up for the **Pattern** field in the **Pattern** tab of the **Change Super String Filling** panel will list the patterns read from the file. See 14.12.9.5 Fills.

Any groups in the pattern file will be displayed as Folders in the pop-up list.



Continue to 40.4.2 12d Patterns Definitions File or return to 40.4 Patterns.

40.4.1 Patterns.4d

Some patterns are installed with ***12d Model*** and users can also define their own patterns.

The definitions of the available 12d patterns are stored in a file called **patterns.4d** which is read in each time ***12d Model*** opens an existing project or creates a new project.

patterns.4d is searched for in the standard set up paths, or the full path of file to use can be given by the environment variable

PATTERNS_4D *path_name_of_file*

The definition of the 12d patterns is given in the section 40.4.2 12d Patterns Definitions File.

Continue to 40.4.2 12d Patterns Definitions File or return to 40.4 Patterns.

40.4.2 12d Patterns Definitions File

The definitions for the available patterns is stored in a file called **patterns.4d** which is read in each time ***12d Model*** opens an existing project or created a new project. *Patterns.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

PATTERNS_4D filename

There is no inbuilt 12d editor for patterns.4d and a text editor is used to create it.The full description of the text file will now be given.

The *patterns.4d* file consists of the word **patterns** followed by at least one space and the an open brace {, then the definitions of each patten and finally a closing brace }.

That is,

patterns {

definition_of_pattern_group_1

definition_of_pattern_group_2

. . .

definition_of_pattern_group_n

}

where each *definition_pattern_group_i* is the definition of a *group* of patterns.

The format of each *definition_of_pattern_group_i* is

(a) group **{**

name *group_name*

definition_of_pattern_1

definition_of_pattern_2

}

where ***group_name*** is the *name* of the group for all the patterns defined inside the *definition_of_pattern_group_1*, and ***definition_of_pattern_i*** is the definition of an individual pattern

or just

(b) *definition_of_pattern_i*

where ***definition_of_pattern_i*** is the definition of an individual pattern. In this case the pattern does not belong to any group.

data defining how the pattern draws (looks like).

Each *definition_of_pattern_i* is the definition of a single pattern and its format is

pattern **{**

name *pattern_name*

pattern_data_1

pattern_data_2

. . .

pattern_data_n

}

where ***pattern_name*** is the *name* of the pattern and each ***pattern_data_i*** is the data defining how part of the pattern draws (looks like).

Each *pattern_name* must be unique within the patterns.4d file and if the name includes imbedded spaces then the name must be enclosed in double quotes **"**.

The format of ***pattern_data_i*** is that of a super string (without pattern fills) in ***12da format*** except that in the super string definition:

```
string super {
```

is replaced by

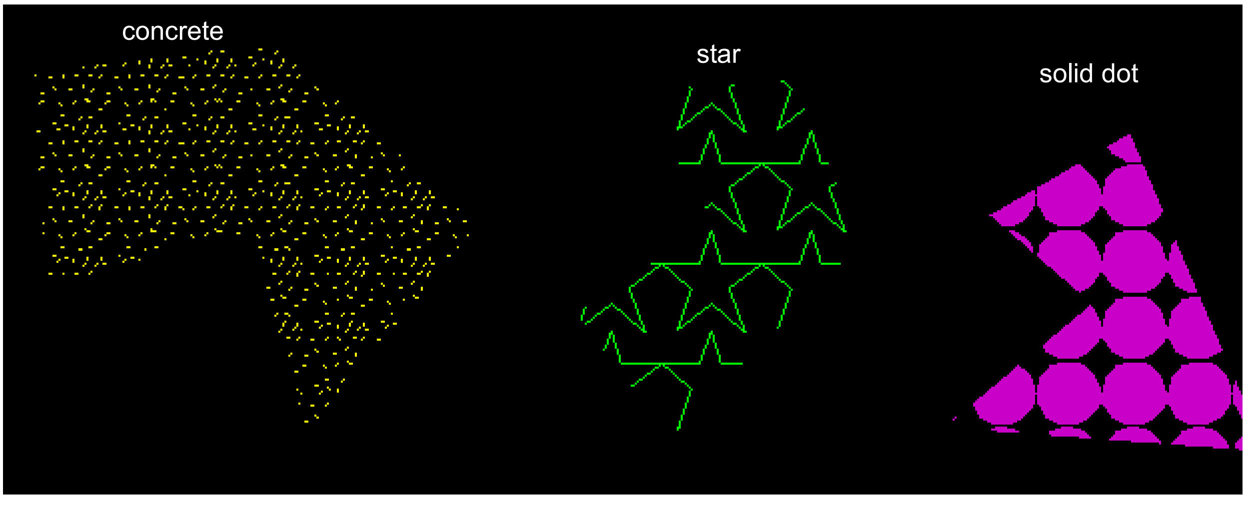
```
data {
```

The super strings must not include any patterns.

For the **12da** format of a super string, see 34.4.8 Super String.

So a ***definition_of_pattern_i*** consists of a a ***unique name*** and the drawing sections of 0 or more super strings.

An example of patterns and the ***patterns.4d*** file defining them is:



```
patterns {

  pattern {
    name "star"
    data {
      chainage  0
      breakline line
      colour    green
      style     1
      closed 1
      data_2d {
        0 40
        6.66666667 20
        30 20
        11.57894737 5.26315789
        20 -20
        0 -4
        -19.65412111 -19.72329689
        -11.57894737 5.26315789
        -30 20
        -6.66666667 20
      }
```

```
    }
  }
  pattern {
    name "solid dot"
    data {

41 Functions Keys, Menus, Toolbars

This appendix contains information about how user defined function keys, menus and toolbars are defined and used in ***12d Model***.

See

41.1 User Defined Function Keys
41.2 User Defined Menus
41.3 User Defined Toolbars

41.1 User Defined Function Keys

The user can define function keys (with possible modifiers) to be used to

(a) bring up most ***12d Model*** menus or panels

(b) toggle certain snaps on or off.

(c) start some geometry snaps

(d) read a layout file

(e) execute a batch file or a program (system call).

(f) run 12d Model 12dPL's (macros) or chains

The function key definitions are given in the file

userkeys.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or is pointed to by the environment variable

FUNCTION_KEYS_4D   file   // function key definitions

The format of the function_keys file is simply a list of function key definitions with only one per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

The function key definition is

MODIFIERS   FUNCTION_KEY   OPERATION

where MODIFIERS can be totally missing or any combination of

shift
control
or alt

FUNCTION_KEY is one of

f1, f2,...f12 (**f7 should be avoided since it is used in 12d Model for typed inpu**t,
f1 & f10 should be avoided since they are reserved by Windows NT)

and OPERATION is one of

menu	menu_name	// raise a menu
panel	panel_name	// raise a panel
snap	toggle_snap	// list of toggle_snaps given below
snap	cogo_snap	// list of cogo_ snaps given below
cogo_command		// list of cogo_ commands given below
layout	layout_file_name	// run a screen layout file
system	batch_file	// run a batch file
system	program	// run a program

or for macros

macro	*options*	user_macro_name	*macro_arguments*

where the macros options are:

-no_console	// don't display macro console
-close_on_exit	// remove console when macro terminates
-buttons	// have buttons for *finish*, *restart* and *quit* on console
-allow_defaults	// allow default answers for console questions

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For information on how to use each item with function keys, see

Menus and Panels
View Menus and Panels
View Toggle Menus
Available Snaps to be Toggled
Available Cogo Snaps
Available Cogo Commands
Layout Files
System Calls
12dPLs (Macros)
Chains

For using $LIB and $User_Lib, see $LIB and $USER_LIB.
For an example of *userkeys.4d*, see Example of a User Function Key File.

Menus and Panels

Menus and panels can be programmed by functions keys by simply giving the name of the menu and panel after the **panel** command.

For example,

f5	panel	"String Inquire"	// this is a panel
f6	panel	"String Create"	// this is a menu

Note: the names for each menus and panel (together) must have unique names so there is no confusion about what is to be run by just giving the name after the command **panel**.

View Menus and Panels

Menus and panels for views can be programmed by functions keys by substituting the text $PLAN_VIEW, $SECTION_VIEW or $PERSPECTIVE_VIEW in place of the view name in the panel name or menu name.

For example,

f9	panel	"Plan Plot $PLAN_VIEW".

A panel for each view type can be programmed for the same modifier and function key combination. If the cursor is over the appropriate view type when the function key is selected, then the panel is fired up.

For example, the three definitions for f5

f5	panel	"Section Plot $SECTION_VIEW"
f5	panel	"Plan Plot $PLAN_VIEW"
f5	panel	"Perspective Plot $PERSPECTIVE_VIEW"

means that a panel will come up when f5 is selected over any of the three view types.

View Toggle Menus

The **toggle menus** available on each view can be set to a function key by

MODIFIERS	FUNCTION_KEY	menu	"Toggle $PLAN_VIEW"
MODIFIERS	FUNCTION_KEY	menu	"Toggle $SECTION_VIEW"
MODIFIERS	FUNCTION_KEY	menu	"Toggle $PERSPECTIVE_VIEW"

As for the view menus, the cursor must be over the appropriate view type when the function key is selected.

For example,

shift f8 menu "Toggle $PLAN_VIEW"

brings up the plan view toggle menu if shift f8 is selected when in a plan view.

Available Snaps to be Toggled

toggle_point_snap
toggle_line_snap
toggle_grid_snap
toggle_cursor_snap
toggle_tin_snap
toggle_input_height_snap
toggle_show_information

For example,

control f2 toggle_point_snap

Available Cogo Snaps

snap create_edit
snap line_create_edit
snap tangent_items_edit
snap fillet_3_points_edit
snap fillet_item_item_cp_edit
snap fillet_item_item_radius_cp_edit
snap locate_divide_edit
snap locate_divide_distance_edit
snap parallel_edit
snap intersect_edit
snap intersect_offset_edit
snap bearings_intersect_edit
snap between_points_edit
snap locate_edit
snap locate_chainage_edit
snap locate_offset_edit
snap locate_deflection_edit
snap locate_drop_perpendicular_edit
snap locate_projection_edit
snap locate_two_point_distances_edit

For example,

shift f1 snap locate_chainage_edit

Available Cogo Commands

All the new cogo commands can be activated by a function key.

create_edit
line_create_edit
tangent_items_edit
fillet_3_points_edit
fillet_item_item_cp_edit
fillet_item_item_radius_cp_edit

locate_divide_edit
locate_divide_distance_edit
parallel_edit
intersect_edit
intersect_offset_edit
bearings_intersect_edit
between_points_edit
locate_edit
locate_chainage_edit
locate_offset_edit
locate_deflection_edit
locate_drop_perpendicular_edit
locate_projection_edit
locate_two_point_distances_edit

For example,

f2 between_points_edit

Layout Files

Layout files can be called up using the **layout** command.

For example,

f8 layout "/temp/contours.slf"

System Calls

Programs and batch files can be called up using the **system** command. The directories defined by the environment variables $LIB_4D and $USER_4D are included in the PATH environment variables so that any batch files or executables in these areas will be accessible without including any path name in the system call.

For example,

```
f4          system    special.exe           // run the program special.exe
shift f4    system    batch.bat             // run a batch file
control f4  system    "start cmd /k  dir"   // do a dir in a command shell
```

12dPLs (Macros)

12d supplied and User 12dPLs (macros) can be run and the macros brought up with or without buttons, and with leaving or removing the macro console when the macro has finished.

The macro command structure and options are:

macro *options* user_macro_name *macro_arguments*

where the macros options are:

-no_console // don't display macro console
-close_on_exit // remove console when macro terminates
-buttons // have buttons for *finish*, *restart* and *quit* on console
-allow_defaults // allow default answers for console questions

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For example,

```
f8    macro  -no_console  -close_on_exit"/area/drape_align.4do"
f9    macro   -buttons"/games/lots.4do"
```

For compatibility with earlier versions of ***12d Model***, the following macro commands are also supported:

macro user_macro_name // run macro without buttons,

		// leave console panel on exit
macro_2	user_macro_name	// run macro without buttons,
		// remove console panel on exit
macro_with_buttons	user_macro_name	// run macro with buttons,
		// leave console panel on exit
macro_with_buttons_2	user_macro_name	// run macro with buttons,
		// remove console panel on exit

Chains

12d supplied and User chains can be run by using the **chain** command.

chain chain_name

For example,

f8 chain "tri_cont_label.chain"

$LIB and $USER_LIB

The variable $LIB and $USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either the library or user library.

For example,

f7	macro	"$LIB/drape_align.4do"
f8	macro	"$USER_LIB/lots.4do"
f9	layout	"$LIB/contours.slf"

Note - if $LIB_4D is not defined, then 12dmodel/6.00/library is used. If $USER_LIB_4D is not defined, then 12dmodel/6.00/user_lib is used

Example of a User Function Key File

// File to define function key usage
// Note: f1, f6 & f10 are reserved by Windows NT
// f7 is reserved by 4D Solutions for typed input
// Available function key modifiers are

// shift control alt

// Note: some alt key combinations are reserved by Windows NT

// Some sample lines may be

// f5 toggle_point_snap
// shift f5 toggle_line_snap
// control shift f7 toggle_input_height_snap

// Note that all function key modifiers must come before the function key itself.

// ---

// **snaps**

f3 toggle_point_snap
f4 toggle_line_snap
f5 toggle_grid_snap
f5 toggle_cursor_snap
f8 toggle_input_height_snap
// **snaps cogo**

f9 snap intersect_offset_edit
f11 snap locate_chainage_edit
f12 snap locate_drop_perpendicular_edit

// **panels**

```
f2          panel  "String Inquire"

shift f1   panel "Edit String"
shift f2   panel "String Delete"
shift f3   panel "Clean Model"
shift f4   panel "Delete Model"
shift f5   panel "Strings Edit Ops"
shift f6   panel "Points Edit Ops"
shift f7   panel "String Attributes"
shift f8   panel "Toggle $PLAN_VIEW"

// layout files

control f4 layout "$LIB/tri_contour_clean.slf"

// user macros

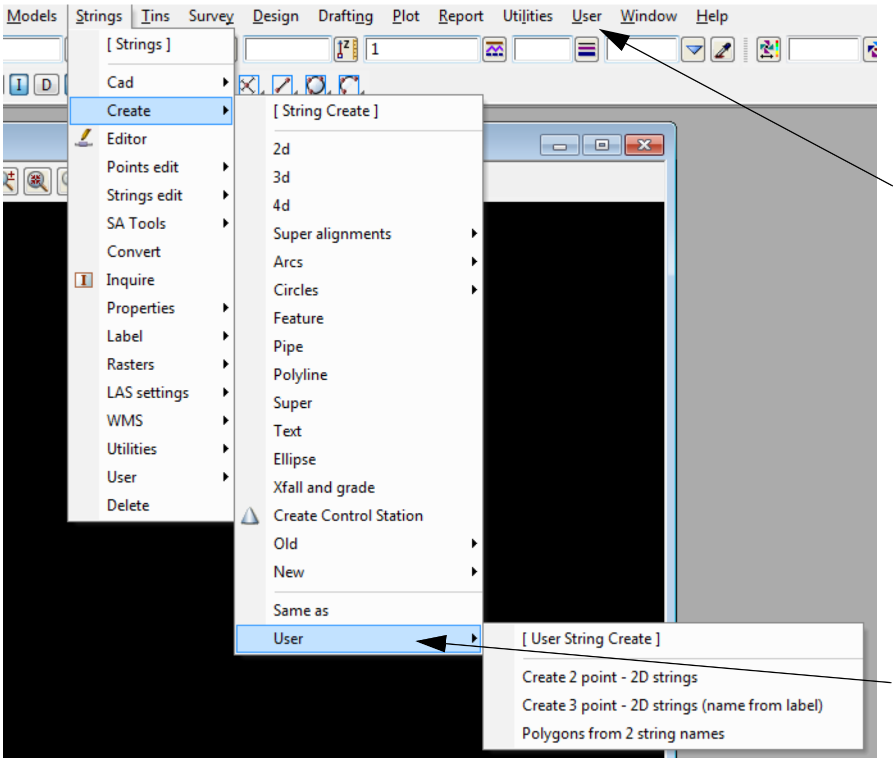
control f5 macro  -no_console  -close_on_exit  "$LIB/Culd.4do"

// ---------------------------------------------------
```

Continue to the next section 41.2 User Defined Menus or return to 41 Functions Keys, Menus, Toolbars.

41.2 User Defined Menus

To help customise ***12d Model***, there is a pull down menu **User** on the Main menu and **User** menus on each of the pull down menus on the Main menu, and some other Menus.



User on the main menu

User String Create on the String Create menu

The **User** menus can run 12d Model macros, external programs, chains, and bring up ***12d Model*** screen layout files, panels and menus.

User menus can have walk-right menus, and any walk-right menus can have further walk-right menus so **User** menus can be used to build sophisticated tailored additions to ***12d Model***. Each of the User Defined menus are also floating (tear away) menus just like standard***12d Model*** menus.

All the **User** menus are defined in the two files: *Usermenu.4d*, which is created by the user, and *Xtramenu.4d*, which supplied by ***12d Solutions***.

When displayed, each **User** menu is divided into two sections with menu options supplied by ***12d Solutions*** in the file *Xtramenu.4d* on the top, and any options supplied by the user (in the file *Usermenu.4d)* underneath.

The default name for the User Defined Menus definition file is

usermenu.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable

USER_OPTIONS_4D file // Customers User menu definition

The default name for the 12d Solutions definition file which includes some macro for **User** is

xtramenu.4d

which is also searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable

EXTRA_OPTIONS_4D file // 12D Solutions User menu definitions

The format for the User Defined Manu's file s given in the next section 41.2.1 Full Definition of User Menus.

Important Note

The file *xtramenu.4d* is for use by ***12d Solutions*** only. Please do not modify it because it may be over written in future updates. The file *usermenu.4d* is for Customer use.

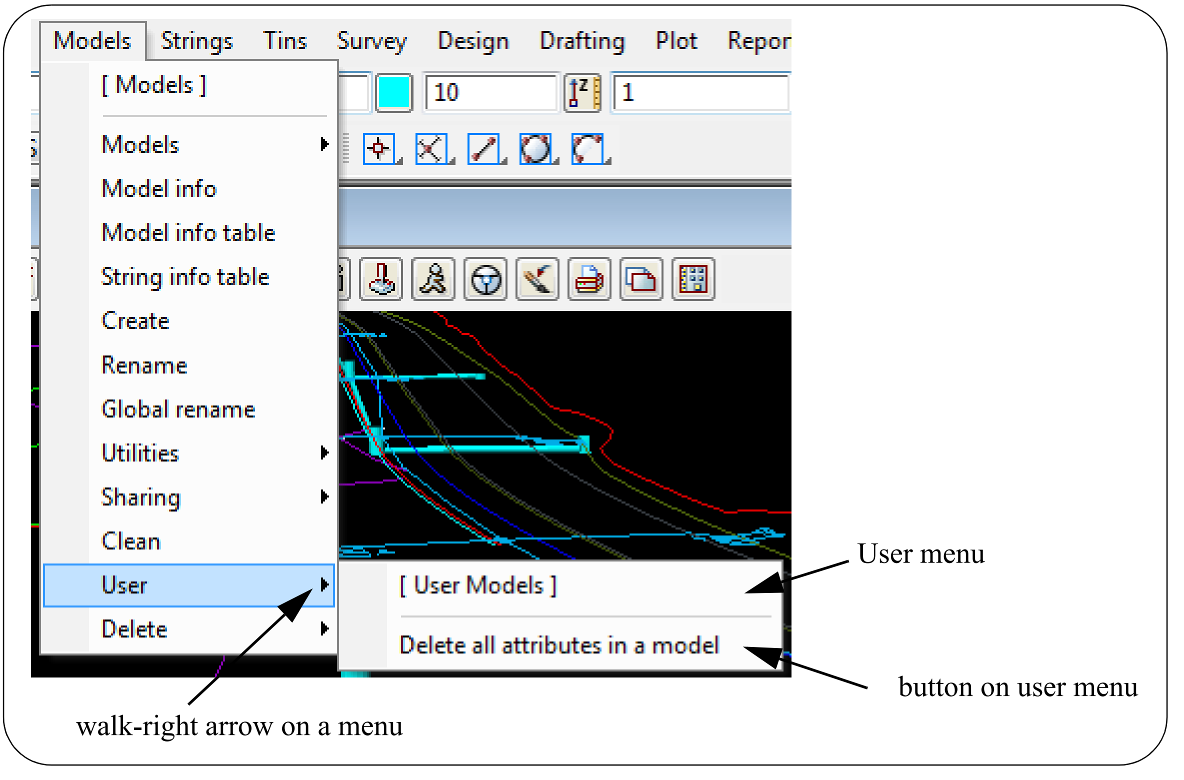
See

41.2.1 Full Definition of User Menus
41.2.2 Using $LIB and $USER_LIB in User Menus
41.2.3 Placing User Defined Menus on User and Other 12d Menus
41.2.5 Example of a User Defined Menu

41.2.1 Full Definition of User Menus

The ***User Defined Menus*** are made up of *buttons* which have text on them and when the left hand mouse button (LB) is pushed down and released on a button, a *command* is executed.

A button can also have a walk-right menu which appears when the left hand mouse button (LB) is moved over the arrow on the right had side of the button. Walk-right menus can have walk-right menus.



The ***text*** for each button in the **User** menus, plus the action taken when the button is selected, is user specified. Any of the buttons can include further walk-right menus.

When a button is **selected**, the action can be to

(a) run a ***12d Model*** macro

(a) run a ***12d Modell*** chain

(b) bring up a***12d Model*** menu or User Defined menu

(c) bring up a***12d Model*** panel

(d) read a screen layout file

(e) execute a batch file or program (system call)

In the *Usermenu.4d* file, a menu is defined by:

```
Menu menu_name  {
                button_1
                button_2
                ...
                button_n
}
```

where a button can include one or both of the keywords *Command* and *Walk_Right*, and the syntax for a button is

```
Button button_name {
            Walk_Right          menu_name_1
and/or      Command             command_name
}
```

The *text* displayed on the button is ***button_name*** and the definitions of the *Walk_Right* and *Command* commands are:

Walk_Right Menu for Buttons

The ***Walk_Right*** keyword specifies that there *is* a walk-right menu for the button and gives the *name* of the menu that is displayed when LB is moved over the walk-right arrow on the button.

The *Walk_Right* command consists of the word *Walk_Right* followed by one or more spaces and then the name of the menu that is displayed when over the walk-right arrow.

Walk_Right ***menu_name***

where *menu_name* is the name of another menu ***defined elsewhere*** in the *usermenu.4d* file.

When the *Walk_Right* keyword exists, a walk-right arrow is created on the button.

If there is no Walk_Right keyword, then there is no walk right arrow on the button.

A *Walk_Right* line is optional.

NOTE - walk-right menus *can* contain walk-right menus.

Commands for Buttons

The ***Command*** keyword defines what action occurs if **LB is clicked on the button.**

The *Command* consists of the word *Command* followed by one or more spaces and then the name of the command and any arguments it requires.

Command ***"command_name command_arguments"***

The ***command_name*** and ***command_arguments*** can do any of:

(a) Run a User Defined or 12d Supplied 12d Model 12dPL (Macro)

Command "**macro** *macro_options* user_macro_name *macro_parameters*" // run macro

where the *macros_options* are:

```
-no_console          // don’t display macro console
-close_on_exit       // remove console when macro terminates
-buttons             // have buttons for finish, restart and quit on console
-allow_defaults      // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For example

```
Button "Write Levels" {
   Command "macro Tinval.4do"
}
Button "ADAC - show attributed/not attributed" {
Command "macro -no_console -close_on_exit Adac_show_panel.4do"
```

```
}
```

(b) Run a chain

Command "**chain** *chain_file_name*"

It is also possible to pass a chain parameter value file (pvf) to be used by the chain through to the chain. The command is

Command "chain *-pvf pvf_file_name chain_file_name*"

where ***pvf_file_name*** is the name of the **pvf** file to use when the chain *chain_file_name* is run.

For example

```
Button "Survey to ADAC 41 chain" {
   Command "chain -pvf $USER/BCC/ADAC_BCC_41.pvf $LIB/ADAC_survey_base.chain"
}
```

Also see 28.3.5.4 Running Chains from User Menus and Toolbars

(c) Bring up a *12d Model* menu and/or a User Defined Menu

Command "12d_model_menu_name"

or

Command "user_defined_menu_name"

The *12d_model_menu_name* is simply the name on the top of the ***12d Model*** menu.

The *user_defined_menu_name* is the name of a User Defined menu that is defined further down in the usermenu.4d file.

For example, for the menu called "Model Utilities", the

```
Button "Bring up the Model Utilities menu" {
   Command "Model Utilities"
}
```

Notice that for a menu, only the menu name in quotes follows the keyword *Command*.

Note: - this works because all the names must be unique amongst the ***12d Model*** menus, *12d* ***Model*** panels and *User Defined* menus.

A menu can occur as a *Walk_Right* menu and/or as a *Command*.

(d) Bring up a*12d Model* panel

Command "12d_model_panel_name"

Every ***12d Model*** menu and panel has a unique name and the *12d_model_panel_name* is simply the name on the top of the panel.

For example, for the menu called "Test Helmert 2d (Advanced) panel", the

```
Button "Bring up a Helmert panel" {
   Command "Test Helmert 2d (Advanced)"
}
```

Notice that for a panel, only the panel name in quotes follows the keyword Command.

Note: - this works because all the names must be unique amongst the ***12d Model*** menus, *12d* ***Model*** panels and *User Defined* menus.

(e) Run a User Defined screen layout file

Command "**layout** layout_file_name"

For example

```
Button "Generate ADAC Tree Spreadsheet" {
   Command "layout ADAC_Tree_Report.slx"
}
```

(f) Execute a batch file or program

Command "**system** program_or_batch_file_name"

Notes

1. A Command Line is optional
2. A button can have both a **Walk_Right** and a **Command** defined for it.
3. If there is only a *Walk_Right* menu and no *Command*, clicking on the button will bring up the **Walk_Right** menu.
4. Both *Walk_Right* and *Command* can be left out.

For example

```
Button "------------------------------" {
}
Button "" {
}
```

will create a button with the text "------------------------------" on it and a button with no text on it.

5. in the *usermenu.4d* file, blank lines are ignored and anything on a line after a **//** is a comment

Continue to the next section 41.2.2 Using $LIB and $USER_LIB in User Menus or return to 41.2 User Defined Menus.

41.2.2 Using $LIB and $USER_LIB in User Menus

The variable $LIB and $USER_LIB can be used in Commands as part of the user_macro_name, chain_file_name, layout_file_name and programe_or_batch_file_name to pick up files from either the *12d Library* or the *User* library.

Note

If $LIB_4D is not defined, then 12dmodel/version_number.00/library is used.

If $USER_LIB_4D is not defined, then 12dmodel/version_number.00/user_lib is used

For example, the definition of a menu called "Lots" could be:

```
Menu "Lots" {
  Button "Create lots" {                          // button called "Create lots" which
    Command "macro -close_on_exit  $USER_LIB/subdiv.4do"  // fires up a 12d Model macro
  }
  Button "Roads" {                    // button with walk-right menu "Roads" and layout file
    Walk_Right "Roads"                            // walk-right menu "Roads"
    Command "layout $USER_LIB/road.slx"           // button invokes a layout file if selected
  }
}
```

Continue to the next section 41.2.3 Placing User Defined Menus on User and Other 12d Menus or return to 41.2 User Defined Menus.

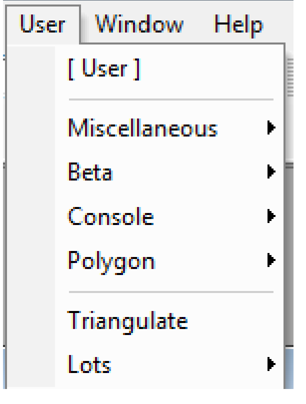
41.2.3 Placing User Defined Menus on User and Other 12d Menus

User Defined Buttons on Main User Menu

The place buttons or menus in the bottom of the **User** menu on the Main menu, put the buttons in a menu called **User** in the usermenu.4d file.

For example

```
Menu "User" {
   Button "Triangulate" {                // button called Triangulate which brings up
      Command "Triangulate a View"       // the "Triangulate a View" panel
    }
   Button "Lots" {                       // button called Lots with its
      Walk_Right "Lots"                  // own walk-right menu called Lots
      Command "Triangulate a View"       // plus clicking on the button brings up the
   }                                     // the "Triangulate a View" pane
}
```



User Defined Menus on Other 12d Menus

It is also possible to define a ***User*** submenu on any ***12d Model*** menus or submenu.

In ***12d Model,*** all menus and sub-menus on the **Main** menu have a unique name. So a **User** menu is defined for any of them by simply having a menu called "User menu_name" in the *usermenu.4d* file.

For example, the menu for the option *Strings=>Create* is called **String Create** (String not Strings) so a ***User*** menu for *Strings=>Create* would be called "User String Create":

```
Menu "User String Create" {
   Button "Create 4d strings" {
      Command "macro  -close_on_exit  $USER_LIB/ref_points.4do"
   }
   Button "Create point strings" {
      Command "macro  -close_on_exit  $USER_LIB/x_sects.4do"
   }
}
```

41.2.4 Names for User Defined Menus

Apart from the names of the special User menus just mentioned, all other menu names in *usermenu.4d* are user defined so they can be easily used in user defined walk-right menus.

And menu referred to in the file *usermenu.4d* that is not one of the special *User menus*, ***must be must be defined*** somewhere in the *usermenu.4d* file.

And remember, all the names must be unique amongst the ***12d Model*** menus, ***12d Model*** panels, special User menu and *user named User Defined* menus.

Continue to the next section 41.2.5 Example of a User Defined Menu or return to 41.2 User Defined Menus.

41.2.5 Example of a User Defined Menu

// the definition of buttons to go on the Main menu option "User"

```
Menu "User" {                           // User menu on Main menu
   Button "Triangulate" {               // button called Triangulate which brings up
      Command "Triangulate a View"      // the "Triangulate a View" panel
   }
   Button "Lots" {                      // button called Lots with its
      Walk_Right "Lots"                 // own walk-right menu called Lots
   }
   Button "Roads" {                                 // button with walk-right menu "Roads"
      Walk_Right "Roads"
      Command "layout $LIB/road.slf"                // button invokes a layout file if selected
   }
}

// the definition of the walk-right menu Lots

Menu "Lots" {
   Button "Create lots" {
      Command "macro $LIB/subdiv9.4do"
   }
   Button "Label lots" {
      Command "macro $LIB/subnum3.4do"
   }
   Button "Write Lot Levels" {
      Command "macro $LIB/Tinval.4do"
   }
}

// the definition of the walk-right menu Roads

Menu "Roads" {
   Button "Roundabout" {
      Command "macro $LIB/Round.4do"
   }
   Button "Culdesac bulb" {
      Command "macro $LIB/Culd.4do"
   }
   Button "Drape alignment string" {
      Command "macro $LIB/Drape_al.4do"
   }
   Button "Create Table drain" {
      Command "macro $LIB/Table_dr.4do"
   }
}
```

// the definition of User on the Main menu option Strings=>Create"

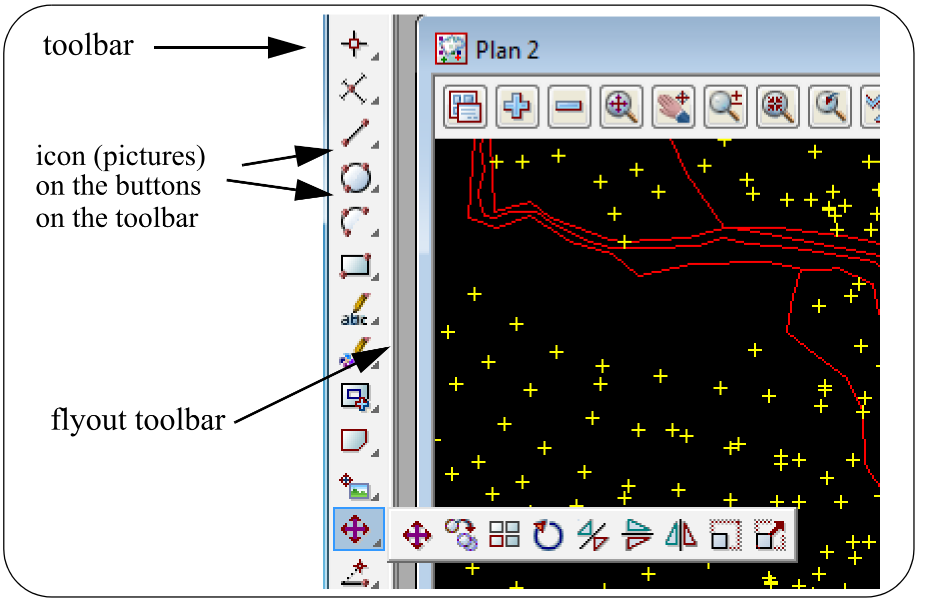
```
Menu "User String Create" {                  // User menu on option Strings=>Create
      Button "Create ref points" {
      Command "macro  -close_on_exit  $LIB/ref_points.4do"
   }
   Button "Create X-sections" {
      Command "macro  -close_on_exit  $LIB/x-Sects.4do"
   }
}
```

Continue to the next section 41.3 User Defined Toolbars or return to 41.2 User Defined Menus.

41.3 User Defined Toolbars

A ***toolbar*** is made up of buttons which can have a picture on them (icons) and when the left hand mouse button (LB) is pushed down and released on the button, a command is executed.

A button can also have a *flyout* toolbar which appears when the left hand mouse button (LB) is held down on the button (note that there can only be one level of flyouts).



Toolbars can be turned on and off, and their positions are remembered when ***12d Model*** is saved. See 4.3.5 Toolbars and Controlbars.

The definitions for *toolbars* in ***12d Model*** are stored in two files - *user_toolbars.4d* and *toolbars.4d*. When ***12d Model*** is installed, *toolbars.4d* is installed in the ***12d Model*** folder *Set_Ups*. *user_toolbars.4d* is for user defined toolbars and is created by the user and should be stored in the folder *User*.

So any user defined toolbars and simply added to *user_toolbars.4d* and saved in the folder *Users*.

The icon for each button on a toolbar, plus the action taken when the button is selected is user specified. A button can include a fly-out toolbar but flyouts can only be to one level (i.e. no flyouts on flyouts).

When a button is **selected**, the action can be to

(a) run a ***12d Model***12dPL (macro) or chain
(b) bring up a ***12d Model*** menu
(c) bring up a ***12d Model*** panel
(d) read a layout file
(e) execute a batch file or program (system call)

When ***12d Model*** starts up, any toolbars defined in *toolbars.4d* and *user_toolbars.4d* that are *not* called as flyouts by another toolbar in *toolbars.4d* or *user_toolbars.4d*, are displayed in the *main toolbar* on the left hand side of the ***12d Model*** screen.

When a toolbars is moved around, its position is saved when ***12d Model*** is saved so the toolbars are in the same final position when the project is reopened.

Go to the next section 41.3.1 Full Definition of Toolbars.

41.3.1 Full Definition of Toolbars

The definition for **Toolbars** is given in the files called

Toolbars.4d and **user_toolbars.4d**

which are searched for in the standard set up areas (local, USER_4D, user, set_ups etc.)

Or instead of *toolbars.4d*, it can be defined and set by the environment variable

TOOLBARS_4D file // Toolbars definition

In the *toolbars.4d* and *user_toolbars.4d* files, a ***toolbar*** is defined by:

```
Toolbar  toolbar_name  {
              button_1
              button_2
              ...
              button_n
}
```

where a button can include none or more the commands *Icon*, *Command* and *Flyout,* and the syntax for button is:

```
Button   button_name {
              Icon          icon_name_1
              Command       command_name_1
              Flyout        toolbar_name_1          // only used if a flyout toolbar is required
}
```

For the definitions of the *Icon*, *Command* and *Flyout* commands see:

41.3.1.1 Icons for Toolbars.
41.3.1.2 Command for Toolbars.
41.3.1.3 Flyout for Toolbars.

41.3.1.1 Icons for Toolbars

The ***Icon*** command defines the bitmap that is displayed for the button in the toolbar. The format of the bitmap is a bmp file (.bmp) of size 16x16. The *Icon* command consists of the word *Icon* followed by one or more spaces and then the name of the bitmap, *icon_name*.

Icon ***icon_name***

The *icon_name* can include a pathname but if no pathname is present, the bitmap is searched for in the folder *Images* under the folders *User* or *Set_Ups*.

If the *Icon* command is missing then a default *Icon* command is used with the *icon_name* ***button_name.bmp***

Icon *button_name.bmp*

Go to the next section 41.3.1.2 Command for Toolbars or return to 41.3.1 Full Definition of Toolbars

41.3.1.2 Command for Toolbars

The ***Command*** command defines what action occurs if LB is clicked on the button. The *Command* command consists of the word *Command* followed by one or more spaces and then the name of the command and any arguments it requires.

Command ***command_name***

The Commands are the same as those for a ***User Defined Menu***. See Commands for Buttons

If the *Command* command is missing then a default *Command* is used with the command name ***button_name*** with no arguments

Command *button_name*

Go to the next section 41.3.1.3 Flyout for Toolbars or return to 41.3.1 Full Definition of Toolbars

41.3.1.3 Flyout for Toolbars

The ***Flyout*** command defines what toolbar is displayed when LB is help down on the button. The *Flyout* command consists of the word *Flyout* followed by one or more spaces and then the name of the toolbar that is displayed.

Flyout ***flyout_toolbar_name***

where *flyout_toolbar_name* is the name of another toolbar defined elsewhere in the toolbars file.

When the *Flyout* command exists, *Icon* and *Command* are not required and if they are present, are ignored.

The icon on the *Flyout* button is the *Icon* from the first button in the flyout toolbar.

The command executed if LB is pressed and released on the Flyout button is the *Command* from the first button in the flyout toolbar.

NOTE - flyouts *can not* be nested so the toolbar *flyout_toolbar_name* can not contain a *Flyout* command.

NOTE - when ***12d Model*** starts up, any toolbars defined in *toolbars.4d* that are *not* called as flyouts by another toolbar in *toolbars.4d*, are displayed in the *main toolbar* on the left hand side of the ***12d Model*** screen.

Example of a User Defined Toolbar

```
// --------------------------------------------
// WARNING: you cannot have the same command using different icons
// ALSO: when using a flyout, the Command & Icon are ignored
//       and the details are taken from the first button
//       on the flyout
// --------------------------------------------
Toolbar "Cad" {
   Button "Points" {
      Command "Create Point"              // this is ignore since it is a flyout
      Icon    "Create Point.bmp"          // this is ignore since it is a flyout
     Flyout  "Cad Points"
  }
   Button "Change String" {
      Flyout  "Change String"
   }

Toolbar "Cad Points" {                    // used as a flyout toolbar
   Button "Create Point" {
      Command "Create Point"
      Icon    "Create Point.bmp"
   }
   Button "Chainage" {
      Command "Locate Chainage"
      Icon    "Chainage.bmp"
   }
}  // end of "Cad Points" toolbar
```

```
Toolbar "Change String" {                    // used as a flyout toolbar
   Button "String Close" {
      Command "String Close"
      Icon    "String Close.bmp"
   }
   Button "String Reverse" {
      Command "String Reverse"
      Icon    "String Reverse.bmp"
   }
   Button "String Trim" {
      Command "String Trim"
      Icon    "String Trim.bmp"
   }
}  // end of "Change String" toolbar
```

$LIB and $USER_LIB

As they were for Commands in User Defined menus, the variables $LIB and $USER_LIB can be used in Commands as part of the user_macro_name, chain_file_name, layout_file_name and programe_or_batch_file_name to pick up files from either the *12d Library* or the *User* library. See 41.2.2 Using $LIB and $USER_LIB in User Menus.

For example, the definition of a toolbar called "Lots" could be:

```
Toolbar   "Lots" {
   Button "Create lots" {                              // button called "Create lots" which
      Command "macro -close_on_exit   $USER_LIB/subdiv.4do"   // fires up a 12d Model macro
   }
   Button "Roads" {                    // button with walk-right menu "Roads" and layout file
      Walk_Right "Roads"                               // walk-right menu "Roads"
      Command "layout $USER_LIB/road.slf"              // button invokes a layout file if selected
   }
}
```

Notes

(a) The variables $LIB and $USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either of the libraries.

(b) blank lines in the toolbars file are ignored and anything on a line after a // is a comment

Another Example of a Toolbar

```
Toolbar "Cogo" {
// in this case, the Command is assumed to be "Create Line"
// the icon is "Create Line.bmp"
// Command is normally the name of the panel/menu
  Button "Create Line" {
 }
// this is a spacer
 Button "" {
 }
// this is a command and also has a flyout capability
```

```
// calling the toolbar called Flyout
// flyouts cannot be nested
  Button "Create Fillet by radius" {
    Command "Create Fillet by radius"
    Icon    "Create Fillet by radius.bmp"
    Flyout  "Flyout"
  }
}
// The flyout toolbar for above (and a normal toolbar as well)
Toolbar "Flyout" {
  Button "Create Line" {
  }
  Button "" {
  }
  Button "Create Arc by Centre Radius" {
    Command "Create Arc by Centre Radius End Points"
    Icon    "Create Arc by Centre Radius End Points.bmp"
  }
  Button "Create Fillet by radius" {
    Command "Create Fillet by radius"
    Icon    "Create Fillet by radius.bmp"
  }
}
```

Return to 41.3.1 Full Definition of Toolbars or 41 Functions Keys, Menus, Toolbars.

42 Special File Formats

42.1 Default File Ending

In any panel pop-up requiring a file name to be displayed, default file endings are used to restrict the **names** of the files selected from the current folder and if they exist, from the library and user library areas.

Whilst a panel is up, the extension being searched for can be changed by typing say "*.xyz" into the panel field requiring a file name, and then pressing <enter>. The list of files ending in ***.xyz*** will be displayed and clicking B3 in the panel field will also bring up a list of all files ending in **".xyz"**. When a new panel is created, the panel fields revert to the default file ending.

A list of the **default** files used in 12d Model pop-ups and their endings is:

File Type	**Default Ending**

4DML's - 12d Solutions programming/macro language

macro source file	.4dm

macro object/executable	.4do
macro listing	.4dl

Note

This list is for the default files used in 12d Model panel fields. It does not include 12d Model setup files which are given in the appendix 39 Setting Up & Configuring 12d.

42.2 Special 12d Solutions File Formats

12d Solutions has a number of special file formats, most of which have already been specified. The remaining formats will now be given.

In any of the files, blank lines ignored and any information after // until the end of that line is ignored. Hence **comments** can easily be inserted into the files by preceding them by ***//***.

Unless enclosed in quotes ("), more than one consecutive space or tab are treated as one space.

42.2.1 Eagle Map File

An eagle map file is a user created file consisting of a list of 12d Model colours and the Eagle pen, dash style, pen thickness and frag to be used for the colour.

The map file is set out with one 12d Model colour per line. The line begins with the 12d Model colour followed by the Eagle pen number, dash style, thickness and frag to be used for the 12d Model colour. Each item is separated by one or more spaces.

For example, if the 12d Model colour **red** is to be mapped to Eagle pen 3, dash style 4, thickness 2 and frag 1, then the line in the eagle map file would be

```
red       3        4        2        1
```

An eagle map file can be used for writing out three dimensional data to Eagle, or when producing plots in Eagle format.

For plotting, the map file must be called **eagleplt.emf**.

When writing three dimensional data out to Eagle, a user specified file name is allowed.

In the output case, as each string is written out, the map file is searched sequentially until a colour match is made. If no match is found, the colour of the string is used as a pen number and default values used for dash, thickness and frag.

Comments can be included in the map file by preceding the comment with a double forward slash (i.e. //). Anything on the line following the // will be ignored.

An example of an Eagle map file is,

```
//12d Model colour to Eagle mapping file
//
//12d Model colour  eagle pen           dash  thickness   frag

black               0                    1        1         1
red                 2                    0        1         5
green               4                    1        1         1
blue                4                    2        1        11
cyan                5                    1        1         1
yellow              6                    1        1         1
magenta             7                    1        1         1
white               1                    1        1         1
orange              15                   1        1         1
purple              14                   1        1         1
grey                13                   1        1         1
"dark green"        12                   1        1         1
"dark red"          11                   1        1         1
"off yellow"        4                    1        1         1
"dark blue"         8                    1        1         1
brown               11                   1        1         1
```

42.2.2 Template File

The 12d Solutions Template file format is a simple text file definition for reading and writing out template definitions for use in the apply options in 12d Model.

The template definition begins with the key word **template** followed by the template name and then the definitions of

fixed, cut, fill and final parts of the template

or fixed and decisional parts

all enclosed within curly braces **{ }**.

```
template fred {                                  template fred {

  fixed {                                                  fixed {
    ...                       or                             ...
  }                                                        }

  cut {                                                    decisional {
    ...                                                      ...
                                                           }
  fill {
    ...
  }
  final {
    ...
  }
}
```

The definition of the **fixed** part of the template begins with the key word **fixed** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the centre-line. Each link begins with the keyword **link** followed by the width, percent cross-fall, colour and name for each link. For the percent cross-fall, positive means up, negative is down and zero horizontal.

For example,

```
fixed {
  link    3.5       -3        cyan      kerb
  link    1         -4        magenta   shoulder
  link    2         -5        blue      verge
}
```

describes a fixed template with three links, the first of width 3.5 with a 3% cross-fall downwards, the next link of width 1 with 4% cross-fall downwards and the third link of width 2 and 5% cross-fall downwards.

The definition of the **cut** part of the template begins with the key word **cut** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword **link** followed by the width, one in slope, colour and name for each link. For cut, the **one in** slope is positive for up, negative for down, and zero for horizontal.

For example,

```
cut {
  link    3        2        yellow    a
  link    2        0        magenta   b
  link    3        -1       yellow    c
  link    2        0        magenta   d
}
```

describes a cut template with four links, the first of width 3 with 1:2 slope upwards, the next link of width 2 horizontally, the third link of width 3 and 1:1 slope downwards and width 2 horizontally.

The definition of the **fill** part of the template begins with the key word **fill** followed by a list of the links enclosed in curly braces {}.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword **link** followed by the width, one in slope, colour and name for each link. For fill, the **one in** slope is positive for down, negative for up, and zero for horizontal. Please note that this is the opposite to **cut**.

For example,

```
fill {
  link    5        2        yellow    e
  link    1        0        magenta   f
  link    10       -1       yellow    g
}
```

describes a fill template with three links, the first of width 5 with 1:2 slope downwards, the next link of width 1 horizontally, and the third link of width 10 and 1:1 slope upwards.

The definition of the **final** part of the template begins with the key word **final** followed the cut slope, fill slope and search distance enclosed in curly braces {}. The key words for the three values are cut_slope, fill_slope and search_distance.

For example,

```
final {
  cut_slope  1  fill_slope  2  search_distance  100
}
```

describes a final cut slope of 1:1 (upwards), fill slope of 1:2 downwards and template with three links, the first of width 5 with 1:2 slope downwards, both going for a maximum distance of 100.

The definition of the **decisions** part of the template begins with the key word **decisional** followed by a list of the decision commands enclosed in curly braces { }.

The decision commands are defined one per line and have the format:

Fixed Xfall Width *value* Height *value* XFall *value* Name *text* Colour *colour*

Fixed Slope Width *value* Height *value* Slope *value* Name *text* Colour *colour*

Tin Width *tin_name* Strip *value* width *value* Name *text* Colour *colour*

String Offset *string_name* Strip *value* Offset *value* Name *text* Colour *colour*

Batter *tin_name* Strip *value* Width *value* Height *value* Slope *value* Name *text* Colour *colour* Goto *label*

Tin Decision *tin_name* Offset *value* Min *value* Max *value* Goto *label*

Label *label_name*

Goto *label_name*

End

For example,

```
template "std" {
  fixed {
    link 3 unknown -3 cyan "kerb"
    link 1 unknown -4 magenta "shoulder"
    link 2 unknown -5 purple "verge"
  }
  decisional {
    Tin_Decision   "rock" 0 0 1000 "cut_rock"
    Tin_Decision   "shale" 0 0 1000 "cut_shale"
    Tin_Decision   "terrain" 0 0 1000 "cut_terrain"
    Label          "fill_terrain"
    Batter         "terrain" 0 8 unknown -3 "f1" blue "alldone"
    Batter     "terrain" 0 1 unknown 0 "f2" "dark green" "alldone"
    Goto           "fill_terrain"
    Label          "cut_rock"
    Tin_Decision   "rock" 0 0 0.3 "cut_rock_done"
    Batter         "rock" 0.3 5 unknown 0.5 "r1" cyan "cut_rock_done"
    Batter         "rock" 0 2.5 unknown 0 "r2" yellow "cut_rock_done"
    Goto           "cut_rock"
    Label          "cut_rock_done"
    Tin_Decision   "shale" 0 0 1000 "cut_shale"
    Goto           "cut_shale_done"
    Label          "cut_shale"
    Tin_Decision   "shale" 0 0 0.6 "cut_shale_done"
    Batter     "shale" 0.6 6 unknown 1 "s1" magenta "cut_shale_done"
    Batter     "shale" 0 3 unknown 0 "s2" "dark red" "cut_shale_done"
    Goto           "cut_shale"
    Label          "cut_shale_done"
    Tin_Decision   "terrain" 0 0 1000 "cut_terrain"
    Goto           "alldone"
    Label          "cut_terrain"
    Batter         "terrain" 0 3 unknown 1.5 "t1" red "alldone"
    Batter         "terrain" 0 2 unknown 0 "t2" green "alldone"
    Goto           "cut_terrain"
    Label          "alldone"
  }
}
```

Notes

1. spaces in text - any text string that includes spaces or only numbers, must be enclosed in double quotes **"**.
2. comments - anything after // until the end of the line is ignored.
3. blank lines - blank lines are ignored

42.2.3 Screen Layout File

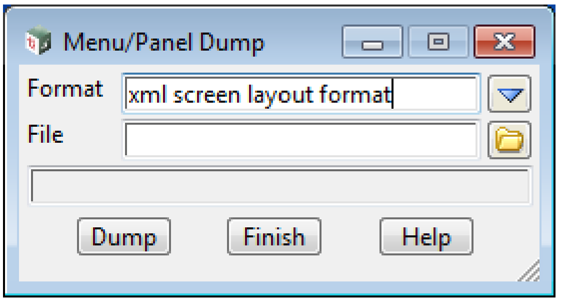
The 12d Model **screen layout file** contains a simple text file definition for 12d Model panels and menus in either the pre-V10 format (slf) or the V10 XML format (slx).

The definition includes a screen position for the panel or menu, and for panels, values for any of the panel fields.

At any time, the layout of the menus and panels on the screen in a 12d Model session can be written out using the menu option

File i/o=>Layouts =>Layout output

Also, the layout for an individual panel or menu can be created by clicking RB in the menu/view title area and selecting the dump option to bring up the **Menu/Panel Dump** panel.



Note: If a screen layout file is created and added to the *layout.4d* file (by selecting *layout.4d* as the file name and selecting **Append**), then the menu/panel will appear whenever a project is opened. See layout.4d

A screen layout file can be read in using the menu options

File i/o=>Layouts =>Layout input or **File i/o=>Layouts =>Layout input files**

Also when a project starts up, the layout file ***layout.4d*** is read in and any menus and panels described in the file are placed on the screen (see 39.2.3 Setup Files Used for New and Existing Projects).

An example of a screen layout file for 'Read x y z s Data' in the V10 format is:

```

42.2.4 Map File for 12d Model V4.0

Up to ***12d Model*** V4.0, the map file format consisted of one or more lines. Each line begins with a key (entity-mask) followed by a string name, model name, colour, breakline type (point or line), and line style separated by one or more spaces. The key can contain wild cards (*) and wild characters (?).

When a string is read in and satisfies a key, the key's corresponding string name, model, colour, breakline type and style is used for that string.

For example, any entity name beginning with **31** can be created as a 12d Model string with the name **picket**, colour **cyan**, breakline type **line**, line style **1** and model **fences** by the map file line

```
31*      picket   fences   cyan     line     1
```

If a map file is used, as each entity is read in, the map file is searched **sequentially** until a match with a key is made and the key's name, colour etc. used. If no match is found, the default colours and model (given in the read panel) are used.

Notes

1. If the entity-name is to be used as the new string name, use an asterisk (*) in place of the string name. For example,

```
fred     *        fences   cyan     line     1
```

2. If the default model for the reader is to be used as the model name, use an asterisk in place of the model name. For example,

```
31       31       *        cyan     line     1
```

3. A * for colour, breakline type and linestyle means that if the entity has a colour, breakline style or linestyle, then it is used rather than be mapped to another one.
4. All model names used in the map file can be given an extra (common) prefix by typing the prefix into the prefix for models field in the read panel.
5. If any information includes a space, then it must be enclosed in quotes **"**. For example, the model name may be "trial 1" or a style "large tanks".
6. Comments can be included in the map file by preceding them with a double forward slash //. Anything on the line after the // is ignored.

An example of a 12d Model map file is

```
// 12d Model map file
// key    name     model    colour   pt-line  linestyle

102      break    breaks   red      line     solid
305      fence    caddast  green    point    dash
998      bdry     bound    cyan     line     solid
spots    *        spot     yellow   point    1
PS*      *        *        yellow   point    1
```

Map File for 12d Model V5.0 and Above

For ***12d Model*** V5.0, the map file was extended to allow for defining properties such as tinability, symbols at vertices, vertex and segment text and pipe and culverts.

To allow for all the different type of mapping in the one file, the map file is broken up into sections (one section for each tab of the map file editor) and each section begins with a header record which is the section name enclosed in braces ({ }). For example, the symbols section has the header

{symbol_data}

Inside each section, the data is similar to the V4.0 map file with lines consisting of a key (entity-mask) followed by the data required for that section. The key can contain wild cards (*) and wild characters (?).

The exact format for the map file is not required since they are created and edited from within 12d Model by the option

File i/o => Map file

42.2.5 12d Patterns File

See 40.4 Patterns

43 Plotters and Plotting

The method of creating plots and sending them to a plotter, or to a pdf, or a Cad system such as AutoCad or Microstation, varies from site to site.

So ***12d Model*** provides tools to enable the user to tailor the plotting system, especially the defining of Plotters and Plotter Mapping Files which are described in this chapter.

See

43.1 12d Model Plotters

43.2 Defining Plotters - Plotters.4d

43.3 Mapping 12d Colours to Pens and RGBs

43.4 Sending Plots to a Plotter

43.5 Sheet Sizes

43.6 Text Units in Plots

43.1 12d Model Plotters

When creating a **plot**, ***12d Model*** has a variety of options about where the potting data goes to.

The user can:

(a) drive the plotters **directly** using Windows printer drivers, raster plotter drivers, hp plotter commands etc.

(b) plot **indirectly** by creating a computer disk file (the plot file) in a variety of formats containing the relevant plotter instructions for producing the plot. The formats include pdf, XPS, DWG and DGN.

(c) plot **indirectly** to a ***12d Model*** **model**

Once the plotting device (**plotter engine)** the decided, there will still be a variety of ways that the ***12d Model*** colours are to appear on the plot.

For example, for some plots you may want all the colours to be plotted as black and shades of grey rather than actual colours. Or for white to be plotted as black.

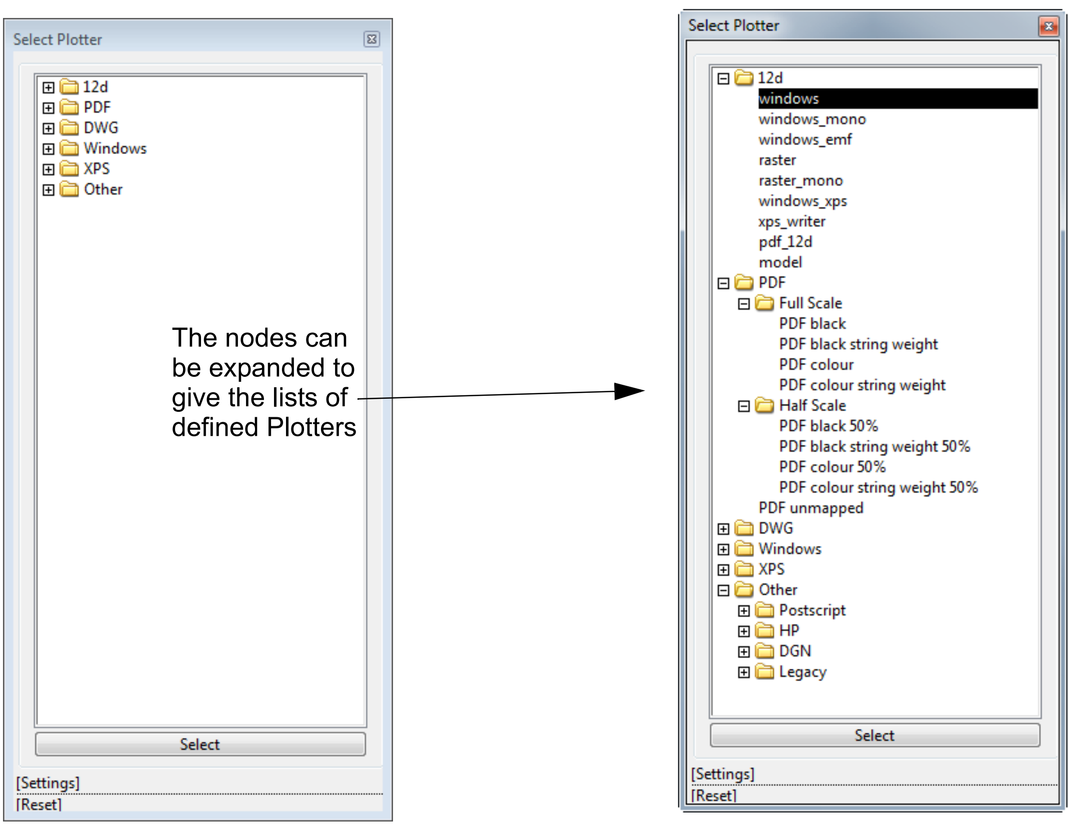
To control **how** a colour is plotted on a particular plot device, there are various user definable parameters and the most flexible for controlling colours is the **plotter mapping file** (pmf file). There are a number of pmf files installed with ***12d Model*** and/or users can also define their own.

So an ***12d Model plotter*** consists of a

1. Unique name for the Plotter
2. The Plot Engine (plot device)
3. Other Parameters to control the plot engine and outputs

The definitions for each of the ***12d Model plotters*** is given in the file **plotters.4d** and it is the list of plotter names from this file that is displayed as the choice list in the when the **Select Plotter** pop-up menu.

The list of ***12d Model*** plotters installed with ***12d Model*** is:



From the list you will see that there can be a number of Plotters using the same plot device (e.g. windows or pdf) and these will differ in one or more of the other plot parameters. For example, having a different plotter mapping file.

When a **plot file** is created, it can be passed to a user specified program or batch file which can do things like automatically directing the plot file to a plotter. See 43.3 Mapping 12d Colours to Pens and RGBs.

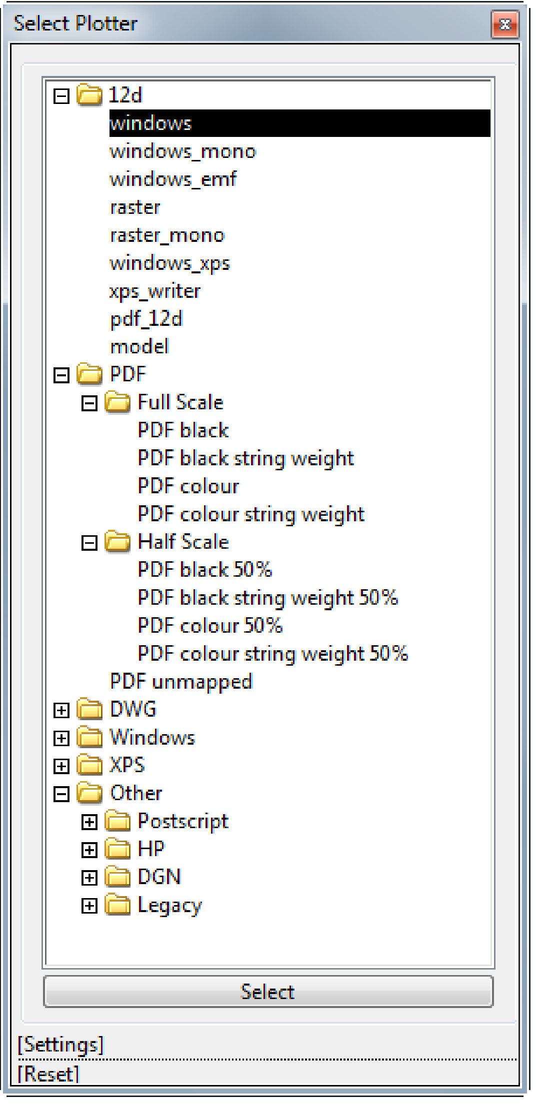
For information on plotters.4d, see 43.2 Defining Plotters - Plotters.4d

43.2 Defining Plotters - Plotters.4d

The file ***plotters.4d*** defines the names of the plotters that appear in the **plotter type** panel field, and the properties of each of these named plotters.

On opening a ***12d Model*** project, if the environment variable ***PLOTTERS_4D*** exists then it has the pathname to the file that defines the plotters otherwise, the file **plotters.4d** is searched for in the *standard set up paths*. See PLOTTER_4D and 39.2.4 Folders Searched for Setup Files).

The pop-up list for the ***plotters.4d*** file shipped with ***12d Model*** is:



but users can delete plotters from this and/or add their own plotters to the file.

For each plotter in *plotters.4d*, it is possible to customize:

(a) the name of the plotter

(b) the plot device (plot engine)

(c) any plotter mapping for mapping colours

(d) a start and end sequence that is sent to a physical plotter

In the plotter file, the definition of a **plotter** of a given name ***plotter_name*** is set out as:

plotter *plotter_name* {
set_up_command_1
set_up_command_2
. . .
set_up_command_n
}

plotter_name must not be blank, and if it includes imbedded spaces then the name must be enclosed in double quotes **"**.

Each *plotter_name* in the file must be unique in the file.

There can be zero or more *set up commands* inside the braces { } and each *set up command* is from the list:

group
engine
extension
map_file
map_pens
output_cmd
colour
header
footer

These *set up commands* are document in the next section 43.2.1 Plotter Set Up Commands.

For a description of some of the Plotters in the default plotters.4d file, see 43.2.2 Some Plotters in the Default Plotters.4d File.

For an example of a ***plotters.4d*** file, see 43.2.3 Example of a Plotters.4d File.

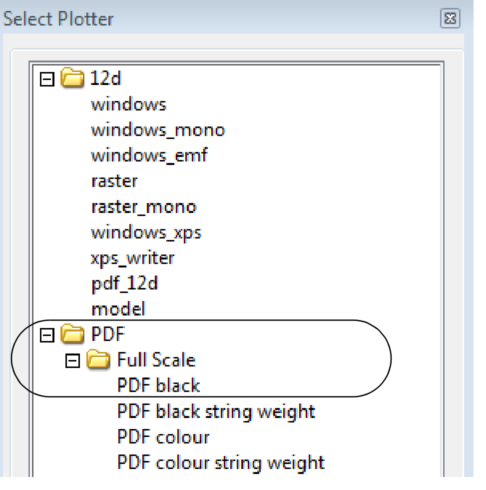
43.2.1 Plotter Set Up Commands

group

although all the *plotter names* have to be different, rather than just listing them in a flat list, the plotter names can be displayed in a tree structure.

The ***group*** command gives the levels in the tree for the plotter name in the pop up list. Each level is separated by a forward slash **/**

For example, if the plotter name was **PDF black** and *group* **PDF/Full Scale** then it will show up in the pop-up list as:



engine

the device that the plot is being created for. For example, model, pdf_12d, xps_writer, dwg_2010, dgn, dgn_v8, postscript and hpgl.

For a complete list of engines, see 43.2.1.1 Plotter Engines.

extension ".xxx"

the extension added to the file name used for the plot file written out by this plotter.

map_file *plotter_mapping_file_name*

if ***map_file exists***, it exists then it points to the *plotter mapping file* which is used to define each ***12d Model* colour** what **pen number** it is mapped to, and for each **pen number**, its **rgb** and **weight** (width).

If ***map_file* does not exist**, and a global mapping file is specified, then it will be used as the plotter mapping file. Otherwise the pen mapping in *Colours.4d* is used.

If the **engine** is any of the **dwg/dxf/dbx** variants, then the **map_file** is an **Autocad mapping file** with the extension of **.amf**, the plotter will use the **colour number** being plotted as the **key** in the Autocad mapping file. This allows the mapping from colour number directly into layer name, Autocad colour and linestyle. Note that if Autocad colour or linetype is BYLAYER, then ***12d Model*** uses the correct values in Autocad. The * character means that the field is ignored. For an example of an amf file, see 43.2.1.3 Definition and Example of a .amf File.

If the **engine** is **dgn/dgn_v8** then the **map_file** is a ***table file*** with the extension of ***.tbl***. The plotter will use the **colour number** being plotted as the **key** in the **table file**. This allows the mapping from the colour number directly into dgn level, weight, style and colour. For an example of a tbl file, see 43.3 Mapping 12d Colours to Pens and RGBs.

map_pens true or false

if ***map_pens*** is ***true***, i***t uses the specified map_file.***

If ***map_pens*** is ***false***, it doesn't use any mappings (map_file, global plotter mapping file or pen mapping table). It leaves the pen number untouched.

map_pens is **ignored** when

(a) the *map_file* is used as a ***tbl file*** (plotter engine is dgn and the map_file has an extension of .dgn. In this case any mapping is occurring via the tbl file where colour is the key.

(b) the map_file is used as a ***amf file*** (plotter engine is dxf or dwg and the map_file has an extension of .dxf. In this case, any mapping is occurring via the .dxf file where colour is the key.

output_cmd path to a *script* or *program*

for this plotter, the given script or program is used on the created plot file. This **replaces** the PLOTTER_4D definition of script or program for this plotter.

colour true or false

This is only used in hpgl2 and postscript.
If **false**, then
for postscript don't send the rgb for colours
for hpgl2, don't send down the block of information with the number of pens and the rgb for each pen.

That is, if false, it stops hpgl2 and postscript writing out the colour definition commands.

header and **footer**

The **header** information in placed in the plot file before any plot commands and the **footer** information is placed at the end of plot file after all the plot commands.

The format for the for the **header** of **footer** is:

header {// this information in placed in the plot file before any plot commands

lines of *text which can include plotter variables*

}

or

footer {// this information is placed at the end of the plot file, after the plot commands

lines of *text which can include plotter variables*

}

Each line of text is surrounded by quotes. For example, "this is some stuff".

The *plotter_variables* used in the **header** or **footer** are:

username

filename

date

time

sheet_width

sheet_height

page_number - not used

minimum_x, minimum_y// plotter dependent

maximum_x, maximum_y// plotter dependent

and are included in the text by preceding them by a + and also following them by a cross if more text follows. For example:

"the user is " + username+"of 4D Solutions"

The appropriate information is substituted for the *plotter_variables* when a plot is created.

Hence

"the user is "+ username+" of 12d Solutions"

would give

"the user is fred of 12d Solutions"

A plotter_variable may not be appropriate for a particular plotter and if a plotter_variable is specified but not used for a plotter, it is substituted by *blank*.

If **header** or **footer** is not specified, then appropriate default information for the plotter is used.

The **header** and **footer** set_up_commands are not used by all plotters. If they are not used for a particular plotter, the **header** or **footer** command is ignored.

At present, only the plotters hpgl, hpgl2, postscript and dxf use **header** and **footer**.

minimum_x etcfor postscript, it is the extent of the plot in mm
sheet_width, sheet_heightfor postscript in mm

For hpgl2

sheet_width, sheet_height in mm/40.

Continue to the next section 43.2.1.1 Plotter Engines or return to 43.2 Defining Plotters - Plotters.4d.

43.2.1.1 Plotter Engines

When creating a **plot**, 12d Model can either use a Windows printer driver to plot directly, or instead of driving the plotter directly, create a computer disk file (the plot file) containing the relevant plotter instructions for producing the plot (which is then sent to the plotter), or in the case of the plotter type **model**, create a 12d Model model.

The available Plotter Engines are:

Engine Name	Action
model	creates a ***12d Model*** model
pdf_12d	creates a pdf file
xps_writer	creates a xps file
windows	use Windows colour printer, or grey scale on mono printers
windows_xps	create a Windows xps file
raster	create a raster file
hp	creates HPGL commands with all of one pen being plotted before the next pen is used
hp_7475	small HP plotter, common hp emulation mode for lasers
hpgl_2	HPGL 2
dwg	creates a binary 2d DWG file
dwg_4d	creates a binary 2d DWG file
dwg_12	creates a binary 2d DWG V12 file
dwg_13	creates a binary 2d DWG V13 file
dwg_14	creates a binary 2d DWG V14 file
dwg_2000	creates a binary 2d DWG 2000 file
dwb_2002	creates a binary 2d DWG 2002 file
dwg_2004	creates a binary 2d DWG 2004 file
dwg_2006	creates a binary 2d DWG 2006 file
dwg_2007	creates a binary 2d DWG 2007 file
dwg_2010	creates a binary 2d DWG 2010 file
dwg_2010	creates a binary 2d DWG 2010 file
dwg_2013	creates a binary 2d DWG 2013 file
dxf	creates a 2d DXF file
dxf_4d	creates a 2d DXF file
dxf_12	creates a 2d DXF V12 file
dxf_13	creates a 2d DXF V13 file
dxf_14	creates a 2d DXF V14 file
dxf_2000	creates a 2d DXF 2000 file
dxf_2002	creates a 2d DXF 2002 file
dxf_2004	creates a 2d DXF 2004 file
dxf_2006	creates a 2d DXF 2006 file
dxf_2007	creates a 2d DXF 2007 file
dxf_2010	creates a 2d DXF 2010 file
dxf_2010	creates a 2d DXF 2010 file
dxf_2013	creates a 2d DXF 2013 file
dxb	creates a binary 2d DXB file
dxb_4d	creates a binary 2d DXB file
dxb_12	creates a binary 2d DXB V12 file

dxb_13	creates a binary 2d DXB V13 file
dxb_14	creates a binary 2d DXB V14 file
dxb_2000	creates a binary 2d DXB 2000 file
dxb_2002	creates a binary 2d DXB 2002 file
dxb_2004	creates a binary 2d DXB 2004 file
dxb_2006	creates a binary 2d DXB 2006 file
dxb_2007	creates a binary 2d DXB 2007 file
dxb_2010	creates a binary 2d DXB 2010 file
dxb_2010	creates a binary 2d DXB 2010 file
dxb_2013	creates a binary 2d DXB 2013 file
dgn	creates a Microstation binary model (**.dgn** file)
dgn_v8	creates a Microstation V8 binary model (**.dgn** file)
pcl5	creates a pcl5 file
eagle_single	creates an Eagle single precision binary model
eagle_double	creates an Eagle double binary model
postscript	creates a postscript file (generally for laser printers)
dogs	creates a Dogs parametric format file
calcomp	creates a Calcomp plot format file
mif	creates a frame maker interface format file.

Continue to the section 43.3 Mapping 12d Colours to Pens and RGBs or return to 43.2 Defining Plotters - Plotters.4d.

43.2.1.2 Definition and Example of a .tbl File

An example of an output mapping file for use with an Microstation (Intergraph) dgn plotter:

```
// -----------------------------------------------------------------
// File: vicplot.tbl
// -----------------------------------------------------------------
// column 112d colour name              (any length - but only 1st four characters passed)
// column 2Vic roads code               (only 1st four characters passed)
// column 3AS2482 feature code
// column 4description         (any length but if embedded spaces then must be quoted)
// column 5line level                   (between 1 and 64)
// column 6line colour                  (between 1 and 256)
// column 7line weight                  (between 1 and ?)
// column 8line style
//
// notes: if column 2 is a * then the 12d name is transmitted (up to 4 characters that is)
//        columns 9 through 16 are only used for point strings which map into characters

1  PM    38010000  "Permanent Survey Mark    " 49  0  1 0
2  BM    38020000  "Bench Mark               " 49   0  1 0
3  TPEG  31000001  "Title peg                " 50  0  1 0
4  STN   38100000  "Instrument Station       " 50  0  1 0
5  SM    38000000  "Survey mark (general)    " 50  0  1 0
6  PCON  38040001  "Photo control point      " 50  0  1 0
7  CHEK  38000001  "Check profile/point      " 52 10  3 0
8  TRIG  38010000  "Trigonometric Station    " 50  0  3 0
9  BMQS  38020001  "Bench Mark QS-1          " 49 11  1 0
10 BMS   38020002  "Bench Mark S-2           " 49 11  1 0
11 BMSH  38020003  "Bench Mark SH-1          " 49 11  1 0
12 RM    38000001  "Reference Mark - General " 50 11  1 0
* ROD    38000002  "Reference Mark - Rod     " 50 11  1 0        // everything else
```

Continue to the section 43.2.1.3 Definition and Example of a .amf File or return to 43.2 Defining Plotters - Plotters.4d.

43.2.1.3 Definition and Example of a .amf File

An example of an AutoCad output mapping file for use with an Autocad plotter:

```
// ------------------------------------------------------------------
// File: acadplot.amf
// ------------------------------------------------------------------
// column 1  match colour    - can include wild cards * and wild characters ?
// column 2  new name        - not output to DXF
// column 3  ACD layer       -
// column 4  ACD colour      - * for 12d Model colour (mapped to ACD),
//                           BYLAYER for ACD BYLAYER
// column 5  ACD line type- * for 12d Model linestyle,
//                           BYLAYER for ACD BYLAYER
// column 6  ACD text style- not yet used, * for 12d Model text style
//
// Notes:
// 1. column 5 (ACD colour) can only be a number between 0 and 256, or * or BYLAYER
// 2. The DWG/DXF file produced needs to be loaded into an existing Autocad drawing
//    which has the ACD layers and linestyles defined.
// column 1    2       3      4              5              6
//
        1    CONT    ljg1    1              1              *
        2    TOP     ljg2    2          CONTINUOUS         *
        3    TOP      *      3              *              *
        4    TOP     ljg4    *           BYLAYER           *
        5    TOP     ljg5   BYLAYER       DASH             *
```

Continue to the section 43.2.2 Some Plotters in the Default Plotters.4d File or return to 43.2 Defining Plotters - Plotters.4d.

43.2.2 Some Plotters in the Default Plotters.4d File

Full Scale >PDF black

The 12d standard **colour numbers 1-15** & **316** plot with **0.25mm black** pens.

The **"pen*"** (**400 series**) colour numbers plot with **black pens** of **specific weights**.

All **"ppf*"** (**900 series**) colour numbers plot with black/grey scale pens of specific weights.

Full Scale >PDF black string weight

If the string has no weight then it is the same as **Full Scale >PDF black** but if the string has a weight then the string weight is used.

So if a non standard weight is required for a particular string then you set the weight for that string. Otherwise do not give the string a weight.

Full Scale >PDF colour

The 12d standard **colour numbers 1-15** & **316** plot with **0.25mm pens** of the **matching colour**, **except**:

a) **white** (**7**) plots to **black**,

b) **yellow** (**5)** plots to a **darker yellow**.

The **"pen*"** (**400 series)** colour numbers plot with **black pens** of **specific weights**.

All **"ppf*"** (**900 series)** colour numbers plot with **black/grey scale** pens of **specific weights**.

Full Scale >PDF colour string weights

If the string has no weight then it is the same as **Full Scale >PDF colour** but if the string has a weight then the string weight is used.

So if a non standard weight is required for a particular string then you set the weight for that string. Otherwise do not give the string a weight.

Half Scale >PDF black, Half Scale >PDF black string weight
Half Scale >PDF colour, Half Scale >PDF colour string weight

These are the same the Full Scale plotters EXCEPT that the **pen width is 0.125mm**

Continue to the section 43.2.3 Example of a Plotters.4d File or return to 43.2 Defining Plotters - Plotters.4d.

43.2.3 Example of a Plotters.4d File

An example of a plotters.4d file is:

```
// -----------------------------------------------------------------
// File:     plotters.4d
// Date:     2014-03-17
// Revised:
// Use:      Version 11+ Standard Plotter Names
// -----------------------------------------------------------------

// 12d Model model
plotter "model" {
  group     "12d" //this puts "model" at the bottom of the list in the hard-wired "12d" group
  engine    model
  extension ""
}

// PDF

plotter "PDF black" {
  group     "PDF/Full Scale"
  engine    pdf_12d
  extension ".pdf"
  map_pens true
  map_file "pmf_black.pmf"
}
plotter "PDF black string weight" {
  Group         "PDF/Full Scale"
  engine        pdf_12d
  extension     ".pdf"
  map_pens      true
  map_file      "pmf_black.pmf"
  stringhalt true //explicit string weights override PMF weights
}
plotter "PDF colour" {
  Group     "PDF/Full Scale"
  engine    pdf_12d
  extension ".pdf"
  map_pens true
  map_file "pmf_colour.pmf"
}
plotter "PDF unmapped" {
  group     "PDF"
  engine    pdf_12d
  extension ".pdf"
  map_pens false
}

//DWG (and DXF/DXB)

plotter "DWG unmapped" {
  group "DWG"
  //engine    dwg_12
  //engine    dwg_13
  //engine    dwg_14
  //engine    dwg_2000
  //engine    dwg_2002
```

```
  //engine    dwg_2004
  //engine    dwg_2005
  //engine    dwg_2006
  //engine    dwg_2007
  engine    dwg_2010
  extension ".dwg"
}
plotter "DXF 2000 with amf" {// output to a dxf file using an autocad map file
  engine    dxf_2000
  extension    ".dxf_2000"
  map_file    "acadplot.amf"
}

// Windows

plotter "Windows colour" {
  group    "Windows/Full Scale"
  engine   windows
  map_pens true
  map_file "pmf_colour.pmf"
}
```

Continue to the section 43.3 Mapping 12d Colours to Pens and RGBs or return to 43.2 Defining Plotters - Plotters.4d.

43.3 Mapping 12d Colours to Pens and RGBs

12d Model uses up to 10,240 different colours and when it comes to plotting, it must be decided how these colours are mapped for the particular plotter device being used.

Some physical plotters may print colours and others only black. And even on a colour plotter, sometimes you may want to print out in black, or black and grey scale.

When plotting to devices such as PDF, or CAD systems such as AutoCad and Microstation, no physical plot is created but the plot image may need to be send colours to special colours, layers and styles in the other system.

For plotting to actual plotters, there are two methods of specifying the colour to pen mappings.

(a) pen mapping using Colours.4d

A simple "colour to pen number" mapping which is mainly used for older pen plotters that only had a fixed number of pens that could be used. It also provides the default pen numbers if they are not mentioned in the *plotters.4d* file. See 43.3.1 Pen Mapping in Colours.4d.

(b) **plotter mapping - Plotters.4d**

An extended colour to pen number mapping is more often used which not only maps colour numbers to pens but can also include a weight (thickness) in millimetres for each pen (**pen_mapping**).

Plus the red, green, blue definition for the pen numbers used on the plotter (**pen_colour**)

This is for the physical plotters such as laser, electrostatic, inkjet and bubblejet plotters, and the non-physical plotters such as pdf. See 43.3.2 Plotter Mapping File.

So for a plotter mapping

Colour number in 12d Model $\xrightarrow{\text{pen\_mapping}}$ Pen number and weight $\xrightarrow{\text{pen\_colour}}$ RGB for Pen number

As Plotter mapping is an extension of pen mapping, only **one** of the two is used for a plot.

See

43.3.1 Pen Mapping in Colours.4d.
43.3.2 Plotter Mapping File.

Or return to 43 Plotters and Plotting.

43.3.1 Pen Mapping in Colours.4d

The ***colours.4d*** file defines the rgb for drawing the colours on a view and also defines the **default plotter pen** associated with the colour numbers.

	Colour No.	Pop-up No.	Colour Name	Legacy Name	Colour Group	Red	Green	Blue		Pen No.	Comment
1	0	-9017	black		12d	0	0	0		0	black
2	7	-9016	white		12d	255	255	255		7	white
3	1	-9015	red		12d	255	0	0		1	red
4	2	-9014	green		12d	0	255	0		2	green
5	3	-9013	blue		12d	0	0	255		3	blue
6	5	-9012	yellow		12d	255	255	0		5	yellow
7	6	-9011	magenta		12d	255	0	255		6	magenta
8	4	-9010	cyan		12d	0	255	255		4	cyan
9	12	-9009	grey		12d	240	220	250		12	grey
10	316	-9008	dark_grey		12d	67	67	67		316	dark_grey
11	11	-9007	dark_red		12d	210	20	0		11	dark_red
12	9	-9006	dark_green		12d	30	155	0		9	dark_green
13	13	-9005	dark_blue		12d	60	60	200		13	dark_blue
14	10	-9004	purple		12d	170	42	250		10	purple
15	15	-9003	brown		12d	150	90	0		15	brown
16	8	-9002	orange		12d	255	165	0		8	orange
17	14	-9001	off_yellow		12d	240	240	170		14	off_yellow

The **Plots=>Pen mapping** option or any other option that brings up the **Edit Colours** panel. can be used to define the correspondence between 12d Model colours. See 39.2.7.2 Colours File (colours.4d).

Continue to 43.3.2 Plotter Mapping File or return to 43.3 Mapping 12d Colours to Pens and RGBs.

43.3.2 Plotter Mapping File

The **plotter mapping file** can be used use with pen plotters but is more specifically designed for laser, electrostatic and inject plotters and allows the user to:

(a) map 12d Model colours to particular plotter pens and also specify a width (thickness or weight) to be used for the pen.

and

(b) specify the red, green and blue mix for the pens.

The ***plotter mapping file*** to be used can be set by either

1. by the environment variable PLOTTER_MAPPING_4D, or is the file *pmf.4d* found in the standard set up areas.
2. defined for a particular plotter in the *Plotters.4d* file. See 43.2 Defining Plotters - Plotters.4d

There are also two **special formats** of the plotter mapping file which are used for plotting to Autocad dwg/dxf and Microstation dgn. The special mapping files use the 12d Model **colour number** as a key to tables which control how the information is passed to DWG/DXF and DGN.

3. .tbl file used with plotting to Microstation dgn
4. .amf used with plotting to Autocad dwg, dxf or dxb

And a superseded method using a plotter mapping file in the **Plotter Mapping Table** panel.

5. Now superseded - the option **Plots =>Plotting setups =>Plotter mapping**. See 25.8.13 Plotter Mapping Table.

The definition of the *Plotter Mapping File (pmf file)* is given in the next section 43.3.2.1 Definition of a Plotter Mapping File and the initiation performed before the pmf file is used is described in 43.3.2.2 Initialisation of the Plotter Mapping File.

43.3.2.1 Definition of a Plotter Mapping File

The plotter mapping file (.pmf) consists of two default values followed by the two sections pen_mapping and pen_colours:

(a) the ***default_weight*** command that goes before the *pen_mapping* or *pen_colours* sections and which is used as the weight for any colour number that is mapped to a pen number but not given a weight in the *pen_mapping* section.

```
default_weight        weight
```

(b) the ***default_colour*** command that also goes before the *pen_mapping* or *pen_colours* sections and which defines the default red, green and blue for any pens used but not set in the *pen_colours* section.

```
default_colour        red        green        blue
```

(c) **pen_mapping** section which defines which pen a colour number is mapped to, and the weight for the pen.

The *pen_mapping* section consists of the key word **pen_mapping** followed by **{** and then one line for each colour number being mapped with the colour number, then the plotter pen number and finally the pen weight that the colour number is mapped to. This is finished with a **}**.

```
pen_mapping {                        // pen mapping and weight table

//          12d        plotter      weight
//          colour     pen no       for pen

            0          1            0.15
            1          2            0.25
            3          1            0.5
//          etc.
}
```

(d) **pen_colours** section which defines the red, green and blue values to be used for the pens on the plotter.

The *pen_colours* section consists of the key word **pen_colours** followed by **{** and then one line for each plotter pen having the rgb defined with the plotter pen number followed by the red, green and blue values for the plotter pen. This is finished with a **}**.

```
pen_colours {            // pen colours table

// plotter
// pen      red        green      blue       values 0-255 for red, green and blue
    0       0          0          0             // pen 0 is black
    1       255        0          0             // pen 1 is red
//          etc.
}
```

Continue to the section 43.3.2.2 Initialisation of the Plotter Mapping File or return to 43.3.2 Plotter Mapping File or 43.3 Mapping 12d Colours to Pens and RGBs.

43.3.2.2 Initialisation of the Plotter Mapping File

Before the ***plotter mapping file*** is used

(a) a default *pen_mapping* table is constructed from the colours in the *colours.4d* file by:

colour n goes to pen n *default_weight*

where **default weight** is the *default_weight* if one is given in the specified *plotter mapping file* or zero if the default_weight does not exist.

(b) a default *pen_colours* table for pens 0 to 10,240 is set up by:

pen n *default_red* *default_green* *default_blue*

where *default_red*, *default_green*, *default_blue* are the red, green and blue of the *default_colour* if one is given in the specified *plotter mapping file*, or rgb 0 0 0 if the default_colour does not exist.

The **plotter mapping file** is then processed and over writes any of the above initial mapping values.

This initialisation sequence means that if a *colour number* is **not** listed in the *pen_mapping* section of the pmf file, then the pen mapping as given for that colour number in the *colours.4d* file is used. Hence the *pen_number* in the *colours.4d* file is the **default pen number**.

Continue to the next section 43.4 Sending Plots to a Plotter or return to 43.3.2 Plotter Mapping File or 43.3 Mapping 12d Colours to Pens and RGBs.

43.4 Sending Plots to a Plotter

When the plot file is created, it can be passed to a user specified program or batch file that can do things like automatically direct the plot file to a specific plotter.

The mechanism is that as plots are created, 12d Model ***can fire up a user supplied batch file/ program with the plot file as the first argument.***

By checking the plot name suffix, the batch file could for example, decide which plotter the plot must be sent to.

The environment variable

PLOTTER_4D *points to batch file/program*

points to the batch file/program which can be fired up whenever a plot is generated. The name of the plot is given as the first parameter of the batch file.

If the tick box **Send plots** in the panel tab **System Settings** of the panel **Defaults** (given by the menu option **Utilities** => **Default**) is set to **on**, the batch file/program is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the batch file/program is called separately for each of the plots.

An example of a batch file to send the plot to port lpt1 for Windows would be

```
@echo off
copy %1  lpt1
```

An example for Windows which looks out for hp files is

```
@echo off
echo.
echo ----------------------------------------------------
:next_file
if "%1" == "" goto done
echo %1 | find /I ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
echo Plotting file %1
shift
goto next_file
:hp_plotter
echo Plotting %1 to HP plotter
copy %1 \\server_name\printer_name
shift
goto next_file
:done
echo ----------------------------------------------------
```

Continue to the next section 43.5 Sheet Sizes or return to 43 Plotters and Plotting.

43.5 Sheet Sizes

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal set up areas, or is pointed to by the environment variable SHEET_SIZES_4D.

The layout of the sheet sizes file is given in the section 39.2.7.4 Sheet Sizes File (sheets.4d).

Continue to the next section 43.6 Text Units in Plots or return to 43 Plotters and Plotting.

43.6 Text Units in Plots

Text occurs in 12d Model plots in a number of ways -

- plotting **text strings**, text in super strings and other strings.
- automatic text such as grid values, x-section and long-section plot annotation.
- text within linestyles.

The most difficult thing about text is that because of the different uses of text, there needs to be more than one systems of **units** to define text heights.

The height of text for a given textstyle is defined to be the height of a capital A. However, in ***12d Model***, there are three methods of defining the units for measuring this height.

- world units - the units used for data
- screen units - pixels
- plot paper units - millimetres.

World Units

World units are the units of user data. For most users, the base unit for user data is metres. However ***12d Model*** is a almost a dimensionless system and the base unit is totally dependent on the user.

The height of world text when displayed in a view depends upon on the ***text height*** and the ***scale*** of the view.

When plotted, the height that world text appears on a plot sheet is the same as for any data defined in world units - the height depends on the **scale** used for the plot.

Text heights that are only given in world units have **(w)** after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a **(u)** after them.

Screen Units - Pixels

When screen units (pixels) are used, the text is a fixed height on the screen. If the user zooms in on text given in pixels, the text remains the same height.

To have a height on a plot, screen unit text needs a height defined in millimetres.

For some screen text, both a pixel and a millimetre height is supplied when the text is defined.

For text with only a pixel height, there is a plotting multiplication parameter called **pixels-to-millimetres** which is used to convert pixel heights to plot paper heights. The value of pixels-to-millimetres is set using the **Plots =>Plotting setups =>Pixels to mm** option and is stored for the project. See 25.7.5 Pixels to mm.

Text heights that are only given in pixels have a **(pix)** or **(p)** after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a **(u)** after them.

Plot Paper Units - Millimetres

Text defined in plot paper units (millimetres) has a well defined height on a plot sheet.

Text heights that are only given in millimetres have **(mm)** after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a **(u)** after them.

Return to 43 Plotters and Plotting.

44 Text Plot Parameters

IMPORTANT WARNING

This information on the text version of teh plot parameters only includes those parameters needed up to ***12d Model*** 7 and is only included for those users still working with old text ppf files.

Text PPFs have been replaced by the ***PPF Editors*** - see 26 PPF Editors.

This appendix contains information about the definitions in the text versions of the plot parameter files. The text plot parameter files are not normally seen by users because the *Plot Parameter* editors create binary plot parameter files.

See

44.1 Plot Frame Plot Parameter File
44.2 Cross Section Plot Parameter File
44.3 Long Section Plot Parameter File
44.4 Pipeline Plot Parameter File
44.5 #Include in Plot Parameter Files

44.1 Plot Frame Plot Parameter File

The plot frame section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash **//** is considered to be a comment.

The set of all parameters for the plot frame plot is enclosed within a set of curly brackets **{ }** with the header

plot_frame_plot "plot *set name"*

before the curly brackets.

That is,

```
plot_frame_plot  "plot set name"  {
            plot parameters
            one per line
}
```

If there is more than one plot_frame_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_long_plot in the same file. The other sets will be ignored when doing plot frame plots.

The only parameters not connected with title block file are

view_name	*view_name*	// name of view used for information // on the plot
single_frames	*frame_name*	// name of plot frame to be plotted
model_of_frames	*model_name*	// model of plot frames which may be

// plotted as a group

Both these parameters exist in the **plot frames plot** panel and when the parameter file is first read, if either of these parameters exist in the plot parameter file then they will be used to replace the corresponding parameters in the panel.

However, if the parameters are subsequently modified in the panel, the new panel value will be the value used for plotting.

44.1.1 Title Block Information

A plot frame plot can have a standard ***12d Model*** title block or a user defined title block.

For a user defined title block, the title block drawing commands are kept in a file whose name is given by the user when setting up the plot frame. The title block drawing commands are almost identical to the linestyle drawing commands.

If a user defined title block has been set for the plot frame, plot frame parameters can be used to pass information though to the title block.

User Title Block

Some of the plot parameters are used to pass information down to variables in a user defined title block specified in the plot frame.

The parameters are:

time_format	*text*	// format for $time
title_1	*text*	// passed down to $title_1
title_2	*text*	// passed down to $title_2
user_text_n	*text*	// where n = 1,2,... 1000 // passed down to $user_text_n
start_page_number	*integer*	// used as the starting value for $page_number. // if missing, $page_number starts at 1.
start_drawing_number	*integer*	// added to $drawing_number in title block file // if missing, $drawing_number starts at 1.
drawing_number_prefix	*text*	// passed down to $drawing_number_prefix
drawing_number_postfix	*text*	// passed down to $drawing_number_postfix

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section 44.2 Cross Section Plot Parameter File.

44.2 Cross Section Plot Parameter File

The cross section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the cross section plot is enclosed within a set of curly brackets **{ }** with the header

section_x_plot   "plot set name"

before the curly brackets.

That is,

```
section_x_plot  "plot set name"   {
            plot parameters
            one per line
}
```

If there is more than one section_x_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_long_plot in the same file. The other sets will be ignored when doing cross section plots.

The plot parameters are documented in following groups:

For the *Plot Sheet layout*, please continue to the section 44.2.1 Plot Sheet Layout.

Boxes and datum area, please continue to the section 44.2.2 Boxes and Datum Area.

Only for the Centre line case:

Datum area, please continue to the section Datum Line.

Labelling the centreline, style etc., please continue to the section Labelling the Centreline Chainage.

Only for the Boxes case:

Datum area, please continue to the section Datum Line.

Labelling the centreline chainages, please continue to the section Labelling the Centreline Chainage.

Defining boxes and what is labelled in them, please continue to the section 44.2.5 Defining Boxes.

For Both the Centre Line and Boxes case:

Graph area parameters, please continue to the section 44.2.6 Graph Area.

Grade labelling, please continue to the section 44.2.7 Grade Labelling.

Labelling points on x-sections, please continue to the section 44.2.8 Labelling Points of the X-Sections

Labelling cuts, please continue to the section 44.2.9 Labelling Cuts of X-Sections Through Strings in a Model.

Hatching cut/fill, please continue to the section 44.2.10 Hatching Cut and Fill Areas.

Drawing extra x-sections, please continue to the section 44.2.11 Extra Models of X-Sections.

Sorting x-sections, please continue to the section 44.2.12 Sorting X-Sections by Chainage.

Title block information, please continue to the section 44.2.13 Title Block Information.

Panel modifying parameters, please continue to the section 44.2.14 Parameters that Modify Fields In the Cross Plot Panel.

Example, please continue to the section 44.2.16 Example of a Cross Section Plot Parameter File.

44.2.1 Plot Sheet Layout

X-sections are normally generated at chainages along a given centreline. This centreline chainage is stored with each x-section string.

The chainages of the actual x-sections are referred to as **offsets** from the centreline position rather than x-section chainages. The offsets of the x-section are set up so that the zero offset occurs where the x-section crossed the centreline string.

The x-sections along the centreline are stored in the one model (the primary model) which is then used to generate the cross section plot.

model_to_plot	*text*	// name of the model of x-sections

Each x-section from the primary model of x-sections generates its own sub-plot for which the x-section is the primary string. Hence the cross section plot consists of many individual plots drawn on one or more plot sheets.

Each plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

sheet_size	*text*	// sheet name, or
	"mm *mm"*	// sheet size: width height

The sheet size name, width and heights can be specified by the user in a file named **sheets.4d** which is in the normal set up areas, or is pointed to by the environment variable

SHEET_SIZES_4D	*file*	// file of plotter sheets sizes

The plotting area is restricted to within the plot sheet by giving margins which are:

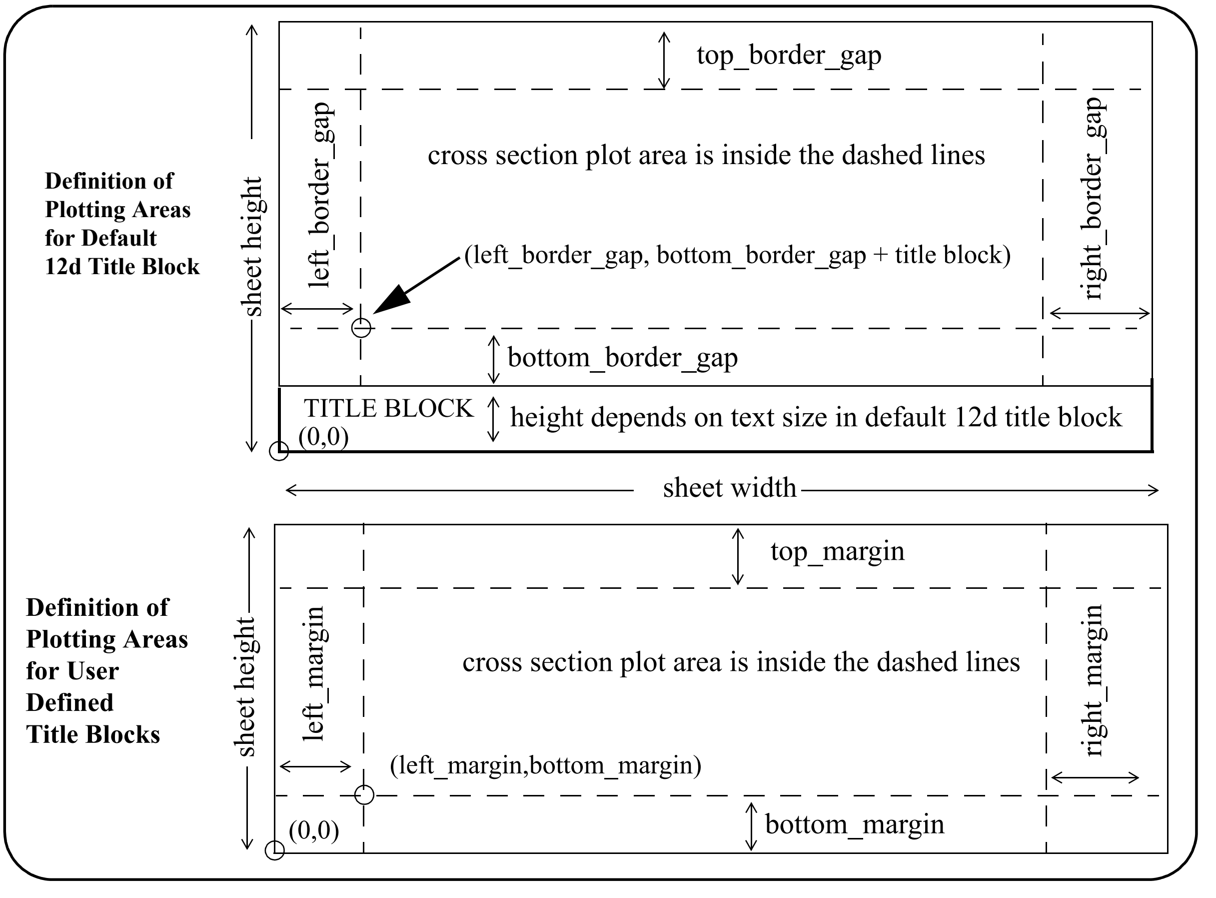
If a *User Defined Title Block* is used:

left_margin	*mm*
right_margin	*mm*
top_margin	*mm*
bottom_margin	*mm*

If the *default 12d title block* is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the *bottom_border_gap* is added to the calculated height of the bottom of the title block.

left_border_gap	*mm*
right_border_gap	*mm*
top_border_gap	*mm*
bottom_border_gap	*mm*

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margin and gap parameters can exist in the one plot parameter file.



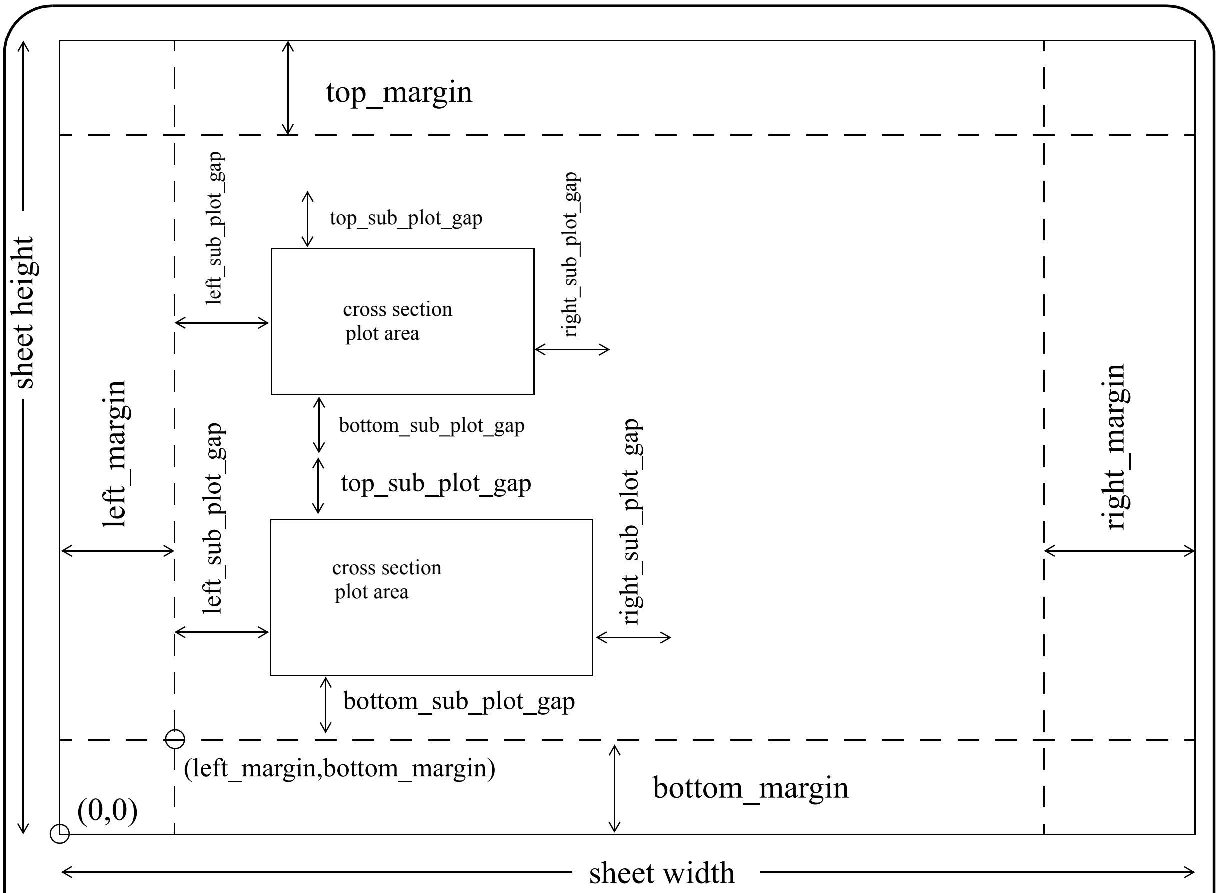
The x-sections are plotted in the order they occur in the x-section model and start being plotted at the bottom left hand corner of the cross section plotting area.

The individual x-section plots are then drawn going up the column, and when the column is full, start from the bottom of the next column.

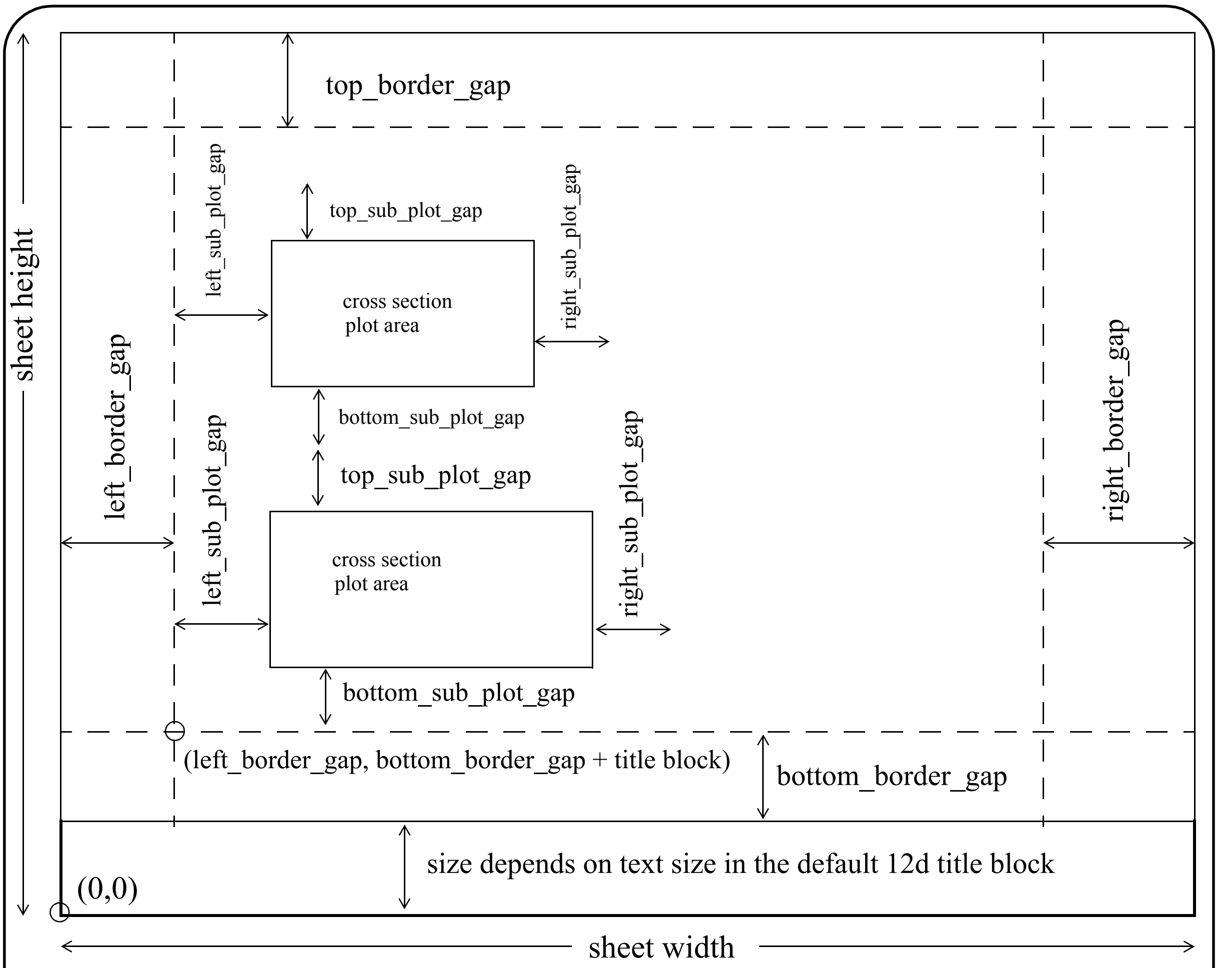
When a sheet is full, a follow on sheet is created.

Each individual x-section sub-plot is positioned with the surrounding gaps:

left_sub_plot_gap	*mm*
right_sub_plot_gap	*mm*
top_sub_plot_gap	*mm*
bottom_sub_plot_gap	*mm*



Definition of Plotting Areas for User Defined Title Blocks



Definition of Plotting Areas for Default 12d Title Block

If required, all the sub-plots in a column can be automatically positioned up so that the zero offsets (the centrelines) of each x-section line up.

line_up_cl	*yes/no*	// yes - line up zero offsets

The width of the plot can be a fixed distance left or right of the centre line (zero offset) or for the full section plus an extra left and right distance:

absolute_extensions	*yes*	// The section goes from the
		// left_extension offset on the left to the
		// right_extension offset on the right.

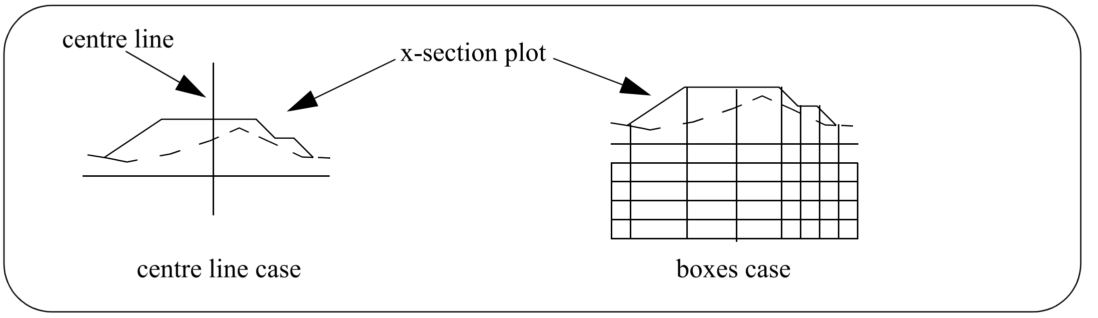
	no	// The section goes for the entire section
		// length plus the left and right extension
		// distances.

left_extension	*world-units*	// left extension value
right_extension	*world-units*	// right extension value

The x-section can be drawn and labelled with either

(a) centreline case - the x-section is plotted and an upright, and the offset and height value at the zero offset (normally the centre line position)

(b) boxes case - the x-section is plotted and the heights of the x-section and the tins at all the x-section points are labelled in boxes under the plot of the x-section.

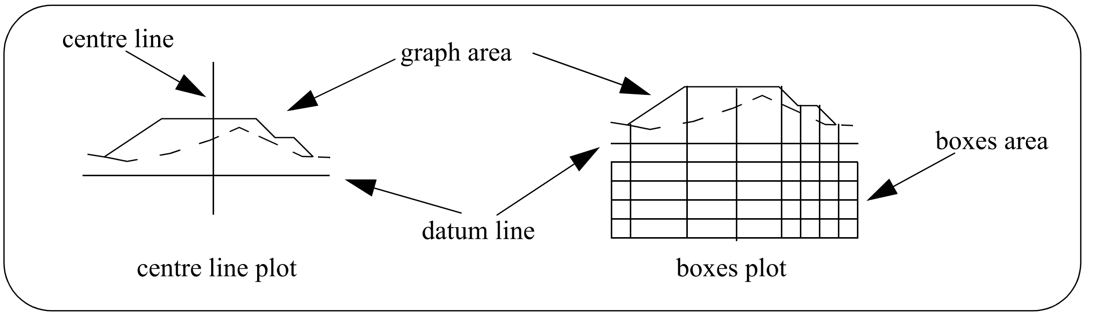


The x-section sub-plot itself consists of the three regions - graph, datum and boxes.

The **graph area** is the area where the actual plots of the strings are drawn. This exists for both the centreline and boxes case.

The **datum area** is the region between graph area and the datum line. This exists for both the centreline and boxes cases.

The **boxes area** is where the offset values and the heights for the strings drawn on the x-section plot are labelled. This only exists for the boxes case.



For both cases, the x-section sub-plot can be labelled with other information such as

(a) grades across the x-section

(b) points across the x- section

(c) cuts the x-section makes through strings

(d) cut and fill areas

All the required parameters will be described in the following sections.

Please continue to the next section 44.2.2 Boxes and Datum Area.

44.2.2 Boxes and Datum Area

The x-section can be labelled with either

(a) an upright, and the offset and height value at the zero offset (normally the centre line position)

(b) the heights of the x-section and the tins at all the x-section points.

The choice is given by the parameter ***label_type***:

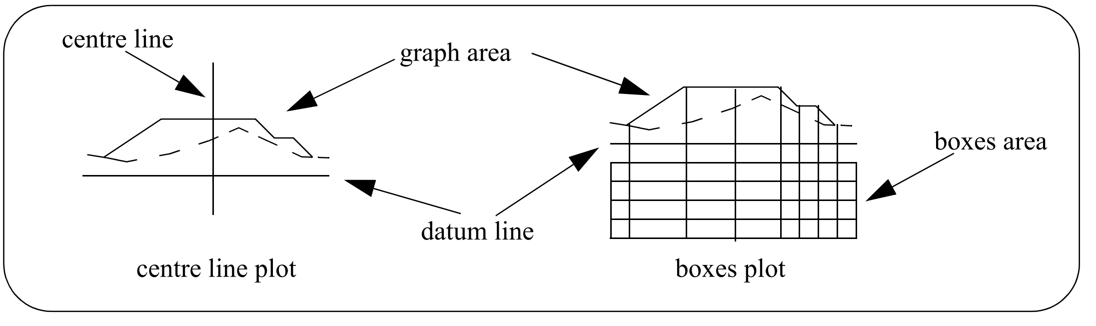
label_type	"centre *line"*	// type (a)
	boxes	// type (b)

A datum line exists for both cases.

For the boxes case, a box area for the offset and heights is created below the datum line. The available parameters for tailoring the box area will be given after describing the datum line parameters.

For the centre line case, the centre line and offset and height of the centre line are shown.

In both cases, the actual cross section plot is drawn above the datum line in the graph area.



Please continue to the next section 44.2.3 Centre Line Case for the centre line parameters.

Please continue to the section 44.2.4 Boxes Case for the boxes parameters.

44.2.3 Centre Line Case

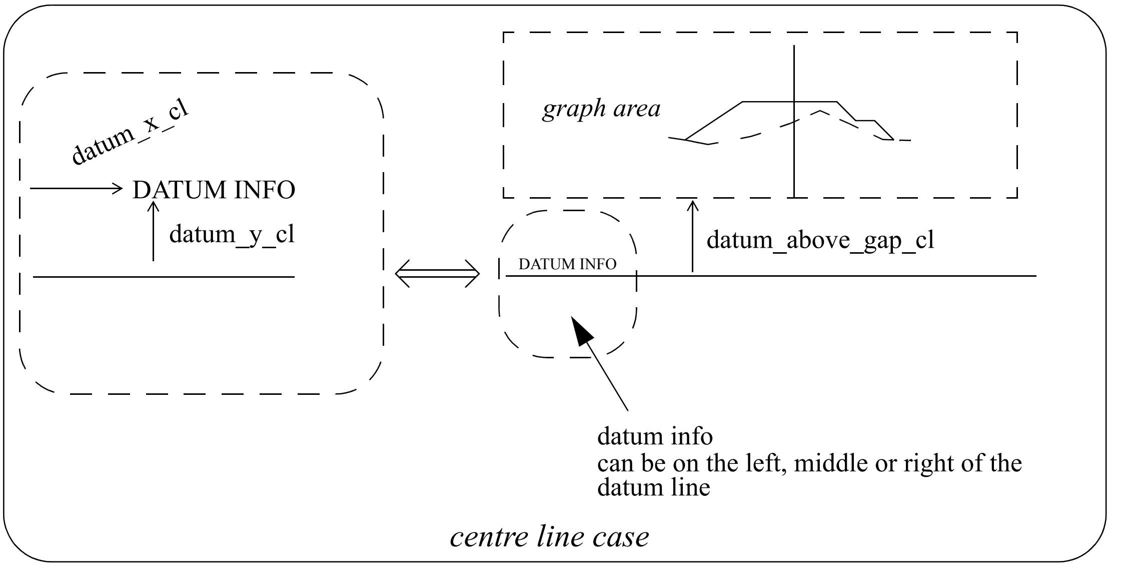
Datum Line

Each x-section sub-plot can be labelled with the datum value for the plot of the x-section string.

This DATUM INFO label is made up of the text strings:

"datum_name" followed by the *datum-value*

and is above the datum line.



For the centreline case, the graph area is positioned the distance ***datum_above_gap_cl*** above the datum line.

datum_above_gap_cl	*mm*	// dist from datum line to bottom of the // graph area

The *datum_above_gap_cl* can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

The datum value can be placed on the left, centre or right side of the datum line.

datum_roundoff	*1.0*	// value to roundoff the datum value to // e.g. 0.5, 0.2, 1.0 (default 1.0)

datum_decimals	*integer*	// number of decimal places to display
		// the datum value (default 1).
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If <0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

datum_side_cl	*0*	// datum text in middle of datum line
	1	// " " " " left of datum line (default)
	2	// " " " " right of datum line
datum_linestyle	*linestyle*	// datum line linestyle (default solid)
datum_name	*text*	// text to write before the datum value
datum_textstyle	*text*	// textstyle for datum information
datum_text_size	*mm*	// size of datum text and value
datum_colour	*colour*	// colour of the datum text
datum_line_colour	*colour*	// colour of the datum line

datum_text_justification_cl	*just*	// justification for datum text
		// NOTE - this is not normally required since
		// by default the text justification is set to
		// match datum_side_cl

datum_x_cl	*mm*	// distance to move the datum text // along the datum line

datum_y_cl	*mm*	// distance to raise the datum text
		// above the datum line (used to be
		// called datum_offset)

The *datum_x_cl* and *datum_y_cl* can be positive, zero or negative.

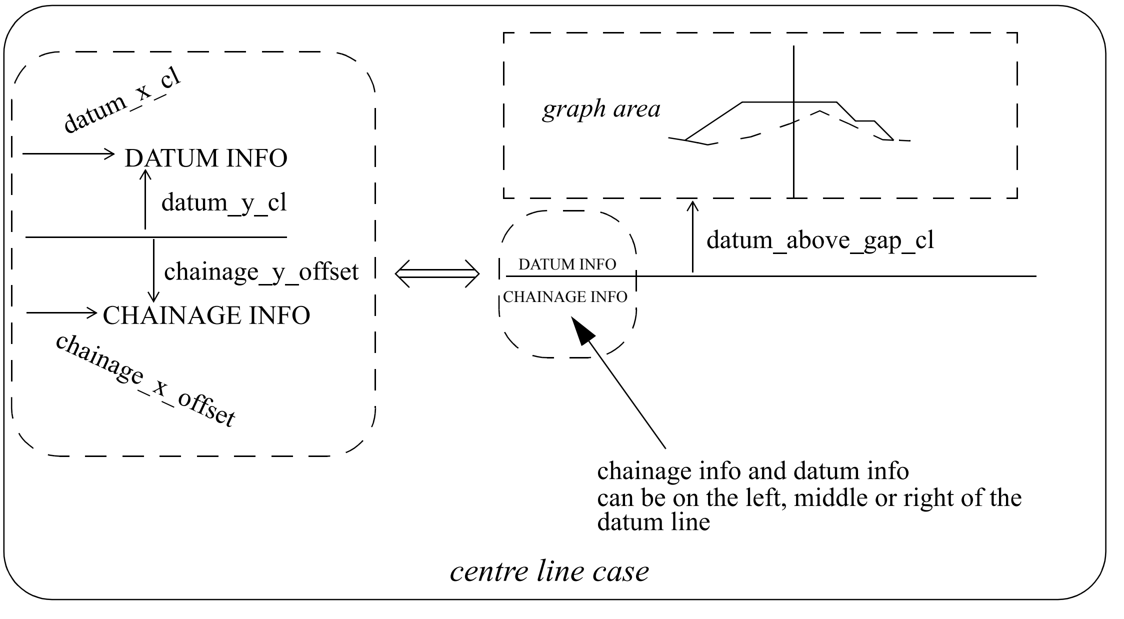
Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string.

This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the *chainage-value*

and is drawn under the datum line.



The chainage value can be placed on the left, centre of right side of the datum line.

chainage_side_cl	*0*	// text in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line

The parameters controlling the labelling are:

chainage_label	0/1	// 1 = label sub-plot with centreline // chainage, 0 don't label.
chainage_title	*text*	// text before the chainage value

chainage_decimals	*integer*	// number of decimals in the chainage
		// value. If <0, the absolute value
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the
		// chainage values.

chainage_colour	*colour*	// colour of the text

chainage_size	*mm*	// size of the text
chainage_textstyle	*colour*	// textstyle for the chainage label
chainage_text_justification_cl	*just*	// justification of the chainage text
chainage_x_offset	*mm*	// x position of text
chainage_y_offset	*mm*	// y position of text

The *chainage_x_offset* is measured from the beginning of the datum line.

The *chainage_y_offset* is measured from the bottom of the datum line with positive being **down**.

Centre Line Linestyle

The upright at the centre line position can have its own linestyle.

cl_linestyle	*linestyle*	//linestyle for centreline

Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the **primary string** (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

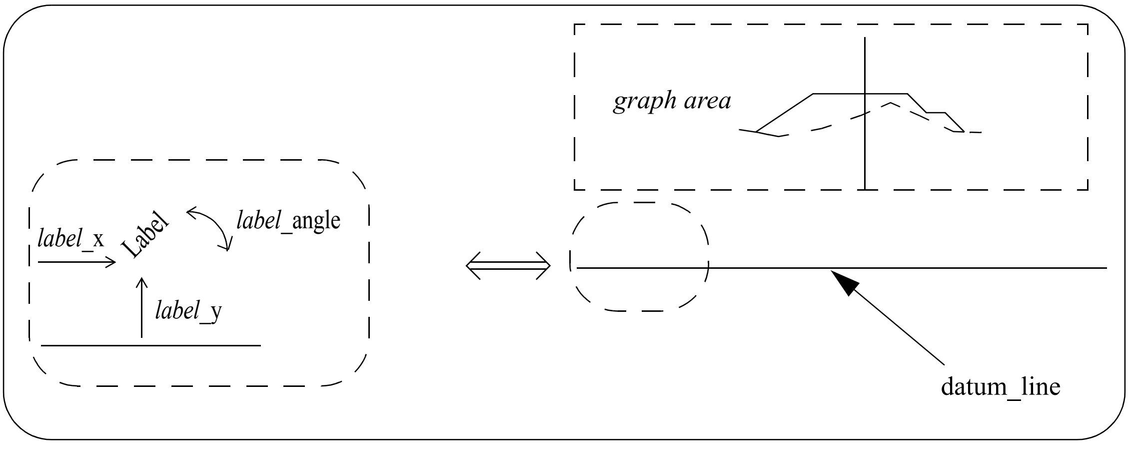
The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

pre_text *value* post_text

where *value* is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.



Parameters for labelling the X Co-ordinate at Zero Offset:

primary_x0_draw_mode	*0*	// don't draw the label -default
	1	// draw the label
primary_x0_position	***0***	// label in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line
primary_x0_pre_text	*text*	// pre-text for label - def " "
primary_x0_post_text	*text*	// post-text for label - def " "
primary_x0_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_x0_x	*mm*	// x adjustment to position of label - def 0
primary_x0_y	*mm*	// y adjustment to position of label - def 0
primary_x0_angle	*degrees*	// angle of the label - def 0
primary_x0_colour	*colour*	// colour of the label
primary_x0_size	*mm*	// size (in mm) of the label
primary_x0_textstyle	*textstyle*	// textstyle of the label
primary_x0_justify	*just*	// justification for text

Parameters for Labelling the Y Co-ordinate at Zero Offset:

primary_y0_draw_mode	***0***	// don't draw the label -default
	1	// draw the label
primary_y0_position	***0***	// label in middle of datum line (default)
	1	// " " " " left of datum line

	2	// " " " " right of datum line
primary_y0_pre_text	*text*	// pre-text for label - def " "
primary_y0_post_text	*text*	// post-text for label - def " "
primary_y0_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_y0_x	*mm*	// x adjustment to position of label - def 0
primary_y0_y	*mm*	// y adjustment to position of label - def 0
primary_y0_angle	*degrees*	// angle of the label - def 0
primary_y0_colour	*colour*	// colour of the label
primary_y0_size	*mm*	// size (in mm) of the label
primary_y0_textstyle	*textstyle*	// textstyle of the label
primary_y0_justify	*just*	// justification for text

Parameters for Labelling the Height of Primary String at Zero Offset:

primary_height_draw_mode	*0*	// don’t draw the label -default
	1	// draw the label
primary_height_position	***0***	// label in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line
primary_height_pre_text	*text*	// pre-text for label - def " "
primary_height_post_text	*text*	// post-text for label - def " "
primary_height_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_height_x	*mm*	// x adjustment to position of label - def 0
primary_height_y	*mm*	// y adjustment to position of label - def 0
primary_height_angle	*degrees*	// angle of the label - def 0
primary_height_colour	*colour*	// colour of the label
primary_height_size	*mm*	// size (in mm) of the label
primary_height_textstyle	*textstyle*	// textstyle of the label
primary_height_justify	*just*	// justification for text

Parameters for Placing Some Text:

extra_text_draw_mode	***0***	// don’t draw the label -default
	1	// draw the label
extra_text_position	***0***	// label in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line
extra_text	*text*	// text for label - def " "
extra_text_x	*mm*	// x adjustment to position of label - def 0
extra_text_y	*mm*	// y adjustment to position of label - def 0
extra_text_angle	*degrees*	// angle of the label - def 0
extra_text_colour	*colour*	// colour of the label
extra_text_size	*mm*	// size (in mm) of the label
extra_text_textstyle	*textstyle*	// textstyle of the label
extra_text_justify	*just*	// justification for text

Parameters for Labelling the Height of a Tin at Zero Offset:

A section along the primary string through each tin on the section view is automatically drawn on the cross section plot but the user can specify whether the tin height at the zero offset is labelled or not.

Hence although there may be a number of tins drawn on the section plot, not all of them need to have their height at zero offset labelled.

The default order for labelling the tins is the order that they were added to the view but it is possible to specify which tin is used for labelling by giving the tin name rather than just using the tin on the section view.

In fact, it is possible to use **any tin** in the project **to label** the height at zero offset, **not just those drawn** on the section view.

tin_n_name	*text*	// n=1, ... no of tins on the section view.
		// use the tin called *text* to label the nth
		// row of tin heights.

If a tin of the name given by ***tin_n_name*** **does** not exist, then the plot is not produced and an error message is given.

The parameters for labelling the height of the tin at zero offset are:

tin_n_height_draw_mode	*0*	// don't draw the label -default
	1	// draw the label
tin_n_height_position	***0***	// label in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line
tin_n_height_pre_text	*text*	// pre-text for label - def " "
tin_n_height_post_text	*text*	// post-text for label - def " "

tin_n_height_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

tin_n_height_x	*mm*	// x adjustment to position of label - def 0
tin_n_height_y	*mm*	// y adjustment to position of label - def 0
tin_n_height_angle	*degrees*	// angle of the label - def 0
tin_n_height_colour	*colour*	// colour of the label
tin_n_height_size	*mm*	// size (in mm) of the label
tin_n_height_textstyle	*textstyle*	// textstyle of the label

Labelling the Centre Line Offset and Height

In the centre line case, the value of the height of the **primary string** (usually the design cross section) at the zero offset can be labelled. This is normally where the alignment string cuts the cross section.

The label is made up of the texts:

primary_title offset_title offset_value height_text height_value

NOTE: These parameters have now been superseded. The parameters for labelling the height of the primary string at zero offset covers this case. To use the zero offset parameters instead, the *primary_height_pre_text* would include all text required for the Primary_title, offset_title, offset_value and height_text (offset_value is always 0.0).

The parameter *primary_mode_cl* controls whether the **primary_title** is included in the label.

primary_mode_cl	*0*	// don't include primary_title, primary_value
	1	// incl. primary_title, primary_value default

The parameter *height_mode_cl* controls whether the **height_title** and **height_value** are included in the label.

height_mode_cl	*0*	// don't include height_title, height_value
	1	// include height_title, height_value default

The parameter *offset_mode_cl* controls whether the **offset_title** and **offset_value** are included in the label.

offset_mode_cl	*0*	// don't include offset_title, offset_value
	1	// include offset_title, offset_value default

The label can be placed on the left, centre of right side of the datum line.

offset_height_side_cl	***0***	// text in middle of datum line (default)
	1	// " " " " left of datum line
	2	// " " " " right of datum line

The size, colour, text justification and text style for the label is given by:

primary_title	*text*	//primary title
offset_title	*text*	// offset label (default "Offset")
height_text	*text*	// height text label (default "Height")
primary_textstyle	*textstyle*	// textstyle used for offset and height // label
primary_colour	colour	//colour for offset and height label
primary_size	mm	//size of the offset and height label

offset_height_text_justification_cl	*justif*	// text justification
		// NOTE - this is not normally required since
		// by default the text justification is set to
		// match offset_height_side_cl

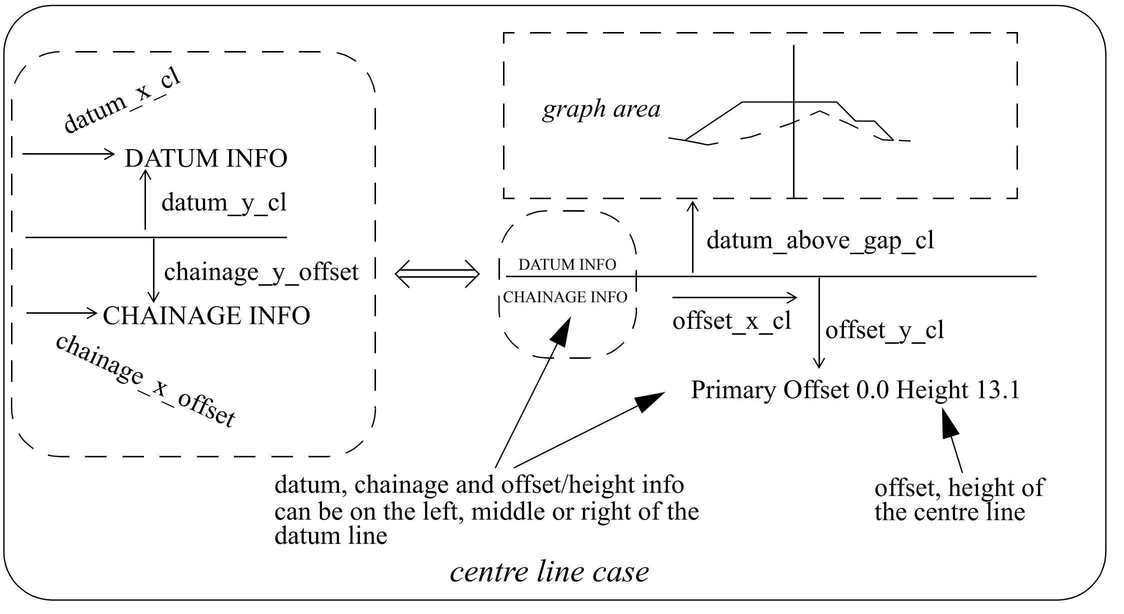
The number of decimals in the offset-value and height-value is controlled by:

number_of_decimals	*integer*	// number of decimal places in the offset,
		// height boxes. If <0, the absolute value
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the offset,
		// heights area.

The label is placed an distance offset_x_cl along the datum line and a distance ***offset_y_cl*** below the datum line of the plot.

offset_x_cl	*mm*	// distance to move the text along the // datum line
offset_y_cl	*mm*	// distance to shift the text below the // datum line

The *offset_y_cl* is measured from the datum line with positive being **down**.



Please continue to the next section 44.2.4 Boxes Case for the boxes parameters.

Please continue to the section 44.2.6 Graph Area if you are not using boxes parameters.

44.2.4 Boxes Case

Datum Line

For the boxes case, the **datum line** is positioned the distance ***datum_below_gap*** above the top of the boxes area and the graph area is then positioned the distance ***datum_above_gap*** above the datum line.

Hence the graph area is distance (datum_below_gap + datum_above_gap) above the top of the boxes area.

datum_above_gap	*mm*	// dist from datum line to bottom of the // graph area
datum_below_gap	*mm*	// dist from datum line to the top of the // boxes
datum_linestyle	*linestyle*	//linestyle for the datum line

The *datum_below_gap* and *datum_above_gap* can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

datum_roundoff	*1.0*	// value to roundoff the datum value to // e.g. 0.5, 0.2, 1.0 (default 1.0)

datum_decimals	*integer*	// number of decimal places to display
		// the datum value (default 1).
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If <0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

datum_name	*text*	// text to write before the datum value
datum_textstyle	*text*	// textstyle for datum information
datum_text_size	*mm*	// size of datum text and value
datum_colour	*colour*	// colour of the datum text
datum_line_colour	*colour*	// colour of the datum line
datum_x	*mm*	// distance to move the datum text // along the datum line

datum_y	*mm*	// distance to raise the datum text
		// above the datum line (used to be
		// called datum_offset)

The *datum_x* and *datum_y* can be positive, zero or negative.

Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string.

This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the *chainage-value*

and is drawn under the boxes area.

The parameters controlling the labelling are:

chainage_label	0/1	// 1 = label sub-plot with centreline // chainage, 0 don't label.
chainage_title	*text*	// text before the chainage value

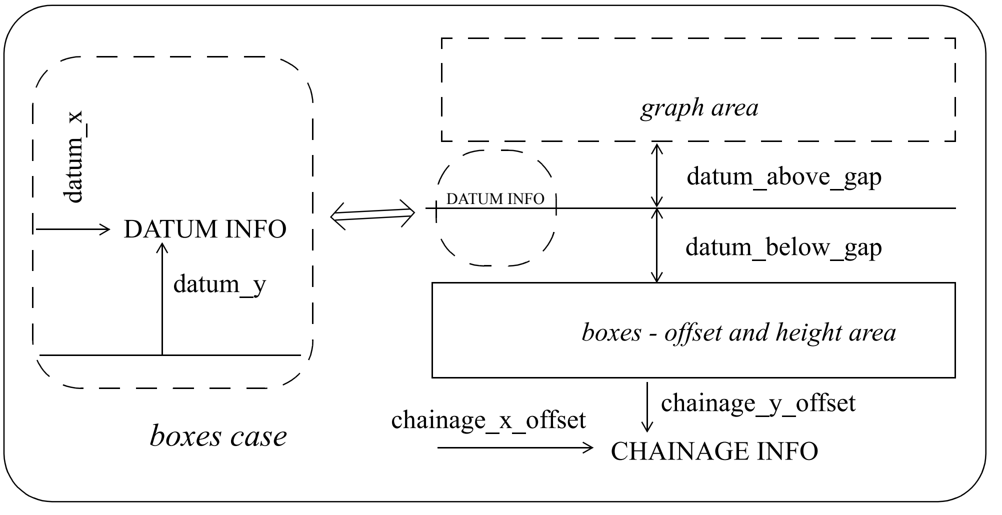
chainage_decimals	*integer*	// number of decimals in the chainage
		// value. If <0, the absolute value
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the

```
                                                    // chainage values.
chainage_size                    mm                 // size of the text
chainage_textstyle               colour             // textstyle for the chainage label
chainage_text_justification      just               // justification of the chainage text
chainage_colour                  colour             // colour of the text
chainage_x_offset                mm                 // x position of text
chainage_y_offset                mm                 // y position of text
```

The *chainage_x_offset* is measured from the beginning of the height boxes.

If *chainage_x_offset* is omitted, the text is centred on heights area.

The *chainage_y_offset* is measured from the bottom of the box area with positive being **down**.



44.2.5 Defining Boxes

When **boxes** is selected for ***label_type***, the primary string (usually the design cross section) and each tin in the x-section sub-plot can be labelled with one or two lines of title, and the height at the offset position for each point in the primary string.

The **title** for the strings, is drawn in the **title area** of the **boxes area**.

The offsets/heights are drawn in the **heights area** of the **boxes area**.

Consequently the boxes area is made up of rows of text consisting of:

string/tin titles followed by the **offset/height values** across the string/tin.

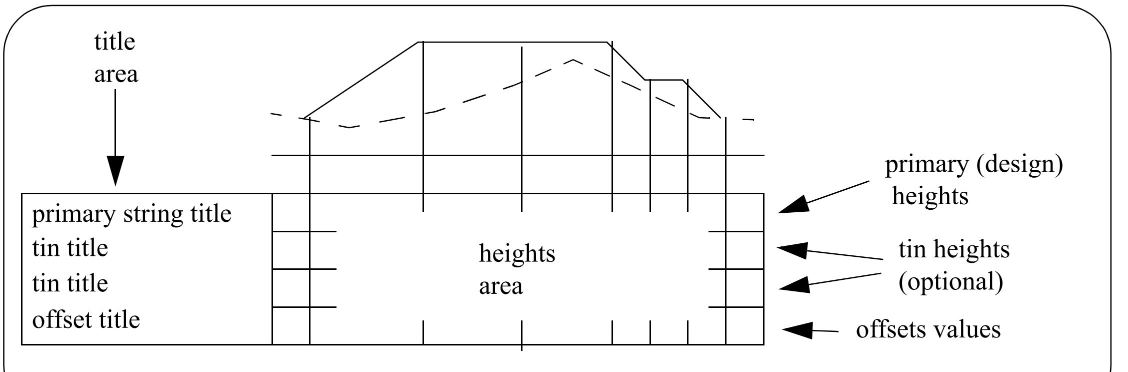
Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is

(a) offset title and values

(b) tin title and heights - natural surface etc. (optional)

(c) primary string title and heights - design x-section (optional)



boxes cross section plot

The **title area** starts at the relative position (left_sub_plot_gap,bottom_sub_plot_gap).

The size of the title text is given by the ***title_box_text_size*** parameter.

The width of the title area is either given by the *space_for_titles* parameter, or if omitted, the required width is automatically calculated.

title_box_text_size	*mm*	// size of the titles in the boxes
space_for_titles	*mm*	// calculated if omitted

There can be two lines of title text and the title text, textstyle and colour can be set independently for the primary string and each tin.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

box_titles_x	*mm*	// distance to move the title text from the // left hand side of the boxes

The **heights area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (*box_text_justification*).

The number of decimal places and the size of the heights text can also be specified.

The height of each individual box area is either given by the *horizontal_line_spacing* parameter, or if omitted, the required height is automatically calculated.

number_of_decimals	*integer*	// number of decimal places in the // height boxes. If <0, the absolute value

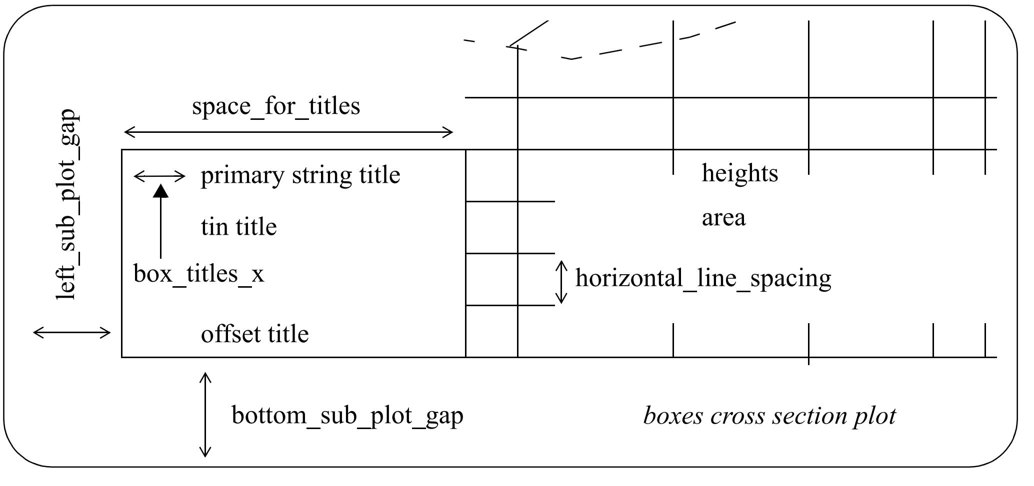
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the heights
		// area.
text_size	*mm*	// size of the height values
offset_textstyle	*textstyle*	// textstyle for height text
offset_colour	*colour*	// colour of height text
box_text_justification	0	// bottom of individual boxes
	1	// top of individual boxes
horizontal_line_spacing	*mm*	// calculated if omitted

The total height of the boxes area is simply given by number of boxes drawn multiplied by the height of one box (they all have the same height).

The **width** of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the labels area plus the width of the heights area.

Many distance definitions in the plot parameter file are given in terms of distance above the **top** of the boxes area.



The text in the title area is the same for each cross section plot on the sheet so it is possible to restrict the title area to be only on the first cross section on the sheet or the first column of cross sections.

label_first_only	0	//title area on all x-sections (default)
	1	// title area on first x-sect of page only
	2	// title area on x-sects in first column

The drawing of the box line work is user defined. This has been extended from V3.1 although *draw_box_mode* has been left in for upward compatibility.

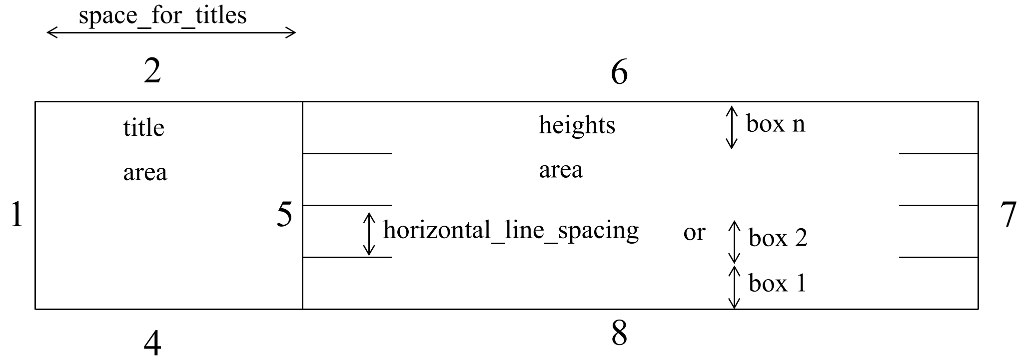
draw_box_mode	*0*	// don't draw box lines
	1	// draw box lines around heights area
		// only
	2	// draw box lines around title and
		// heights areas
	3	// use draw_box_side_n,
		// box_line_draw_mode and
		// box_line_mode_n

box_colour	*colour*	// colour of the boxes

For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters *draw_box_side_n* and *box_side_colour_n*, and the separation lines inside the boxes are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n* where the box numbering, n, starts from the bottom box.

Note: The following parameters are only used if ***draw_box_mode*** is set to **3**.

draw_box_side_1	***1***	// draw the left side of the title area (def)
	0	// don't draw the left side
box_side_colour_1	*colour*	// colour to draw left side of title area
		// default box_colour
draw_box_side_2	***1***	// draw top of the title area (default)
	0	// don't draw the top
box_side_colour_2	*colour*	// colour to draw top of title area
		// default box_colour
draw_box_side_4	***1***	// draw bottom of the title area (default)
	0	// don't draw the bottom
box_side_colour_4	*colour*	// colour to draw bottom of title area
		// default box_colour
draw_box_side_5	***1***	// draw left side of the heights area (def)
	0	// don't draw the left side
box_side_colour_5	*colour*	// colour to draw left side of heights area
		// default box_colour
draw_box_side_6	***1***	// draw top of the heights area (default)
	0	// don't draw the top
box_side_colour_6	*colour*	// colour to draw top of heights area
		// default box_colour
draw_box_side_7	***1***	// draw right side of the heights area def
	0	// don't draw the right side
box_side_colour_7	*colour*	// colour for right side of heights area
		// default box_colour
draw_box_side_8	***1***	// draw bottom of the heights area (def)
	0	// don't draw the bottom
box_side_colour_8	*colour*	// colour for bottom of heights area
		// default box_colour



lines to draw for draw_box_side_1 to draw_box_side_8

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n*.

The separation lines can be drawn just in the title area, just in the heights area or in both areas.

The parameter *box_line_draw_mode* can be set to control all the separation lines but there are additional parameters, *box_line_mode_n*, which override *box_line_draw_mode* for each of the individual boxes where n = 1, ... number of boxes -1.

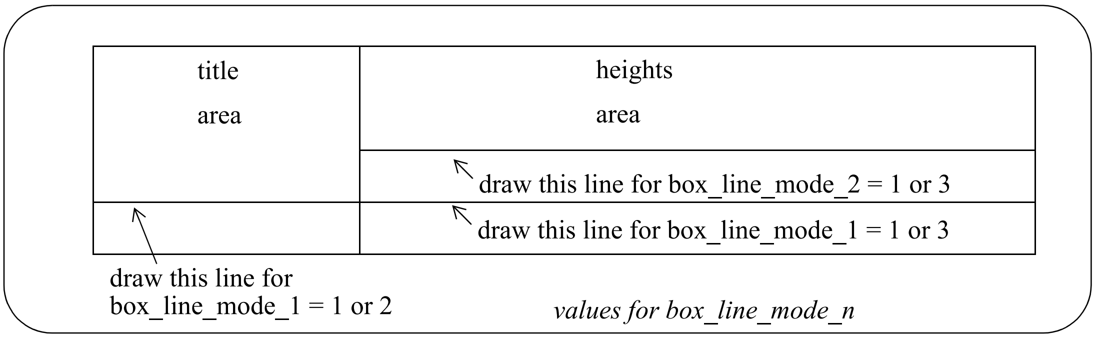
The top of the top box is not controlled by box_line_mode_n but is controlled by the parameters *draw_box_side_2* and *draw_box_side_6.*

box_line_draw_mode	*0*	// don't draw any separation lines inside // the title and heights areas
	1	// draw the separation lines inside the // title and heights areas (default)
	2	// draw the separation lines inside the // title area only
	3	// draw the separation lines inside the // heights area only

box_line_mode_n	*0*	// for the nth box, don't draw any
		// line at the top of the box for either
		// the title or the heights areas

	1	// for the nth box, draw the line at the
		// top of the box for both the
		// title and heights areas

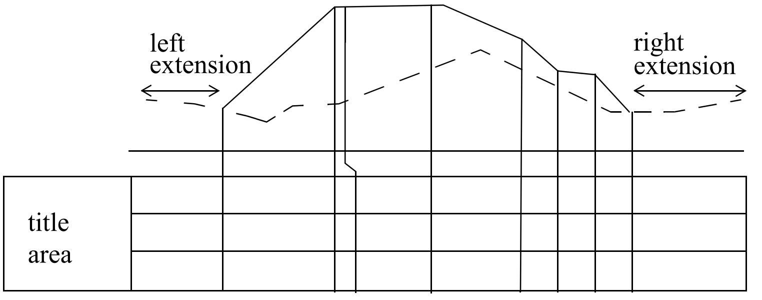
	2	// for the nth box, draw the line at the // top of the box for the title area only
	3	// for the nth box, draw the line at the // top of the box for the heights area only



values for box_line_mode_n

Finally, the right hand end of the boxes can stop at the end of the design x-section or extend to the end of the *right_extension* distance.

box_extension_mode	*0*	// default - stop right end of boxes at the // end of design x-section
	1	// extend right end of boxes to the end of // the right_extension distance.



if box_extension_mode = 1 then the boxes extend to the end of the right extension

Offset Titles and Values

If the ***label_type*** is set to boxes, the offsets of the points across the primary string (usually the design cross section) are always labelled.

offset_title	*text*	// first line of offset title (def **offsets**)
offset_title_2	*text*	// second line of offset title
offset_title_textstyle	*textstyle*	// textstyle for offset title
offset_title_colour	*colour*	// offset title text colour
offset_title_size	*mm*	// offset title text size
offset_colour	*colour*	// colour of offset values
offset_textstyle	*textstyle*	// textstyle for offset values
offset_size	*mm*	// size for offset values

Example of Offset Titles Parameters

// offset titles and values

offset_title	“Offset”
offset_title_2	“metres”
offset_title_colour	grey

Primary String Titles and Heights

Sometimes the primary string (the design cross section) is only required to define the offset positions to label and the section line for the tin sections. In this case, the primary string would not be drawn on the cross section plot.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string*.

If the primary string is drawn, by default a row of labelling is included in the boxes area with up to two lines of title information and heights for each point across the cross section.

primary_string	*yes*	// draw and label the primary string
	no	// don't draw or label the primary string
primary_title	*text*	// first line of string title
primary_title_2	*text*	// second line of string title
primary_title_textstyle	*textstyle*	// textstyle for primary string titles
primary_title_colour	*colour*	// colour of the string titles
primary_title_size	*mm*	// primary title text size
primary_textstyle	*textstyle*	// textstyle for primary string heights

primary_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// primary title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the primary title.

primary_colour	*colour*	// colour of the primary string heights
primary_size	*mm*	// primary text size

primary_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// primary height text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the primary height text.

primary_decimals	*integer*	// number of dec places in primary height // < 0 to keep all trailing zeros

Example of Labelling Primary String Titles

```
 primary_title              "Design"
// primary_title_2           "primary2"      // not being used - commented out
 primary_colour             "purple"
 primary_title_colour       "red"
```

Tin Titles, Heights and Depths

A section along the primary string through each tin on the section view is automatically drawn on the cross section plot, but the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that they were added to the view but it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use **any tin** in the project **to label** a row, **not just those drawn** on the section view.

tin_n_name	*text*	// n=1, ... no of tins on the section view.
		// use the tin called *text* to label the nth
		// row of tin heights.

If a tin of the name given by ***tin_n_name* does** not exist, then the plot is not produced and an error message is given.

For the following parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the *n*th tin on the section view or if *tin_n_name* is set, by the tin specified by *tin_n_name*.

tin_n_draw_mode	***1***	// draw the nth tin (default))
	0	// don't draw the nth tin
tin_n_draw_colour	*colour*	// colour to draw the nth tin // if omitted then use the tin colour
tin_n_label	***1***	// label the nth tin (default)
	0	// don't label the nth tin
tin_n_title	*text*	// first line of nth tin title
tin_n_title_2	*text*	// second line of nth tin title
tin_n_title_textstyle	*textstyle*	// textstyle for nth tin titles
tin_n_title_colour	*colour*	// colour for nth tin titles
tin_n_title_size	*mm*	// size for nth tin titles

tin_n_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// tin title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the tin heights.

tin_n_decimals	*integer*	// number of dec places in tin height // < 0 to keep all trailing zeros
tin_n_textstyle	*textstyle*	// textstyle of the tin heights
tin_n_colour	*colour*	// colour for heights **and** depths
tin_n_size	*mm*	// default nth tin's title size

tin_n_y_pos	*mm*	//if set, the height in mm above the
		//bottom of all the boxes that the
		// tin height text is drawn.
		//If not set, then the text is placed at a
		//height that puts it inside the default
		// box for the tin heights.

tin_n_depth_label	1/0	// 1 to label, 0 don't label depths
tin_n_depth_title	*text*	// first line of tin depth title
tin_n_depth_title_2	*text*	// second line of tin depth title
tin_n_depth_title_textstyle	*textstyle*	// textstyle of the tin depth titles

tin_n_depth_title_colour	*colour*	// colour for titles of depths
tin_n_depth_title_size	*mm*	// size for title of depths

tin_n_depth_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// tin depth title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the tin heights.

tin_n_depth_decimals	*integer*	// number of dec places in tin height // < 0 to keep all trailing zeros
tin_n_depth_textstyle	*textstyle*	// textstyle of the tin depths
tin_n_depth_colour	*colour*	// colour for depths
tin_n_depth_size	*mm*	// size for depths

tin_n_depth_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// tin depth text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the tin heights.

Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin, at a particular offset is defined as

depth = tin height value - height of the primary string

That is, the depth that the primary string is **below** the tin.

Before plotting, the value of depth is multiplied by either the *depth_positive_factor* or *depth_negative_factor*.

if (depth >= 0) plotted_depth_value = depth * depth_positive_factor

if (depth < 0) plotted_depth_value = depth * depth_negative_factor

Hence the definition of depth can be modified by the parameters:

depth_positive_factor	*value*	// multiplier for positive depths
depth_negative_factor	*value*	// multiplier for negative depths

For example, if the opposite sign is required for depth, that is,

depth = height of the primary string - tin height value

simply set

depth_positive_factor -1

depth_negative_factor- 1

Example of Labelling Tins

```
//    tin label 1 for on
//              0 for off

 tin_1_label              1

 tin_1_title             “Natural”
// tin_1_title_2         “Surface”
 tin_1_colour             grey
 tin_1_title_colour       red
```

tin_2_label	1
tin_2_title	"Water table"
tin_2_colour	grey
tin_2_title_colour	red

Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the **primary string** (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

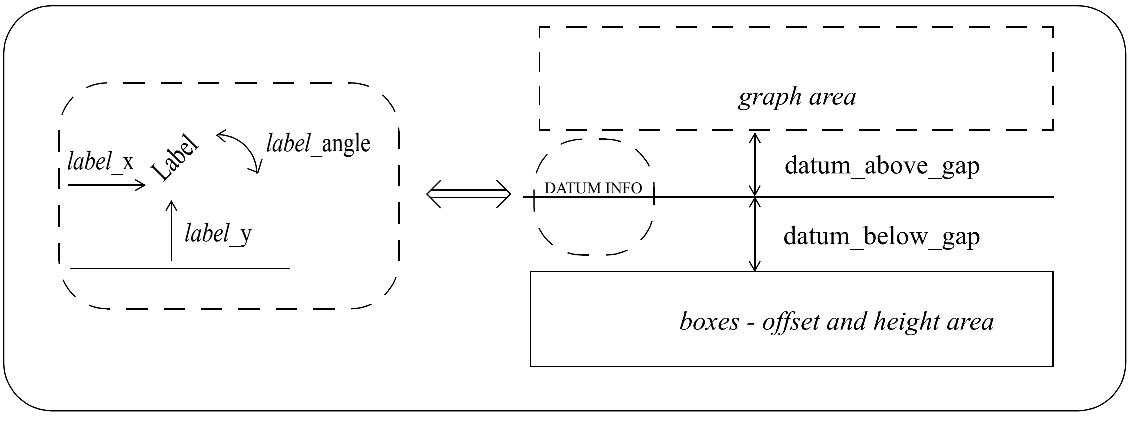
The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

pre_text *value* post_text

where *value* is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.



Parameters for labelling the X Co-ordinate at Zero Offset:

primary_x0_draw_mode	*0*	// don't draw the label -default
	1	// draw the label
primary_x0_pre_text	*text*	// pre-text for label - def " "
primary_x0_post_text	*text*	// post-text for label - def " "
primary_x0_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_x0_x	*mm*	// x adjustment to position of label - def 0
primary_x0_y	*mm*	// y adjustment to position of label - def 0
primary_x0_angle	*degrees*	// angle of the label - def 0
primary_x0_colour	*colour*	// colour of the label
primary_x0_size	*mm*	// size (in mm) of the label
primary_x0_textstyle	*textstyle*	// textstyle of the label
primary_x0_justify	*just*	// justification for text

Parameters for Labelling the Y Co-ordinate at Zero Offset:

primary_y0_draw_mode	***0***	// don't draw the label -default
	1	// draw the label

primary_y0_pre_text	*text*	// pre-text for label - def " "
primary_y0_post_text	*text*	// post-text for label - def " "
primary_y0_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_y0_x	*mm*	// x adjustment to position of label - def 0
primary_y0_y	*mm*	// y adjustment to position of label - def 0
primary_y0_angle	*degrees*	// angle of the label - def 0
primary_y0_colour	*colour*	// colour of the label
primary_y0_size	*mm*	// size (in mm) of the label
primary_y0_textstyle	*textstyle*	// textstyle of the label
primary_y0_justify	*just*	// justification for text

Parameters for Labelling the Height of Primary String at Zero Offset:

primary_height_draw_mode	*0*	// don't draw the label -default
	1	// draw the label
primary_height_pre_text	*text*	// pre-text for label - def " "
primary_height_post_text	*text*	// post-text for label - def " "
primary_height_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
primary_height_x	*mm*	// x adjustment to position of label - def 0
primary_height_y	*mm*	// y adjustment to position of label - def 0
primary_height_angle	*degrees*	// angle of the label - def 0
primary_height_colour	*colour*	// colour of the label
primary_height_size	*mm*	// size (in mm) of the label
primary_height_textstyle	*textstyle*	// textstyle of the label
primary_height_justify	*just*	// justification for text

Parameters for Placing Some Text:

extra_text_draw_mode	***0***	// don't draw the label -default
	1	// draw the label
extra_text_pre_text	*text*	// pre-text for label - def " "
extra_text_post_text	*text*	// post-text for label - def " "
extra_text_decimals	*integer*	// number of decimal places to display - def 1
		// If > 0, trailing zeros are removed after
		// the decimal point
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed
extra_text_x	*mm*	// x adjustment to position of label - def 0
extra_text_y	*mm*	// y adjustment to position of label - def 0
extra_text_angle	*degrees*	// angle of the label - def 0
extra_text_colour	*colour*	// colour of the label
extra_text_size	*mm*	// size (in mm) of the label
extra_text_textstyle	*textstyle*	// textstyle of the label
extra_text_justify	*just*	// justification for text

Offset Selection for Uprights and Staggering of Heights

For each sub-plot, the offsets of the points across the x-section string (primary string) are used for positioning uprights (leader lines), and the offset and height labels for the uprights.

By default, there is an upright at each point across the primary string.

However, if the primary string is a 4d string, then the text at the points on the 4d string can be used as a key to **suppress** the labelling and upright at that point.

The parameters to **stop** labelling and uprights are:

mask_name_n	*4d_string_point_text*	where n=1,100

Note -the text *4d_string_point_text* can include wild cards (*) and characters (?).

After any *name masks* have been applied, it is often desirable to weed out offset values that are too close together before doing any labelling.

offset_label_tolerance	*value*	// weed out offset values closer together // (in offset units) than this value

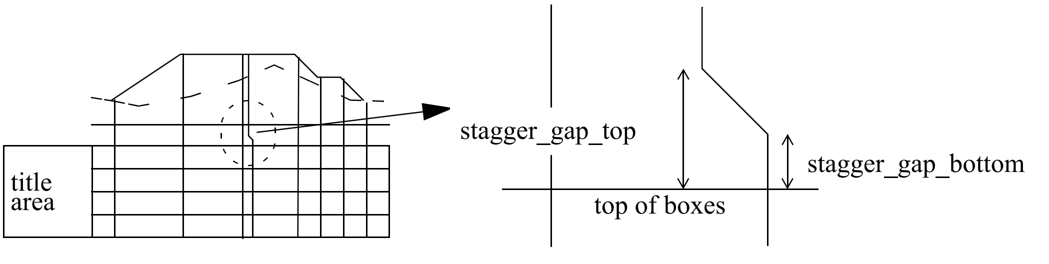
If the real offset position is used for the horizontal position of the offset/height text, text over writing can easily occur. To prevent over writing, the text is automatically **staggered**.

When staggering occurs, the real offset position is then indicated by the offset markers which are drawn at the top of the text boxes from the staggered text position back to the actual offset position of the text.

The size and position of the staggers are given by:

stagger_gap_top	*mm*	// distance from boxes to top of stagger
stagger_gap_bottom	*mm*	// distance from boxes to bottom of // stagger
stagger_gap_factor	*value*	// distance between staggers is // box_text_size * stagger_gap_factor

When staggering occurs, it is possible for the heights area to be wider than the graph area.



boxes cross section plot

Uprights

Uprights (leader lines) can be drawn from the top of the staggers to strings drawn on the plot.

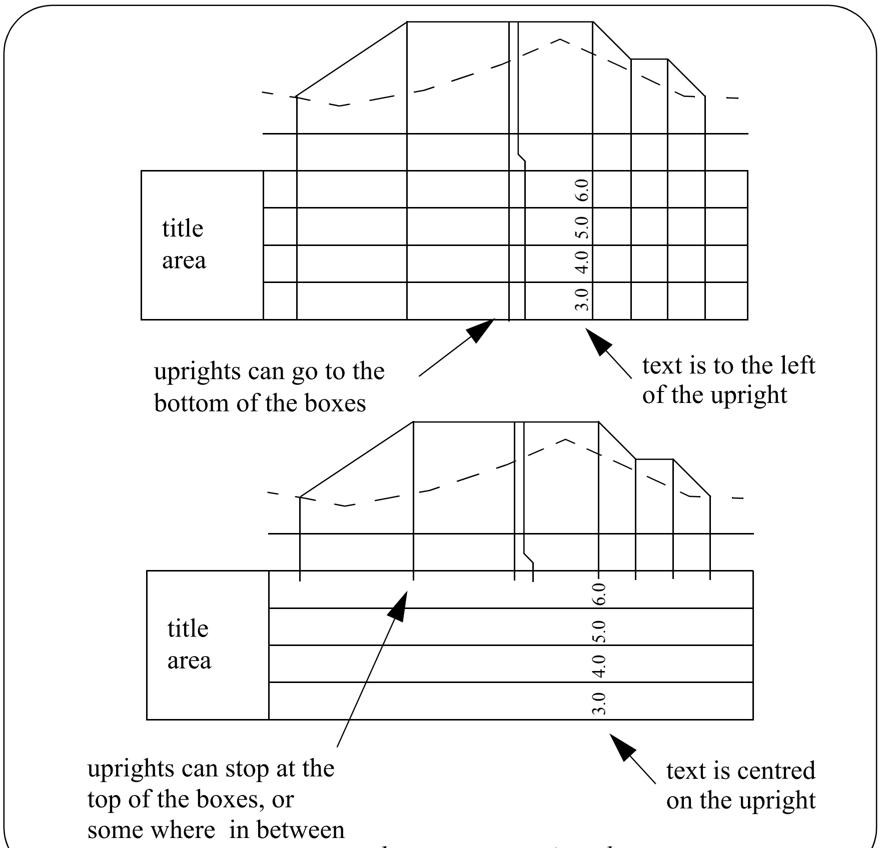
The height of the uprights is given by the ***uprights_draw_mode***:

uprights_draw_mode	0	// none
	1	// to maximum string height at that // chainage
	2	// ticks, to stagger height
	3	// to uprights_y above the boxes
	100	// to the primary string
	101-500	// to tin1 or tin2 etc.
uprights_y	*mm*	// distance to draw the uprights for // mode 3
uprights_colour	*colour*	// uprights colour (def boxes colour)

The uprights can go below the top of the boxes.

uprights_bottom_mode	*0*	// stop at top of boxes (default)
	1	// draw to bottom of boxes
	2	// draw to uprights_bottom_y below the // top of the boxes
	3	// draw to uprights_bottom_y above the // bottom of the boxes
	4	// ticks at chainage
uprights_bottom_y	*mm*	//distance
uprights_text_offset_factor	*value*	// move the text by this factor*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.



boxes cross section plot

Please continue to the next section 44.2.6 Graph Area.

44.2.6 Graph Area

The **graph area** for each section sub-plot is the area where the actual plot of the x-section string is drawn.

The **width** of the graph area is determined by the width of the x-section string being plotted, the left and right extensions and horizontal scale (scale) given by parameters or in the **section x plot** panel, and the vertical exaggeration given by the section view or a parameter.

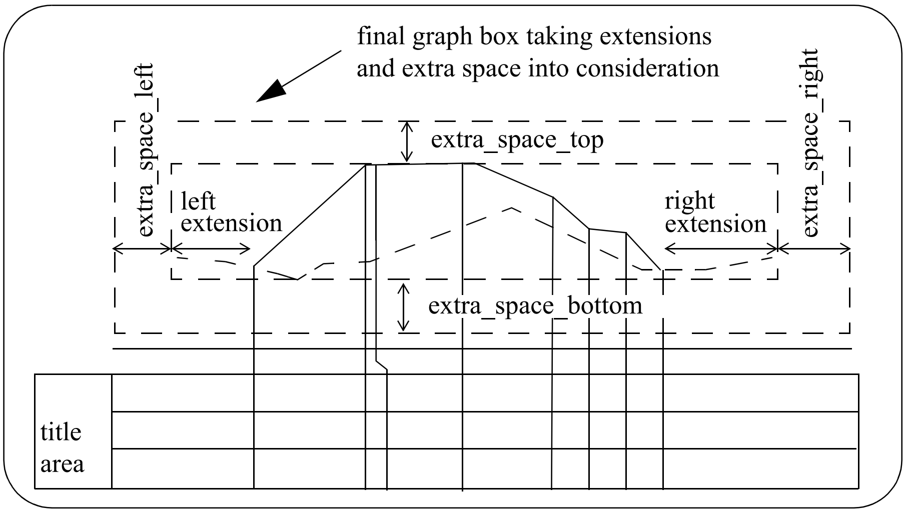
view_name	*text*	// default is **section view** in panel.
vertical_exaggeration	*value*	// default is vertical exag for view
scale	*value*	// 1:value - horizontal scale, default is
		// **scale 1:** in panel.
left_extension	*world-units*	// left extension value
right_extension	*world-units*	// right extension value

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The **height** of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The size of the graph area can also be extended to allow for symbols by the parameters:

extra_space_units	***0***	// extra space values are world units - default
	1	// " " " are millimetres on plot page
extra_space_left	*units*	// subtract from left of plot area, def 0
extra_space_right	*units*	// add to right of plot area, default 0
extra_space_top	*units*	// add to top of plot area, default 0
extra_space_bottom	*units*	// subtract from bottom of plot area,
		// default 0



The types of strings that are drawn in the graph area of a cross section plot are:

(a) primary string the x-section string from the x-section model that is being drawn. Called the primary string and is usually the design x-section.

(b) tins sections of the primary string through any tins either in models on the section view or in corridor models.

(c) services parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The **colour** of the strings in the plot is the actual string colour for cases (a) and (c), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are labelled with heights.

Primary String (Design Cross Section)

The primary string (the design cross section) is used to define

(a) the design cross section
(b) the chainage of the section
(c) the offset positions for labelling heights and drawing uprights
(d) the section line used for sectioning through tins
(e) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the cross section plot, it doesn't have to be drawn on the cross section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string* which was described earlier.

The **colour** of the primary string in the plot is the actual primary string colour.

Tins

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The **colour** and **linestyle** of the tin section in the plot is the actual tin colour and tin linestyle.

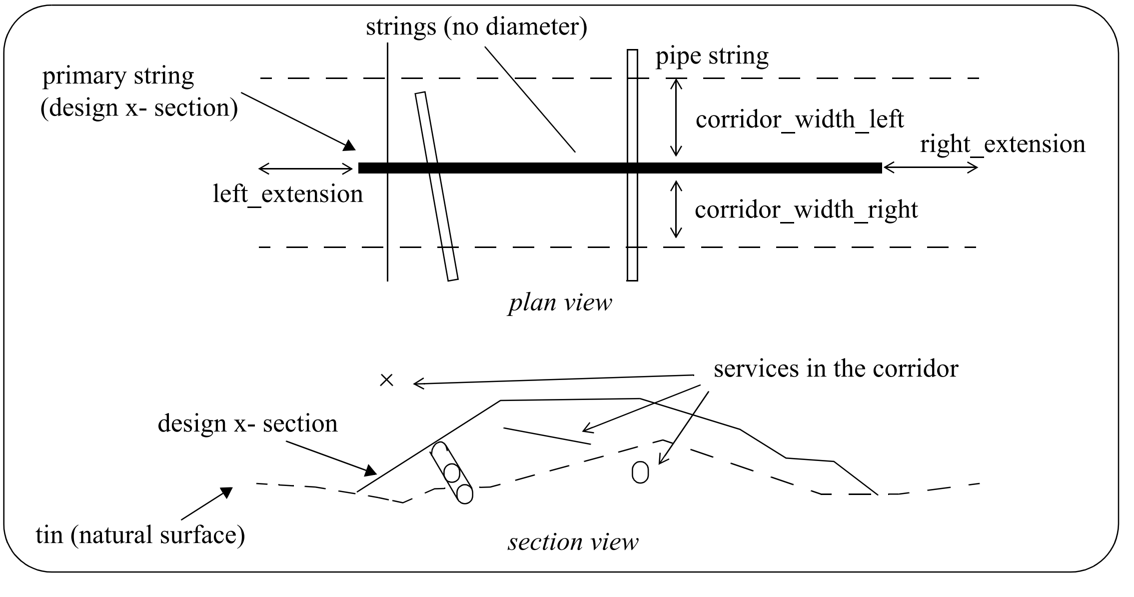
Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

Corridor and Services

A corridor around the primary string is defined by giving a left and right corridor width and a left and right extension.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the cross section plot.

Strings do not have to cross the primary string, but just be in the corridor.



The corridor defining parameters are

```
left_extension          world-units     // left extension value
right_extension         world-units     // right extension value
corridor_width_left     world-units     // corridor left and right widths
corridor_width_right    world-units     // defaults are the section view values
corridor_overlap_left   world-units     // corridor left and right overlaps.
corridor_overlap_right  world-units     // defaults are the section view values
corridor_chord_arc      world-units     // chord-arc tolerance used to
                                        // approximate arcs in the corridor.
                                        // default is the section view value
```

The models containing tins for sectioning and strings for services are taken from the section view or given by the parameters

```
corridor_model_n        model           // n = 1, 2 ... 100
                                        // models containing tins and service
                                        // strings to be drawn on the view.
```

If any *corridor_model_n* parameters are defined, then only the models given by the parameters are used. If no *corridor_model_n* parameters are set, then the models added to the given section view are used.

That is, either the *corridor_model_n* parameters are used or if none exist, then the models added to the section view are used for tins and service strings.

The **colour** and **diameter** of the service strings drawn in the plot are the actual strings colour and diameter.

Please continue to the next section 44.2.7 Grade Labelling.

44.2.7 Grade Labelling

The plot of the x-section string is made up of straight lines joining the individual points of the x-section.

The **grades** of these lines can be labelled:

grade_label	0	// don't label grades (default)
	1	// label grades

Either the individual lines can be used as the segments to be labelled for grade, or adjacent lines of the same grade can be considered to be just one segment and labelled only once.

Hence the segments to be labelled for grade can be the individual lines of the x-section, or the segments defined by changes of grade.

grade_change_only	0	// label individual lines
	1	// label change of grade segments

It is also possible to ignore segments smaller that a given minimum width on the plot.

grade_minimum_width	*mm*	// segments smaller are not labelled

The grade labels are drawn parallel to the segment, centred about the segments end points, and a distance *grade_offset* above the segment. The size, colour and number of decimal places can all be set.

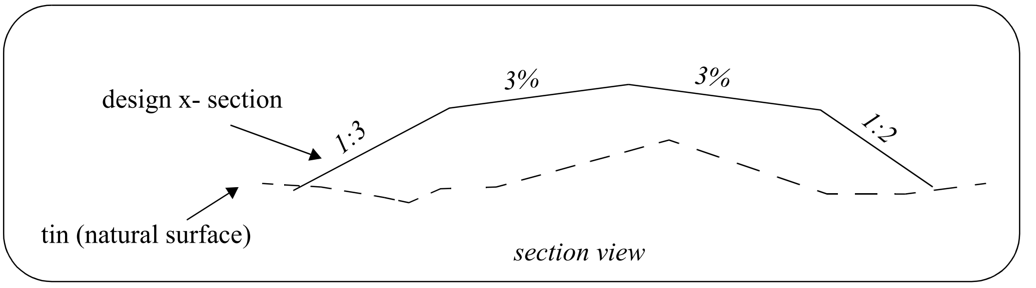
grade_decimals	*integer*	// number of decimal places in grade
grade_size	*mm*	// size of the grade label
grade_textstyle	*text*	// textstyle of the grade label
grade_colour	*colour*	// colour of the grade label
grade_offset	*mm*	// distance above the segment for label
grade_signed	*yes*	// default - grades are signed
	no	// absolute value of grades

The grade can be labelled as percent cross-fall, 1 in slope, m/m or VicRoads x:1.

Also a threshold value can be set and any grades whose absolute value are below the threshold can be labelled in one way, and those above the threshold labelled a different way.

Hence, if the absolute value of the grade is less that or equal to the absolute value of *grade_threshold*, then ***grade_mode*** is used, otherwise ***grade_upper_mode*** is used.

grade_mode	0	// % grade
	1	// 1 in
	2	// m/m
	3	// VicRoads x:1
grade_threshold	value	// grade threshold for type of grade
		// labelling
grade_threshold_mode	0-3	// type of grade value given in
		// grade_threshold types are the same as
		// grade_mode
grade_upper_mode	0	// % grade
	1	// 1 in
	2	// m/m
	3	// VicRoads x:1
grade_upper_decimals	*integer*	// number dec places in grades above
		// threshold value



Example of Grade Labelling

```
grade_label                    1                  // turn grade labels on
grade_mode                     0                  // percent grade
grade_decimals                 1                  // one decimal place, no trailing zeros
grade_change_only              1                  // only label when change of grade

// text size for grade annotations

grade_size                     2
grade_colour                   yellow

// how far the annotation is (perpendicularly)
//    from the string itself

grade_offset                   1

//  label all annotations separated by more than
//  the minimum width in plot units

grade_minimum_width            0

//  threshold and threshold mode describe the value
//   at which the grade labelling changes
//   mode to grade_upper_mode

grade_threshold                7                  // change labelling when over 7%
grade_threshold_mode           0                  // units for threshold - %
grade_upper_mode               1                  // label as 1:x
```

Please continue to the next section 44.2.8 Labelling Points of the X-Sections.

44.2.8 Labelling Points of the X-Sections

The points across each x-section can be automatically labelled on the x-section plots.

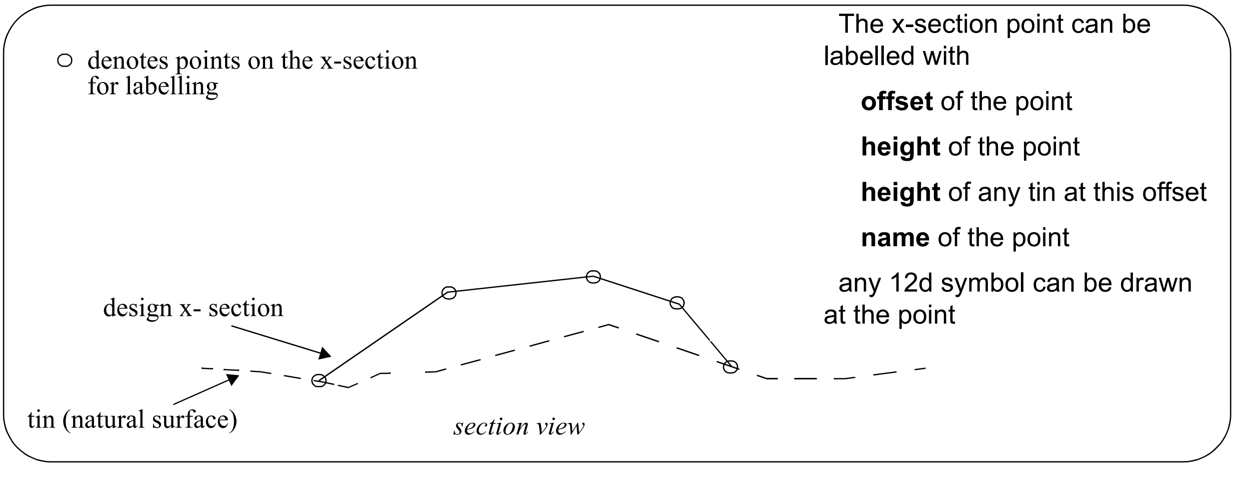
The **height**, **offset** and **name** of the point can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the point.

The height position for the labelling can be specified as the

(a) top of the boxes for the x-section
(b) above the maximum height of the strings on the plot
(c) height of the point on the x-section string (primary string)
(d) height of a tin.

The actual position of the label is defined relative to the above point.



Note:

Only case (b) involves the actual height of the point on the cross section string. For all other cases, only the offset of the cut string is used.

Other heights, for example, the height of the tin at that offset can be used as the height (case (d)).

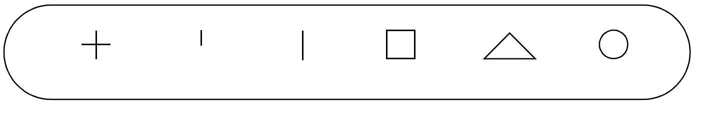
Text justification refers to the actual position and is given by

"top-left"	"top-centre"	"top-right"
"middle-left"	"middle-centre"	"middle-right"
"bottom-left"	"bottom-centre"	"bottom-right"

A choice of six special symbols and/or or any of the 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are



Up to twenty five (25) separate sets of points can be labelled.

Parameters for Labelling Points of X-Sections

The points of the x-section to be for labelled for the nth set of parameters is restricted to all the points whose name satisfying the *points_n_mask*:

points_n_mask *point_name*s // points to be labelled

where *point_names* is a text string containing the name masks, each separated by one or more spaces, to test the point name against. Each mast can include wild cards and wild characters.

For example

points_1_mask "ke*"

or points_1_mask "?bank*"

or, if both masks are required,

points_1_mask "ke* ?bank*"

The parameters for drawing a **symbol** are

points_symbol_n_mode	0	// cross
	1	// up from centre of box
	2	// up and down from centre of box
	3	// square
	4	// triangle, base at bottom
	5	//circle
	6	// use a 12d symbol

predefined symbols for

If *points_symbol_n_mode* is 6, then the plot symbol is given by

points_symbol_n_style *plotsymbol* // name of the 12d symbol to draw at point

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

(a) the parameter *plot_symbols* in the ppf file

plot_symbols *filename*

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D

PLOT_SYMBOLS_4D *filename* *// default plotsym.4d*

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file *plotsym.4d*

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D

SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

points_symbol_n_position	1	// above point height value
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string (same as 1)
	101-500	// to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

points_symbol_n_x	*mm*	// offset adjustment to position
points_symbol_n_y	*mm*	// height adjustment to position
points_symbol_n_angle	*degrees*	// rotation about point
points_symbol_n_colour	*colour*	// colour of symbol

and for all values of *points_symbol_n_mode* **other** than 6:

points_symbol_n_size	*mm*	// size of symbol, 0 don't draw

The value of the **offset** of the point can be labelled using the parameters

points_offset_n_position	1	// above point height value
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
points_offset_n_x	*mm*	// offset adjustment to position
points_offset_n_y	*mm*	// height adjustment to position
points_offset_n_angle	*degrees*	// rotation about point
points_offset_n_size	*mm*	// size of text, 0 don't label
points_offset_n_colour	*colour*	// colour of text
points_offset_n_textstyle	*textstyle*	// textstyle to use for points offset text.
points_offset_n_pre_text	*text*	// text before the offset value
points_offset_n_post_text	*text*	// text after the offset value
points_offset_n_justification	*justification*	// justification of the text
points_offset_n_no_decimals	*integer*	// number of decimals in offset

The value of a **height** at the offset of the point can be calculated and labelled using the parameters

points_height_n_mode	*1*	// use height of point itself
	3	// use real world height of position
		// above boxes
	100	// height of primary string (same as 1)
	101-500	// use height of to tin1 or tin2 etc.

points_height_n_position	*1*	// at points position
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string (same as 1)
	101-500	// to tin1 or tin2 etc.
points_height_n_x	*mm*	// offset adjustment to position
points_height_n_y	*mm*	// height adjustment to position
points_height_n_angle	*degrees*	// rotation about point
points_height_n_size	*mm*	// size of text, 0 don't label
points_height_n_colour	*colour*	// colour of text

points_height_n_textstyle	*textstyle*	// textstyle to use for points height text.
points_height_n_pre_text	*text*	// text before the height value
points_height_n_post_text	*text*	// text after the height value
points_height_n_justification	*justification*	// justification of the text
points_height_n_no_decimals	*integer*	// number of decimals in height

A **label** which can include the **name** of the point is drawn by using the parameters

points_label_n_position	*1*	// at the points position
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string (same as 1)
	101-500	// to tin1 or tin2 etc.
points_label_n_mode	0	// don't include point name
	1	// include point name in label
points_label_n_x	*mm*	// offset adjustment to position
points_label_n_y	*mm*	// height adjustment to position
points_label_n_angle	*degrees*	// rotation about point
points_label_n_size	*mm*	// size of text, 0 don't label
points_label_n_colour	*colour*	// colour of text
points_label_n_textstyle	*textstyle*	// textstyle to use for points label text.
points_label_n_pre_text	*text*	// text before the point name
points_label_n_post_text	*text*	// text after the point name
points_label_n_justification	*justification*	// justification of the text

Please continue to the next section 44.2.9 Labelling Cuts of X-Sections Through Strings in a Model.

44.2.9 Labelling Cuts of X-Sections Through Strings in a Model

The cuts that each x-section string makes though any strings in user given models can be automatically labelled on the x-section plots.

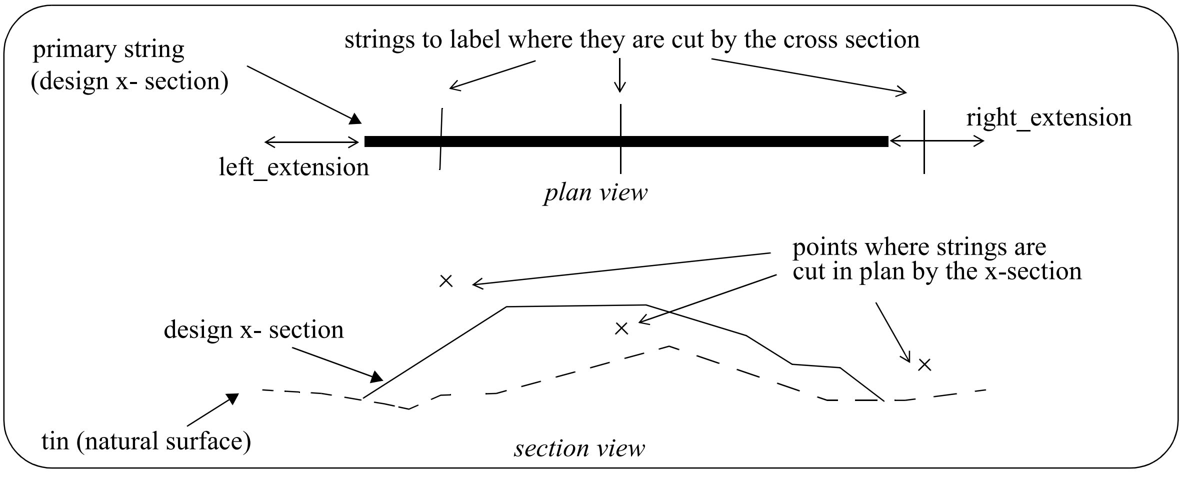
The **height**, **offset** and **name** of the cut string can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the cut string.

The height position for the labelling can be specified as the

(a) top of the boxes on the x-section
(b) above the maximum height of the strings on the plot
(c) height value of the cut string
(d) height of the x-section string (the primary string)
(e) height of a tin.

The actual position of the label is defined relative to the above point.



Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the offset of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the offset is required and the height of the tin at that offset can be used as the height (case (d)).

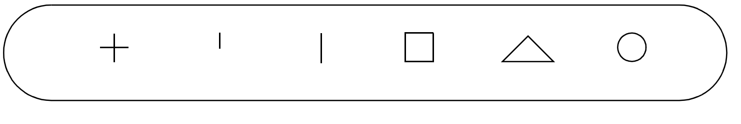
Text justification refers to the actual position and is given by

"top-left"	"top-centre"	"top-right"
"middle-left"	"middle-centre"	"middle-right"
"bottom-left"	"bottom-centre"	"bottom-right"

A choice of six special symbols and/or or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are



Up to twenty five (25) separate models of strings can be cut and labelled.

Parameters for Labelling Cuts of X-Sections Through Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the **model** which contains the strings, and then a **name mask** which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the nth set (where n can be from 1 to 25) of cuts of the x-sections with the strings in the model are given by:

cuts_n_model   *model_name*   // model of strings to be cut

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

cuts_n_mask   *name_mask*   // strings to check for cuts
// and if a cut occurs,
// parameters show how to
// label the cut

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mast can include wild cards and wild characters.

For example

cuts_1_mask   "ke*"

or   cuts_1_mask   "?bank*"

or, if both masks are required,

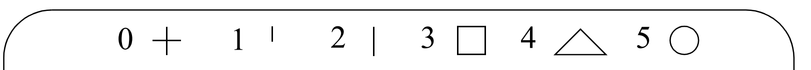
cuts_1_mask   "ke*   ?bank*"

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "*".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the x-sections, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the nth set.

The parameters for drawing a **symbol** at the cut points are:

cuts_symbol_n_mode	0	// cross
	1	// up from centre of box
	2	// up and down from centre of box
	3	// square
	4	// triangle, base at bottom
	5	// circle
	6	// use a 12d symbol



predefined symbols for

If *cuts_symbol_n_mode* is 6, then the plot symbol is given by

cuts_symbol_n_style   *plotsymbol*   // 12d symbol to draw at cut

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

(a) the parameter *plot_symbols* in the ppf file

plot_symbols   *filename*

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D

PLOT_SYMBOLS_4D *filename* *// default plotsym.4d*

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file *plotsym.4d*

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D

SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

```
cuts_symbol_n_position     1          // above point height value
                           3          // above top of boxes
                           4          // above top of graph area but not including
                                      // the extra_space_top
                           100        // to primary string
                           101-500    // to tin1 or tin2 etc.
```

The symbol can be adjusted by the parameters:

```
cuts_symbol_n_x            mm         // offset adjustment to position
cuts_symbol_n_y            mm         // height adjustment to position
cuts_symbol_n_angle        degrees    // rotation about point
cuts_symbol_n_colour       colour     // colour of symbol
```

and for all values of *cuts_symbol_n_mode* **other** than 6:

```
cuts_symbol_n_size         mm         // size of symbol, 0 don't draw
```

The value of the **offset** of the cut string can be labelled using the parameters

```
cuts_offset_n_position     1          // above cut strings height value
                           3          // above top of boxes
                           4          // above top of graph area but not including
                                      // the extra_space_top
                           100        // to primary string
                           101-500    // to tin1 or tin2 etc.

cuts_offset_n_x            mm         // offset adjustment to position
cuts_offset_n_y            mm         // height adjustment to position
cuts_offset_n_angle        degrees    // rotation about point
cuts_offset_n_size         mm         // size of text, 0 don't label
cuts_offset_n_colour       colour     // colour of text
cuts_offset_n_textstyle    textstyle  // textstyle to use for cuts offset text.
cuts_offset_n_pre_text     text       // text before the offset value
cuts_offset_n_post_text    text       // text after the offset value
cuts_offset_n_justification justification // justification of the text
cuts_offset_n_no_decimals  integer    // number of decimals in offset
```

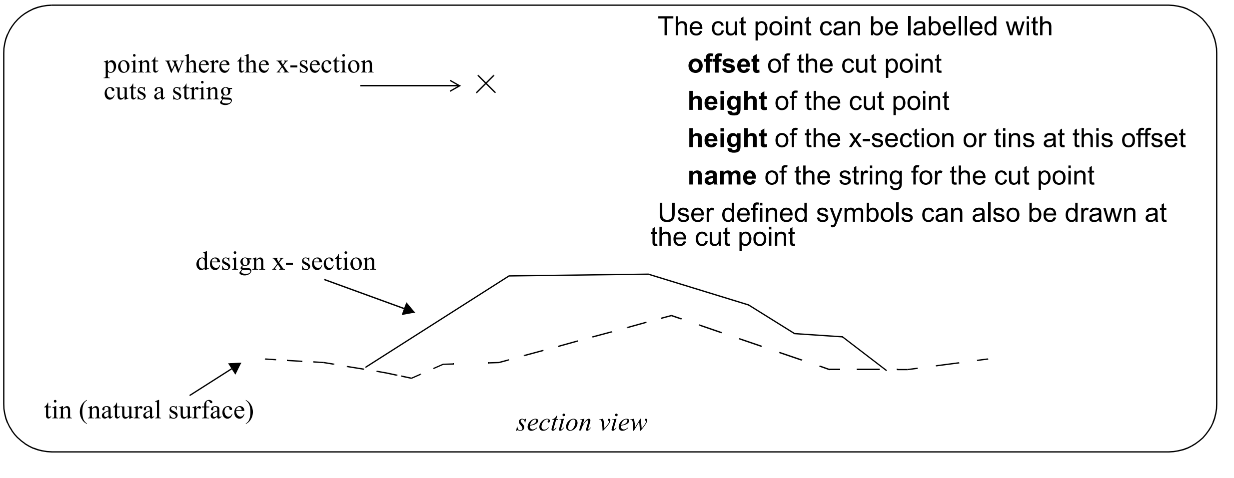
The value of a **height** at the offset of the point can be calculated and labelled using the parameters

```
cuts_height_n_mode         1          // use height of cut point itself
                           3          // use real world height of position
```

		// above boxes
	100	// height of primary string
	101-500	// use height of to tin1 or tin2 etc.
cuts_height_n_position	*1*	// at points position
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_height_n_x	*mm*	// offset adjustment to position
cuts_height_n_y	*mm*	// height adjustment to position
cuts_height_n_angle	*degrees*	// rotation about point
cuts_height_n_size	*mm*	// size of text, 0 don't label
cuts_height_n_colour	*colour*	// colour of text
cuts_height_n_textstyle	*textstyle*	// textstyle to use for cuts heights text.
cuts_height_n_pre_text	*text*	// text before the height value
cuts_height_n_post_text	*text*	// text after the height value
cuts_height_n_justification	*justification*	// justification of the text
cuts_height_n_no_decimals	*integer*	// number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters:

cuts_label_n_position	1	// above cut strings height value
	3	// above top of boxes
	4	// above top of graph area but not including
		// the extra_space_top
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_label_n_mode	0	// don't include cut string name
	1	// include cut string name in label
cuts_label_n_x	*mm*	// offset adjustment to position
cuts_label_n_y	*mm*	// height adjustment to position
cuts_label_n_angle	*degrees*	// rotation about point
cuts_label_n_size	*mm*	// size of text, 0 don't label
cuts_label_n_colour	*colour*	// colour of text
cuts_label_n_textstyle	*textstyle*	// textstyle to use for cuts label text.
cuts_label_n_pre_text	*text*	// text before the string name
cuts_label_n_post_text	*text*	// text after the string name
cuts_label_n_justification	*justification*	// justification of the text



Please continue to the next section 44.2.10 Hatching Cut and Fill Areas.

44.2.10 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

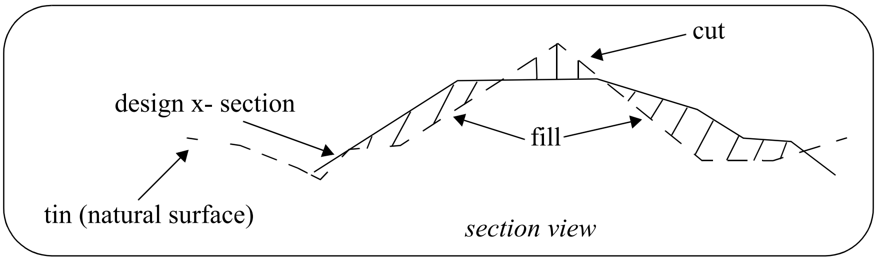
The parameters for labelling cuts and/or fill regions between tins are given by:

hatch_original_tin_n	*tin_name*	// tin_name for original surface
hatch_new_tin_n	*tin_name*	// tin_name for final surface
hatch_cut_separation_n	*mm*	// distance between cut hatch lines
	0	// don't do cut hatching
hatch_cut_angle_n	*degrees*	// angle in degrees of cut hatching
hatch_cut_colour_n	*colour*	// colour of the cut hatching
hatch_cut_linestyle_n	*linestyle*	// linestyle for cut hatching
hatch_cut_draw_sides_n	1/0	// 1 = draw sides of cut regions
hatch_cut_draw_original_n	1/0	// 1 = draw original tin in cut regions
hatch_cut_draw_new_n	1/0	// 1 = draw new tin in cut regions
hatch_fill_separation_n	*mm*	// distance between fill hatch line
	0	// don't do fill hatching
hatch_fill_angle_n	degrees	// angle in degrees of fill hatching
hatch_fill_colour_n	colour	// colour of the fill hatching
hatch_fill_linestyle_n	linestyle	// linestyle for fill hatching
hatch_fill_draw_sides_n	1/0	// 1 = draw sides of fill regions
hatch_fill_draw_original_n	1/0	// 1 = draw original tin in fill regions
hatch_fill_draw_new_n	1/0	// 1 = draw new tin in fill regions

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting *hatch_cut_separation_n* to 0.0.
fill hatching is turned off by setting *hatch_fill_separation_n* to 0.0.



Please continue to the next section 44.2.11 Extra Models of X-Sections.

44.2.11 Extra Models of X-Sections

The order and centreline chainages of the x-section subplots for the x-section plot are defined by the sections from the primary model of cross sections.

The sections through any specified triangulations and service models, and offsets for labelling are fully defined by these primary x-sections.

However it is also possible to plot extra x-sections on each of the sub-plots by supplying extra models of x-sections which are at the same plan positions as the primary x-section strings.

Only those x-sections from the extra models that are within a user specified tolerance of a primary x-section are plotted.

The extra models of x-sections and the plan tolerance for checking that the extra cross-sections are the same position as the primary x-sections are

extra_model_tolerance_1 *value* // tolerance in ***12d Model*** units

extra_model_n *model_name* // where n=1, ... 100
// extra models of x-sections

The actual colour of the extra x-sections is used as their plotting colour.

Please continue to the next section 44.2.12 Sorting X-Sections by Chainage.

44.2.12 Sorting X-Sections by Chainage

The chainage on the design string that the x-section is created at is stored with the cross-section.

When the x-sections are created by the apply functions, they are created in the order of increasing chainage and added to the *model for sections* in that order.

Hence if the cross sections are plotted, the natural order would be in increasing chainage order.

However, it is possible to upset the order in the model by manually adding in extra sections.

Hence there is a parameter in both the **section x plot** panel and the plot parameter file to ensure that the cross sections are sorted in increasing chainage order before they are plotted.

sort_sections	***1***	// sort sections by design chainage
	0	// use order of sections in model

Please continue to the next section 44.2.13 Title Block Information.

44.2.13 Title Block Information

The plot can have a standard ***12d Model*** title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard ***12d Model*** title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter *plot_border*.

plot_border	*yes/no*	*// yes plots a standard title block* *// default yes*
title_1	*text*	
title_2	*text*	
title_text_size	*value*	
title_colour	*colour*	

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The *plot_border* parameter should also be set to *no* so that the standard title block is not also drawn.

use_title_file	*yes/no*	*// yes draws the title block given in title_file* // default no
title_file	*filename*	
plot_border	*no*	*// turn off standard title block*

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

user_text_n		*text*

The special plot parameters are:

time_format	*text*	// format for $time
user_text_n	*text*	// where n = 1,2,... 1000 // passed down to $user_text_n
title_1	*text*	// passed down to $title_1
title_2	*text*	// passed down to $title_2
start_page_number	*integer*	// used as the starting value for // $page_number. If missing, // $page_number starts at 1.

start_drawing_number	*integer*	// added to $drawing_number in title
		// block file. If missing,
		// $drawing_number starts at 1.

drawing_number_prefix	*text*	// passed down to // $drawing_number_prefix
drawing_number_postfix	text	// passed down to // $drawing_number_postfix

Please continue to the next section 44.2.14 Parameters that Modify Fields In the Cross Plot Panel.

44.2.14 Parameters that Modify Fields In the Cross Plot Panel

A number of parameters match those in the **section x plot** panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters in the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the **section x plot** panel are:

view_name	*text*
plotter_type	*text*
model_to_plot	*text*
plot_stem	*text*
start_chainage	*chainage*
end_chainage	*chainage*
sheet_size	*text* or *"width height"*
scale	*value*
absolute_extensions	*yes/no*
left_extension	*world-units*
right_extension	*world-units*
line_up_cl	*yes/no*
primary_string	*yes/no*
label_type	*yes/no*
box_colour	*colour*
text_size	*mm*
sort_sections	*yes/no*
use_title_file	*yes/no*
title_file	*filename*
plot_border	*yes/no*
title_1	*text*
title_2	*text*
title_text_size	*value*
title_colour	*colour*
global_textstyle	*textstyle*

Please continue to the next section 44.2.15 Generating Cross Section Plots Without a View.

44.2.15 Generating Cross Section Plots Without a View

The cross section plot parameters are comprehensive enough that it is possible to completely generate a cross section plot without referencing a section view, or even using the **section X plot** panel.

Such a ppf can be run using the **plots=>plot a ppf** option or from the 4D Solutions programming language, 4DL.

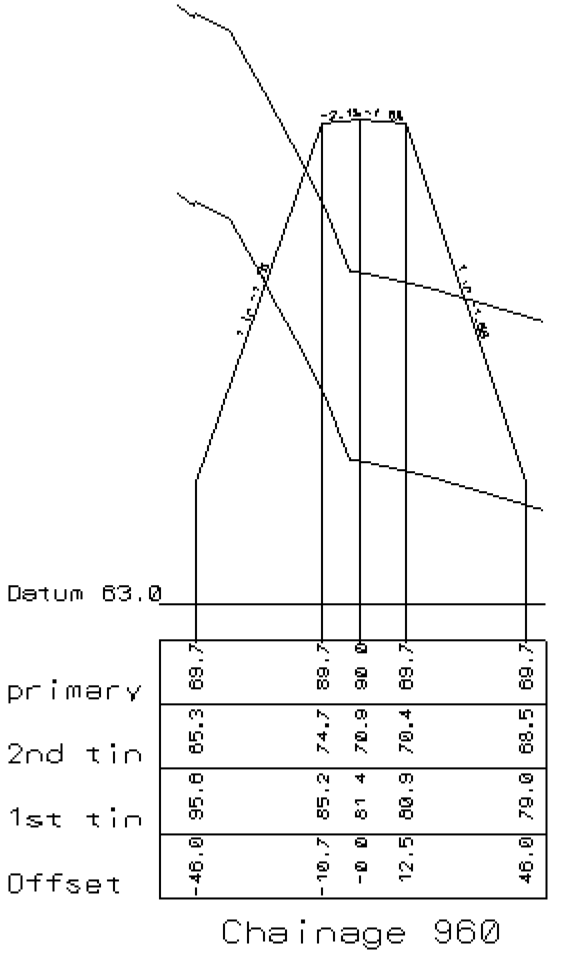
When generating a cross section plot using the **section X plot** panel, a plot parameter file containing all the parameters needed to regenerate the plot using **plots=>plot a ppf** can be written out by simply giving a name for the ppf file in the **plot parameters write** field of the **section X plot** panel.

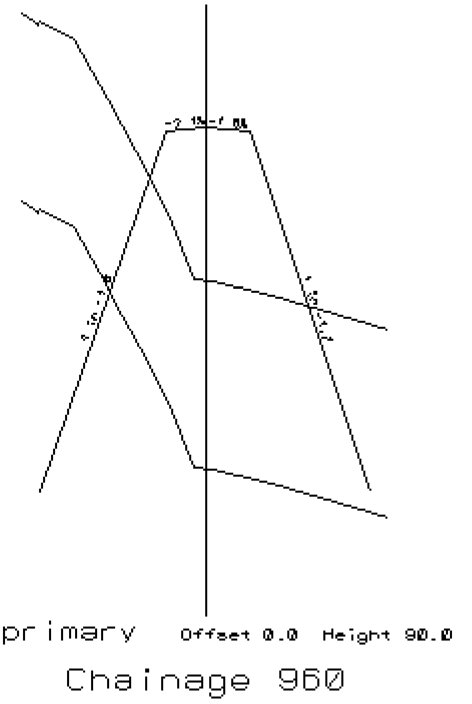
Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section 44.2.16 Example of a Cross Section Plot Parameter File.

44.2.16 Example of a Cross Section Plot Parameter File





// ppf file to generate x-section example

```
section_x_plot "plot 2" {

Please continue to the next section 44.3 Long Section Plot Parameter File.

44.3 Long Section Plot Parameter File

The long section plot parameters are placed in a file with ending **.ppf**

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the long section plot is enclosed within a set of curly brackets **{ }** with the header

section_long_plot "plot set name"

before the curly brackets.

That is,

```
section_long_plot   "plot set name"   {
            plot parameters
            one per line
}
```

If there is more than one section_long_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_x_plot in the same file. The other sets will be ignored when doing a long section plot.

The plot parameters are documented in following groups:

Defining chainage range	44.3.1 Possible Chainage Range.
Breaking the plot into pages	44.3.2 Pagination.
Plot Sheet layout	44.3.3 Plot Sheet Layout.
Boxes area	44.3.4 Boxes Area.
Defining chainages and staggering	44.3.5 Chainage Selection and Staggering.
Defining uprights	44.3.6 Uprights.
Datum area	44.3.7 Datum Area.
Graph (drawing)	44.3.8 Graph Area.
Defining bubbles	44.3.9 Bubbles Definitions.
Quick HG	44.3.10 Quick Horizontal Geometry Labelling.
Extensive HG	44.3.11 Extensive Horizontal Geometry Labelling.
Quick VG	44.3.12 Quick Vertical Geometry Labelling.
Extensive VG,	44.3.13 Extensive Vertical Geometry Labelling.
Labelling heights	44.3.14 Labelling Chainages and Heights in the Graph Area.
Symbols	44.3.15 Labelling With Symbols.
Hatching cut/fill	44.3.16 Hatching Cut and Fill Areas.
Labelling cuts	44.3.17 Labelling Cuts of Design Through Strings in a Model.
Labelling string name	44.3.18 Labelling the Primary String Name on the Plot.
Labelling with scale	44.3.19 Labelling the Scale on the Plot.
Title block information	44.3.20 Title Block Information.
Panel modifying parameters	44.3.21 Parameters that Modify Fields In the Long Plot Panel.
Example	44.3.23 Example of a Long Section Plot Parameter File.

44.3.1 Possible Chainage Range

In the panel, the field **Use HG VG for min, max** determines whether the horizontal geometry (HG) and the vertical geometry (VG) are both used to determine the minimum and maximum chainages for drawing. This allows the vertical geometry to be plotted when it is outside the horizontal geometry (e.g. kerb returns).

The equivalent parameter in the ppf is

use_vg_hg_for_min_max	***1***	// the chainage range available for plotting
		// is from the minimum of the horizontal
		// geometry (HG) and the vertical geometry
		// (VG) to the maximum of the HG and VG.
		// This is useful for kerb returns

	0	// the chainage range available for
		// plotting is from the minimum of the
		// horizontal geometry (HG) to the
		// maximum of the HG.

44.3.2 Pagination

If the long section plot is too long to fit on one page, it can be broken into a number of pages (sheets).

The parameter, *pagination_length*, controls the amount of new chainage length on each plot page. Each page of the long section plot can also included a set chainage amount from the end of the **previous** plot.

Hence apart from the first page and possibly the last page, the plot will have a chainage length given by the sum of the *pagination_length* and *pagination_overlap*.

pagination	*yes/no*	// if yes, then break the plot into pages
pagination_mode	*chainage*	// length and overlap in chainage units
	*millimet*re	// length and overlap in millimetres
pagination_length	*chainage or*	
	millimetres	// new chainage range on each page
pagination_overlap	*chainage or*	
	millimetres	// overlap between pages

Note

The *pagination_length* and *pagination_overlap* are given in chainage units **or** millimetres.The user must choose values which will fit on the selected sheet size or the end of each plot will be truncated by the sheet.

44.3.3 Plot Sheet Layout

The plot **page** or **sheet** is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

sheet_size	*text*	// sheet name, or
	"mm mm"	// sheet size: width height

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable

SHEET_SIZES_4D	*file*	// file of plotter sheets sizes

The plotting area is restricted to within the plot sheet by giving margins which are:

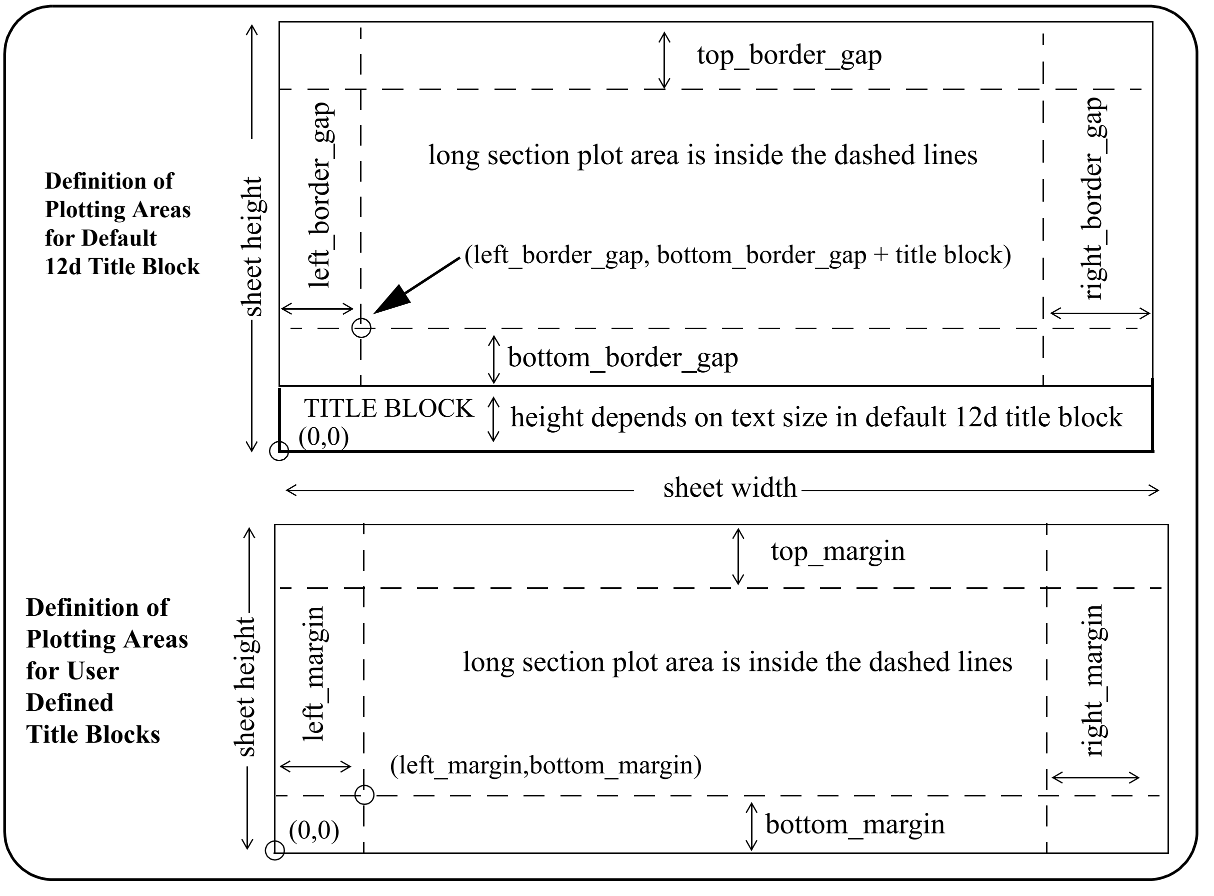
If a *User Defined Title Block* is used:

left_margin	*mm*
right_margin	*mm*
top_margin	*mm*
bottom_margin	*mm*

If the *default 12d title block* is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the *bottom_border_gap* is added to the calculated height of the bottom of the title block.

left_border_gap	*mm*
right_border_gap	*mm*
top_border_gap	*mm*
bottom_border_gap	*mm*

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margins and gap parameters can exist in the one plot parameter file.



The long plot itself consists of the three regions - boxes, datum and graph areas.

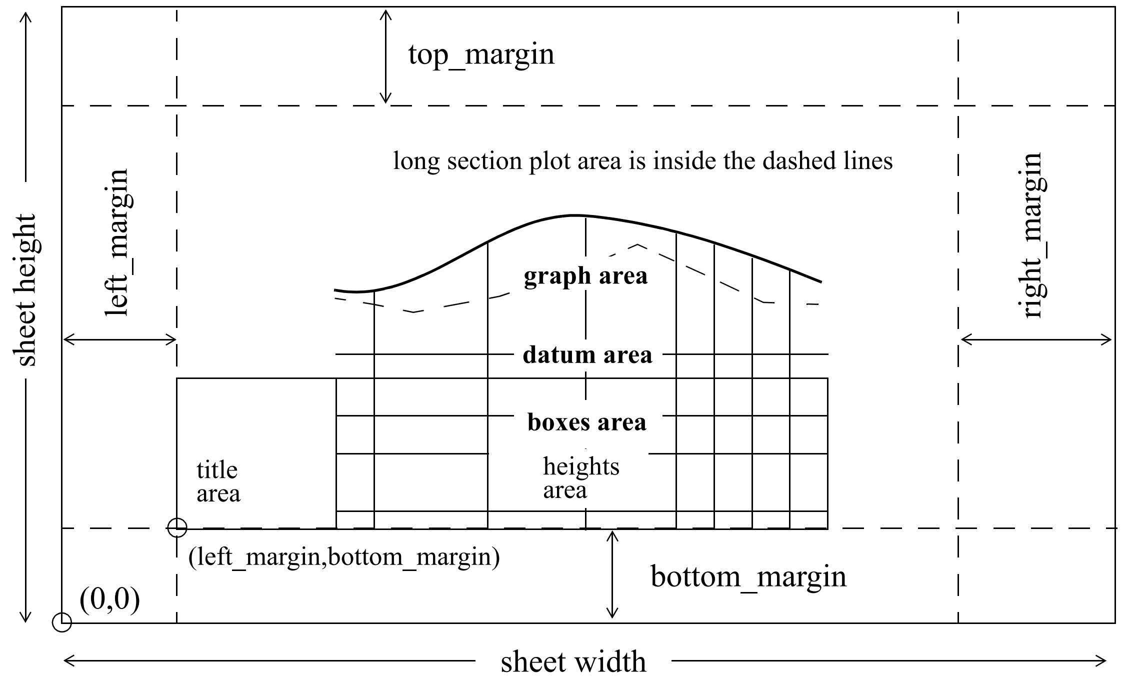
The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

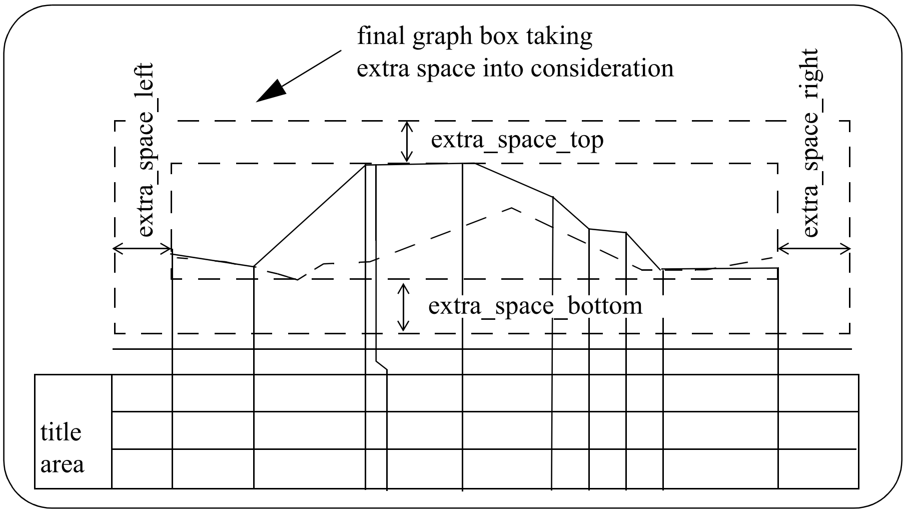
Apart from information labelled in the boxes area, the long section plot can label other information such as

(a) horizontal geometry
(b) vertical geometry
(c) chainage, heights at special points
(d) symbols at special points
(e) bubbles at special chainages
(f) cuts the design string makes through strings
(g) cut and fill areas



The size of the graph area can also be extended to allow for plot symbols by the parameters:

extra_space_units	***0***	// extra space values are world units - default
	1	// " " " are millimetres on plot page
extra_space_left	*units*	// subtract from left of plot area, def 0
extra_space_right	*units*	// add to right of plot area, default 0
extra_space_top	*units*	// add to top of plot area, default 0
extra_space_bottom	*units*	// subtract from bottom of plot area, // default 0



Please continue to the next section 44.3.4 Boxes Area.

44.3.4 Boxes Area

Each string in the long section plot can be labelled with one or two lines of title, and the chainages/heights/depths at the user specified chainages for the strings.

The **title** for the strings, is drawn in the **title area** of the **boxes area**.

The **chainages/heights/depths** are drawn in the **heights area** of the **boxes area**.

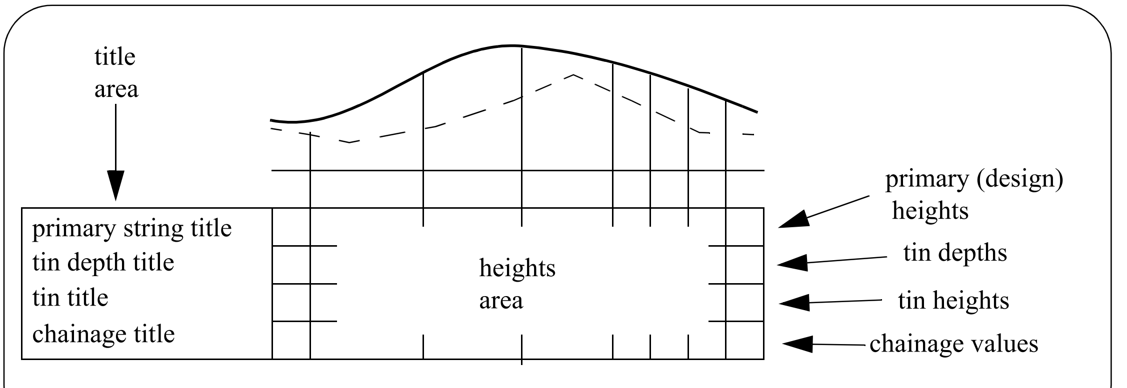
Consequently the boxes area is made up of rows of text consisting of:

string/tin titles followed by the **chainage/height/depth** values along the string.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is

(a) optional super-elevation diagram
(b) chainage values
(c) can be primary string heights - user choice
(d) tin heights and depths
(e) offset heights and depths
(f) optional volumes or earth works
(g) can be primary string heights - user choice
(h) zero or more blank boxes



boxes for long section plot

The blank boxes are used to place other information in (such as horizontal or vertical geometry) or for other user supplied information.

Placing the primary string label before the bank boxes or just after the chainage box in controlled by the parameter *primary_label_mode*.

number_of_blank_boxes	*integer*	// integer > 0
primary_label_mode	0	//put primary string labels in last box // before blank boxes
	1	// or first box above the chainages

Although the order of the boxes may appear to be fixed, in practice they can be in any order. This is possible because for each box, there is a parameter to set the height in millimetres from the bottom of all the boxes that the text in the box is drawn at (the *_y_pos* parameters).

The **title area** starts at the co-ordinate (left_margin,bottom_margin).

The size of the title text is given by the ***title_box_text_size*** parameter.

The **width** of the title area is either given by the *space_for_titles* parameter, or if omitted, the required width is automatically calculated.

title_box_text_size	*mm*	// size of the title text for boxes
space_for_titles	*mm*	// calculated if omitted

There can be two lines of title text and the title text, textstyle and colour can be set independently for each box.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

box_titles_x	*mm*	// distance to move the title text from the // left hand side of the boxes

The y position of the title text can be set separately for each type of title. The parameters are given later under each of the title types (e.g. chainages, primary string, tins, depths etc.).

After the title area there can be a user defined gap, followed by the heights area

box_gap	*mm*	// blank area between the title area // and the heights area default 0

The **heights area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (*box_text_justification*).

The number of decimal places (*number_of_decimals*), and the size of the heights text (*box_text_size*) can be specified globally but there is a parameter for each box which overrides these defaults for each box of heights.

box_text_justification	0 1	// bottom of individual boxes // top of individual boxes

number_of_decimals	*integer*	// number of decimal places in the
		// height boxes. If <0, the absolute value
		// is taken as the number of decimal
		// places i.e. no trailing zeros are
		// removed for the values in the heights
		// area.

box_text_size	*mm*	// size of the height text values

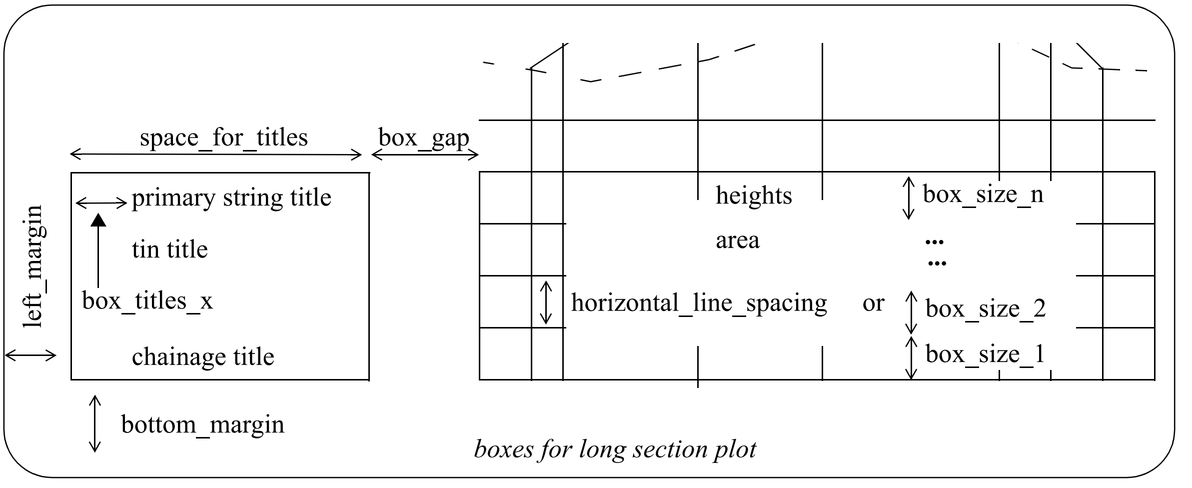
A global height for the individual boxes is either given by the *horizontal_line_spacing* parameter, or if omitted, a height to fit the largest height or depth value is calculated and used as the default box height.

horizontal_line_spacing	*mm*	// calculated if omitted

However, the height of each box can be individually set by parameters *box_size_n* where the boxing numbering, n. starts from the bottom box. The value of *horizontal_line_spacing* is used for any of the *box_size_n* parameters not specified.

box_size_n	*mm*	// height of the nth box, numbered from // bottom up.

The total height of the boxes area is simply given by the sum of the heights of each box.



The **width** of the **heights area** is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the **title area** plus box_gap, plus the width of the **heights area**.

Many distance definitions in the plot parameter file are given in terms of distance above the **top** of the boxes area so that the distances are independent of the number of boxes and box sizes.

The drawing of the box line work, the box colour, the position of the primary string labels and the number of blank boxes are all set by parameters.

First, all the line work for the box itself is user defined. This has been extended from V3.1 although *draw_box_mode* has been left in for upward compatibility.

draw_box_mode	*0*	// don't draw box lines
	1	// draw box lines around heights area // only
	2	// draw box lines around title and // heights areas

	3	// use draw_box_side_n,
		// box_line_draw_mode and
		// box_line_mode_n

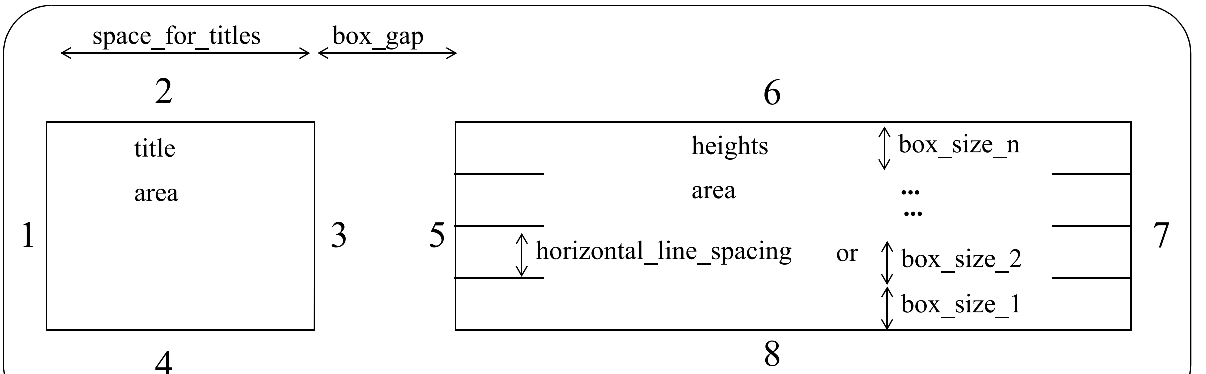
box_colour	*colour*	// colour of the boxes

For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters *draw_box_side_n* and *box_side_colour_n*, and the separation lines inside the boxes are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n* where the box numbering, n, starts from the bottom box.

Note: The following parameters are only used if ***draw_box_mode*** is set to **3**.

draw_box_side_1	***1***	// draw the left side of the title area (def)
	0	// don't draw the left side
box_side_colour_1	*colour*	// colour to draw left side of title area // default box_colour
draw_box_side_2	***1***	// draw top of the title area (default)
	0	// don't draw the top
box_side_colour_2	*colour*	// colour to draw top of title area // default box_colour
draw_box_side_3	*1*	// draw right side of the title area

		// (default if box_gap is non-zero)
	0	// don't draw the right side
		// (default if box_gap is zero)
box_side_colour_3	*colour*	// colour to draw right side of title area
		// default box_colour
draw_box_side_4	***1***	// draw bottom of the title area (default)
	0	// don't draw the bottom
box_side_colour_4	*colour*	// colour to draw bottom of title area
		// default box_colour
draw_box_side_5	***1***	// draw left side of the heights area (def)
	0	// don't draw the left side
box_side_colour_5	*colour*	// colour to draw left side of heights area
		// default box_colour
draw_box_side_6	***1***	// draw top of the heights area (default)
	0	// don't draw the top
box_side_colour_6	*colour*	// colour to draw top of heights area
		// default box_colour
draw_box_side_7	***1***	// draw right side of the heights area def
	0	// don't draw the right side
box_side_colour_7	*colour*	// colour for right side of heights area
		// default box_colour
draw_box_side_8	***1***	// draw bottom of the heights area (def)
	0	// don't draw the bottom
box_side_colour_8	*colour*	// colour for bottom of heights area
		// default box_colour



lines to draw for draw_box_side_1 to draw_box_side_8

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters *box_line_draw_mode* and *box_line_mode_n*.

The separation lines can be drawn in just the title area, just the heights area or in both areas.

The parameter *box_line_draw_mode* can be set to control all the separation lines but there are additional parameters, *box_line_mode_n*, which override *box_line_draw_mode* for each of the individual boxes where n = 1, ... number of boxes -1.

The top of the top box is not controlled by box_line_mode_n but is controlled by the parameters *draw_box_side_2* and *draw_box_side_6.*

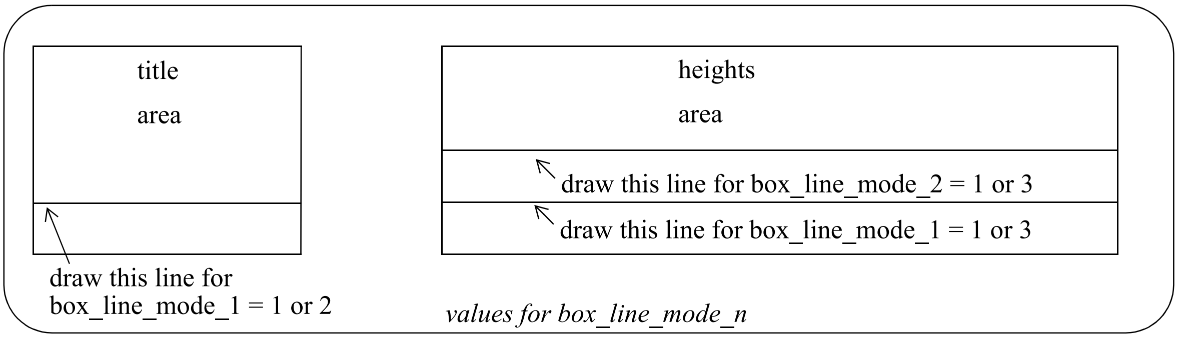
box_line_draw_mode	*0*	// don't draw any separation lines inside
		// the title and heights areas
	1	// draw the separation lines inside the
		// title and heights areas (default)
	2	// draw the separation lines inside the
		// title area only

	3	// draw the separation lines inside the // heights area only

box_line_mode_n	*0*	// for the nth box, don't draw any
		// line at the top of the box for either
		// the title or the heights areas

	1	// for the nth box, draw the line at the
		// top of the box for both the
		// title and heights areas

	2	// for the nth box, draw the line at the // top of the box for the title area only
	3	// for the nth box, draw the line at the // top of the box for the heights area only



Chainage Titles and Values

The chainages are always labelled

chainage_title	*text*	// first line of chainage title // (default chainages)
chainage_title_2	*text*	// second line of chainage title
chainage_title_textstyle	*textstyle*	// textstyle of the chainage titles
chainage_title_colour	*colour*	// default chainage title colour
chainage_title_size	*mm*	// default chainage title size

chainage_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// chainage title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the chainage.

chainage_decimals	*integer*	// number of decim places for chainages
chainage_textstyle	*textstyle*	// textstyle of the chainage values
chainage_colour	colour	// colour of chainages, def is box_colour
chainage_size	mm	// size of chainages, def is box_text_size

chainage_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// chainage values text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the chainage.

Example of Chainage Titles

chainage_title	"DESIGN"
chainage_title_2	"CHAINAGE"

chainage_title_colour	“yellow”	
chainage_colour	“grey”	// colour of chainage text
chainage_decimals	-3	// 3 decimal places - leave trailing zeros

Primary String Title and Heights

Sometimes the primary string is only required to define chainages or the horizontal path for tin sections. In this case, the primary string would not be drawn on the long section plot.

If the primary string is drawn, it is automatically labelled.

Also the drawing of crosses at the vertical intersection points can be controlled from the ppf file.

primary_draw_vips	***1***	// draw crosses at VIPS (default)
	0	// don’t draw VIP crosses

The position of the primary string label box can be either straight after the chainage box, or after the tin and offset boxes but before the blank boxes.

primary_string	*yes*	// draw and label the primary string
	no	// don't draw or label the primary string
primary_label_mode	*0*	// last box before blank boxes
	1	// first box above the chainages
primary_title	*text*	// first line of string title
primary_title_2	*text*	// second line of string title, default is // the primary string name.
primary_title_textstyle	*textstyle*	// textstyle of the primary string titles
primary_title_colour	*colour*	// colour of the string titles
primary_title_size	*mm*	// default primary title size
primary_title_y_pos	*mm*	// if set, the height in mm above the // bottom of all the boxes that the // primary string title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the primary string.
primary_decimals	*integer*	// number of decimal places
primary_textstyle	*textstyle*	// textstyle of the primary string heights
primary_colour	*colour*	// colour of the heights
primary_size	*mm*	// default primary value size
primary_y_pos	*mm*	// if set, the height in mm above the // bottom of all the boxes that the // primary string height text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the primary string.
primary_ch_tolerance	*mm*	*// for a given chainage, if no z value exists, // this distance is added to/subtracted from the // chainage to search for a valid z value.*

Example of Primary String Titles

primary_title	“DESIGN”	
primary_title_2	“CENTRELINE”	
primary_title_colour	“yellow”	
primary_colour	“grey”	// colour of height text
primary_decimals	-2	// 2 decimal places - leave trailing zeros

Tin Titles and Heights

A section along the primary string through each tin on the section view can be automatically drawn on the long plot, and the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that the tins were added to the view however it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use **any tin** in the project **to labe**l a row, **not just those drawn** on the section view.

The parameter to define the nth tin by name is *tin_n_name*:

```
tin_n_name          text          // n=1, ... no of tins on the section view.
                                  // use the tin named text to label the nth
                                  // row of tin heights and depths.
```

If a tin of the name ***tin_n_name*** **does** not exist, then the plot is not produced and an error message is given.

For the following parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth tin on the section view, or if *tin_n_name* is set, for the tin specified by *tin_n_name*.

```
tin_n_draw_mode              1            // draw the nth tin (default)
                             0            // don't draw the nth tin
tin_n_draw_colour            colour       // colour to draw the nth tin.
                                          // If omitted, then use the tin colour
tin_n_label                  1            //label the tin's heights (default)
                             0            // don't label the tin's heights

tin_n_title                  text         // first line of tin title
tin_n_title_2                text         // second line of tin title
tin_n_title_textstyle        textstyle    // textstyle of the tin titles
tin_n_title_colour           colour       // colour for titles of heights
tin_n_title_size             mm           // default nth tin's title size
tin_n_title_y_pos            mm           // if set, the height in mm above the
                                          // bottom of all the boxes that the
                                          // tin title text is drawn.
                                          // If not set, then the text is placed at a
                                          // height that puts it inside the default

                                          // box for the tin depths.
```

Offset Model Titles and Heights

For 12d Model V3.2, Each string in the offset model given in the **section long plot** panel can be automatically projected onto the primary string and drawn on the long section plot.

For **12d Model V4.0**, the idea of an offset model has been modified to allow strings to be projected onto the primary string to be specified by model and name, rather than just projecting all the strings in a given model. The string can also be labelled with either the string name, its model name or both.

The string is specified by

```
offset_n_mask               "model_name->string_name"
```

For each n, a set of plot parameters determine if the string's heights and/or depths from the primary string are labelled in the boxes area.

If only the *string_name* is given, then the model given in the **Offset model** field of the **Section Long Plot** panel.

If there is **more than one string** with the given model and name, then it will be considered to be one string and at any primary string chainage, the closest of the strings will be the part used for projecting. For example, strings of the same name on either side of a road intersection will be considered to be the one string for projecting.

If any *offset_n_mask* is used, then the Offset option expects all the strings to be specified by an offset_n_mask. Then if no mask exists for any value of n, then that parameter set is ignored and no string projected.

If no offset masks are used (that is, no *offset_n_mask*'s are used), then the Offset option works as it did in 12d Model V3.0. That is, plot parameters determine whether each string in the offset model is drawn, and if the string's heights and depths from the primary string are labelled in the boxes area. The order that the strings are then plotted and labelled is the same as the order of the strings in the Offset model.

For the following sets of parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth string given by *offset_n_mask* or, if no offset masks are given, the nth string in the *Offset model*.

```
offset_n_mask               "model_name->string_name"

offset_n_draw_mode          1             // draw the nth offset string (default)
```

	0	// don't draw the nth offset string

offset_n_lw	*value*	// default 1000. Distance to search to the left
		// of the primary string for the offset string.
		// If 0, don't search to the left.

offset_n_rw	*value*	// default 1000. Distance to search to the right
		// of the primary string for the offset string.
		// If 0, don't search to the right.

offset_n_draw_colour	*colour*	// colour to draw the nth offset string. // If omitted, then use the string colour
offset_n_label	*1*	//label the string's heights (default)
	0	// don't label the string's heights

The default title for each set each parameter set, is the string name but this can be changed to just the model name or the model and string name:

offset_title_mode	*0*	// label with string name (default)
	1	// label with model name
	2	// label with model->string as name

or, for any set, the *offset_title_mode* can be replaced by two lines of user defined title:

offset_n_title	*text*	// first line of title
offset_n_title_2	*text*	// second line of title
offset_n_title_textstyle	*textstyle*	// textstyle of the offset titles

The rest of the parameters for the set are:

offset_n_title_colour	*colour*	// colour for titles of heights
offset_n_title_size	*size*	// colour for titles of heights

offset_n_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// offset title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the offset heights.

offset_n_decimals	*integer*	// number of dec places in offset height
offset_n_textstyle	*textstyle*	// textstyle of the offset heights
offset_n_colour	*colour*	// colour for heights
offset_n_size	*size*	// size for heights

offset_n_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// offset height text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the offset heights.

offset_n_depth_label	1/0	// 1 to label, 0 don't label depths
offset_n_depth_title	*text*	// first line of offset depth title
offset_n_depth_title_2	*text*	// second line of offset depth title
offset_n_depth_title_textstyle	*textstyle*	// textstyle of the offset depth titles
offset_n_depth_title_colour	*colour*	// colour for titles of depths
offset_n_depth_title_size	*mm*	// size for titles of depths

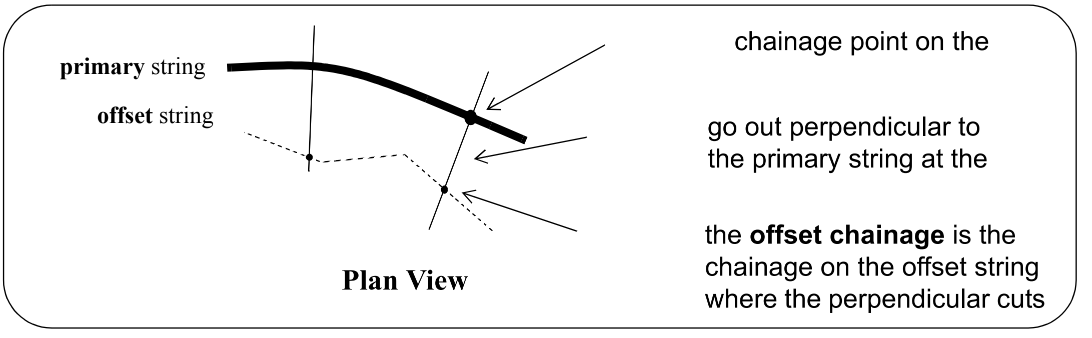
offset_n_depth_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// offset depth title text is drawn.
		// If not set, then the text is placed at a

		// height that puts it inside the default
		// box for the offset depths.
offset_n_depth_decimals	*integer*	// number of dec places in offset depth
offset_n_depth_textstyle	*textstyle*	// textstyle of the offset depths
offset_n_depth_colour	*colour*	// colour for depths
offset_n_size	*size*	// size for depths
offset_n_depth_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// offset depth text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the offset depths.

Chainages of Offset Strings - Offset Chainages

For a string other than the primary string, it is possible to label the chainages that are obtained *from the other string* by going out perpendicular to the primary string at a chainage, cutting the other string and then calculating the *chainage from the other string* at the cut point.

The other string is known as an ***offset*** string and the chainage from the offset string corresponding to a primary chainage is called the *offset chainage*.



Up to twenty sets of offset chainages can be labelled - each is defined by its own set of parameters:

Note no box is automatically created for the offset chainages. An empty box must be defined and the appropriate values set for *chainage_n_title_y_pos* and *chainage_n_y_pos*

chainage_n_offset_mode	*tick box*	// *if ticked, use nth offset string* for calculations
chainage_n_offset_string	"*model_name->string_name*"	// string to calculate offset chainages for
chainage_n_title	*text*	// first line of offset chainage title
chainage_n_title_2	*text*	// second line of offset chainage title
chainage_n_title_textstyle	*textstyle*	// textstyle of the offset chainage titles
chainage_n_title_colour	*colour*	// offset chainage title colour
chainage_n_title_size	*mm*	// offset chainage title size

chainage_n_title_y_pos	*mm*	// the height in mm above the
		// bottom of all the boxes that the
		// offset chainage title text is drawn.

chainage_n_decimals	*integer*	// number of decim places for offset chainages
chainage_n_textstyle	*textstyle*	// textstyle of the offset chainage values
chainage_n_colour	colour	// colour of offset chainages
chainage_n_size	mm	// size of offset chainages

chainage_n_y_pos	*mm*	// the height in mm above the
		// bottom of all the boxes that the
		// chainage values text is drawn.

Example of Offset Chainage and Titles

chainage_1__offset_string	“Design->RKERB”	
chainage_1__title	“RIGHT KERB”	
chainage_1_title_2	“CHAINAGE”	
chainage_1_title_colour	“yellow”	
chainage_1_colour	“grey”	// colour of offset chainage text
chainage_1_decimals	-3	// 3 decimal places - leave trailing zeros

Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin or to a string from the offset model, at a particular chainage is defined as

depth = tin height value - height of the primary string

or

depth = offset string height value - height of the primary string

That is, the depth that the primary string is **below** the tin or a string from the offset model.

Before plotting, the value of depth is multiplied by either the *depth_positive_factor* or *depth_negative_factor*.

if (depth >= 0) plotted_depth_value = depth * depth_positive_factor

if (depth < 0) plotted_depth_value = depth * depth_negative_factor

Hence the definition of depth can be modified by the parameters:

```
depth_positive_factor    value    // multiplier for positive depths
depth_negative_factor    value    // multiplier for negative depths
```

For example, if the opposite sign is required for depth, that is,

depth = height of the primary string - tin/offset string height value

simply set

```
depth_positive_factor    -1
depth_negative_factor    -1
```

Super-Elevation Diagram

The optional *super-elevation diagram* draws the values of the cross-fall (x-fall) between two strings using the primary string as the reference string. The cross-fall at a given chainage on the primary string is calculated by sectioning perpendicular to the reference string at that chainage and cutting the two strings. The cross-fall is defined as the cross-fall between the two cuts points on the strings.

The diagram has levels for the cross fall for a pair of strings on the left of the primary string, and a pair of strings on the right of the primary string. The diagram also has uprights in the super-elevation box with chainage values at the change of super values.

For the left hand side, the cross-fall is calculated at right angles to the primary string between the user given left hinge string and the left edge string.

There are plot parameters to control all aspects of the super diagram.

super_draw_mode	*0*	// default, don't draw a super diagram
	1	// draw super using *super_sample_interva*l
	2	// sample super using chainages of x-sections
	3	// sample super using chainages from a string
super_sample_interval	*value*	// if super_draw_mode = 1, default 20
		// chainage distance to sample x-fall
super_sample_name	*model_name*	// if super_draw_mode = 2
	model_name->string_name	// if super_draw_mode = 3
super_tolerance	*value*	// If super_draw_mode is 1, the change
		// of super is greater than super_tolerance,
		// draw uprights
super_title	*text*	// first line of super title
		// def *Super elevation*
super_title_textstyle	*textstyle*	// textstyle of the super titles
super_title_colour	*colour*	// super title colour, def box_colour
super_title_size	*mm*	// super title size, def label_text_size
super_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// super title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the super.
super_xfall_textstyle	*textstyle*	// textstyle of the super x-fall labels
super_xfall_colour	*colour*	// super x-fall colour, def box_colour

Volume Cut and Fill Values

The values of calculated cut and fill volumes (cut and fill earth works) can be read from a file and then interpolated to produce cut and fill volumes for a given interval along the primary string.

There are plot parameters to control all aspects of the volume diagram.

volume_draw_mode	*0*	// default, don't draw a volume diagram
	1	// draw a volume diagram
volume_text_centre_mode	*0*	// default, the text of cut and fill are labelled // along the uprights
	1	// the text are centred in between the uprights
volume_sample_interval	*value*	// interval to display volumes, default 20
volume_file_name	*file_name*	// the volumes report file
volume_y_pos	*mm*	// if set, the volume box is positioned at this // height from the bottom of the first box
volume_box_size	mm	// if set, the uprights and volume and titles // are plotted in accordance with this heights
volume_title	*text*	// first line of volume title // default *Earthworks*
volume_title_textstyle	*textstyle*	// textstyle of the volume titles
volume_title_colour	*colour*	// volume title colour, def box_colour
volume_title_size	*mm*	// volume title size, def label_text_size

volume_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// volume title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the volumes.

volume_cut_title	*text*	// first line of volume sub title // default *cut*
volume_cut_title_textstyle	*textstyle*	// textstyle of the cut volume titles
volume_cut_title_colour	*colour*	// cut volume title colour, def box_colour
volume_cut_title_size	*mm*	// cut volume title size, def label_text_size

volume_cut_title_y	*mm*	// if set, the height in mm above the
		// default position.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the cut volumes.

volume_fill_title	*text*	// first line of volume sub title // default *fill*
volume_fill_title_textstyle	*textstyle*	// textstyle of the fill volume titles
volume_fill_title_colour	*colour*	// fill volume title colour, def box_colour
volume_fill_title_size	*mm*	// fill volume title size, def label_text_size

volume_fill_title_y	*mm*	// if set, the height in mm above the
		// default position.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the fill volumes.

volume_cut_textstyle	*textstyle*	// textstyle of the cut values
volume_cut_text_colour	*colour*	// cut value colour, def box_colour
volume_cut_text_size	*mm*	// cut value size, def label_text_size

volume_cut_text_x	*mm*	// the x distance to move the cut text from the
		// default cut text position, def 0, it is not used
		// if volume_text_centre_mode=1

volume_cut_text_y	*mm*	// the y distance to move the cut text from the // default cut text position, def 0
volume_cut_decimals	*integer*	// number decimal places in cut values //def number_of_decimals

volume_fill_textstyle	*textstyle*	// textstyle of the fill values
volume_fill_text_colour	*colour*	// fill value colour, def box_colour
volume_fill_text_size	*mm*	// fill value size, def label_text_size

volume_fill_text_x	*mm*	// the x distance to move the fill text from the
		// default fill text position, def 0, it is not used
		// if volume_text_centre_mode=1

volume_fill_text_y	*mm*	// the y distance to move the fill text from the // default fill text position, def 0
volume_fill_decimals	*integer*	// number decimal places in fill values //def number_of_decimals
volume_cl_linestyle	*linestyle*	// linestyle of horizontal cut/fill dividing line
volume_cl_line_colour	*colour*	// colour of horizontal cut/fill dividing line
volume_uprights_draw_mode	*0*	// default, don't draw cut/fill uprights
	1	// draw cut/fill uprights
volume_uprights_line_colour	*colour*	// colour of uprights
volume_sub_upright_colour	*colour*	// colour of sub uprights line
volume_sub_uprights_x	*mm*	// the distance to move from the default // sub uprights position, def 0
volume_sub_title_x	*mm*	// the distance to move the sub title text // from the volume sub uprights

            volume_cut_text_y                 5
//          volume_cut_text_x
            volume_cut_decimals               0
            volume_fill_text_size             3
//          volume_fill_text_colour
//          volume_fill_textstyle
            volume_fill_text_y                245
//          volume_fill_text_x
            volume_fill_decimals              0

            volume_cl_linestyle               "PHANTOM"
            volume_cl_line_colour             red

            volume_uprights_draw_mode         1
            volume_uprights_line_colour       "purple"

            volume_sub_upright_colour         23
            volume_sub_uprights_x             10

            volume_sub_title_x                3
```

X,Y Values

The values of the X and Y coordinate for selected chainages can be labelled as separate boxes. The chainages specified are limited to the base set of chainages already defined in the chainage selection and staggering section. i.e. an upright must exist for the X and Y value to be labelled. Not all of the uprights have to be labelled, just those specified in this section.

There are plot parameters to control all aspects of the X and Y labelling.

Chainages are used for positioning X and Y labels.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

xy_order	0	// 0 = X on bottom, Y on top
	1	// 1 = Y on bottom, X on top
xy_chord_arc	0	// don't use chord/arc chainages
	1	// include chainages for chord/arc
xy_start_chainage	*value*	// start chainage of labelling range
xy_end_chainage	*value*	// end chainage of labelling range
xy_interval	*value*	// regular interval (0 = no regulars)
xy_label_hcp	0/1	// 1 = include tangents, spirals
xy_label_hip	0/1	// 1 = include hip points
xy_label_vip	0/1	// 1 = include vip points
xy_label_vtp	0/1	// 1 = include tangent points
xy_label_crest	0/1	// 1 = include crest points
xy_label_sag	0/1	// 1 = include sag points
xy_label_grade_change	0/1	// 1 = include change of vertical grade
xy_special_n_file	*filename*	// n = 1 to 20 - include chainages from // the file (one chainage per line)
xy_label_tolerance	*value*	// > 0 use as weeding tolerance // <= 0, don't weed

For X parameters:

x_label	*0/1*	// 0 = Don't label X values/titles // 1 = Label X values/titles
x_title	*text*	// first line of X title // (default "Easting")
x_title_2	*text*	// second line of X title
x_title_textstyle	*textstyle*	// textstyle of the X titles
x_title_colour	*colour*	// default X title colour
x_title_size	*mm*	// default X title size

x_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// X title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the X.

x_label_decimals	*integer*	// number of decim places for X values
x_label_textstyle	*textstyle*	// textstyle of the X values
x_label_colour	colour	// colour of X values, def is box_colour
x_label_size	mm	// size of X values, def is box_text_size

x_label_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// X value text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the X value.

For Y parameters:

y_label	*0/1*	// 0 = Don't label Y values/titles // 1 = Label Y values/titles
y_title	*text*	// first line of Y title // (default "Easting")
y_title_2	*text*	// second line of Y title
y_title_textstyle	*textstyle*	// textstyle of the Y titles
y_title_colour	*colour*	// default Y title colour
y_title_size	*mm*	// default Y title size

y_title_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// Y title text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the Y.

y_label_decimals	*integer*	// number of decim places for Y values
y_label_textstyle	*textstyle*	// textstyle of the Y values
y_label_colour	colour	// colour of Y values, def is box_colour
y_label_size	mm	// size of Y values, def is box_text_size

y_label_y_pos	*mm*	// if set, the height in mm above the
		// bottom of all the boxes that the
		// Y value text is drawn.
		// If not set, then the text is placed at a
		// height that puts it inside the default
		// box for the Y value.

Please continue to the next section 44.3.5 Chainage Selection and Staggering.

44.3.5 Chainage Selection and Staggering

Chainages are used for positioning height labels, uprights (leader lines) and bubbles.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

chord_arc	0	// don't use chord/arc chainages
	1	// include chainages for chord/arc
chainage_interval	*value*	// regular interval (0 = no regulars)
chainage_label_ends	0/1	// 1 = include start and end chainages
chainage_label_hcp	0/1	// 1 = include tangents, spirals
chainage_label_hip	0/1	// 1 = include hip points
chainage_label_vip	0/1	// 1 = include vip points
chainage_label_vtp	0/1	// 1 = include tangent points
chainage_label_crest	0/1	// 1 = include crest points
chainage_label_sag	0/1	// 1 = include sag points
chainage_label_grade_change	0/1	// 1 = include change of vertical grade
chainage_special_n_file	*filename*	// n = 1 to 20 - include chainages from // the file (one chainage per line)
chainage_label_tolerance	*value*	// > 0 use as weeding tolerance // <= 0, don't weed
chainage_merge_bubbles	0/1	// 1 = merge in the bubble chainages
chainage_merge_tolerance	value	// > 0, weeding tol after bubble merge // <= 0, don't weed after merge

Default values

chainage_label_tolerance = 1.0 exp -4 (world units)
chainage_merge_tolerance = 1.0 exp -8 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a chainage special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a *//* is a comment.

If the real chainage position is used for the horizontal position of the chainage/height/depth text, text over writing can easily occur.

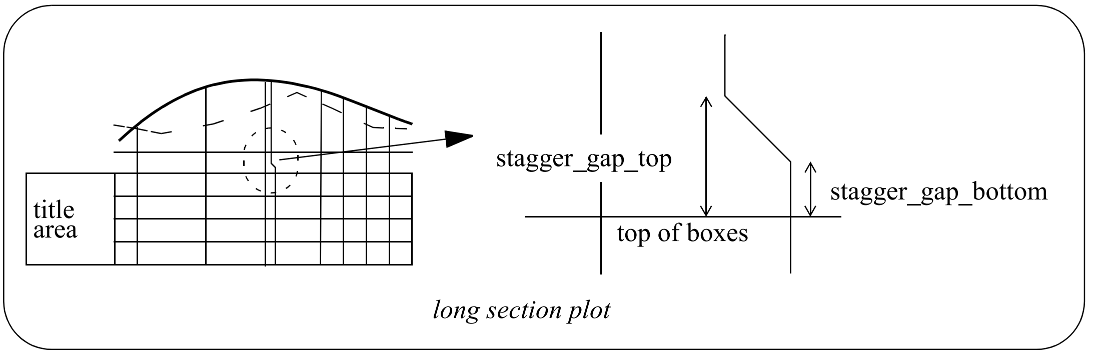
To prevent over writing, the text can be **staggered**.

If the ***stagger_mode*** parameter is set to 1, the text position is adjusted so that the text does not over write.

The real chainage position is then indicated by the chainage markers which are drawn at the top of the text boxes from the staggered text position back to the actual chainage position of the text.

stagger_mode	0	// no staggering, allow over writing
	1	// stagger text to prevent over writing
stagger_gap_top	*mm*	// distance from boxes to top of stagger
stagger_gap_bottom	*mm*	// distance from boxes to bottom of // stagger
stagger_gap_factor	*value*	// distance between staggers is // box_text_size * stagger_gap_factor

When staggering occurs, it is possible for the heights area to be longer than the graph area.



Please continue to the next section 44.3.6 Uprights.

44.3.6 Uprights

Uprights, or leader lines, can be drawn from the top of the staggers to the strings drawn on the plot.

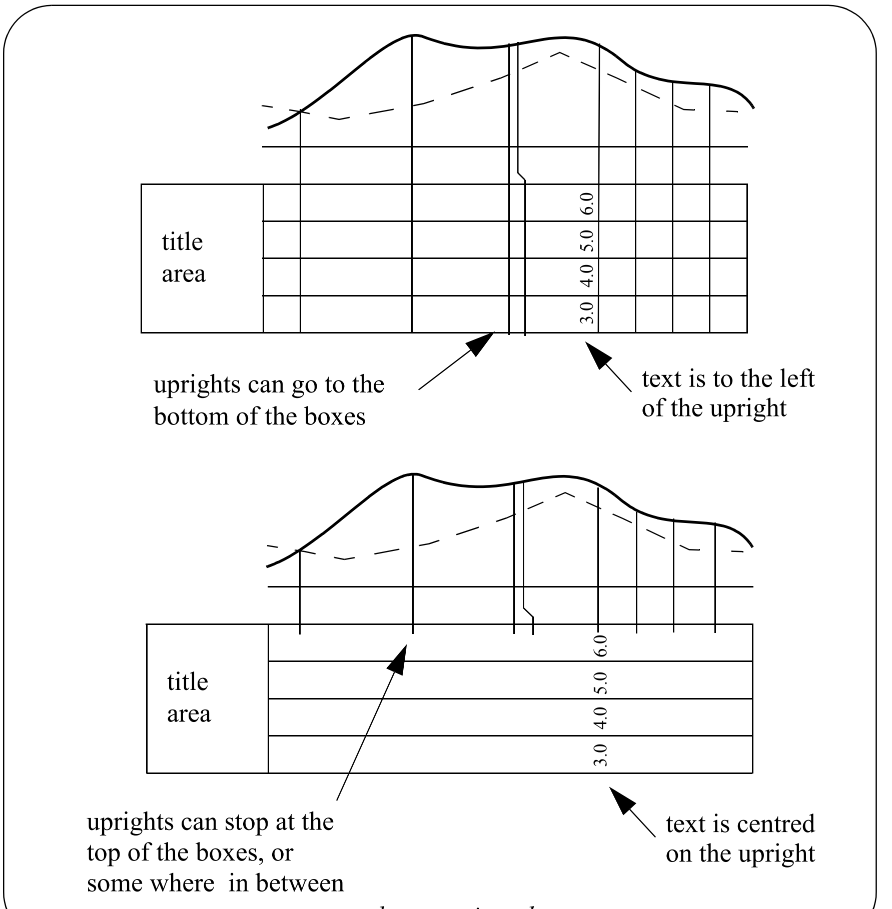
The height of the uprights is given by the uprights_draw_mode:

uprights_draw_mode	0	// none
	1	// to maximum string height at that // chainage
	2	// ticks, to stagger height
	3	// to uprights_y above the boxes
	100	// to the primary string
	101-500	// to tin1 or tin2 etc.
	501-900	// to offset1 or offset2 etc.
uprights_y	*mm*	// distance to draw the uprights for // mode 3
uprights_colour	*colour*	// uprights colour (default *boxes_colour*)

The uprights can go below the top of the boxes.

uprights_bottom_mode	*0*	// stop at top of boxes (default)
	1	// draw to bottom of boxes
	2	// draw to uprights_bottom_y below the // top of the boxes
	3	// draw to uprights_bottom_y above the // bottom of the boxes
	4	// ticks at chainage
uprights_bottom_y	*mm*	//distance
uprights_text_offset_factor	*value*	// move the text by this factor*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.



long section plot

Please continue to the next section 44.3.7 Datum Area.

44.3.7 Datum Area

The **datum area** is the region between the boxes area and the graph area.

The **datum line** is positioned the distance ***datum_below_gap*** above the top of the boxes area and the graph area is positioned the distance ***datum_above_gap*** above the datum line.

Hence the graph area is distance (datum_below_gap + datum_above_gap) above the top of the boxes area.

datum_above_gap	*mm*	// distance from datum line to the // bottom of the graph area
datum_below_gap	*mm*	// distance from datum line to the top of // the boxes
datum_linestyle	*linestyle*	// linestyle for datum line (default solid)

The *datum_below_gap* and *datum_above_gap* can be zero or positive.

A value for the datum can be specified by the parameter ***datum_value*** or if the *datum_value* is not set, a datum value is automatically calculated for the long section using a roundoff specified by the user (default 1.0).

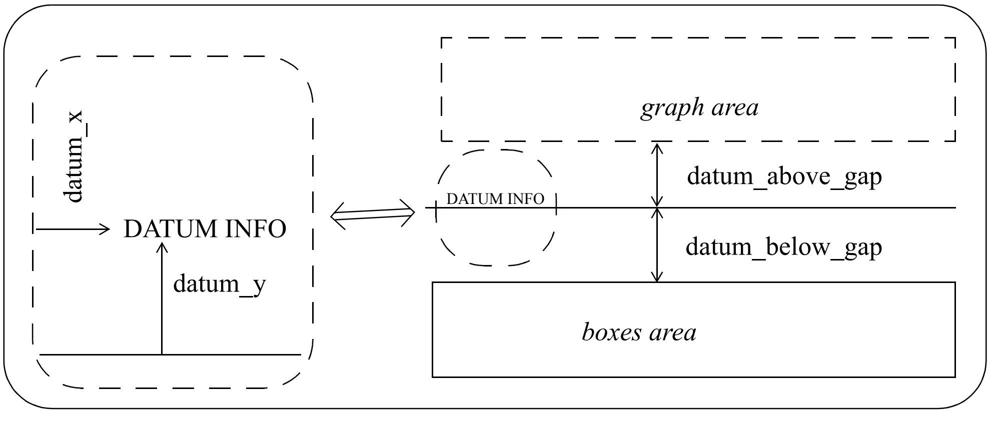
datum_value	*value*	// if set, the value to use for datum.
		//If not set, the datum is automatically
		// calculated (using datum_roundoff)

datum_roundoff	*1.0*	// value to roundoff the datum value to // e.g. 0.5, 0.2, 1.0 (default 1.0)

datum_decimals	*integer*	// number of decimal places to display
		// the datum value (default 1).
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If <0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

datum_name	*text*	// text to write before the datum value
datum_textstyle	*textstyle*	// textstyle for the datum text
datum_text_size	*mm*	// size of datum text and value
datum_colour	*colour*	// colour of the datum text and line
datum_x	*mm*	// distance to move the datum text // along the datum line

datum_y	*mm*	// distance to raise the datum text
		// above the datum line (used to be
		// called datum_offset)



Please continue to the next section 44.3.8 Graph Area.

44.3.8 Graph Area

The **graph area** is the area where the actual plots of the strings are drawn.

The string used to define the horizontal position and chainage of the plot is called the **primary string** and is either

(a) the string being profiled on the given section view
or

(b) the string given by the parameter

string_to_plot	*"model->string_name"*	// name of string to profile

When the primary string is being written out to a plot parameter file by 12d Model, a *string_to_plot* parameter and special parameters recording the internal id's for the string and it's model are all written out.

primary_model_id	*integer*	// internal ***12d Model*** parameter
primary_string_id	*integer*	// internal***12d Model*** parameter

The **length** of the graph area is determined by the length of the primary string being plotted (restricted to the specified start and end chainages) and the horizontal scale (scale) given by parameters or in the **section long plot** panel, and the vertical exaggeration given by the section view or a parameter.

view_name	*text*	// default is **section view** in panel.
vertical_exaggeration	*value*	// default is vertical exag for the view
scale	*value*	// 1:value - horizontal scale, default is
		// **scale 1:** in panel
start_chainage	*value*	// " " means use start of primary string
end_chainage	*value*	// " " means use end of primary string

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The **height** of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The types of strings that can be drawn in the graph area of a long section plot are:

(a) primary string — the string being profiled (usually the design string).

(b) tins — sections of the primary string through any tins either in models on the section view or in corridor models.

(c) offset strings — strings in the **offset model** that are projected back onto the primary string

(d) services — parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The **colour** of the strings in the plot is the actual string colour for cases (a), (c) and (d), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are labelled with heights and/or depths.

Primary String (Design String)

The primary string (the design string) is used to define

(a) the design long section

(b) the chainage positions for labelling heights and drawing uprights

(c) the section line used for sectioning through tins

(d) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the long section plot, it doesn't have to be drawn on the long section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter *primary_string* which was described earlier.

The **colour** of the primary string in the plot is the actual primary string colour.

Tins

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The **colour** and **linestyle** of the tin section in the plot is the actual tin colour and tin linestyle.

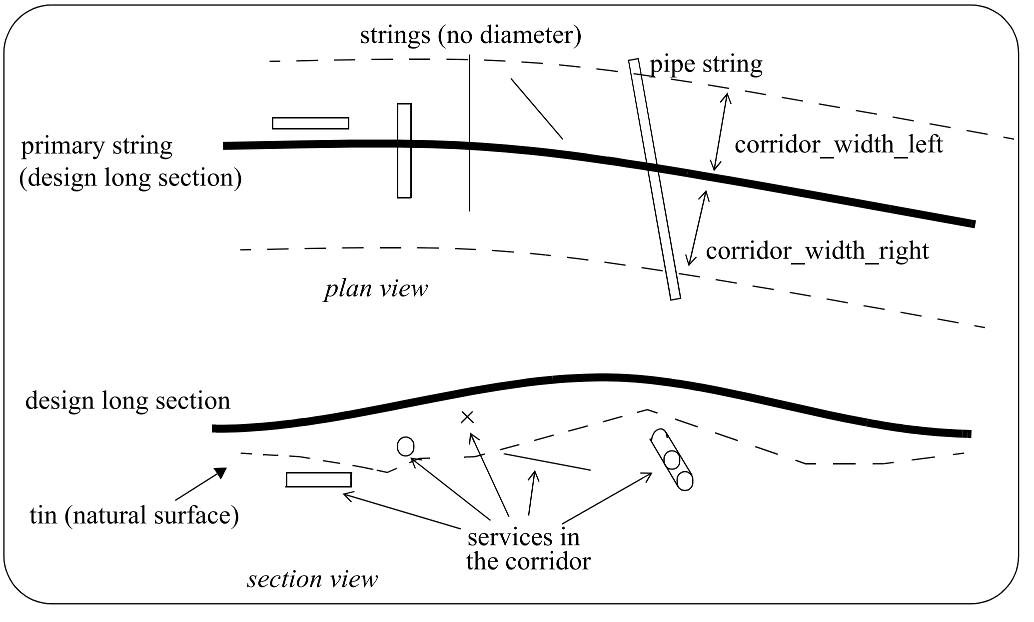
Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

Corridor and Services

A corridor around the primary string is defined by giving a left and right corridor width.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the long section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.



The corridor defining parameters are

corridor_width_left	*world-units*	// corridor left and right widths
corridor_width_right	*world-units*	// defaults are the section view values
corridor_overlap_left	*world-units*	// corridor left and right overlaps.
corridor_overlap_right	*world-units*	// defaults are the section view values

corridor_chord_arc	*world-units*	// chord-arc tolerance used to
		// approximate arcs in the corridor.
		// default is the section view value

The models containing tins for sectioning and strings for services are taken from the section view or given by the parameters

corridor_model_n	model	// n = 1, 2 ... 100
		// models containing tins and service
		// strings to be drawn on the view.

If any *corridor_model_n* parameters are defined, then only the models given by the parameters are used. If no *corridor_model_n* parameters are set, then the models added to the given section view are used.

That is, either the *corridor_model_n* parameters are used or if none exist, then the models added to the section view are used for tins and service strings.

The **colour** and **diameter** of the service strings drawn in the plot are the actual strings colour and diameter.

The graph area sits on top of the boxes and datum areas, so there may not be enough room left on the sheet for the full plot height. In this case, the plot will be truncated at the top of the allowed graph area.

Please continue to the next section 44.3.9 Bubbles Definitions.

44.3.9 Bubbles Definitions

Circles with the string name and a unique number (**bubbles**) can be drawn on the long section plot. Bubbles are normally used for lip profiles.

The chainages used for the bubbles are given by a set of parameters similar to the chainage parameters. The resulting set of bubbles are sequentially numbered (starting with one) in chainage order.

Although many bubbles can be defined by the bubble parameters, a bubble is only drawn on the plot if there is a labelled chainage to draw it above.

Hence not all bubbles given by the bubble chainage parameters are drawn but for the ones that are drawn, the bubble number is taken from the full bubble set.

chainage_bubbles	0	// don't drawn bubbles
	1	// draw bubbles
bubble_radius	*mm*	// radius of the bubbles
bubble_colour	*colour*	// colour for the bubbles
bubble_text_string_name_mode*0*		// do not label with string name
	1	// label string name
	2	// *label* with *model->string name*
bubble_pre_text	*text*	
bubble_post_text	*text*	
bubble_textstyle	*textstyle*	
bubble_text_size	*mm*	
bubble_text_colour	*colour*	
bubble_text_offset	*mm*	
bubble_upright_distance	*mm*	// distance bubbles are above boxes/uprights
bubble_mode	0	// bubble_upright_distance is above boxes
	1	// bubble_upright_distance is above // uprights
bubble_draw_upright	0/1	// 1 = draw extra upright if // bubble_mode = 1
bubble_start_chainage	*value*	// start chainage for bubbles
bubble_end_chainage	*value*	// end chainage for bubbles
bubble_chord_arc	0/1	// 1 = use chord-arc chainages
bubble_interval	*value*	// include regular interval // (0 = no regulars)
bubble_label_ends	0/1	// 1 = include start and end chainages
bubble_label_hcp	0/1	// 1 = include tangents, spirals
bubble_label_hip	0/1	// 1 = include hip points
bubble_label_vip	0/1	// 1 = include vip points
bubble_label_vtp	0/1	// 1 = include tangent points
bubble_label_crest	0/1	// 1 = include crests
bubble_label_sag	0/1	// 1 = include sags
bubble_label_grade_change	0/1	// 1 = include change of grade
bubble_special_n_file	*filename*	// n = 1 to 20 include chainages from the // file
bubble_label_tolerance	*value*	// > 0 use as weeding tolerance // <= 0, don't weed

Defaults

bubble_label_tolerance = 1.0 exp -4 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a bubble special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a ***//*** is a comment.

Please continue to the next section 44.3.10 Quick Horizontal Geometry Labelling.

44.3.10 Quick Horizontal Geometry Labelling

The standard horizontal geometry arrows can be drawn at a given distance above the top of the boxes area.

horizontal_geometry_y‘	*mm*	// dist above boxes
		// 0 = don't draw
horizontal_geometry_arrow_text_colour	*colour*	
horizontal_geometry_arrow_textstyle	*textstyle*	
horizontal_geometry_arrow_text_size	*mm*	
horizontal_geometry_arrow_colour	*colour*	
horizontal_geometry_arrow_height	*mm*	
horizontal_geometry_label_text	*text*	
horizontal_geometry_label_textstyle	*textstyle*	
horizontal_geometry_label_text_colour	*colour*	
horizontal_geometry_label_text_size	*mm*	
horizontal_geometry_label_decimals	*number*	

Please continue to the next section 44.3.11 Extensive Horizontal Geometry Labelling.

44.3.11 Extensive Horizontal Geometry Labelling

For complicated horizontal geometry labelling, there are sets of horizontal geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the horizontal geometry of ***alignment*** strings other than the primary string. To plot such a string on the same plot, the chainage position of the horizontal geometry for the non-primary alignment strings is *projected* onto the primary string to give a primary string chainage for plotting. The values of the horizontal geometry (such as radius and spiral length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting horizontal geometry, the user can give up to twenty sets of these labels and they can be used to label spirals, curves and tangent information for the primary string and/or additional alignment strings.

Each label set consists of three parts:

(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

For the following parameters, n takes the value 1 to 20 and specifies the nth parameter set.

h_g_n_type	0	// label spirals
	1	// label horizontal curves
	2	// label horizontal tangents

If *h_g_n_type* is missing, then the set is ignored.

h_g_n_value_mode		
for spiral labelling	0	// nothing
	1	// length
for curve labelling	0	// nothing
	1	// length
	2	// radius
for tangent labelling	0	// nothing
	1	// length
for spiral labelling	0	// nothing
	1	// length
	2	// radius*length
h_g_n_label_y	*mm*	// distance of arrow line above the top of // the boxes

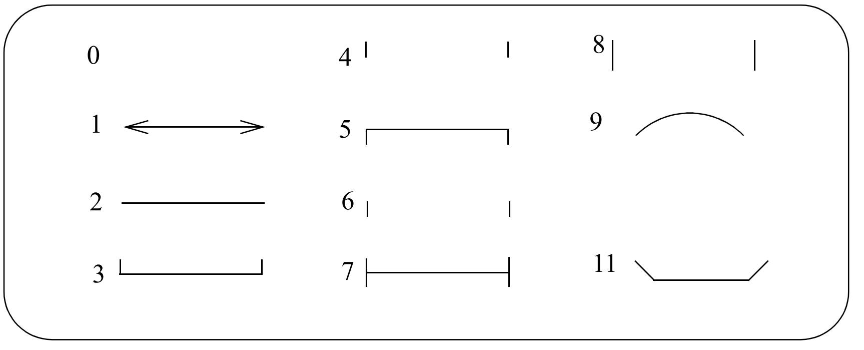
Parameters for the left hand label of the line of the horizontal geometry arrows:

h_g_n_label_x	*mm*	// distance from the left hand side of the // labels area
h_g_n_label_offset	*mm*	// distance to raise the label_text above // arrow line
h_g_n_label_text_size	*mm*	
h_g_n_label_text_colour	*colour*	
h_g_n_label_text	*text*	
h_g_n_label_textstyle	*textstyle*	*// textstyle used*

Parameters for arrow type

h_g_n_draw_mode	0	// no arrow
	1	// arrow
	2	// line
	3	// line with uprights at ends
	4	// uprights, no line

	5	// line with downrights
	6	// downrights, no line
	7	// line with up and downrights at ends
	8	// up and downrights, no line
	9	// draw curve
	11	// radius*length curve



h_g_n_left_gap	*mm*	// *size of gap for left side of arrow*
h_g_n_right_gap	*mm*	// *size of gap for right side of arrow*
h_g_n_colour	*colour*	// colour of the arrow
h_g_n_height	*mm*	// height of the arrow
h_g_n_gap	0	// no gap
	1	// leave gap in arrow for text

Parameters for text on the arrows

h_g_n_text_colour	*colour*	// colour of the text
h_g_n_text_size	*mm*	// size of the text
h_g_n_text_offset	*mm*	// distance to raise the text above the // arrow line
h_g_n_pre_text	*text*	// text before the arrow text
h_g_n_post_text	*text*	// text after the arrow text
h_g_n_textstyle	*textstyle*	// textstyle used
h_g_n_no_decimals	*integer*	// number of decimal places in arrow // text. // If > 0, all trailing zeros after the // decimal place are removed. // If < 0, the absolute value is taken as // the number of decimal places and **no** // trailing zeros are removed after the // decimal point.
h_g_n_rotate	*mm*	// *if ticked, the text on the arrows will be rotated to fit*.

If the set of parameters is to apply to the horizontal geometry of an alignment string *other* than the primary string, then simply add the following parameter to define the other alignment string

h_g_n_offset_string "model->string_name"

or

h_g_n_offset_string "string_name"

and the model is the *Offsets mode*l from the **Section Long Plot** panel.

If the *h_g_n_offset_string* parameter does not exist, then the set of horizontal geometry parameters is applied to the primary string.

Example of Extensive Horizontal Geometry

```
// Parameter to stop the drawing of the quick horizontal geometry
                    horizontal_geometry_y          0
// Set 1 - Extensive Horizontal Geometry Labelling - label the horizontal curve radius
                    h_g_1_type                 1                  // label horizontal curve
                                                                   // if this param is missing then set is ignored
                    h_g_1_value_mode           2                  // label curve radius
                    h_g_1_label_y              45
                    h_g_1_label_x              0
                    h_g_1_label_offset         2
                    h_g_1_label_text_size      4
                    h_g_1_label_text_colour    YELLOW
                    h_g_1_label_text           "Horiz Curve Data"
// Parameters for arrow type
                    h_g_1_draw_mode            1
                    h_g_1_colour               "white"
                    h_g_1_height               1.5
                    h_g_1_gap                  0
// Parameters for text on the arrows
                    h_g_1_text_colour          YELLOW
                    h_g_1_text_size            3.5
                    h_g_1_text_offset          2.5
                    h_g_1_pre_text             "R"
                    h_g_1_post_text            "m"
                    h_g_1_no_decimals          2
```

Example of Extensive Horizontal Geometry for use with a Non-primary Alignment String

```
// Set 2 labels the horizontal curves radii of the kerb string projected onto primary stings
                    h_g_2_offset_string        "left offsets->kerb"          // non-primary string to do VG of

                    h_g_2_type                 1                  // label horizontal curve
                                                                   // if this param is missing then set is ignored
                    h_g_2_value_mode           2                  // label curve radius
                    h_g_2_label_y              55
                    h_g_2_label_x              0
                    h_g_2_label_offset         2
                    h_g_2_label_text_size      4
                    h_g_2_label_text_colour    GREEN
                    h_g_2_label_text           "Left Kerb - Horiz Curve Data"
// Parameters for arrow type
                    h_g_2_draw_mode            1
                    h_g_2_colour               "white"
                    h_g_2_height               1.5
                    h_g_2_gap                  0
// Parameters for text on the arrows
                    h_g_2_text_colour          GREEN
                    h_g_2_text_size            3.5
                    h_g_2_text_offset          2.5
```

```
h_g_2_pre_text        "R"
h_g_2_post_text       "m"
h_g_2_no_decimals     2
```

Please continue to the next section 44.3.12 Quick Vertical Geometry Labelling.

44.3.12 Quick Vertical Geometry Labelling

The standard vertical geometry arrows can be drawn at a given distance above the top of the boxes area.

vertical_geometry_grade_y	*mm*	// dist above boxes
		// 0 = don't draw
vertical_geometry_grade_mode	0	// %
	1	// 1 in

Please continue to the next section 44.3.13 Extensive Vertical Geometry Labelling.

44.3.13 Extensive Vertical Geometry Labelling

For complicated vertical geometry labelling of the *primary alignment* string, there are sets of vertical geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the vertical geometry of ***alignment*** strings other than the primary string. To plot such a string on the same plot, the chainage position of the vertical geometry for the non-primary alignment strings is *projected* onto the primary string to give a primary string chainage for plotting. The values of the vertical geometry (such as grade and curve length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting vertical geometry, the user can give up to twenty sets of these labels and they can be used to label grades or vertical curve information for the primary string and/or additional alignment strings.

Each label set consists of three parts:

(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

For the following parameters, n takes the value 1 to 20 and specifies the nth parameter set.

v_g_n_type	0	// labelling grades
	1	// labelling vg curve information

If *v_g_n_type* is missing, then the entire nth set is ignored.

The interpretation of the value of the

parameter *v_g_n_value_mode* depends on whether the set is being used for grade labelling or curve labelling:

v_g_n_value_mode		
for grade labelling	0	// nothing
	1	// % grade
	2	// 1 in grade
	3	// m/m grade
	4	// chainage length between vertical
		// curve points
	5	// per chord - Queensland Rail
for curve labelling	0	// nothing
	1	// length - chainage for parabolic vc's
		// arc length for circular vc's
	2	// radius
	3	// K value
	5	// curve constant - Queensland Rail

Vertical curve points to draw the arrows between (for grade labelling only)

v_g_n_between_mode	0	// between chainages at the vip's
	1	// between chainages at the vtp's

Position of the Arrow Line

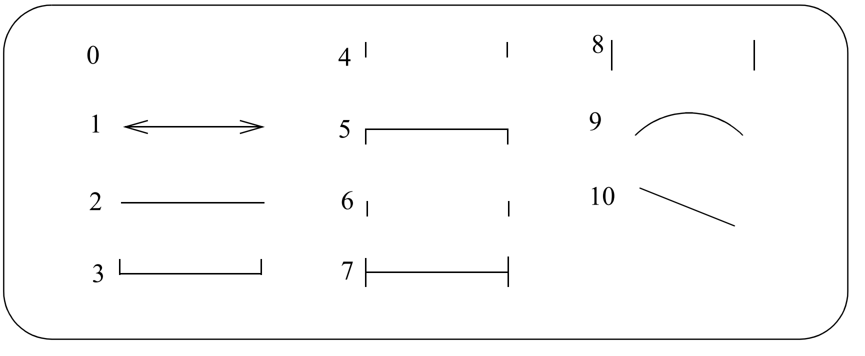
v_g_n_label_y	*mm*	// distance of arrow line above the top of
		// the boxes this can be negative

Parameters for the left hand label of the whole line of the vg arrows:

v_g_n_label_x	*mm*	// distance from the left hand side of the // labels area
v_g_n_label_offset	*mm*	// distance to raise the label_text above // arrow line
v_g_n_label_text	*text*	
v_g_n_label_textstyle	*textstyle*	
v_g_n_label_text_size	*mm*	
v_g_n_label_text_colour	*colour*	

Parameters for arrow type

v_g_n_draw_mode	0	// no arrow
	1	// arrow
	2	// line
	3	// line with uprights at ends
	4	// uprights, no line
	5	// line with downrights
	6	// downrights, no line
	7	// line with up and downrights at ends
	8	// up and down rights, no line
	9	// draw curve
	10	// draw grade



v_g_n_left_gap	*mm*	*// size of gap for left side of arrow*
v_g_n_right_gap	*mm*	*// size of gap for right side of arrow*
v_g_n_colour	*colour*	// colour of the arrow
v_g_n_height	*mm*	// height of the arrow
v_g_n_gap	0	// no gap
	1	// leave gap in arrow for text

Parameters for text on the arrows

v_g_n_text_colour	*colour*	// colour of the text
v_g_n_text_size	*mm*	// size of the text
v_g_n_text_offset	*mm*	// distance to raise the text above the // arrow line
v_g_n_pre_text	*text*	// text before the arrow text
v_g_n_post_text	*text*	// text after the arrow text
v_g_n_textstyle	*textstyle*	// textstyle used

v_g_n_no_decimals	*integer*	// number of decimal places in arrow
		// text.
		// If > 0, all trailing zeros after the
		// decimal place are removed.
		// If < 0, the absolute value is taken as
		// the number of decimal places and **no**

// trailing zeros are removed after the
// decimal point.

v_g_n_rotate *mm* // *if ticked, the text on the arrows will be rotated to fit*.

If the set of parameters is to apply to the vertical geometry of an alignment string *other* than the primary string, then simply add the following parameter to define the other alignment string

v_g_n_offset_string "model->string_name"

or

v_g_n_offset_string "string_name"

and the model is the *Offsets mode*l from the **Section Long Plot** panel.

If the *v_g_n_offset_string* parameter does not exist, then the set of vertical geometry parameters is applied to the primary string.

Example of Extensive Vertical Geometry

// Parameter to not to draw the quick vertical geometry

vertical_geometry_grade_y 0

// Set 1 labels the vertical curves with length

v_g_1_type 1 // curve
v_g_1_value_mode 1 // chainage length

v_g_1_label_y 45
v_g_1_height 4
v_g_1_label_offset -2
v_g_1_label_text "VG Curves"
v_g_1_text_offset 2
v_g_1_label_text_size 6
v_g_1_pre_text ""
v_g_1_post_text " L"
v_g_1_gap 0
v_g_1_draw_mode 8
v_g_1_text_size 4

// Set 2 labels the vertical curves with K value

v_g_2_type 1 // curve
v_g_2_value_mode 3 // K value

v_g_2_label_y 45
v_g_2_height 1.5
v_g_2_label_text ""
v_g_2_text_offset -5
v_g_2_pre_text ""
v_g_2_post_text " K"
v_g_2_gap 0
v_g_2_draw_mode 1
v_g_2_text_size 4

Example of Extensive Vertical Geometry for use with a Non-primary Alignment String

// Set 3 labels the vertical curves with length with the kerb string projected onto primary stings

```
v_g_3_offset_string        "left offsets->kerb"        // non-primary string to do VG of
v_g_3_type              1    // curve
v_g_3_value_mode        1    // chainage length

v_g_3_label_y           55
v_g_3_height             4
v_g_3_label_offset      -2
v_g_3_label_text        “Left kerb - VG Curves”
v_g_3_text_offset        2
v_g_3_label_text_size    6
v_g_3_pre_text          ““
v_g_3_post_text         “ L”
v_g_3_gap                0
v_g_3_draw_mode          8
v_g_3_text_size          4
```

Please continue to the next section 44.3.14 Labelling Chainages and Heights in the Graph Area.

44.3.14 Labelling Chainages and Heights in the Graph Area

The chainage and/or height values for certain points (given by *label_n_type*) can be labelled.

Up to twenty sets of chainage/height labels can be done.

label_n_type	0	// chainage of vip, height of vip
	1	// chainage of vip, height of primary
	2	// crest
	3	// sag
	4	// vtp
	5	// hcp
	6	// change of grade
	7	// mid-ordinate of the vertical curve

If *label_n_type* is missing, then the set is ignored.

label_n_y_mode	0	// height in mm above boxes
	1	// above height value (default)
	2	// above primary height
label_n_y	*mm*	// distance above point
label_n_angle	*degrees*	// rotation about point
label_n_x	*mm*	// distance along from point
label_n_offset	*mm*	// text raise height
label_n_justification	0	// left end
	1	// middle
	2	// end
label_n_size	*mm*	
label_n_colour	*size*	
label_n_textstyle	*textstyle*	
label_n_value_mode	0	// no values labelled
	1	// val 1 = chainage
	2	// val 1 = height
	3	// val 1 = chainage, val 2 = height
	4	// val 1 = height, val 2 = chainage
label_n_pre_text	*text*	
label_n_mid_text	*text*	
label_n_post_text	*text*	
label_n_textstyle	*textstyle*	*// textstyle to use*
label_n_no_decimals_1	*integer*	// number of decimal places in val 1
label_n_no_decimals_2	*integer*	// number of decimal places in val 2

If the **number of decimal places is greater than zero (> 0)**, then any trailing zeros after the decimal point are removed.

If the **number of decimal places is less than zero (< 0)**, the absolute value is taken as the number of decimal places and **no** trailing zeros after the decimal point are removed.

Example of Labelling Chainage and Heights

```
// label the crests with chainage on one line
// and height (elevation) on the next

label_1_type             2   // crest
label_1_y_mode           2   // above string
label_1_y               10
label_1_angle            0
label_1_justification    1   // centre
label_1_size             4
label_1_colour         red
label_1_value_mode       1   // chainage
```

```
label_1_pre_text            "CH "
label_1_no_decimals_1       1

label_2_type                2   // crest
label_2_y_mode              2   // above string
label_2_y                   2
label_2_angle               0
label_2_justification       1   // centre
label_2_size                4
label_2_colour              red
label_2_value_mode          2   // height
label_2_pre_text            "EL "
label_2_no_decimals_1       1
```

Please continue to the next section 44.3.15 Labelling With Symbols.

44.3.15 Labelling With Symbols

Symbols can be placed at certain points given by *symbol_n_type*.

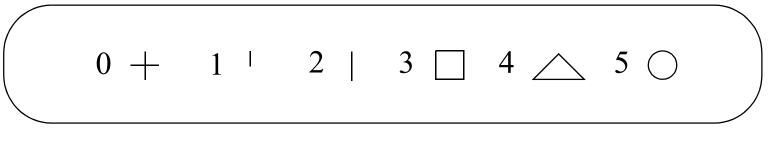
The symbol is drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

Up to twenty sets of symbol labelling can be done.

symbol_n_type	0	// chainage of vip, height of vip
	1	// chainage of vip, height of primary
	2	// crest
	3	// sag
	4	// vtp
	5	// hcp
	6	// change of grade

If *symbol_n_type* is missing, then the set is ignored.

symbol_n_y_mode	0	// height in mm above boxes
	1	// above height value (default)
	2	// above primary height
symbol_n_y	*mm*	// distance above point given by mode
symbol_n_angle	*degrees*	// rotation about point
symbol_n_x	*mm*	// distance along from point
symbol_n_size	*mm*	//
symbol_n_colour	*colour*	// colour of symbol
symbol_n_draw_mode	0	// cross
	1	// upright from centre of box
	2	// up and downright from centre of box
	3	// square
	4	// triangle, base at bottom
	5	// circle



Example of Labelling with Symbols

// draw a triangle symbol at the crest

symbol_1_type	2	// crest
symbol_1_y_mode	2	// above string
symbol_1_y	0	
symbol_1_angle	0	
symbol_1_size	2	
symbol_1_colour	red	
symbol_1_draw_mode	4	// triangle

Please continue to the next section 44.3.16 Hatching Cut and Fill Areas.

44.3.16 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

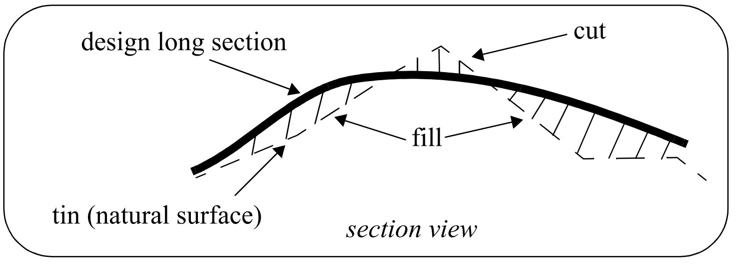
The parameters for labelling cuts and/or fill regions between tins are given by:

hatch_original_tin_n	*tin_name*	// tin_name for original surface
hatch_new_tin_n	*tin_name*	// tin_name for final surface
hatch_cut_separation_n	*mm*	// distance between cut hatch lines
	0	// don't do cut hatching
hatch_cut_angle_n	*degrees*	// angle in degrees of cut hatching
hatch_cut_colour_n	*colour*	// colour of the cut hatching
hatch_cut_linestyle_n	*linestyle*	// linestyle for cut hatching
hatch_cut_draw_sides_n	1/0	// 1 = draw sides of cut regions
hatch_cut_draw_original_n	1/0	// 1 = draw original tin in cut regions
hatch_cut_draw_new_n	1/0	// 1 = draw new tin in cut regions
hatch_fill_separation_n	*mm*	// distance between fill hatch line
	0	// don't do fill hatching
hatch_fill_angle_n	*degrees*	// angle in degrees of fill hatching
hatch_fill_colour_n	*colour*	// colour of the fill hatching
hatch_fill_linestyle_n	*linestyle*	// linestyle for fill hatching
hatch_fill_draw_sides_n	1/0	// 1 = draw sides of fill regions
hatch_fill_draw_original_n	1/0	// 1 = draw original tin in fill regions
hatch_fill_draw_new_n	1/0	// 1 = draw new tin in fill regions

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting *hatch_cut_separation_n* to 0.0.
fill hatching is turned off by setting *hatch_fill_separation_n* to 0.0.



Please continue to the next section 44.3.17 Labelling Cuts of Design Through Strings in a Model.

44.3.17 Labelling Cuts of Design Through Strings in a Model

The cuts that the primary string (design line) makes though any strings in user given models can be automatically labelled on the long section plots.

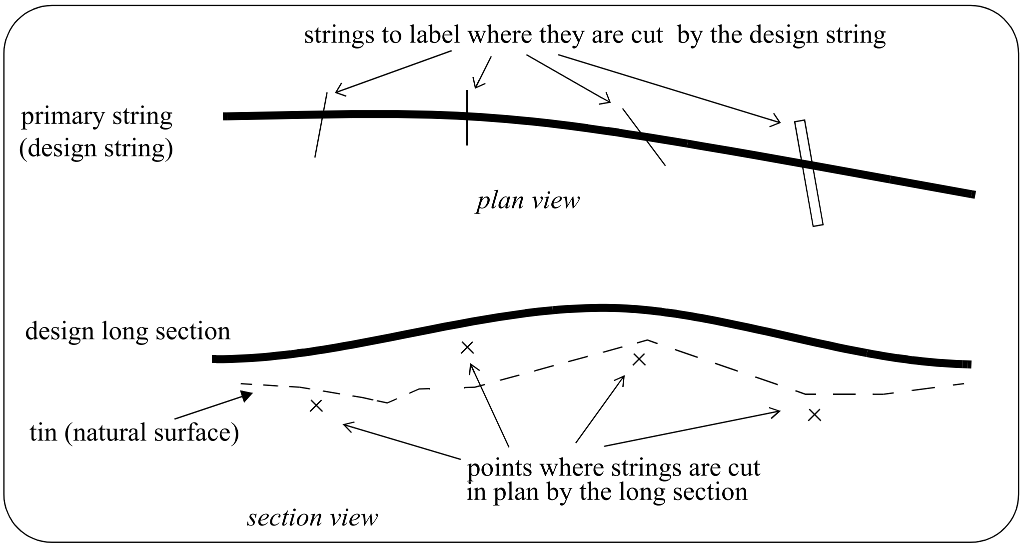
The **height**, **chainage** and **name** of the cut string can be labelled as well as a **symbol**. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the

(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.



Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

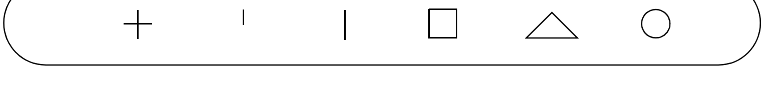
Text justification refers to the actual position and is given by

"top-left"	"top-centre"	"top-right"
"middle-left"	"middle-centre"	"middle-right"
"bottom-left"	"bottom-centre"	"bottom-right"

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are



Up to twenty five (25) separate models of strings can be cut and labelled.

Parameters for Labelling Where the Design Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the **model** which contains the strings, and then a **name mask** which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the nth set (where n can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

cuts_n_model *model_name* // model of strings to be cut

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

cuts_n_mask *name_mask* // strings to check for cuts
// and if a cut occurs,
// parameters show how to
// label the cut

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mast can include wild cards and wild characters.

For example

cuts_1_mask "ke*"
or cuts_1_mask "?bank*"

or, if both masks are required,

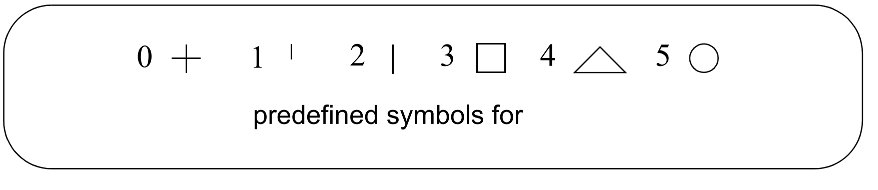
cuts_1_mask "ke* ?bank*"

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "*".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the design string, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the nth set.

The parameters for drawing a **symbol** at the cut points are

cuts_symbol_n_mode 0 // cross
1 // up from centre of box
2 // up and down from centre of box
3 // square
4 // triangle, base at bottom
5 // circle
6 // use a 12d symbol



If *cuts_symbol_n_mode* is 6, then the 12d symbol is given by

cuts_symbol_n_style *plotsymbol* // plot symbol to draw at cut

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

(a) the parameter *plot_symbols* in the ppf file

plot_symbols *filename*

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D

PLOT_SYMBOLS_4D *filename* *// default plotsym.4d*

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file *plotsym.4d*

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D

SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

cuts_symbol_n_position	1	// above point height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

cuts_symbol_n_x	*mm*	// offset adjustment to position
cuts_symbol_n_y	*mm*	// height adjustment to position
cuts_symbol_n_angle	*degrees*	// rotation about point
cuts_symbol_n_colour	*colour*	// colour of symbol

and for all values of *cuts_symbol_n_mode* **other** than 6:

cuts_symbol_n_size	*mm*	// size of symbol, 0 don't draw

The value of the **chainage** of the cut string can be labelled using the parameters

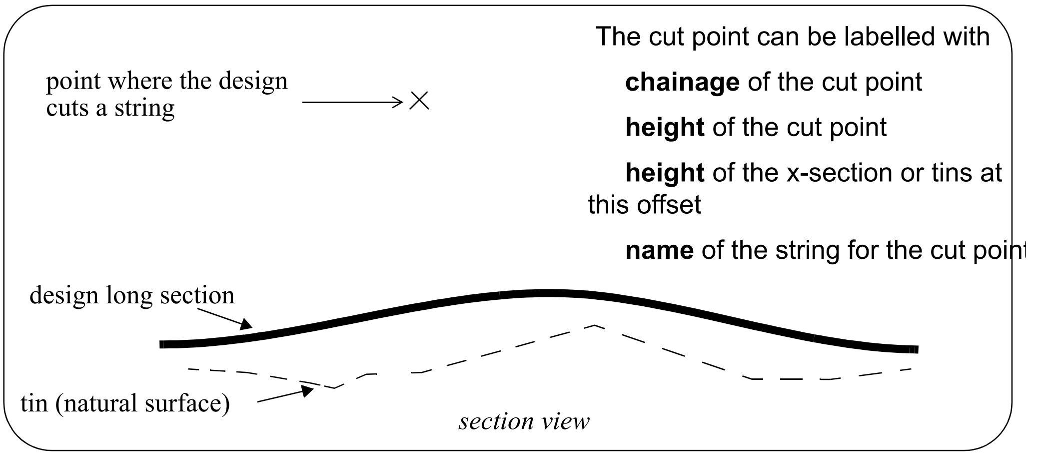
cuts_chainage_n_position	1	// above cut strings height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_chainage_n_x	*mm*	// chainage adjustment to position
cuts_chainage_n_y	*mm*	// height adjustment to position
cuts_chainage_n_angle	*degrees*	// rotation about point
cuts_chainage_n_size	*mm*	// size of text, 0 don't label
cuts_chainage_n_colour	*colour*	// colour of text
cuts_chainage_n_textstyle	*text*	// textstyle of text chainage
cuts_chainage_n_pre_text	*text*	// text before the chainage value
cuts_chainage_n_post_text	*text*	// text after the chainage value
cuts_chainage_n_justification	*justification*	// justification of the text
cuts_chainage_n_no_decimals	*integer*	// number of decimals in chainage

The value of a **height** at the chainage of the point can be calculated and labelled using the parameters

cuts_height_n_mode	*1*	// use height of cut point itself
	3	// use real world height of the position
		// of the label above the boxes
	100	// height of primary string
	101-500	// use height of to tin1 or tin2 etc.
cuts_height_n_position	*1*	// at points position
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_height_n_x	*mm*	// chainage adjustment to position
cuts_height_n_y	*mm*	// height adjustment to position
cuts_height_n_angle	*degrees*	// rotation about point
cuts_height_n_size	*mm*	// size of text, 0 don't label
cuts_height_n_colour	*colour*	// colour of text
cuts_height_n_textstyle	*text*	// textstyle of text height
cuts_height_n_pre_text	*text*	// text before the height value
cuts_height_n_post_text	*text*	// text after the height value
cuts_height_n_justification	*justification*	// justification of the text
cuts_height_n_no_decimals	*integer*	// number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters

cuts_label_n_position	1	// above cut strings height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_label_n_mode	0	// don't include cut string name
	1	// include cut string name in label
cuts_label_n_x	*mm*	// chainage adjustment to position
cuts_label_n_y	*mm*	// height adjustment to position
cuts_label_n_angle	*degrees*	// rotation about point
cuts_label_n_size	*mm*	// size of text, 0 don't label
cuts_label_n_colour	*colour*	// colour of text
cuts_label_n_textstyle	*text*	// textstyle of text label
cuts_label_n_pre_text	*text*	// text before the string name
cuts_label_n_post_text	*text*	// text after the string name
cuts_label_n_justification	*justification*	// justification of the text



Please continue to the next section 44.3.18 Labelling the Primary String Name on the Plot.

44.3.18 Labelling the Primary String Name on the Plot

The plot can be labelled with a name under the boxes area.

The name is made up of concatenation the text strings:

plot_name_pre_text	primary-string-name	plot_name_post_text

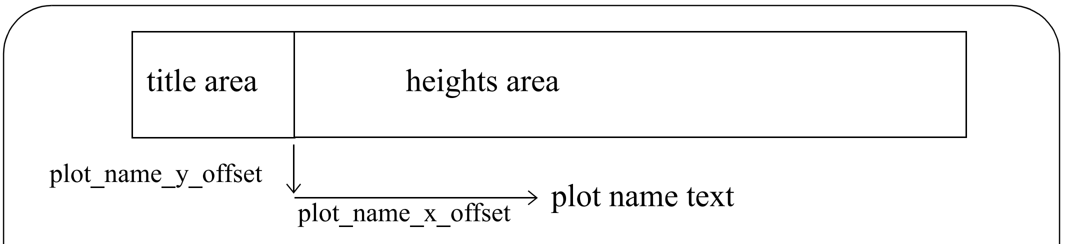
The plot name is positioned under the boxes.

plot_name_string_name	0	// don't use the primary string name
	1	// use primary string name
	2	// use model->string name
plot_name_pre_text	*text*	
plot_name_post_text	*text*	
plot_name_textstyle	*textstyle*	
plot_name_size	*mm*	
plot_name_colour	*colour*	
plot_name_x_offset	*mm*	
plot_name_y_offset	*mm*	

The *plot_name_x_offset* is measured from the beginning of the height boxes.

The default for *plot_name_x_offset* is centred on heights area.

The *plot_name_y_offset* is measured from the bottom of the box area with positive being **down**.



labelling primary string name on long section plots

Example of Labelling Primary String Name

plot_name_pre_text	"Long Section Plot for String"
plot_name_post_text	""
plot_name_size	15
plot_name_colour	red
plot_name_string_name	1
plot_name_y_offset	30

Please continue to the next section 44.3.19 Labelling the Scale on the Plot.

44.3.19 Labelling the Scale on the Plot

The plot can be labelled with the horizontal and vertical scale under the boxes area.

The scale label is made up of concatenation the text strings:

scale_horizontal_pre_text	horizontal scale value	scale_horizontal_post_text
and		
scale_vertical_pre_text	vertical scale value	scale_vertical_post_text

The horizontal scale value is the value given by the scale parameter.

The vertical scale value is calculated from the horizontal scale and the vertical exaggeration for the section view.

The scales are positioned under the boxes.

scale_horizontal_pre_text	*text*
scale_horizontal_post_text	*text*
scale_horizontal_textstyle	*textstyle*
scale_horizontal_size	*mm*
scale_horizontal_colour	*colour*
scale_horizontal_x_offset	*mm*
scale_horizontal_y_offset	*mm*
scale_horizontal_decimals	*integer*
scale_vertical_pre_text	*text*
scale_vertical_post_text	*text*
scale_vertical_textstyle	*textstyle*
scale_vertical_size	*mm*
scale_vertical_colour	*colour*
scale_vertical_x_offset	*mm*
scale_vertical_y_offset	*mm*
scale_vertical_decimals	*integer*

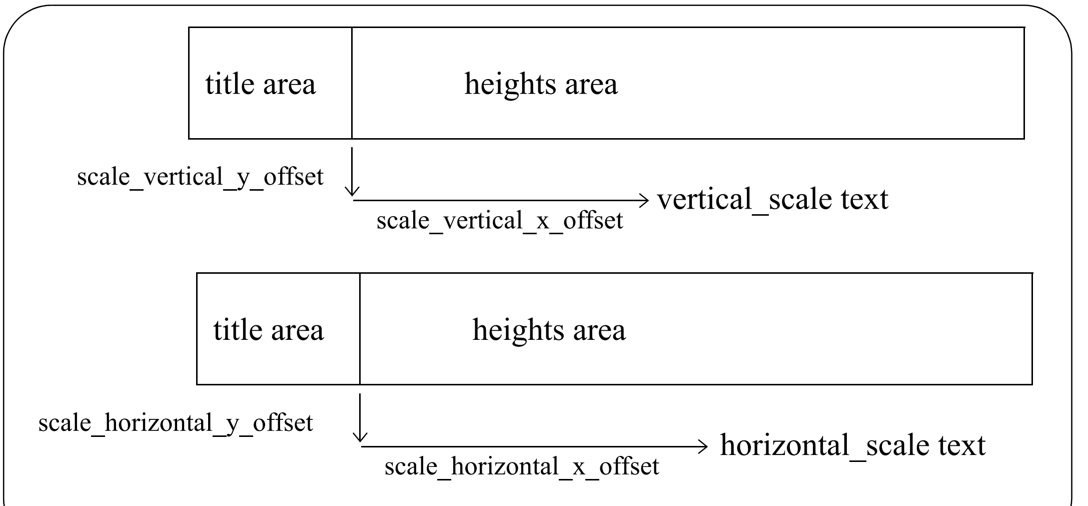
The *scale_vertical_x_offset* and *scale_horizontal_x_offset* are measured from the beginning of the heights area.

The default for *scale_vertical_x_offset* and *scale_horizontal_x_offset* are centred on the heights area.

The *scale_vertical_y_offset* and *scale_horizontal_y_offset* are measured from the bottom of the box area with positive being **down**.

If the **number of decimal places is greater than zero (> 0)**, then any trailing zeros after the decimal point are removed.

If the **number of decimal places is less than zero (< 0)**, the absolute value is taken as the number of decimal places and **no** trailing zeros after the decimal point are removed.



labelling of scales on the long section plots

Example of Labelling Horizontal and Vertical Scales

scale_horizontal_pre_text	"Horizontal Scale 1:"
scale_horizontal_post_text	""
scale_horizontal_size	15
scale_horizontal_colour	yellow
scale_horizontal_y_offset	60

scale_vertical_pre_text	"Vertical Scale 1:"
scale_vertical_post_text	""
scale_vertical_size	15
scale_vertical_colour	green
scale_vertical_y_offset	90

Please continue to the next section 44.3.20 Title Block Information.

44.3.20 Title Block Information

The plot can have a standard ***12d Model*** title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard ***12d Model*** title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter *plot_border*.

plot_border	*yes/no*	*// yes plots a standard title block* *// default yes*
title_1	*text*	
title_2	*text*	
title_text_size	*value*	
title_colour	*colour*	

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The *plot_border* parameter should also be set to *no* so that the standard title block is not also drawn.

use_title_file	*yes/no*	*// yes draws the title block given in title_file* // default no
title_file	*filename*	
plot_border	*no*	*// turn off standard title block*

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

user_text_n	*text*

The special plot parameters are:

time_format	*text*	// format for $time
user_text_n	*text*	// where n = 1,2,... 1000 // passed down to $user_text_n
title_1	*text*	// passed down to $title_1
title_2	*text*	// passed down to $title_2
start_page_number	*integer*	// used as the starting value for // $page_number. If missing, // $page_number starts at 1.

start_drawing_number	*integer*	// added to $drawing_number in title
		// block file. If missing,
		// $drawing_number starts at 1.

drawing_number_prefix	*text*	// passed down to // $drawing_number_prefix
drawing_number_postfix	text	// passed down to // $drawing_number_postfix

Please continue to the next section 44.3.21 Parameters that Modify Fields In the Long Plot Panel.

44.3.21 Parameters that Modify Fields In the Long Plot Panel

A number of parameters match those in the **section long plot** panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the **section long plot** panel are:

scale	*value*
start_chainage	*value*
end_chainage	*value*
chainage_interval	*value*
chord_arc	0/1
plotter_type	*text*
plot_file	*text*
view_name	*text*
offset_model	*text*
plot_border	*yes/no*
label_depths	*yes/no*
primary_string	*yes/no*
datum_value	*value*
sheet_size	*text* or "width *height"*
box_text_size	*mm*
box_colour	*colour*
use_title_file	*yes/no*
title_file	*filename*
plot_border	*yes/no*
title_1	*text*
title_2	*text*
title_text_size	*value*
title_colour	*colour*
pagination	*yes/no*
pagination_length	*value*
pagination_overlap	*value*
global_textstyle	*textstyle*

Please continue to the next section 44.3.22 Generating Long Section Plots Without a View.

44.3.22 Generating Long Section Plots Without a View

The long section plot parameters are comprehensive enough that it is possible to completely generate a long section plot without referencing a section view, or even using the **section long plot** panel.

Such a ppf can be run using the **plots=>plot a ppf** option or from the 4D Solutions programming language, 4DML.

When a long section plot is being generated entirely from a file, an extra parameter is needed to specify whether the datum value is calculated or the *datum_value* parameter is used.

manual_datum	1	// use the datum_value parameter for // the datum
	0	// ignore the datum_value and let // 12d Model calculate the datum.

When generating a long section plot using the **section long plot** panel, a plot parameter file containing all the parameters needed to regenerate the plot using **plots=>plot a ppf** can be written out by simply giving a name for the ppf file in the **plot parameters write** field of the **section long plot** panel.

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section 44.3.23 Example of a Long Section Plot Parameter File.

44.3.23 Example of a Long Section Plot Parameter File

Please continue to the next section 44.5 #Include in Plot Parameter Files.

44.4 Pipeline Plot Parameter File

The **pipeline plot** option is used to make special long section plots for a **network** of pipeline strings.

Some of the look of the pipeline long section plot can be controlled from the **plot pipeline network** panel itself, however a wider selection of control parameters is available by using a pipeline long plot, plot parameter file.

The pipeline long section plot parameters are placed in a file with ending **.ppf**.

Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash **//** is considered to be a comment.

The set of all parameters for the pipeline long section plot is enclosed within a set of curly brackets **{ }** with the header

pipeline_long_plot "plot set name"

before the curly brackets.

That is,

```
pipeline_long_plot    "plot set name"    {
            plot parameters
            one per line
}
```

If there is more than one pipeline_long_plot parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as section_x_plot in the same file.

The other sets will be ignored when doing a pipeline long section plot.

44.4.0.1 Plot Sheet Layout

The plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

sheet_size	*text*	// sheet name, or
	"*mm mm*"	// sheet size: width height

The sheet size name and width and heights can be specified by the user in a file named sheet_sizes_definitions which is in the normal set up areas, or is pointed to by the environment variable

SHEET_SIZES_4D	*file*	// file of plotter sheets sizes

The long plot is then positioned within the plot sheet by giving the margins

left_margin	*mm*
right_margin	*mm*
top_margin	*mm*
bottom_margin	*mm*

The (left_margin,bottom_margin) defines the left hand corner position of the long plot on the plot sheet.

The right_margin and top_margin need not be set and if missing, will be calculated from the other plot parameters defining the plot layout.

The pipeline long section plot will break an individual plot up if it doesn't fit across the sheet. There can be one or more rows of plot on the same sheet.

The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

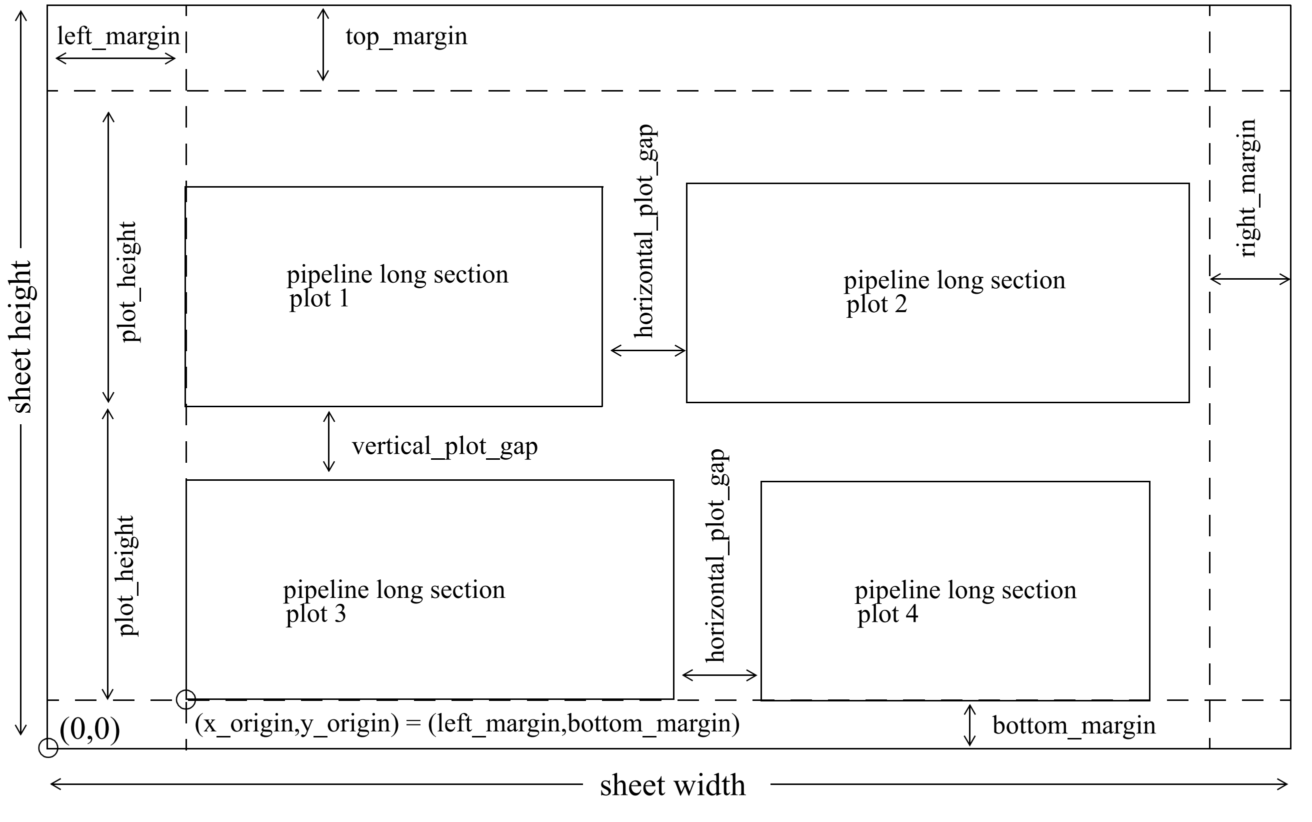
When a sheet is full, a follow on sheet is created.

As soon as one pipeline string is completed, the next pipeline string in the network model is plotted beginning on the same row as the previous pipeline string and with a horizontal gap of size horizontal_plot_gap between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

The position of the left hand bottom corner of the first plot in the bottom row is given by the parameters, left_margin and bottom_margin.

If there are two or more rows of plots, the position of the first plot in each row is given by adding multiples of the (plot_height+vertical_plot_gap) to the bottom_margin.

network_model	*text*	// model of pipeline strings
left_margin	*mm*	// Position of the left hand bottom
bottom_margin	*mm*	// corner of first plot in the bottom row.
only_one_line	***0***	// more than one row on a sheet
	1	// only one row of plot on a sheet
plot_height	*mm*	// total height of a plot row. It doesn't // includes the vertical_plot_gap.
horizontal_plot_gap	*mm*	// gap between plots on same row
vertical_plot_gap	*mm*	// gap between rows of plots



The pipeline long plot itself consists of seven areas. From the bottom up, they are

boxes, below datum, bottom stagger, graph, top stagger, arrow 4 area and top.

The **boxes area** is where the chainages and various values for the pipeline strings are labelled.

The **below datum area** is a region between the boxes area and the datum line.

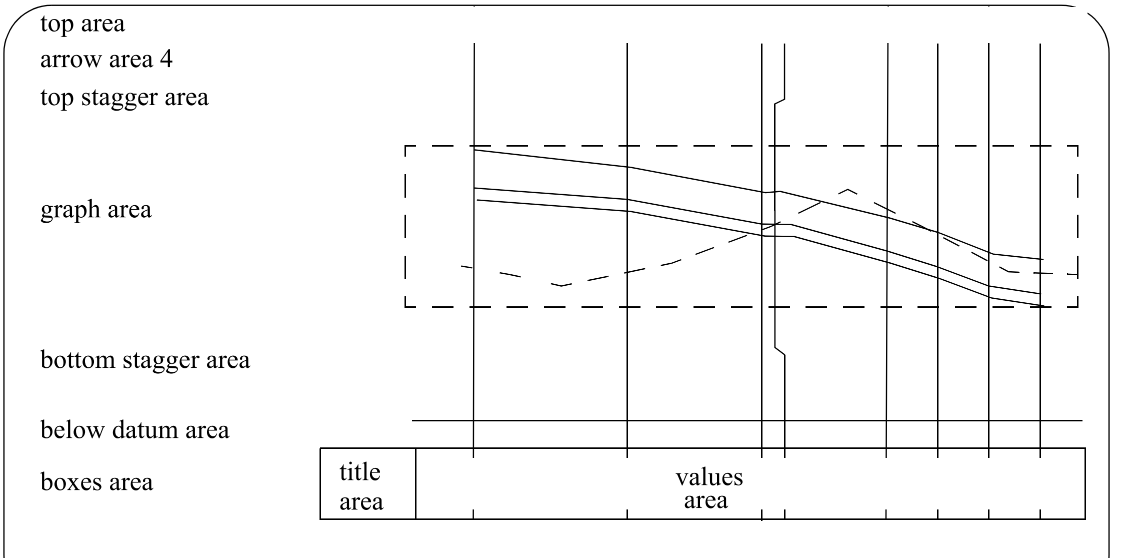
The **bottom stagger area** is where the upright line staggers occur before going up from the boxes area to the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

The **top stagger area** is where the upright line staggers occur above the graph area.

The **arrow 4 area** is an extension of the uprights above the top stagger area to allow for the drawing of arrows where the arrows go between the staggered uprights above the graph area.

The **top area** is an annotation area above the arrow 4 area (the top of the plot) and is used for pegs and deflection angles.



pipeline long section plot

Apart from information labelled in the boxes and top areas, the pipeline long section plot can place arrows between ips for other information such as

(a) pipe grade
(b) vertical geometry
(c) horizontal geometry

Also the chainages where services cross the pipeline line are automatically labelled.

44.4.0.2 Chainages, Staggering and Uprights

For the pipeline plot, the labelling of pipe invert levels, pipe invert, depth to invert, pipe grade and natural surface level are done at the chainages:

(a) pegs given by the peg_interval
(b) horizontal and vertical defection points
(c) points in the specials model
(d) crossing services

The points in the specials model are projected onto the pipeline string and the chainages used for labelling. If the point is a 4d string, then the text at the point is used as a text label at the top of the plot.

The peg interval and specials model are given by the parameters

peg_interval	*world-units*	// distance between pegs
specials_model	*text*	// model name

Uprights, or leader lines, are drawn from the values at the bottom of the plot to the top of the plot for cases (a), (b) and (c), or to the crossing service in the graph area for case (d).

If the text values are placed at the real chainage positions at the bottom of the plot, text overwriting can easily occur if the chainages are very close together.

To prevent such overwriting, the text can be **staggered**.

That is, if the text is going to overwrite a previous text value, the next text value is actually moved along until there is no overwriting.

Since the text is no longer at the correct chainage position, the uprights to the pegs and services start at the text position and then bend back to the correct chainage position on the plot. The region where the bending occurs is called the stagger area.

For the pipeline plot, there is an area below the graph where the uprights bend backwards from the staggered text position to the real chainage position (bottom stagger area).

There is a second area above the graph where the uprights bend forwards from the real chainage position to the staggered text position (top stagger area).

Hence annotation above the top stagger area will line up with the staggered values below the bottom stagger area.

The stagger area below the graph area is defined by

stagger_height_1	*mm*	// distance from the top of datum to the // start of the staggers
stagger_height_2	*mm*	// distance over which stagger occurs
stagger_gap_bottom	*mm*	// distance from end of staggers to the // bottom of the graph area

The stagger area above the graph area is defined

stagger_gap_top	*mm*	// distance from top of the graph area to // the start of the staggers
stagger_height_3	*mm*	// distance over which stagger occurs
stagger_height_4	*mm*	// distance from end of staggers to the // bottom of above upper staggers area

The distance to be left for text to avoid overwriting is:

horizontal_text_gap	*m*m	// minimum distance to leave for text // after peg values
services_text_gap	*mm*	// minimum distance to leave for text // after service values

When staggering occurs, it is possible for the values area to be longer than the graph area.

For the uprights that are drawn from the text to the pegs, specials and services:

line_colour	*colour*	// colour of uprights to the pegs and // specials
service_line_colour	*colour*	// colour of upright to the crossing // services
service_text_colour	*colour*	// colour of the name of the service.
service_text_size	*mm*	// size of the service text.

service_il_text_size	*mm*	// size of the service invert level text.

service_il_textstyle	*text*	// textstyle of the service il text
service_il_text_colour	*colour*	// colour of the service il text

Label vertical geometry:

v_g_text_size	*mm*	// size of the vertical geometry text
v_g_textstyle	*text*	// text style of the vertical geometry text
v_g_text_colour	*colour*	// colour of the vertical geometry text

Label horizontal geometry:

h_g_text_size	*mm*	// size of the horizontal geometry text
h_g_textstyle	*text*	// textstyle of the horizontal geometry text
h_g_text_colour	*colour*	// colour of the horizontal geometry text

Label pegs:

peg_text_size	*mm*	// size of the peg label
peg_textstyle	*text*	// text style of the peg label
peg_text_colour	*colour*	// colour of the peg label

Label special chainage:

chainage_special_text_size	*mm*	// size of the special chainage text
chainage_special_textstyle	*text*	//textstyle of the special chainage text
chainage_special_text_colour	*colour*	// colour of the special chainage text

44.4.0.3 Boxes Area

The pipeline string values of chainage, invert level, depth to pipe invert or depth to top of pipe, grade and natural surface level can be labelled in the pipeline long section plot with one line of title, and the actual values given at the chainage of each peg in the pipeline string.

The **titles** for the string values, are drawn in the **titles area** of the **boxes area** and the values are drawn in the **values area** of the **boxes area**.

Consequently the boxes area is made up of rows of text consisting of:

title followed by the **values** along the string.

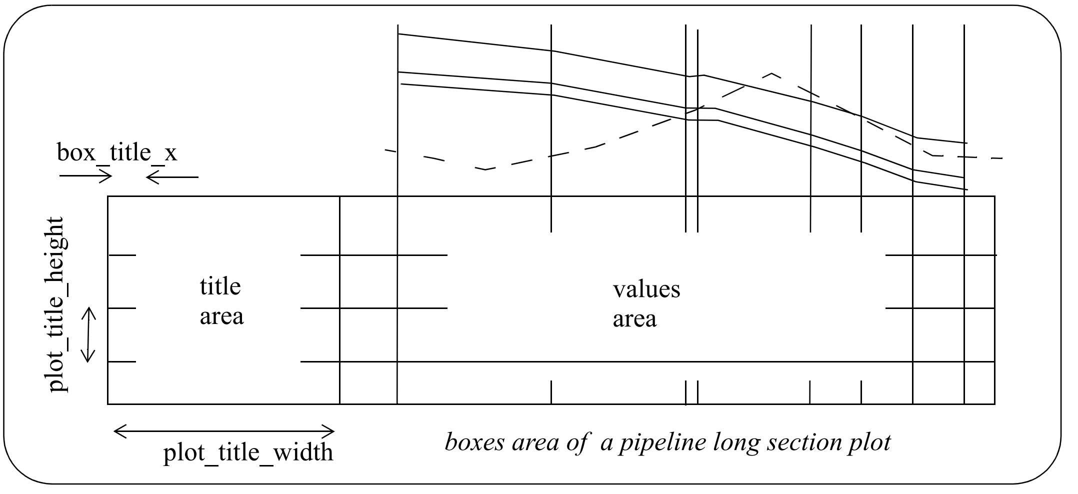
Each row is surrounded by lines to form a box.

The **titles area** for the left plot in the bottom row starts at the co-ordinate (left_margin, bottom_margin) and each row is begun by adding the distance (plot_height + vertical_plot_gap) to the bottom_margin.

The width of the title box is given by the **plot_title_width** parameter and the height of each box is given by **plot_title_height**.

plot_title_width	*mm*	// width of the label boxes.
plot_title_height	*mm*	// height of each box
box_titles_x	*mm*	// the distance between the left of the // title box and the title

The **values area** starts at the end of the label area and the values text is written at right angles to the bottom of the boxes.



The colour of the box line work is given by:

plot_title_line_colour	*colour*	// colour of the lines in the boxes

A default text size and colour can be specified for the title text, and the size and colour of the values. These can be overridden by parameters (given later in this section).

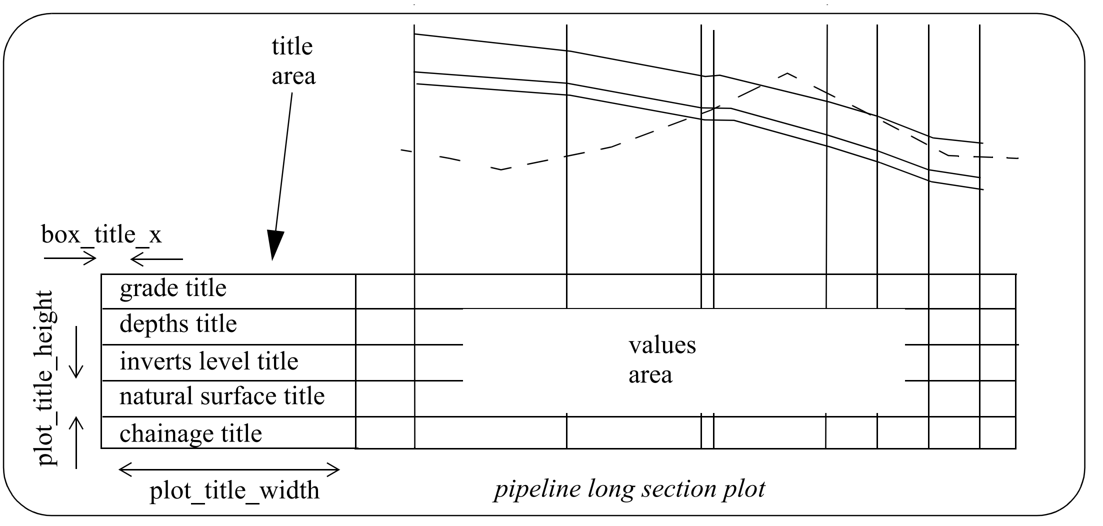
plot_title_text_size	*mm*	// size of label text in boxes
plot_title_text_colour	*colour*	// colour of label text in boxes
text_size	*mm*	// size of value text
text_colour	*colour*	// colour of values in boxes

The width of the **values** area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

The total width of the boxes area is the width of the labels area plus the width of the values area which depends on the amount of staggering that occurs.

The order of drawing and labelling the boxes from the bottom up is

(a) chainage values
(b) natural surface heights
(c) pipe invert levels
(d) depth to invert or depth to top of pipe
(e) grade of pipeline



The text, size, textstyle and colour for the title text and values text for each box can be set by:

(a) pipeline string chainages

```
plot_title_chainage_name      text       // label for chainages box
chainage_title_text_size      mm         // size of chainage title text in boxes
chainage_title_textstyle      text       // the textstyle of chainage title text in boxes
chainage_title_text_colour    colour     // colour of chainage title text in boxes

chainage_text_colour          colour     // colour of chainage text in boxes
chainage_text_size            mm         // size of chainage text in boxes
chainage_textstyle            text       // the textstyle of chainage text in boxes
chainage_decimals             integer    // number of decimal places
                                         // If  > 0, trailing zeros are removed after
                                         // the decimal point.
                                         // If  < 0, the absolute value is taken as the
                                         // number of decimal places to report
                                         // i.e. no trailing zeros are removed
```

(b) natural surface values

```
plot_title_surface_name   text      // label for the pipeline ns value
ns_title_text_size        mm        // size of ns title text in boxes
ns_title_textstyle        text      // the textstyle of ns title text in boxes
ns_title_text_colour      colour    // colour of ns title text in boxes

ns_text_colour            colour    // colour of ns text in boxes
ns_text_size              mm        // size of ns text in boxes
ns_textstyle              text      // the textstyle of ns text in boxes
ns_decimals               integer   // number of decimal places
                                    // If  > 0, trailing zeros are removed after
                                    // the decimal point.
                                    // If  < 0, the absolute value is taken as the
                                    // number of decimal places to report
                                    // i.e. no trailing zeros are removed
```

(c) pipe invert values

```
plot_title_invert_name    text      // label for the invert level
il_title_text_size        mm        // size of il title text in boxes
il_title_textstyle        text      // the textstyle of il title text in boxes
il_title_text_colour      colour    // colour of il title text in boxes
```

il_text_colour	*colour*	// colour of il text in boxes
il_text_size	*mm*	// size of il text in boxes
il_textstyle	*text*	// the textstyle of il text in boxes

il_decimals	*integer*	// number of decimal places
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

(c) depth to invert or depth to top of pipe

depth_mode	***0***	// if 0, depth to invert of pipe - default 0
	1	// if 1, depth to top of pipe (cover)
plot_title_depth_name	*text*	// label for depth of invert
depth_title_text_size	*mm*	// size of depth title text in boxes
depth_title_textstyle	*text*	// the textstyle of depth title text in boxes
depth_title_text_colour	*colour*	// colour of depth title text in boxes
depth_text_colour	*colour*	// colour of depth text in boxes
depth_text_size	*mm*	// size of depth text in boxes
depth_textstyle	*text*	// the textstyle of depth text in boxes

depth_decimals	*integer*	// number of decimal places
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

(d) grade of pipeline

plot_title_grade_name	*text*	// grade of pipe at the peg
grade_title_text_size	*mm*	// size of grade title text in boxes
grade_title_textstyle	*text*	// the textstyle of grade title text in boxes
grade_title_text_colour	*colour*	// colour of grade title text in boxes
grade_text_colour	*colour*	// colour of grade text in boxes
grade_text_size	*mm*	// size of grade text in boxes
grade_textstyle	*text*	// the textstyle of grade text in boxes

grade_decimals	*integer*	// number of decimal places
		// If > 0, trailing zeros are removed after
		// the decimal point.
		// If < 0, the absolute value is taken as the
		// number of decimal places to report
		// i.e. no trailing zeros are removed

44.4.0.4 Below Datum Area

The **below datum area** is the region between the boxes area and the arrow_1 area. The datum line is drawn at the top of the below datum area.

datum_title_text_size	*mm*	// size of datum title text and value
datum_title_textstyle	*text*	// textstyle of datum title text and value
datum_title_text_colour	*colour*	// colour of the datum title text and line

The size of the below datum area is

datum_gap	*mm*	// height of the below datum area

The datum value is placed above the datum line.

Since the datum value is automatically calculated to try and fit the plot vertically into the graph area, the datum value can change along the plot. When a datum change occurs, the new datum value is written on the datum line at the relevant chainage position.

The datum name, text size and colour are controlled by:

datum_text_size	*mm*	// size of datum title text and value
datum_textstyle	*text*	// textstyle of datum title text and value
datum_text_colour	*colour*	// colour of the datum title text and line

datum_name	*text*	// text to write before the datum value
datum_text_size	*mm*	// size of datum text and value
datum_colour	*colour*	// colour of the datum text and line

44.4.0.5 Graph Area

The **graph area** is the area where the actual plots of the pipeline strings are drawn.

The length of the graph area is determined by the length of the pipelines string to be plotted (given by the start and end chainages) and the horizontal scale (given by scale) of the plot.

scale	*value*	// 1:value - horizontal scale
		// The vertical scale is determined by the
		// horizontal scale and the vertical
		// exaggeration for the section view.

start_chainage	*value*	// " " means use start of pipeline strings
end_chainage	*value*	// " " means use end of pipeline strings

The vertical exaggeration is taken from the section view specified for the plot by the parameter:

view_name	*text*

The tins to be sectioned through by the pipeline strings and any service models and corridor settings for the graph area are also taken from the specified section view.

The height of the graph is calculated by subtracting the height of the first five areas (i.e. don't include the top area) from the plot height.

If the plot will not fit horizontally into a row on the sheet, then the plot will be broken at an appropriate peg and the plot continued on another row.

Datum breaks at pegs are used to try and fit the plot vertically into the graph area but if the plot still cannot fit, then it will be truncated at the bottom.

The types of strings that can be drawn in the graph area of the pipeline long section plot are:

(a)	pipeline string	the strings from the network model
(b)	tins	sections of the pipeline string through any tins on the section view.
(c)	services	parts of strings from any models on the section view that cut the corridor for the section view.

The **colour** of the strings in the plot is the actual string colour for cases (a) and (c), the colour of the tin used for the section in case (b).

44.4.0.6 Arrow 4 Area

This is just an extension of the stagger lines before the top of the plot. It leaves an area that can be used for extra annotation after the plot is produced.

The height of the area is

plot_title_top_height	*mm*	// height of the arrow 4 area

44.4.0.7 Top Area

The **top area** is an annotation area at the top of the plot (above the arrow 4d area).

It can be used for peg names and horizontal and vertical deflection angles in the pipeline.

The height of the top area is given by

vertical_plot_gap	*mm*	// size of the top area. If it is not large
		// enough, the text will overwrite the
		// plot in the row above.

44.4.0.8 Change of Direction At Intersection Points

If there is a horizontal or vertical intersection point without a curve on it, the deflection angle at the intersection point is drawn in the top area.

The text is drawn at the distance **angle_text_offset** above the top of the plot and if there is more than one angle, they are spaced horizontally by the distance **angled_text_gap** to the right.

The size and colour of the deflections is given by text_size and text_colour.

angled_text_offset	*m*m	// distance of direction text above // top of the plot
angled_text_gap	*mm*	// distance of direction text to the right // of previous text.
angled_text_angle	*value*	// angle of direction text

44.4.0.9 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

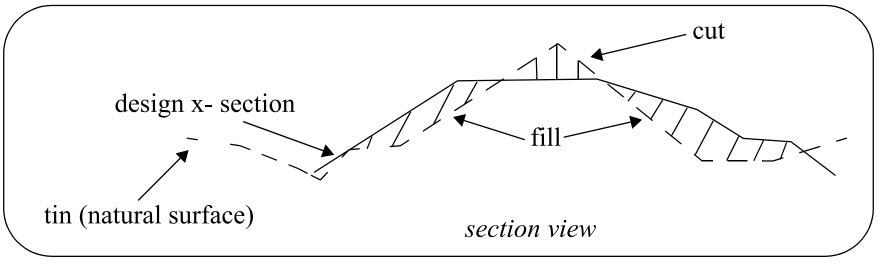
The parameters for labelling cuts and/or fill regions between tins are given by:

hatch_original_tin_n	*tin_name*	// tin_name for original surface
hatch_new_tin_n	*tin_name*	// tin_name for final surface
hatch_cut_separation_n	*mm*	// distance between cut hatch lines
	0	// don't do cut hatching
hatch_cut_angle_n	*degrees*	// angle in degrees of cut hatching
hatch_cut_colour_n	*colour*	// colour of the cut hatching
hatch_cut_linestyle_n	*linestyle*	// linestyle for cut hatching
hatch_cut_draw_sides_n	*1/*0	// 1 = draw sides of cut regions
hatch_cut_draw_original_n	*1/0*	// 1 = draw original tin in cut regions
hatch_cut_draw_new_n	*1/0*	// 1 = draw new tin in cut regions
hatch_fill_separation_n	*mm*	// distance between fill hatch line
	0	// don't do fill hatching
hatch_fill_angle_n	*degrees*	// angle in degrees of fill hatching
hatch_fill_colour_n	*colour*	// colour of the fill hatching
hatch_fill_linestyle_n	*linestyle*	// linestyle for fill hatching
hatch_fill_draw_sides_n	*1/0*	// 1 = draw sides of fill regions
hatch_fill_draw_original_n	*1/0*	// 1 = draw original tin in fill regions
hatch_fill_draw_new_n	*1/0*	// 1 = draw new tin in fill regions

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting hatch_cut_separation_n to 0.0.
fill hatching is turned off by setting hatch_fill_separation_n to 0.0.



44.4.0.10 Labelling Cuts of Pipeline Through Strings in a Model

The cuts that the pipeline string makes though any strings in user given models can be automatically labelled on the long section plots.

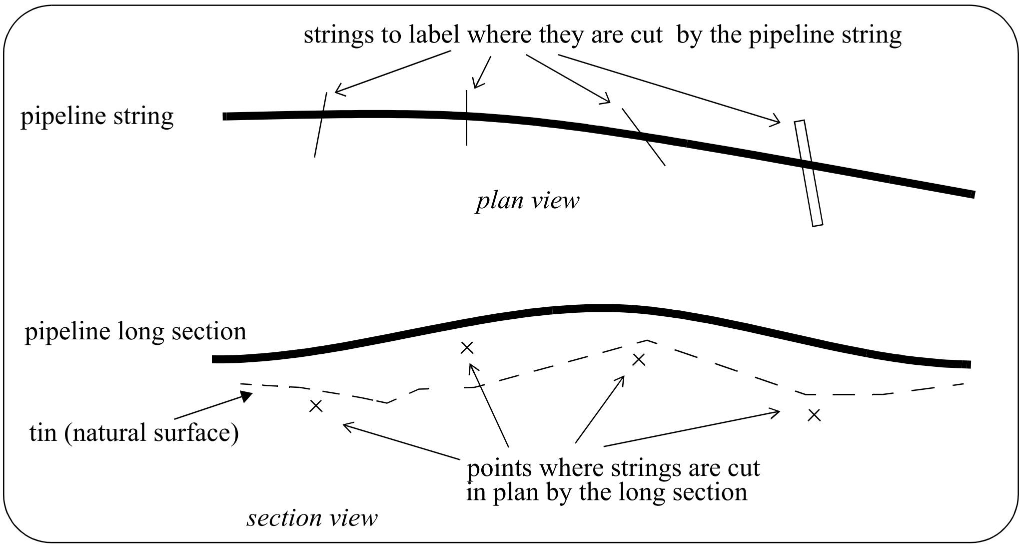
The **height**, **chainage** and **name** of the cut string can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the

(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.



Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

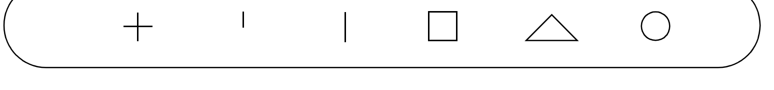
Text justification refers to the actual position and is given by

"top-left"	"top-centre"	"top-right"
"middle-left"	"middle-centre"	"middle-right"
"bottom-left"	"bottom-centre"	"bottom-right"

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are



Up to twenty five (25) separate models of strings can be cut and labelled.

44.4.0.11 Parameters for Labelling Where the Pipeline Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the **model** which contains the strings, and then a **name mask** which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the n'th set (where n can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

cuts_n_model	*model_name*	// model of strings to be cut

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

cuts_n_mask	*name_mask*	// strings to check for cuts
		// and if a cut occurs,
		// parameters show how to
		// label the cut

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mast can include wild cards and wild characters.

For example

	cuts_1_mask	"ke*"
or	cuts_1_mask	"?bank*"

or, if both masks are required,

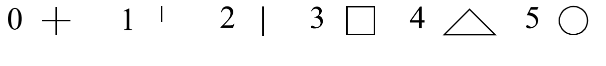
	cuts_1_mask	"ke* ?bank*"

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "*".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the design string, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the n'th set.

The parameters for drawing a **symbol** at the cut points are

cuts_symbol_n_mode	0	// cross
	1	// up from centre of box
	2	// up and down from centre of box
	3	// square
	4	// triangle, base at bottom
	5	// circle
	6	// use a 12d symbol



predefined symbols for cut_symbol_n_modes 0 to 5

If *cuts_symbol_n_mode* is 6, then the 12d symbol is given by

cuts_symbol_n_style	*plotsymbol*	// 12d symbol to draw at cut

Important Note

The plot symbol of name *plotsymbol* is defined in the file given by:

(a) the parameter *plot_symbols* in the ppf file

plot_symbols *filename*

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D

PLOT_SYMBOLS_4D *filename* *// default plotsym.4d*

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file *plotsym.4d*

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D

SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, *symbols.4d*

The position of the symbol is given by:

```
cuts_symbol_n_position    1       // above point height value
                          3       // above top of boxes
                        100       // to primary string
                        101-500   // to tin1 or tin2 etc.
```

The symbol can be adjusted by the parameters:

```
cuts_symbol_n_x         mm        // offset adjustment to position
cuts_symbol_n_y         mm        // height adjustment to position
cuts_symbol_n_angle     degrees   // rotation about point
cuts_symbol_n_colour    colour    // colour of symbol
```

and for all values of *cuts_symbol_n_mode* **other** than 6:

```
cuts_symbol_n_size      mm        // size of symbol, 0 don't draw
```

The value of the **chainage** of the cut string can be labelled using the parameters

```
cuts_chainage_n_position1         // above cut strings height value
                        3         // above top of boxes
                        100       // to primary string
                        101-500   // to tin1 or tin2 etc.

cuts_chainage_n_x       mm        // chainage adjustment to position
cuts_chainage_n_y       mm        // height adjustment to position
cuts_chainage_n_angle   degrees   // rotation about point
cuts_chainage_n_size    mm        // size of text, 0 don't label
cuts_chainage_n_colour  colour    // colour of text

cuts_chainage_n_textstyle   text  // textstyle of text chainage
cuts_chainage_n_pre_text    text  // text before the chainage value
cuts_chainage_n_post_text   text  // text after the chainage value

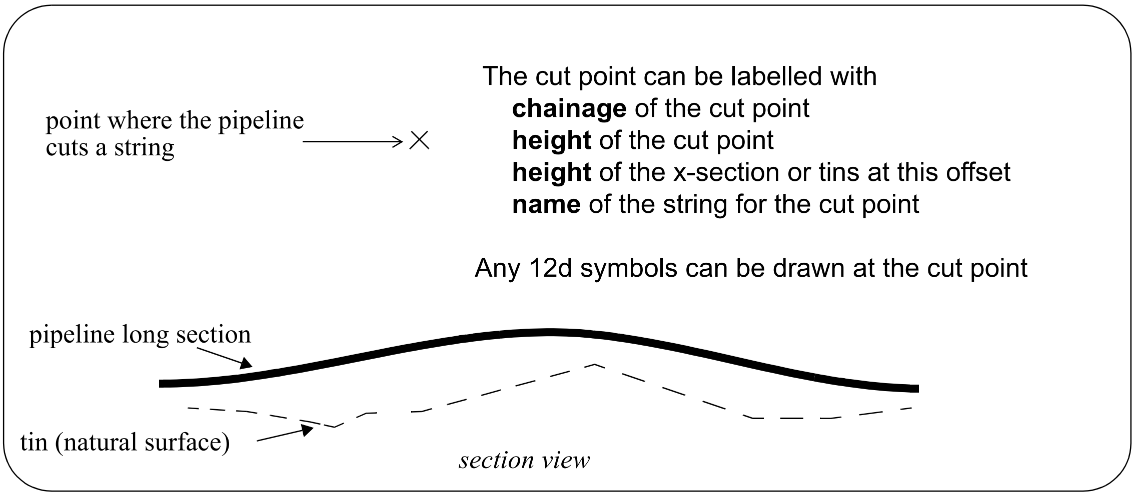
cuts_chainage_n_justification   justification   // justification of the text
cuts_chainage_n_no_decimals     integer         // number of decimals in
chainage
```

The value of a **height** at the chainage of the point can be calculated and labelled using the parameters

cuts_height_n_mode	*1*	// use height of cut point itself
	3	// use real world height of position
		// above boxes
	100	// height of primary string
	101-500	// use height of to tin1 or tin2 etc.
cuts_height_n_position	*1*	// at points position
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_height_n_x	*mm*	// chainage adjustment to position
cuts_height_n_y	*mm*	// height adjustment to position
cuts_height_n_angle	*degrees*	// rotation about point
cuts_height_n_size	*mm*	// size of text, 0 don't label
cuts_height_n_colour	*colour*	// colour of text
cuts_height_n_textstyle	*text*	// textstyle of text height
cuts_height_n_pre_text	*text*	// text before the height value
cuts_height_n_post_text	*text*	// text after the height value
cuts_height_n_justification	*justification*	// justification of the text
cuts_height_n_no_decimals	*integer*	// number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters

cuts_label_n_position	1	// above cut strings height value
	3	// above top of boxes
	100	// to primary string
	101-500	// to tin1 or tin2 etc.
cuts_label_n_mode	0	// don't include cut string name
	1	// include cut string name in label
cuts_label_n_x	*mm*	// chainage adjustment to position
cuts_label_n_y	*mm*	// height adjustment to position
cuts_label_n_angle	*degrees*	// rotation about point
cuts_label_n_size	*mm*	// size of text, 0 don't label
cuts_label_n_colour	*colour*	// colour of text
cuts_label_n_textstyle	*text*	// textstyle of text label
cuts_label_n_pre_text	*text*	// text before the string name
cuts_label_n_post_text	*text*	// text after the string name
cuts_label_n_justification	*justification*	// justification of the text



44.4.0.12 Title Block Information

The plot can have a standard ***12d Model*** title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

44.4.0.12.1 Standard Title Block

For the standard ***12d Model*** title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter *plot_border*.

plot_border	*yes/no*	*// yes plots a standard title block* *// default yes*
title_1	*text*	
title_2	*text*	
title_text_size	*value*	
title_colour	*colour*	

44.4.0.12.2 User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of 44 Text Plot Parameters.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The *plot_border* parameter should also be set to *no* so that the standard title block is not also drawn.

use_title_file	*yes/no*	*// yes draws the title block given in title_file* *// default no*
title_file	*filename*	
plot_border	*no*	*// turn off standard title block*

Some special plot parameters are used to pass information down to variables in a user defined title block

For example, inside the title block file it is possible to have run time user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

user_text_n	*text*

The special plot parameters are:

time_format	*text*	// format for $time
user_text_n	*text*	// where n = 1,2,... 1000 // passed down to $user_text_n
title_1	*text*	// passed down to $title_1
title_2	*text*	// passed down to $title_2
start_page_number	*integer*	// used as the starting value for // $page_number. If missing, // $page_number starts at 1.

start_drawing_number	*integer*	// added to $drawing_number in title
		// block file. If missing,
		// $drawing_number starts at 1.

drawing_number_prefix	*text*	// passed down to // $drawing_number_prefix
drawing_number_postfix	text	// passed down to // $drawing_number_postfix

44.4.0.13 Parameters that Modify Fields In the Plot Pipeline Network Panel

A number of parameters match those in the **plot pipeline network** panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for the parameter.

The plot parameters that also occur in the **plot pipeline network** panel are:

network_model	text	
plotter_type	text	
plot_stem	text	
view_name	text	// name of section view for tins, services, // vertical exaggeration etc.
specials_model	text	
peg_interval	world-units	
scale	value	
sheet_size	*text* or “width *height”*	
plot_height	mm	
start_chainage	world-units	
end_chainage	world-units	
left_margin	*mm*	
right_margin	*mm*	
top_margin	*mm*	
bottom_margin	*mm*	
plot_border	*yes/no*	
title_1	*text*	
title_2	*text*	
title_text_size	*value*	
title_text_colour	*colour*	
use_title_file	*yes/no*	
title_file	*filename*	

44.5 #Include in Plot Parameter Files

The plot parameter file also recognizes the CCCP preprocessor rules including #include which can be used to include other files in the plot parameter file.

The format of the #include command is:

#include ***file_name***

Hence a block of plot parameters can be set up in a file and included in another file using #include rather than typing them all in again.

Any number of #include's can be placed in the plot parameter file.

To return to the beginning of this appendix, click on 44 Text Plot Parameters.

45 Glossary

Glossary of Common Terms

Arc

Part of the circumference of a circle.

Affine Transformation 2D

A two dimensional transformation where one set of points is fitted to another. The transformation is a six parameter transformation, i.e., x displacement, y displacement, x scale factor, y scale factor, a x-rotation and y-rotation. If more variables exist than degrees of freedom, i.e., more than three control points are used, a least squares solution is calculated.

AGD

Australian Geodetic Datum.

AGD66

Australian Geodetic Datum 1966.

AGD84

Australian Geodetic Datum 1984.

AMG

Australian Map Grid.

Angle, Cartesian Angle, Mathematical Angle

The angle of a point is the counter-clockwise angle from the x-axis (horizontal or East line) to the line joining the point to the origin.

The angle of a line is the counter-clockwise angle measured from the x-axis to the line.

Batter

A steeply sloping surface (usually the wall of an earth bank).

Bearing

The bearing of a point is the clockwise angle from the y-axis (vertical or North line) to the line joining the point to the origin.

The bearing of a line is the clockwise angle measured from the y-axis to the line.

Blend

Use to define how opaque/translucent/transparent the fill of a polygon, face or tin is.

The value of blend is between 0 and 1.
0 means the fill is totally transparent (and hence invisible) and 1 means that the fill is opaque (non-translucent) and can't be seen through at all.

Breakline

A line on a surface joining a series of points on a common change-of-grade line. For example, the ridge top or spur, top or toe of batter, creek bank. See also *tinable segment*.

Cartesian Angle

See Angle.

Chainage

Chainage is a measure of the plan length along a string. The chainage at a point on a string is the start chainage of the string plus the plan length of the string from the beginning of the string to that point.

Circular Curve

Curves defined as an arc.

Cross Fall

The lateral grade or slope of a surface (particularly of a road pavement); usually expressed as a percentage of the proportion of metres vertically to metres horizontally.

End Chainage

The chainage of the last point of a string.

Eye-Point

For a perspective view, it is the point where the observer of the perspective view looks from.

GDA

Geocentric Datum of Australia.

GDA94

Geocentric Datum of Australia 1994.

GPS

Global Positioning System.

Grade

The longitudinal slope of a surface (particularly of road pavement). Usually expressed as a cross fall percentage or as a ratio of one unit vertically to a number of units horizontally. For example, 3% or 1:10.

GRS80

Geocentric Reference System 1980.

Helmert Transformation 2D

A two dimensional transformation where one set of points is fitted to another. The transformation is a four parameter transformation, i.e., x displacement, y displacement, scale factor and rotation. If more variables exist than degrees of freedom, i.e., more than two control points are used, a least squares solution is calculated.

Helmert Transformation 3D

A three dimensional transformation where one set of points is fitted to another. The transformation is a seven parameter transformation, i.e., x displacement, y displacement, z displacement, scale factor and three rotations. If more variables exist than degrees of freedom, i.e., more than two control points are used, a least squares solution is calculated.

Hidden Line

Lines that are hidden between protruding landforms, etc. in perspective views.

Horizontal Alignment

The plan position of an alignment string (centre line) defined by intersection points, spirals and arcs.

Intersection Point (IP)

The point where two lines intersect. Usually horizontal intersection points (HIP) or vertical intersection points (VIP)

Invert

The lower inner surface of a drain or sewer pipe.

ISG

Integrated Survey Grid (NSW Australia).

MGA, MGA94

Map Grid of Australia 1994.

NTv2

National Transform Version 2. Special grid file format used in Australia, NZ and Canada for converting longitude and latitude.

Null Value

In three dimensional data, it is possible that a point can have a valid plan position but an undefined height. In 12d Model, there is a special **null** value which is used internally when height is undefined (-9.9e29).

Obvert

The upper inner surface of a drain or sewer pipe.

Parabolic Curve

Curves defined as a parabola.

Plot File

A file of plotting instructions in a format to suit a particular plotter. In 12d Model, HPGL is the default format for plot files.

Polygon

A string where the first point and the last point have the same plan co-ordinate. That is, the string closes on itself.

Screen Units

The unit of resolution for the computer screen - usually called pixels.

Shade

For a shade for a perspective view, the colour of all triangle faces are adjusted depending on the angle they make with a specified light source.

Slope

The inclination or grade of a surface or line, usually expressed as a ratio between one unit vertically to a number of units horizontally. For example, 1:10.

Snapping

A process where the element to be selected does not have to be exactly located. A tolerance is specified (the snap tolerance) and if the cursor is placed within the tolerance distance of the element then the cursor is moved directly ("snaps") to the element.

Different snap settings determine what parts of the element are considered for snapping to. For example, points on the string (point snap), drop perpendicular on the lines of an element (line snap) and grid points (grid snap).

Spiral

The special type of curve used for transitioning between straights and arcs in an alignment string (centre line). Also known as a transition curve or transition spiral.

Start Chainage

The chainage of the first point of a string.

String

A string is an ordered series of points.

Apart from the first and last point in a string, each point in a string has a unique next point (successor) and a unique previous point (predecessor). The previous and next points for a point are called its string neighbours. The lines joining a point with its neighbours are called string links.

A string which has the same first and last point is called a closed string otherwise a string is said to be open.

Strings are very useful in the modelling of terrain and design surfaces. 12d Model uses a number of different **types** of strings which as defined in the Tools and Concepts.

Sweep Angle

For an arc, the sweep angle is the angle, measured in the ***clockwise*** direction, between the line joining the arc start point to the arc centre and the line joining the arc end point to the arc centre.

Tangent Point

A point at which a curve touches a line or another curve such that the tangent vector at that point is the same for the two touching items.

Target-Point

For a perspective view, it is the point that the observer is looking at.

Template

Standardized cross-section which is applied to a string at defined chainage points.

MTF Modifiers

12d Model commands which modify the definition of a template, as well as create and modify strings without them even being in a template. MTF Modifiers are used in preference to defining hundreds of different templates.

TIN

Triangulated **I**rregular **N**etwork. A TIN is a set of triangles which do not non-overlap in plan. Each vertex of a triangle has a z-value so that the TIN represents a surface in three dimensional space made up of triangular faces. When a TIN is created from a data set, the triangles are formed so that all non-null points are vertices of triangles. If breaklines are preserved in the TIN, then triangles are constrained so that any link from a breakline string is a side of a triangle.

Tinable vertex or point

If a vertex or point is tinable, then the vertex/point is included in triangulations. If the vertex/point is not tinable, then the vertex/point is ignored when triangulating.

Tinable segment or line

If a segment or line is tinable (and both the vertices at the ends of the segment/line are tinable and the z-values not null), then the segment/line is used as a side of a triangle during triangulation. This may not be possible if there are *crossing* tinable segments/lines.

A tinable segment is also known as a *breakline*.

Note that for a segment/line to be used as a side of a triangle, then its end vertices must be tinable and the z-values not null.

Triangulation

A set triangles, which do not overlap in a plan view, created from a set of data points. See TIN.

UTM

Universal Transverse Mercator.

View

The area in 12d Model used for displaying (drawing) graphical information. In 12d Model there are three types of views - plan, section and perspective.

Vertical Alignment

The long section position of an alignment string (centre line) defined by vertical intersection points (VIP's) and parabolic or circular curves.

WGS84

World Geodetic System 1984.

World Units

The fundamental units used in 12d Model - usually metres.
