Floating Arc: Known Point and Grade at Point

The **Floating Arc** passes through a known point and has a known grade for the tangent to the arc at the known point.

It may not always be possible for the Floating Arc to actually solve.

For example in the case where it follows a fixed line, if the perpendicular distance between the known point and the line is greater than the given radius, then there is no solution.

---

**Example**

*Floating Arc* going through a known point with a grade at that point of -50 per cent.

Vertical Exaggeration = 1

21.9.5.6 Vertical Computators

Not yet documented.
21.10 Text Format of Files

Go to

21.10.1 Text Format of the MTF File
21.10.2 Text Format of the Boxing File
21.10.1 Text Format of the MTF File

In the text version of the mtf file, most of (a) to (h) begin with a key word, following by an equals sign (=) and then special commands enclosed in { }.

\[
\text{key_word} = \{ \text{commands} \}
\]

The key words for each case above are

(a) left_side, right_side
(b) specials
(c) hinge_modifier
(d) left_side_modifier, right_side_modifier
(e) stripping
(f) boxing_file, left_boxing, right_boxing, left_boxing_2, right_boxing_2 ... left_boxing_8, right_boxing_8
(g) auto_super_tables, left_auto_super, left_auto_width, right_auto_super, right_auto_width
(h) loops
(i) section_width
(j) string_modifiers

If any of the key words exist, then they must be in the following order in the mtf file:

\[
\begin{align*}
\text{left_side} &= \{ \ldots \} \\
\text{right_side} &= \{ \ldots \} \\
\text{specials} &= \{ \ldots \} \\
\text{hinge Modifier} &= \{ \ldots \} \\
\text{left_side_modifier} &= \{ \ldots \} \\
\text{right_side_modifier} &= \{ \ldots \} \\
\text{stripping} &= \{ \ldots \} \\
\text{boxing_file} &= \text{“something.bf”} \ \\
\text{left_boxing} &= \{ \ldots \} \\
\text{right_boxing} &= \{ \ldots \} \\
\text{section_width} &= \text{value} \\
\text{string_modifiers} &= \{ \ldots \} \\
\text{auto_super_tables} &= 1 \text{ or } 0 \\
\text{left_auto_super} &= \{ \ldots \} \\
\text{left_auto_width} &= \{ \ldots \} \\
\text{right_auto_super} &= \{ \ldots \} \\
\text{right_auto_width} &= \{ \ldots \} \\
\text{loop_removals} &= \{ \ldots \} \\
\end{align*}
\]

The format for boxing_file is simply

\[
\text{boxing_file} = \text{“something.bf”}
\]

where something.bf is the name of a file containing boxing definitions to use for the mtf.

The format for (g) is simply

\[
\text{section_width} = \text{value} \quad // \text{default is 10000}
\]
where \textit{value} is the distance to search from the hinge string for strings required in some options. If \textit{section\_width} is missing, then it takes the default value of 10000.

The key words, \textit{left\_side} and \textit{right\_side} which are for initially applying templates (for part (a)), have already been described under the Design=>Apply=>Apply MTF option but will be summarised in the next section \textit{21.2.1 MTF Hinge Modifiers}.

The documentation for the \textbf{text file syntax} of the MTF file now follows.

See \textit{21.10.1.1 MTF Templates File Format}
\textit{21.10.1.2 MTF Specials File Format}
\textit{21.10.1.3 MTF Hinge Modifier File Format}
\textit{21.10.1.4 MTF MTF Modifiers File Format}
\textit{21.10.1.12 MTF Stripping File Format}
\textit{21.10.1.13 MTF Boxing File Format}
\textit{21.10.1.14 MTF Width File Format}
\textit{21.10.1.15 MTF String Modifiers File Format}
\textit{21.10.1.16 Substitutions in the Modifiers and Templates File}
21.10.1.1 MTF Templates File Format

The templates on the left and right hand sides of the centre line (or Hinge string if one is selected) are specified separately in the *Modifiers and Templates File*. Apart from a key word denoting whether the following part of the definition is for the left side or the right side, the set out for the left-side is identical to the right-side. Hence, only the left-side will be described in detail.

The left-side definition begins with the key words

```
left_side =
```

A list of chainages (in ascending order, one per line) with corresponding template names then follows. This list of chainages and templates is enclosed in curly braces `{}`.

**Note** if the template name includes spaces, then the name must be enclosed in quotes "". For example, "left 1".

The chainage-template lists are assembled as follows

**(a)** To represent a template starting at a given chainage, the chainage value followed by the template name is given. The chainage and name are separated by one or more spaces. For example, the template `std` starting at chainage 150 is represented by

```
150 std
```

The template is assumed to apply until the chainage given on the next line of the left-side definition.

If the template is to go to the end of the centre-line, add a line with a chainage greater than or equal to the end chainage. For example,

```
150 std
99999
```

**(b)** if no template exists from a chainage, simply include the chainage with no template name following it. For example, if there is no template from chainage 250, this is represented by

```
250
```

The non-existence of a template is assumed to apply until the chainage given on the next line of the left-side definition

**(c)** the case of a linear change from one template to another template over a specified chain-age range is represented by giving the start chainage of the linear change, followed on the same line by the start template, a comma, and the end template. For example, if the template is to vary linearly between the template `std` and the template `left`, beginning at the chainage 350, then the line in the file would be

```
350 std, left
```

The linear change takes place over the interval beginning at the chainage given on the defining line and ending at the chainage given on the next line of the left-side. Distances and percent cross-falls are interpolated linearly and slopes are interpolated on the radian value of the slope angles.

Combining these rules, the following lines in a template file

```
left_side = {
100 std
200 std, "left 1"
250 "left 1"
300
350 std
99999
}
```

describes the situation

1. the left-hand side of the centre-line has no template from the beginning of the centre-line until chainage 100.
2. at chainage 100, the template `std` begins and continues until chainage 200.
3. there is a linear change from the template *std* to the template *left 1* between chainage 200 and chainage 250.

4. the template *left 1* goes from chainage 250 to chainage 300.

5. there is a gap between chainage 300 and chainage 350.

6. the template *std* goes from chainage 350 to chainage 99999, or if the end chainage is smaller than 99999, to the end of the centre-line.

The right-side template definition begins with the key word right_side. The rest of the definition follows the same rules at the left hand side of the centre-line. For example,

```plaintext
right_side = {
    100  std
    200  std , right
    250  right
    300  right , std
    350  std
    400
}
```

The left and right sides can vary independently.

**Restrictions on the Template File Definitions**

1. If one template stops at the same chainage that another template begins, then the two templates must have the same number of fixed and variable links. The templates will be varied linearly from the stopping template to the starting template over one section separation distance.

2. If there is a linear variation between two templates, the two templates must have the same number of fixed and variable links.

3. If two templates do not have the same number of links, they must be separated by a gap, that is, by a region with no template.

**Summarising:**

The templates on the left and right hand sides of the centre line are specified separately in the Modifiers and Templates File.

The left-side (right-side) definition begins with the key words

```plaintext
left_side =
right_side =
```

with a list of chainages (in ascending order, one per line) with template names. This list of chainages and templates is enclosed in curly braces `{}`.

The chainage-template lists are assembled as follows

(a) To represent a template starting at a given chainage, the chainage value followed by the template name is given. The chainage and name are separated by one or more spaces. For example, the template *std* starting at chainage 150 is represented by

```plaintext
150  std
```

The template is assumed to apply until the chainage given on the next line of the left-side definition.

If the template is to go to the end of the centre-line, add a line with a chainage greater than or equal to the end chainage. For example,

```plaintext
150  std
99999
```

(b) if no template exists from a chainage, simply include the chainage with no template name following it. For example, if there is no template from chainage 250, this is represented by
The non-existence of a template is assumed to apply until the chainage given on the next line of the left-side definition.

(c) the case of a linear change from one template to another template over a specified chainage range is represented by giving the start chainage of the linear change, followed on the same line by the start template, a comma, and the end template. For example, if the template is to vary linearly between the template std and the template left, beginning at the chainage 350, then the line in the file would be

```
350 std, left
```

The linear change takes place over the interval beginning at the chainage given on the defining line and ending at the chainage given on the next line of the left-side. Distances and percent cross-falls are interpolated linearly and slopes are interpolated on the radian value of the slope angles.

### A Left and Right Side File Example

```plaintext
left_side = {
    100 std,
    200 std, "left 1",
    250 "left 1",
    300,
    350 std,
    99999
}
```

```plaintext
right_side = {
    100 std,
    200 std, right,
    250 right,
    300 right, std,
    350 std,
    400
}
```

The left_side describes the situation:

1. the left-hand side of the centre-line has no template from the beginning of the centre-line until chainage 100.
2. at chainage 100, the template std begins and continues until chainage 200.
3. there is a linear change from the template std to the template left 1 between chainage 200 and chainage 250.
4. the template left 1 goes from chainage 250 to chainage 300.
5. there is a gap between chainage 300 and chainage 350.
6. the template std goes from chainage 350 to chainage 99999, or if the end chainage is smaller than 99999, to the end of the centre-line.

Go to the next section [21.10.1.2 MTF Specials File Format](#) or back to [21.10.1 Text Format of the MTF File](#)
21.10.1.2 MTF Specials File Format

In the Modifiers and Templates File, the specials definition begins with the key word

\[
\text{specials} =
\]

This is followed by a list of

(a) chainages, in any order, one per line

and/or

(b) the names of files (enclosed in quotes "") which include lists of chainages (The default ending for a special chainage file is *.spc)

The list of chainages and/or file names is enclosed in curly braces {}.

**A Specials Example**

\[
\text{specials} = \{
\begin{align*}
125.3 \\
1925.4 \\
\text{“fred”} & \quad \text{// file of chainages to read in} \\
3007 \\
\text{“joe”}
\end{align*}
\}
\]

Go to the next section 21.10.1.3 MTF Hinge Modifier File Format or back to 21.10.1 Text Format of the MTF File
21.10.1.3 MTF Hinge Modifier File Format

In the Modifiers and Templates File, the **hinge modifier** definition begins with the key word

```
    hinge_modifier =
```

followed by one or more of the hinge modifier commands **offset**, **height**, **coord** and **nohinge** enclosing curly braces `{}`.

```
    hinge_modifier = {
        hinge modifier commands
    }
```

The definition of the hinge modifier commands will now be given.

**Offset**

The **Offset** modifier will move the hinge point a given offset distance (perpendicular to the reference string) from its current plan position. A positive offset is to the right of the hinge string and a negative offset to the left.

The format of the modifier to vary the **offset** is

```
offset st_ch end_ch st_offset end_offset absrel type extra_start extra_end
```

where

- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **st_offset** offset to be used at the start modifier chainage, **st_ch**
- **end_offset** offset to be used at the end modifier chainage, **end_ch**.
- **absrel** relative (default) or absolute
- **type** linear (default) or cubic
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage

**offset** is **relative** (the default) then

the **st_offset** is added to the current position of the hinge point at chainage **st_ch**.

and

the **end_offset** is added to the current position of the hinge point at chainage **end_ch**.

**offset** is **absolute**, then

the offset of the hinge point is taken with respect to the original position of the hinge string at chainage **st_ch**.

and

the offset of the hinge point is taken with respect to the original position of the hinge string at chainage **end_ch**.

**offset** is **linear** (the default), then the offset is varied linearly (with respect to the reference chainage) between the offsets at chainage **st_ch** and chainage **end_ch**.

**offset** is **cubic**, then the offset is varied as a reverse cubic (with respect to the reference chainage) between the offsets at chainage **st_ch** and chainage **end_ch**.

---

```
    reference string
    hinge string
    original point to apply template from hinge
```

**offset** moves the hinge point along the line perpendicular to the reference string.
Offset to String

The offset for the hinge point can also be varied by going out to another 12d Model string.

`offset`  `st_ch`  `end_ch`  `full_string_name`  `extra_start`  `extra_end`

where

`st_ch`  start chainage for the modifier
`end_ch`  end chainage for the modifier
`full_string_name`  name of a 12d Model string to take the hinge point out to. The format of the string name is “model_name->string_name”.
`extra_start`  optional - adds in an extra x-section 0.1mm before start chainage
`extra_end`  optional - adds in an extra x-section 0.1mm before end chainage

Height

The height modifier varies the height of the hinge point between the given chainages.

`height`  `st_ch`  `end_ch`  `st_height`  `end_height`  `absrel`  `type`  `extra_start`  `extra_end`

where

`st_ch`  start chainage for the modifier
`end_ch`  end chainage for the modifier
`st_height`  height to be used at the start modifier chainage, st_ch
`end_height`  height to be used at the end modifier chainage, end_ch.
`absrel`  relative (default) or absolute
`type`  linear (default) or cubic
`extra_start`  optional - adds in an extra x-section 0.1mm before start chainage
`extra_end`  optional - adds in an extra x-section 0.1mm before end chainage

If `absrel` is relative (the default) then

the st_height is added to the current height of the hinge point at chainage st_ch.
the end_height is added to the current height of the hinge point at chainage end_ch.

If `absrel` is absolute, then

the height of the hinge point is set to st_height above the original hinge string at
chainage st_ch.
the height of the hinge point is set to end_height above the original hinge string
at chainage end_ch.

If `type` is linear (the default), then the height is varied linearly (with respect to the reference
chainage) between the height at chainage st_ch and chainage end_ch.

If `type` is cubic, then the height is varied as a reverse cubic (with respect to the reference
chainage) between the height at chainage st_ch and chainage end_ch.

Height to String

The height of the hinge point can also be specified by taking the height from another
12d Model string.

`height`  `st_ch`  `end_ch`  `full_string_name`  `extra_start`  `extra_end`

where

`st_ch`  start chainage for the modifier
`end_ch`  end chainage for the modifier
`full_string_name`  name of a 12d Model string to take the hinge point height from. The format of the string name is “model_name->string_name”.
`extra_start`  optional - adds in an extra x-section 0.1mm before start chainage
`extra_end`  optional - adds in an extra x-section 0.1mm before end chainage
Coord to String

The coord modifier is used to replace the x, y and z position of the hinge point by the x, y and z position of another 12d Model string between given chainages. Hence coord replaces the hinge string by another string between the given chainages.

coord  st_ch  end_ch  full_string_name  extra_start  extra_end  
where

st_ch    start chainage for the modifier
end_ch   end chainage for the modifier
full_string_name name of the 12d Model string used to replace the hinge string between the chainages st_ch and end_ch. The format of the string name is “model_name->string_name”.
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage

Nohinge

The nohinge modifier is used to stop the hinge string (and hence the apply) between given chainages. This will leave a gap in the strings created by the apply between the given chainages.

nohinge  st_ch  end_ch  extra_start  extra_end  
where

st_ch    start chainage to stop the apply
end_ch   end chainage for stopping the apply
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage

A Hinge Modifier Example

hinge_modifier = {  
  offset  0 250 0 3  // linearly offset the hinge by 0 to 3  
  // over the chainage range 0 to 250.  
  height  125 300 2 2  // add 2 to the hinge height  
  // over the chainage range 125 to 300.  
  coord  300 400 "mod->new_string"  // use the position of the string  
  // new_string over the chainage  
  // range 300 to 400.  
  nohinge  400 500 2 2  // stop the apply between the chainages  
  // over the chainage range 400 to 500.  
}  

Go to the next section 21.10.1.4 MTF MTF Modifiers File Format or back to 21.10.1 Text Format of the MTF File
21.10.1.4 MTF MTF Modifiers File Format

In the Modifiers and Templates File, the **template modifier** definition begins with the key word

left_side_modifier =

and/or

right_side_modifier =

followed by one or more of the template modifier commands enclosing curly braces { }

(a) fixed link modifiers - commands working on fixed links

```
insert

remove
```

width, height, xfall, xfall_crc, copy_width, copy_height, copy_xfall, tin_height, tin_xfall

(b) stop and start decisions commands

```
decision
```

(c) variable cut and fill link modifiers - commands working on cut/fill links

```
insert_cut, insert_fill

remove_cut, remove_fill
```

cut_width, cut_height, cut_slope, copy_cut_width, copy_cut_height, copy_cut_slope, tin_cut_height, tin_cut_slope

```
fill_width, fill_height, fill_slope, copy_fill_width, copy_fill_height, copy_fill_slope, tin_fill_height, tin_fill_slope
```

(d) final cut/fill link modifiers

```
final_width, final_cut_slope, final_no_cut_slope

final_fill_slope, final_no_fill_slope
```

(e) snippets - inserting groups of modifier commands

```
snippet
```

That is,

```
left_side_modifier = { template modifier commands }
```

and/or

```
right_side_modifier = { template modifier commands }
```

The definition of the template modifier commands and their file format will now be given.

For **Start mode** and **End mode**, go to the section 21.10.1.5 Start and End Chainages in the Modifier File Format.

For **Fixed Link** modifiers, go to the section 21.10.1.6 MTF Fixed Link Modifiers File Format.
For Decision Link modifiers, go to the section 21.10.1.7 Decision File Format.
For Cut and Fill Link modifiers, go to the section 21.10.1.8 Cut and Fill Variable Link Modifiers File Format.
For Final Link modifiers, go to the section 21.10.1.9 Final Link Modifiers File Format.
For Snippets, go to the section 21.10.1.10 Snippets File Format.
Please continue to the next section 21.10.1.5 Start and End Chainages in the Modifier File Format.
21.10.1.5 Start and End Chainages in the Modifier File Format

Modifiers work between two chainages and in each modifier command, the position of the start and end chainages for the commands are denoted by:

\[
\begin{align*}
st_ch & \quad \text{start chainage for the modifier} \\
end_ch & \quad \text{end chainage for the modifier}
\end{align*}
\]

However, there are a number of ways for defining the start and end chainages in the modifier command (called Start mode and End mode on the modifier panels).

**Start Mode - st_ch**

For each of the Start modes, the replacement for \texttt{st\_ch} is:

(a) Typed

the actual typed in chainage value

(b) Start of reference string

\texttt{$null$

(c) Start of other string

\texttt{chainage\_start "model\_of\_string->string\_name"}

where model\_of\_string and string\_name are the model and name of the string to take the start chainage from. The double quotes (") are needed.

(d) End of other string

\texttt{chainage\_final "model\_of\_string->string\_name"}

where model\_of\_string and string\_name are the model and name of the string to take the end chainage from. The double quotes (") are needed.

(e) Lowest dropped chainage of other string

\texttt{chainage\_low "model\_of\_string->string\_name"}

where model\_of\_string and string\_name are the model and name of the string to take the lowest dropped chainage from. The double quotes (") are needed.

(f) Highest dropped chainage of other string

\texttt{chainage\_high "model\_of\_string->string\_name"}

where model\_of\_string and string\_name are the model and name of the string to take the highest dropped chainage from. The double quotes (") are needed.

(g) Named part of reference other string

\texttt{named\_part "part\_specifier" start\_extension\_value}

where part\_specifier is the full specification of the part of the reference string to use. The
start_extension_value is added to the chainage. The double quotes (") are needed.

(h) Named part of other string

\[
\text{named_part } \text{"model_of_string->string_name" } \text{"part_specifier" } \text{start_extension_value}
\]

where model_of_string and string_name are the model and name of the string to take the name part from, and part_specifier is the full specification of the part from that string. The start_extension_value is added to the chainage. The double quotes (") are needed.

(i) Named position of reference

\[
\text{named_position } \text{"pos_name" } \text{start_extension_value}
\]

where pos_name is the name of the named position of the reference string to use. The start_extension_value is added to the chainage. The double quotes (") are needed.

(j) Named position on other string

\[
\text{named_position } \text{"model_of_string->string_name" } \text{"pos_name" } \text{start_extension_value}
\]

where model_of_string and string_name are the model and name of the string to take the name position from, and pos_name is the name of the named position from that string. The start_extension_value is added to the chainage. The double quotes (") are needed.

(k) Cut of other string

\[
\text{cut_other } \text{"model_of_string->string_name" } \text{"name" } \text{start_extension_value}
\]

where model_of_string and string_name are the model and name of the selected string. A chainage is calculated from the cut of the string with the reference string. The start_extension_value is added to the chainage. The double quotes (") are needed.

**Note:** If there are no cuts, or if there is more than one cut, then the command is not processed.

### End Mode - end_ch

For each of the **End modes**, the replacement for end_ch is:

(a) Typed  
the actual typed in chainage value
(b) End of reference string
$null

(c) Start of other string

chainage_start "model_of_string->string_name"

where model_of_string and string_name are the model and name of the string to take the start chainage from. The double quotes (") are needed.

(d) End of other string

chainage_final "model_of_string->string_name"

where model_of_string and string_name are the model and name of the string to take the end chainage from. The double quotes (") are needed.

(e) Lowest dropped chainage of other string

chainage_low "model_of_string->string_name"

where model_of_string and string_name are the model and name of the string to take the lowest dropped chainage from. The double quotes (") are needed.

(f) Highest dropped chainage of other string

chainage_high "model_of_string->string_name"

where model_of_string and string_name are the model and name of the string to take the highest dropped chainage from. The double quotes (") are needed.

(g) Named part of reference other string

named_part "part_specifier" start_extension_value

where part_specifier is the full specification of the part of the reference string to use. The start_extension_value is added to the chainage. The double quotes (") are needed.

(h) Named part of other string

named_part "model_of_string->string_name" "part_specifier" end_extension_value

where model_of_string and string_name are the model and name of the string to take the name part from, and part_specifier is the full specification of the part from that string. The end_extension_value is added to the chainage. The double quotes (") are needed.

(i) Named position of reference

named_position "pos_name" end_extension_value

where pos_name is the name of the named position of the reference string to use. The end_extension_value is added to the chainage. The double quotes (") are needed.

(j) Named position on other string

named_position "model_of_string->string_name" "pos_name" end_extension_value

where model_of_string and string_name are the model and name of the string to take the name position from, and pos_name is the name of the named position from that string. The end_extension_value is added to the chainage. The double quotes (") are needed.

(k) Cut of other string

cut_other "model_of_string->string_name" "name" start_extension_value

where model_of_string and string_name are the model and name of the selected string. A chainage is calculated from the cut of the string with the reference string. The end_extension_value is added to the chainage. The double quotes (") are needed.

Note: is there is no cuts or more than one cut then the command is not processed.

Please continue to the next section 21.10.1.6 MTF Fixed Link Modifiers File Format.
21.10.1.6 MTF Fixed Link Modifiers File Format

Fixed - Link Insert

Fixed links can be created by one of three `insert` commands by specifying either width and height, width and xfall, or height and xfall.

```
insert link_name colour width height unknown st_ch end_ch optional // use width, height
insert link_name colour width unknown xfall st_ch end_ch optional // use width, xfall
insert link_name colour unknown height xfall st_ch end_ch optional // use height, xfall
```

where `unknown` takes the place of the one of width, height or xfall not being used, and

- **link_name** name of the link being created
- **colour** colour of the link being created
- **width, height, xfall** width, height or xfall of the created link
- **st_ch** start chainage for creating the link
- **end_ch** end chainage for creating the link

and **optional** can be none, one or more of the following

- **name** if non-blank, insert before the link name in the template
  - if blank, then append after the last link of the fixed template table
- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1 mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1 mm before end chainage
- **inactive** if **inactive** is there then the command is not processed.
  - If inactive is not there then the command is processed
- **// text** the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Fixed - Link Remove

Fixed links can be deleted by the `remove` command:

```
remove link_list st_ch end_ch optional
```

where

- **link_list** one or more names of links to be removed, in the form `name1 name2 ... namei`
- **st_ch** start chainage for removing the link
- **end_ch** end chainage for removing the link

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1 mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1 mm before end chainage
inactive if inactive is there then the command is not processed.
// text
the text is a comment
See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Fixed - Width
The width modifier is used to modify the width of fixed links originally defined by width.
The format of the modifier to vary the width of the fixed links given by link_list is
width link_list st_ch end_ch st_wid end_wid absrel type optional
where
link_list one or more names of fixed links given in the template definition; with format
name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
st_wid width to be used at the start modifier chainage, st_ch
end_wid width to be used at the end modifier chainage, end_ch.
absrel relative (default) or absolute
If absrel is relative (the default) then
the st_wid is added to the current width of links in link_list at chainage st_ch.
the end_wid is added to the current width of links in link_list at chainage end_ch.
If absrel is absolute, then
the width of links in link_list are set to st_wid at chainage st_ch.
the width of links in link_list are set to end_wid at chainage end_ch.
type linear (default) or cubic
If type is linear (the default), then the width of links in link_list are varied linearly (with respect
to the reference chainage) between the width at chainage st_ch and chainage end_ch.
If type is cubic, then the width of links in link_list is varied as a reverse cubic (with respect to
the reference chainage) between the width at chainage st_ch and chainage end_ch.
and optional can be none, one or more of
interval if interval exists, then sections are created at the interval_value for the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
// text
the text is a comment

The width for a link can also be varied by going out to another 12d Model string or by taking
the width between two 12d Model strings.
width link_list st_ch end_ch full_string_name side optional
width link_list st_ch end_ch str_name_1 side_1 str_name_2 side_2 optional
where
link_list one or more names of fixed links given in the template definition;
Chapter 21  Advanced Design

Text Format of Files

st_ch        start chainage for the modifier
end_ch       end chainage for the modifier
full_string_name name of a **12d Model** string to take links in link_list out to.
The format of the string name is “model_name->string_name”.
side          side to search for string:   -1 for left, 0 for left and right, 1 for right

str_name_1    name of the first **12d Model** string. The format of the string name is “model_name->string_name”.
side_1        side to search for string_1:   -1 for left, 0 for left and right, 1 for right

str_name_2    name of the second **12d Model** string. The format of the string name is “model_name->string_name”.
side_2        side to search for string_2:   -1 for left, 0 for left and right, 1 for right

and **optional** can be none, one or more of

interval       if interval exists, then sections are created at the interval_value for the range of this command
                if interval is missing, then the interval for the Apply MTF is used
            interval_value only exists if interval exists
extra_start    optional - adds in an extra x-section 0.1mm before start chainage
extra_end      optional - adds in an extra x-section 0.1mm before end chainage
inactive       if *inactive* is there then the command is not processed.
                If inactive is not there then the command is processed
// text         the text is a comment

The **width** of links in link_list are taken to be the distance between str_name_1 and str_name_2.
See [21.10.1.5 Start and End Chainages in the Modifier File Format](#) for the format for st_ch and end_ch.

**Fixed- Width from Link**

The **width from link** modifier is used to modify the width of fixed links originally defined by width to be the same as another link. That is, the width of the link is a copy of the width of another link.

The format of the modifier to vary the **width from link** of the fixed links given by link_list is

**copy_width** link_list  st_ch  end_ch  from_link  zone  optional

where

link_list     one or more names of fixed links given in the template definition; with format name1 name2 ... namei
st_ch         start chainage for the modifier
end_ch        end chainage for the modifier
from_link     name of link to take the width from
zone          section of the template that the from_link is from (i.e. fixed, cut or fill)

and **optional** can be none, one or more of

interval       if interval exists, then sections are created at the interval_value for the range of this command
                if interval is missing, then the interval for the Apply MTF is used
Fixed - Height

The **height** modifier is used to modify the height of fixed links originally defined by height.

The format of the modifier to vary the **height** of the fixed links in the **link_list** is almost identical to varying the width and is:

```
height  link_list  st_ch  end_ch  st_ht  end_ht  absrel  type  optional
```

where

- **link_list**: one or more names of fixed links given in the template definition; with format `name1  name2  ...  namei`
- **st_ch**: start chainage for the modifier
- **end_ch**: end chainage for the modifier
- **st_ht**: height to be used at the start modifier chainage, st_ch
- **end_ht**: height to be used at the end modifier chainage, end_ch.
- **absrel**: relative (default) or absolute
  - If **absrel** is **relative** (the default) then
    - the st_ht is added to the current height of links in link_list at chainage st_ch.
    - the end_ht is added to the current height of links in link_list at chainage end_ch.
  - If **absrel** is **absolute**, then
    - the height of links in link_list are set to st_ht at chainage st_ch.
    - the height of links in link_list are set to end_ht at chainage end_ch.

- **type**: linear (default) or cubic
  - If **type** is **linear** (the default), then the height of links in link_list are varied linearly (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.
  - If **type** is **cubic**, then the height of links in link_list is varied as a reverse cubic (with respect to the reference chainage) between the height at chainage st_ch and chainage end_ch.

and **optional** can be none, one or more of:

```
interval         only exists if interval exists
extra_start      optional - adds in an extra x-section 0.1mm before start chainage
extra_end        optional - adds in an extra x-section 0.1mm before end chainage
inactive         if inactive is there then the command is not processed.
// text           the text is a comment
```

The height for a link can also be varied by taking the height from a 12d Model string or by
taking the height between two 12d Model strings.

**height** link_list st_ch end_ch full_string_name side optional

**height** link_list st_ch end_ch str_name_1 side1 str_name_2 side2 optional

where

- **link_list**: one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- **st_ch**: start chainage for the modifier
- **end_ch**: end chainage for the modifier
- **full_string_name**: name of a 12d Model string to take links in link_list out to. The format of the string name is “model_name->string_name”.
- **side**: side to search for string: -1 for left, 0 for left and right, 1 for right
- **str_name_1**: name of the first 12d Model string. The format of the string name is “model_name->string_name”.
- **side2**: side to search for string: -1 for left, 0 for left and right, 1 for right
- **str_name_2**: name of the second 12d Model string. The format of the string name is “model_name->string_name”.
- **side2**: side to search for string: -1 for left, 0 for left and right, 1 for right

and **optional** can be none, one or more of

- **interval**: if interval exists, then sections are created at the interval_value for the range of this command. If interval is missing, then the interval for the Apply MTF is used
- **interval_value**: only exists if **interval** exists
- **extra_start**: optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end**: optional - adds in an extra x-section 0.1mm before end chainage

// text the text is a comment

The height of links in link_list are taken to be the height between str_name_1 and str_name_2.

See [21.10.1.5 Start and End Chainages in the Modifier File Format](#) for the format for st_ch and end_ch.

### Fixed - Height from Link

The height from link modifier is used to modify the height of fixed links originally defined by height to be the same height as another link. That is, the height of the link is a copy of the height of another link.

The format of the modifier to vary the height from link of the fixed links given by link_list is

**copy_height** link_list st_ch end_ch from_link zone optional

where

- **link_list**: one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- **st_ch**: start chainage for the modifier
- **end_ch**: end chainage for the modifier
- **from_link**: name of link to take the height from
- **zone**: section of the template that the from_link is from (i.e. fixed, cut or fill)

and **optional** can be none, one or more of
interval if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text the text is a comment
See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Fixed - Cross Fall

The xfall modifier is used to modify the cross fall of fixed links originally defined by xfall.
The format of the modifier to vary the cross-fall of the fixed links in the link_list is almost identical
to varying the width and is:

xfall link_list st_ch end_ch st_xfall end_xfall absrel type optional

where

link_list one or more names of fixed links given in the template definition; with format
        name1 name2 ... namei

st_ch start chainage for the modifier
end_ch end chainage for the modifier
st_xfall xfall to be used at the start modifier chainage, st_ch
end_xfall xfall to be used at the end modifier chainage, end_ch.
absrel relative (default) or absolute
If absrel is relative (the default) then
    the st_xfall is added to the current xfall of links in link_list at chainage st_ch.
    the end_xfall is added to the current xfall of links in link_list at chainage end_ch.
If absrel is absolute, then
    the xfall of links in link_list are set to st_xfall at chainage st_ch.
    the xfall of links in link_list are set to end_xfall at chainage end_ch.
type linear (default) or cubic
If type is linear (the default), then the xfall of links in link_list are varied linearly (with respect
to the reference chainage) between the xfall at chainage st_ch and chainage end_ch.
    cubic, then the xfall of links in link_list are varied as a reverse cubic (with respect
to the reference chainage) between the xfall at chainage st_ch and chainage end_ch.
    rotate, then the angle of the xfall of the links in link_list is varied linearly (with
respect to the reference chainage) between the angle of the xfall at chainage st_ch and
chainage end_ch.
and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
The xfall of a link can be defined by using the xfall from the **beginning of the link** (i.e. the end of the previous link or the hinge string if it is the first link) to another 12d Model, or by taking the **xfall between two 12d Model strings**.

\[
\text{xfall} \quad \text{link_list} \quad \text{st_ch} \quad \text{end_ch} \quad \text{full_string_name} \quad \text{side} \quad \text{optional}
\]

\[
\text{xfall} \quad \text{link_list} \quad \text{st_ch} \quad \text{end_ch} \quad \text{str_name_1} \quad \text{side1} \quad \text{str_name_2} \quad \text{side2} \quad \text{optional}
\]

where

- **link_list** one or more names of fixed links given in the template definition; with format
  - name1
  - name2 ...
  - namei
- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **full_string_name** name of a 12d Model string to use to calculate xfall. The format of the string name is “model_name->string_name”.
- **side** side to search for string: -1 for left, 0 for left and right, 1 for right
- **str_name_1** name of the first 12d Model string. The format of the string name is “model_name->string_name”.
- **side1** side to search for string_1: -1 for left, 0 for left and right, 1 for right
- **str_name_2** name of the second 12d Model string.
- **side2** side to search for string_2: -1 for left, 0 for left and right, 1 for right

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage
- **inactive** if inactive is there then the command is not processed. If inactive is not there then the command is processed

// text

The xfall of links in link_list are taken to be the xfall between str_name_1 and str_name_2.

See **21.10.1.5 Start and End Chainages in the Modifier File Format** for the format for st_ch and end_ch.

**Fixed - Cross Fall Circular Reverse Curve**

The xfall_crc modifier is used to modify the cross fall of fixed links originally defined by xfall using the circular reverse curve formula.

The format of the modifier to vary the cross-fall of the fixed links (using circular reverse curves) in the link_list is:

\[
\text{xfall_crc} \quad \text{link_list} \quad \text{st_ch} \quad \text{end_ch} \quad \text{st_xfall} \quad \text{end_xfall} \quad \text{st_len} \quad \text{end_len} \quad \text{optional}
\]

where

- **link_list** one or more names of fixed links given in the template definition; with format
  - name1
  - name2 ...
  - namei
Text Format of Files

st_ch  start chainage for the modifier
end_ch  end chainage for the modifier
st_xfall xfall to be used at the start modifier chainage, st_ch
end_xfall xfall to be used at the end modifier chainage, end_ch.
st_len  length of the start circular arc to be used at the start modifier chainage, st_ch.
end_len  length of the end circular arc to finish at the end modifier chainage, st_ch.

and optional can be none, one or more of

interval  if interval exists, then sections are created at the interval_value for
          the range of this command
          if interval is missing, then the interval for the Apply MTF is used
interval_value  only exists if interval exists
extra_start  optional - adds in an extra x-section 0.1mm before start chainage
extra_end  optional - adds in an extra x-section 0.1mm before end chainage
inactive  if inactive is there then the command is not processed.
          If inactive is not there then the command is processed
// text  the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Fixed - Xfall from Link

The xfall from link modifier is used to modify the xfall of fixed links originally defined by xfall to be the same xfall as another link. That is, the xfall of the link is a copy of the xfall of another link.
The format of the modifier to vary the xfall from link of the fixed links given by link_list is

```
copy_xfall  link_list  st_ch  end_ch  from_link  zone  optional
```
where

link_list  one or more names of fixed links given in the template definition; with format
           name1  name2  ...  namei
st_ch  start chainage for the modifier
end_ch  end chainage for the modifier
from_link  name of the link to take the xfall from
zone  section of the template that the from_link is from (i.e. fixed, cut or fill)

and optional can be none, one or more of

interval  if interval exists, then sections are created at the interval_value for
          the range of this command
          if interval is missing, then the interval for the Apply MTF is used
interval_value  only exists if interval exists
extra_start  optional - adds in an extra x-section 0.1mm before start chainage
extra_end  optional - adds in an extra x-section 0.1mm before end chainage
inactive  if inactive is there then the command is not processed.
          If inactive is not there then the command is processed
// text  the text is a comment

Important Note

The link to copy cross fall from can be defined in terms of cross fall or slope.
If the link to copy is defined by slope, then the cross fall is calculated to match the slope.
See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.
Fixed - Tin Height

The tin height modifier is used to modify the height of the link so that the link will sit on the tin at the given width.

The tin height can only be used for a fixed link defined by width and height.

The format of the modifier to vary the tin height of the fixed links in the link_list is:

```
tin_height link_list st_ch end_ch tin_name optional
```

where

- **link_list** one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **tin_name** name of the tin to be used in defining the height.

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage
- **inactive** if **inactive** is there then the command is not processed.
  - If inactive is not there then the command is processed
- ```// text``` the text is a comment

See [21.10.1.5 Start and End Chainages in the Modifier File Format](#) for the format for st_ch and end_ch.

Fixed - Tin Xfall

The tin xfall modifier is used to modify the xfall of the link so that the link will sit on the tin at the given width.

The tin xfall can only be used for a fixed link defined by width and xfall.

The format of the modifier to vary the tin xfall of the fixed links in the link_list is:

```
tin_xfall link_list st_ch end_ch tin_name
```

where

- **link_list** one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **tin_name** name of the tin to be used in defining the xfall.

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage
- **inactive** if **inactive** is there then the command is not processed.
  - If inactive is not there then the command is processed
- ```// text``` the text is a comment

See [21.10.1.5 Start and End Chainages in the Modifier File Format](#) for the format for st_ch and end_ch.
If inactive is not there then the command is processed

// text the text is a comment

Please continue to the next section 21.10.1.7 Decision File Format.

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.
21.10.1.7 Decision File Format

Each template is made up of the sections fixed, decisions, cut, fill and final cut/fill. If a template has a decisions section then by default it is used instead of the cut, fill and final cut/fill sections.

Hence by default, either the decisions section

or

the cut, fill and final cut/fill sections

from the template being used over the chainage range.

Using the decision modifier, it is possible to override the default and for a given chainage range

use the cut, fill and final cut/fill sections instead of the decisions section

or

use the decisions section from another template instead of the current templates sections.

The format of the decision modifier is

decision template_name st_ch end_ch optional

decision " " st_ch end_ch optional

where

template_name name of template to take the decision section from.

If the template name is given as " ", then the decision section for the template being used in the chainage range is ignored, and the cut, fill and final cut/fill tables for the template are used instead. Hence this overrides the default of using the decisions section in preference to the cut, fill and final cut/fill sections of the template.

st_ch start chainage for applying/removing the decision

end_ch end chainage for applying/removing the decision

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for the range of this command

if interval is missing, then the interval for the Apply MTF is used

interval_value only exists if interval exists

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

inactive if inactive is there then the command is not processed.

If inactive is not there then the command is processed

// text the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Note

The full description of the Decisions section of a template is given in 21.8 Full Definition of Template Decisions.

Please continue to the next section 21.10.1.8 Cut and Fill Variable Link Modifiers File Format.
21.10.1.8 Cut and Fill Variable Link Modifiers File Format

Cut and Fill Link Insert
Cut and fill links can be created by one of three `insert` commands by specifying either width and height, width and slope, or height and slope.

\[
\text{insert\_cut} \quad \text{link\_name} \quad \text{colour} \quad \text{width} \quad \text{height} \quad \text{unknown} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{width, ht}
\]
\[
\text{insert\_fill} \quad \text{link\_name} \quad \text{colour} \quad \text{width} \quad \text{height} \quad \text{unknown} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{width, ht}
\]
\[
\text{insert\_cut} \quad \text{link\_name} \quad \text{colour} \quad \text{width} \quad \text{unknown} \quad \text{slope} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{width, slope}
\]
\[
\text{insert\_fill} \quad \text{link\_name} \quad \text{colour} \quad \text{width} \quad \text{unknown} \quad \text{slope} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{width, slope}
\]
\[
\text{insert\_cut} \quad \text{link\_name} \quad \text{colour} \quad \text{unknown} \quad \text{height} \quad \text{slope} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{ht, slope}
\]
\[
\text{insert\_fill} \quad \text{link\_name} \quad \text{colour} \quad \text{unknown} \quad \text{height} \quad \text{slope} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional} // \text{ht, slope}
\]

where `unknown` takes the place of the one of width, height or slope not being used, and

\[
\begin{align*}
\text{link\_name} & \quad \text{name of the link being created} \\
\text{colour} & \quad \text{colour of the link being created} \\
\text{width, height, slope} & \quad \text{width, height or slope of the created link} \\
\text{st\_ch} & \quad \text{start chainage for creating the link} \\
\text{end\_ch} & \quad \text{end chainage for creating the link}
\end{align*}
\]

and `optional` can be none, one or more of the following

\[
\begin{align*}
\text{name} & \quad \text{if non-blank, insert before the link name in the template} \\
& \quad \text{if blank, then append after the last link of the fixed template table} \\
\text{interval} & \quad \text{if interval exists, then sections are created at the interval\_value for} \\
& \quad \text{the range of this command} \\
& \quad \text{if interval is missing, then the interval for the Apply MTF is used} \\
\text{interval\_value} & \quad \text{only exists if `interval` exists} \\
\text{extra\_start} & \quad \text{optional - adds in an extra x-section 0.1mm before start chainage} \\
\text{extra\_end} & \quad \text{optional - adds in an extra x-section 0.1mm before end chainage} \\
\text{inactive} & \quad \text{if `inactive` is there then the command is not processed.} \\
& \quad \text{If inactive is not there then the command is processed} \\
// \text{text} & \quad \text{the text is a comment}
\end{align*}
\]

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for `st\_ch` and `end\_ch`.

Cut and Fill Link Remove
Cut and fill links can be deleted by the `remove` commands:

\[
\text{remove\_cut} \quad \text{link\_list} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional}
\]
\[
\text{remove\_fill} \quad \text{link\_list} \quad \text{st\_ch} \quad \text{end\_ch} \quad \text{optional}
\]

where

\[
\begin{align*}
\text{link\_list} & \quad \text{one or more names of links to be removed, in the form} \\
& \quad \text{name1 name2 ... namei} \\
\text{st\_ch} & \quad \text{start chainage for removing the link} \\
\text{end\_ch} & \quad \text{end chainage for removing the link}
\end{align*}
\]

and `optional` can be none, one or more of

\[
\begin{align*}
\text{interval} & \quad \text{if interval exists, then sections are created at the interval\_value for} \\
& \quad \text{the range of this command}
\end{align*}
\]
Text Format of Files

Chapter 21  Advanced Design

Cut and Fill Width

The cut_width modifier is used to modify the width of variable cut links originally defined by width. Similarly the fill_width modifier is used to modify the width of variable fill links originally defined by width.

The format of the modifier to vary the width of the variable cut/fill links in link_list is

\[
\text{cut_width link_list st_ch end_ch st_wid end_wid absrel type optional}\\
\text{fill_width link_list st_ch end_ch st_wid end_wid absrel type optional}
\]

where

link_list one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

st_wid width to be used at the start modifier chainage, st_ch

end_wid width to be used at the end modifier chainage, end_ch.

absrel relative (default) or absolute

If absrel is relative (the default) then

the st_wid is added to the current width of links in link_list at chainage st_ch.

the end_wid is added to the current width of links in link_list at chainage end_ch.

If absrel is absolute, then

the width of links in link_list are set to st_wid at chainage st_ch.

the width of links in link_list are set to end_wid at chainage end_ch.

type linear (default) or cubic

If type is linear (the default), then the width of links in link_list are varied linearly (with respect to the reference chainage) between the width at chainage st_ch and chainage end_ch.

If type is cubic, then the width of links in link_list are varied as a reverse cubic (with respect to the reference chainage) between the width at chainage st_ch and chainage end_ch.

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for the range of this command

interval_value only exists if interval exists

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

inactive if inactive is there then the command is not processed.

If inactive is not there then the command is processed

// text the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.
The **width** for a variable link can also be varied by going out to another **12d Model** string.

**cut_width** link_list st_ch end_ch full_string_name side optional

**fill_width** link_list st_ch end_ch full_string_name side optional

where

- link_list: one or more names of cut/fill links given in the template definition; with format name1 name2 ... namei
- st_ch: start chainage for the modifier
- end_ch: end chainage for the modifier
- full_string_name: name of a **12d Model** string to take links in link_list out to. The format of the string name is "model_name->string_name".
- side: side to search for string: -1 for left, 0 for left and right, 1 for right

and **optional** can be none, one or more of

- interval: if interval exists, then sections are created at the interval_value for the range of this command.
- interval_value: only exists if interval exists
- extra_start: optional - adds in an extra x-section 0.1mm before start chainage
- extra_end: optional - adds in an extra x-section 0.1mm before end chainage
- inactive: if inactive is there then the command is not processed.
- // text: the text is a comment

The **width** for a link can also be varied by using the **width between two **12d Model** strings str_name_1 and str_name_2.**

**cut_width** link_list st_ch end_ch str_name_1 str_name_2 side1 side2 optional

**fill_width** link_list st_ch end_ch str_name_1 str_name_2 side1 side2 optional

See **21.10.1.5 Start and End Chainages in the Modifier File Format** for the format for st_ch and end_ch.

**Cut and Fill Width from Link**

The cut and fill **width from link** modifiers are used to modify the width of cut and fill links originally defined by width, to be the same as another link. That is, the width of the link is a copy of the width of another link.

The format of the modifier to vary the cut and fill **width from link** of the fixed links given by link_list is

**copy_cut_width** link_list st_ch end_ch from_link zone optional

**copy_fill_width** link_list st_ch end_ch from_link zone optional

where

- link_list: one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- st_ch: start chainage for the modifier
- end_ch: end chainage for the modifier
- from_link: name of the link to take the width from
- zone: section of the template that the from_link is from (i.e. fixed, cut or fill)
and *optional* can be none, one or more of

- **interval**: if interval exists, then sections are created at the interval_value for the range of this command. If interval is missing, then the interval for the Apply MTF is used.
- **interval_value**: only exists if *interval* exists.
- **extra_start**: optional - adds in an extra x-section 0.1mm before start chainage.
- **extra_end**: optional - adds in an extra x-section 0.1mm before end chainage.
- **inactive**: if *inactive* is there then the command is not processed. If inactive is not there then the command is processed.
- **// text**: the text is a comment.

See [21.10.1.5 Start and End Chainages in the Modifier File Format](#) for the format for *st_ch* and *end_ch*.

### Cut and Fill Height

The **cut_height** modifier is used to modify the height of variable cut links originally defined by *height*. Similarly the **fill_height** modifier is used to modify the height of variable fill links originally defined by *height*.

The format of the modifier to vary the height of the variable cut/fill links in **link_list** is

- **cut_height** `link_list` *st_ch* `end_ch* *st_ht* `end_ht* absrel *type* optional
- **fill_height** `link_list` *st_ch* `end_ch* *st_ht* `end_ht* absrel *type* optional

where

- **link_list**: one or more names of cut/fill links given in the template definition; with format `name1` `name2` ... `namei`
- **st_ch**: start chainage for the modifier.
- **end_ch**: end chainage for the modifier.
- **st_ht**: height to be used at the start modifier chainage, *st_ch*.
- **end_ht**: height to be used at the end modifier chainage, *end_ch*.
- **absrel**: relative (default) or absolute.

If **absrel** is *relative* (the default) then

- the *st_ht* is added to the current height of links in **link_list** at chainage *st_ch*.
- the *end_ht* is added to the current height of links in **link_list** at chainage *end_ch*.

If **absrel** is *absolute*, then

- the height of links in **link_list** are set to *st_ht* at chainage *st_ch*.
- the height of links in **link_list** are set to *end_ht* at chainage *end_ch*.

- **type**: linear (default) or cubic.

If **type** is *linear* (the default), then the height of links in **link_list** are varied linearly (with respect to the reference chainage) between the height at chainage *st_ch* and chainage *end_ch*.

If **type** is *cubic*, then the height of links in **link_list** are varied as a reverse cubic (with respect to the reference chainage) between the height at chainage *st_ch* and chainage *end_ch*.

and *optional* can be none, one or more of

- **interval**: if interval exists, then sections are created at the interval_value for the range of this command. If interval is missing, then the interval for the Apply MTF is used.
- **interval_value**: only exists if *interval* exists.
- **extra_start**: optional - adds in an extra x-section 0.1mm before start chainage.
The height for a variable link can also be varied by taking the height from a 12d Model string.

cut_height link_list st_ch end_ch full_string_name side optional
fill_height link_list st_ch end_ch full_string_name side optional

where

link_list one or more names of cut/fill links given in the template definition; with format
name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
full_string_name name of a 12d Model string to take links in link_list out to. The
format of the string name is “model_name->string_name”.
side side to search for string: -1 for left, 0 for left and right, 1 for right

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text the text is a comment

The height for a link can also be varied by using the height between two 12d Model strings str_name_1 and str_name_2.

cut_height link_list st_ch end_ch str_name_1 side1 str_name_2 side2 optional
fill_height link_list st_ch end_ch str_name_1 side1 str_name_2 side2 optional

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Cut and Fill Height from Link

The cut and fill height from link modifiers are used to modify the height of cut and fill links
originally defined by height, to be the same as another link. That is, the height of the link is a copy
of the height of another link.

The format of the modifier to vary the cut and fill height from link of the fixed links given by
link_list is

copy_cut_height link_list st_ch end_ch from_link zone optional
copy_fill_height link_list st_ch end_ch from_link zone optional

where

link_list one or more names of fixed links given in the template definition; with format
name1 name2 ... namei
st_ch   start chainage for the modifier
end_ch   end chainage for the modifier
from_link   name of the link to take the height from
zone   section of the template that the from_link is from (i.e. fixed, cut or fill)

and optional can be none, one or more of

interval   if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value   only exists if interval exists
extra_start   optional - adds in an extra x-section 0.1mm before start chainage
extra_end   optional - adds in an extra x-section 0.1mm before end chainage
inactive   if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text   the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Cut and Fill Slope

The cut_slope modifier is used to modify the slope of variable cut links originally defined by
slope. Similarly the fill_slope modifier is used to modify the slope of variable fill links originally
defined by slope.

The format of the modifier to vary the cut/fill slope of the variable links in link_list is

cut_slope link_list st_ch end_ch st_slope end_slope absrel type optional
fill_slope link_list st_ch end_ch st_slope end_slope absrel type optional

where

link_list   one or more names of cut/fill links given in the template definition; with format
name1 name2 ... namei
st_ch   start chainage for the modifier
end_ch   end chainage for the modifier
st_slope   slope to be used at the start modifier chainage, st_ch
end_slope   slope to be used at the end modifier chainage, end_ch.

absrelrelative (default) or absolute
If absrel is relative (the default) then
the st_slope is added to the current slope of links in link_list at chainage st_ch.
the end_slope is added to the current slope of links in link_list at chainage
end_ch.
If absrel is absolute, then
the slope of links in link_list is set to st_slope at chainage st_ch.
the slope of links in link_list is set to end_slope at chainage end_ch.

type   linear (default) or cubic
If type is linear (the default), then the slope of links in link_list is varied linearly (with respect
to the reference chainage) between the slope at chainage st_ch and chainage end_ch.
cubic, then the angle of the slope of links in link_list are varied as a reverse cubic
(with respect to the reference chainage) between the angle of the slope at chainage st_ch
and chainage end_ch.
rotate, then the angle of the slope of the links in link_list are varied linearly (with
respect to the reference chainage) between the angle of the slope at chainage st_ch and
chainage end_ch.
and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text the text is a comment

The slope of a link can also be defined by using the slope from the beginning of the link (i.e. the end of the previous link or the hinge string if its the first link) to a given 12d Model string.

cut_slope link_list st_ch end_ch full_string_name side optional
fill_slope link_list st_ch end_ch full_string_name side optional

where

link_list one or more names of cut/fill links given in the template definition; with format
name1 name2 ... namei
st_ch start chainage for the modifier
end_ch end chainage for the modifier
full_string_name name of a 12d Model string to use to calculate slope. The format of
the string name is “model_name->string_name”.
side side to search for string: -1 for left, 0 for left and right, 1 for right

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for
the range of this command
if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text the text is a comment

The slope of a link can also be defined by using the slope between two 12d Model strings str_name_1 and str_name_2.

cut_slope link_list st_ch end_ch str_name_1 side1 str_name_2 optional
fill_slope link_list st_ch end_ch str_name_1 side1 str_name_2 side2 optional

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Cut and Fill Slope from Link

The cut and fill slope_from_link modifiers are used to modify the slope of cut and fill links originally defined by slope, to be the same slope or xfall as another link. That is, the slope of the link is a copy of the slope of another link.

The format of the modifier to vary the cut and fill slope_from_link of the fixed links given by
link_list is

**copy_cut_slope** link_list st_ch end_ch from_link zone optional
**copy_fill_slope** link_list st_ch end_ch from_link zone optional

where

link_list one or more names of fixed links given in the template definition; with format
name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

from_link name of the link to take the slope or xfall from

zone section of the template that the from_link is from (i.e. fixed, cut or fill)

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for the range of this command

if interval is missing, then the interval for the Apply MTF is used

interval_value only exists if interval exists

extra_start optional - adds in an extra x-section 0.1mm before start chainage

extra_end optional - adds in an extra x-section 0.1mm before end chainage

inactive if inactive is there then the command is not processed.

If inactive is not there then the command is processed

// text the text is a comment

**Important Note**
The link to copy slope from can be defined in terms of slope or cross fall.

If the link to copy is defined by cross fall, then the slope is calculated to match the cross fall. Hence this command can be used with cut and fill slopes to match to rotation of cross fall of fixed links for super-elevation.

See **21.10.1.5 Start and End Chainages in the Modifier File Format** for the format for st_ch and end_ch.

**Cut and Fill Tin Height**
The **cut and fill tin height** modifiers are used to modify the height of the link so that the link will sit on the tin at the given width.

The tin height can only be used for a cut or fill link defined by width and height.

The format of the modifiers to vary the **cut** and **fill tin height** of the links in the **link_list** are:

**tin_cut_height** link_list st_ch end_ch tin_name optional

**tin_fill_height** link_list st_ch end_ch tin_name optional

where

link_list one or more names of cut/fill links given in the template definition; with format
name1 name2 ... namei

st_ch start chainage for the modifier

end_ch end chainage for the modifier

tin_name name of the tin to be used in defining the height.

and optional can be none, one or more of

interval if interval exists, then sections are created at the interval_value for the range of this command

if interval is missing, then the interval for the Apply MTF is used
interval_value only exists if interval exists
extra_start optional - adds in an extra x-section 0.1mm before start chainage
extra_end optional - adds in an extra x-section 0.1mm before end chainage
inactive if inactive is there then the command is not processed.
If inactive is not there then the command is processed
// text the text is a comment
See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Cut and Fill Tin Slope

The **cut and fill tin slope** modifier is used to modify the slope of the link so that the link will sit on the tin at the given width.

The cut and fill tin slope can only be used for a cut/fill link defined by width and slope.

The format of the modifiers to vary the **cut** and fill **tin slope** of the links in the **link_list** are:

\[
\text{cut_slope} \quad \text{link_list} \quad \text{st_ch} \quad \text{end_ch} \quad \text{tin_name} \quad \text{optional}
\]

\[
\text{fill_slope} \quad \text{link_list} \quad \text{st_ch} \quad \text{end_ch} \quad \text{tin_name} \quad \text{optional}
\]

where

- **link_list** one or more names of fixed links given in the template definition; with format name1 name2 ... namei
- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **tin_name** name of the tin to be used in defining the slope.

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if interval exists
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage
- **inactive** if inactive is there then the command is not processed.
  If inactive is not there then the command is processed
- **// text** the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

Please continue to the next section 21.10.1.9 Final Link Modifiers File Format.
21.10.1.9 Final Link Modifiers File Format

**Final Width**

The format of the modifier to vary the **width** of the final cut and fill link *link_name* is

```
final_width link_name st_ch end_ch st_wid end_wid absrel type optional
```

where

- **link_name**: name of final link given in the template definition
- **st_ch**: start chainage for the modifier
- **end_ch**: end chainage for the modifier
- **st_wid**: width to be used at the start modifier chainage, *st_ch*
- **end_wid**: width to be used at the end modifier chainage, *end_ch*
- **absrel**: relative (default) or absolute

If **absrel** is **relative** (the default) then

- the **st_wid** is added to the current width of *link_name* at chainage **st_ch**.
- the **end_wid** is added to the current width of *link_name* at chainage **end_ch**.

If **absrel** is **absolute**, then

- the width of *link_name* is set to **st_wid** at chainage **st_ch**.
- the width of *link_name* is set to **end_wid** at chainage **end_ch**.

- **type**: linear (default) or cubic

  - If **type** is **linear** (the default), then the width of *link_name* is varied linearly (with respect to the reference chainage) between the width at chainage **st_ch** and chainage **end_ch**.
  
  - If **type** is **cubic**, then the width of *link_name* is varied as a reverse cubic (with respect to the reference chainage) between the width at chainage **st_ch** and chainage **end_ch**.

and **optional** can be none, one or more of

- **interval**: if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
  - if **interval** exists only exists if **interval** exists
  - **extra_start**: optional - adds in an extra x-section 0.1mm before start chainage
  - **extra_end**: optional - adds in an extra x-section 0.1mm before end chainage
  
  **inactive**: if **inactive** is there then the command is not processed.
  - If inactive is not there then the command is processed

  // text the text is a comment

See **21.10.1.5 Start and End Chainages in the Modifier File Format** for the format for **st_ch** and **end_ch**.

**Final Cut and Fill Slope**

The format of the modifier to vary the cut/fill slope of the final link *link_name* is

```
final_cut_slope link_name st_ch end_ch st_slope end_slope absrel type optional
final_fill_slope link_name st_ch end_ch st_slope end_slope absrel type optional
```

where

- **link_name**: name of final link given in the template definition
- **st_ch**: start chainage for the modifier
- **end_ch**: end chainage for the modifier
- **st_slope**: slope to be used at the start modifier chainage, *st_ch*
- **end_slope**: slope to be used at the end modifier chainage, *end_ch*
- **absrel**: relative (default) or absolute
If `absrel` is **relative** (the default) then
the `st_slope` is added to the current slope of `link_name` at chainage `st_ch`.
the `end_slope` is added to the current slope of `link_name` at chainage `end_ch`.

If `absrel` is **absolute**, then
the slope of `link_name` is set to `st_slope` at chainage `st_ch`.
the slope of `link_name` is set to `end_slope` at chainage `end_ch`.

**type**

- linear (default) or cubic

If `type` is **linear** (the default), then the slope of `link_name` is varied linearly (with respect to
the reference chainage) between the slope at chainage `st_ch` and chainage `end_ch`.
**cubic**, then the angle of the slope of `link_name` is varied as a reverse cubic (with
respect to the reference chainage) between the angle of the slope at chainage `st_ch` and
chainage `end_ch`.

and **optional** can be none, one or more of

- `interval` if interval exists, then sections are created at the `interval_value` for
  the range of this command
  if interval is missing, then the interval for the Apply MTF is used
  `interval_value` only exists if `interval` exists
- `extra_start` optional - adds in an extra x-section 0.1mm before start chainage
- `extra_end` optional - adds in an extra x-section 0.1mm before end chainage
- `inactive` if `inactive` is there then the command is not processed.
  If inactive is not there then the command is processed
  // text the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for `st_ch` and `end_ch`.

**Stopping Final Cut and Fill Slope**

The final link can be stopped altogether in either cut or fill.
The format of the modifier to stop the cut/fill slope of the final link `link_name` is

- `final_no_cut_slope` *link_name* `st_ch` `end_ch` optional
- `final_no_fill_slope` *link_name* `st_ch` `end_ch` optional

where

- `link_name` name of final link given in the template definition
- `st_ch` start chainage for the final link to stop
- `end_ch` end chainage for the final link to stop

and **optional** can be none, one or more of

- `interval` if interval exists, then sections are created at the `interval_value` for
  the range of this command
  if interval is missing, then the interval for the Apply MTF is used
  `interval_value` only exists if `interval` exists
- `extra_start` optional - adds in an extra x-section 0.1mm before start chainage
- `extra_end` optional - adds in an extra x-section 0.1mm before end chainage
- `inactive` if `inactive` is there then the command is not processed.
  If inactive is not there then the command is processed
  // text the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for `st_ch` and `end_ch`.
Please continue to the next section 21.10.1.10 Snippets File Format.
21.10.1.10 Snippets File Format

Snippets are a method of inserting groups of modifiers at once. Snippets can have parameters but the values of the parameters are saved in the actual MTF.

```
snippet snippet_file st_ch end_ch param_name_1 param_value_1...
                       param_name_n param_value_n  optional
```

where **unknown** takes the place of the one of width, height or xfall not being used, and

- **snippet_file** file containing the snippet definition
- **st_ch** start chainage for creating the link
- **end_ch** end chainage for creating the link
- **param_name_n** name of the nth parameter - must be in quotes ("")
- **param_value_n** value for the nth parameter - must be in quotes

and **optional** can be none, one or more of

- **interval** if interval exists, then sections are created at the interval_value for the range of this command
  - if interval is missing, then the interval for the Apply MTF is used
- **interval_value** only exists if **interval** exists
- **extra_start** optional - adds in an extra x-section 0.1mm before start chainage
- **extra_end** optional - adds in an extra x-section 0.1mm before end chainage

- **inactive** if **inactive** is there then the command is not processed.
  - If inactive is not there then the command is processed
- **// text** the text is a comment

See 21.10.1.5 Start and End Chainages in the Modifier File Format for the format for st_ch and end_ch.

For more information on the inserting and use of snippets, see 21.5 Defining and Using Snippets.

Please continue to the next section 21.10.1.11 A Template Modifier File Example.
21.10.1.11 A Template Modifier File Example

```plaintext

"Text Format of Files"
Go to the next section 21.10.1.12 MTF Stripping File Format or back to 21.10.1 Text Format of the MTF File.
21.10.1.12 MTF Stripping File Format

The stripping depth is given in the Modifiers and Templates File (*.mtf) and is similar to the format for applying templates except there is no separate left and right side.

The stripping definition begins with the key words

    stripping =

A list of chainages (in ascending order, one per line) with corresponding stripping depth then follows. The list of chainages and stripping depths is enclosed in curly braces {}.

The chainage-stripping lists are assembled as follows

(a) to represent a stripping depth starting at a given chainage, the chainage value followed by the stripping depth is given. The chainage and stripping depth are separated by one or more spaces. For example, the stripping depth 0.03 starting at chainage 150 is represented by

    150 0.03

The stripping depth is assumed to apply until the chainage given on the next line of the stripping definition.

If the stripping depth is to go to the end of the reference string, add a line with a chainage greater than or equal to the end chainage. For example

    150 0.03
    9999 0.0

Warning - unlike applying templates, a stripping depth must exist after a chainage, however the stripping depth can be zero.

(b) linearly varying stripping depth between chainages is represented by giving the start chainage for the variation followed on the same line by the start depth and the end depth separated by a comma.

The linear change takes place over the interval beginning at this chainage and ending at the chainage given on the next line of the stripping definition.

For example, to linearly vary the stripping depth from 0.02 to 0.03 between the chainages 350 and 500, use

    350 0.02, 0.03
    500 0.03

A Stripping Example

An example of a stripping command is

    stripping = {
        -999 0.03
        30 0.0
        70 0.03, 0.05
        110.5 0.05
        999 0.05
    }

Go to the next section 21.10.1.13 MTF Boxing File Format or back to 21.10.1 Text Format of the MTF File
21.10.1.13 MTF Boxing File Format

Apart from a key word specifying whether the following part of the definition is for the left or the right, the set out for the left boxing is identical to the right boxing. Hence only the left boxing will be described in detail.

The left boxing definition begins with the key words

```
left_boxing =
```

A list of chainages (in ascending order, one per line) with corresponding boxing names then follows. The list of chainages and boxing is enclosed in curly braces `{ }`.

The chainage-boxing lists are assembled as follows

(a) to represent a boxing starting at a given chainage, the chainage value followed by the boxing name is given. The chainage and boxing name are separated by one or more spaces. For example, the boxing `left` starting at chainage 150 is represented by

```
150 left
```

The boxing is assumed to apply until the chainage given on the next line of the left_boxing definition.

(b) if no boxing exists from a chainage, simply include the chainage with no boxing name following it. For example, if there is no boxing from chainage 250, this is represented by

```
250
```

The non-existence of boxing is assumed until the chainage given on the next line of the left_side definition.

If the boxing is to go to the end of the reference string, add a line with a chainage greater than or equal to the end chainage. For example

```
150 left
9999
```

When using the Apply MTF option, the name of the boxing definitions file is given by a `boxing_file` command in the Modifiers and Templates File.

```
boxing_file = boxing_definitions_file
```

When using the boxing many option, if a file name is given in the boxing file panel field, it is used for the boxing definitions file, otherwise the boxing_file command in the Modifiers and Templates File is used.

**Note** - if the boxing name includes spaces, then the name must be enclosed in quotes “. For example, “left 1”.

**An Applying Boxing Example**

```
boxing_file = "boxing_for_client.bf"
left_boxing = {
    -999 left
    30
    70 "left narrow"
    110.5 left
    999
}
right_boxing = {
    -999 right
    30
    70 "right narrow"
    110.5 right
```
Warning - no interpolation or modifiers exist for boxing.

Go to the next section 21.10.1.14 MTF Width File Format or back to 21.10.1 Text Format of the MTF File
21.10.1.14 MTF Width File Format

The format for section width in the mtf file is simply

\[ \text{section\_width} = \text{value} \quad \text{// default is 10000} \]

where value is the distance to search from the hinge string for strings required in some options. If section_width is missing, then it takes the default value of 10000.

For example

\[ \text{section\_width} = 100.0 \]

Go to the next section 21.10.1.15 MTF String Modifiers File Format or back to 21.10.1 Text Format of the MTF File
21.10.1.15 MTF String Modifiers File Format

In the Modifiers and Templates File, the **string modifiers** definition begins with the key word

```
string_modifiers =
```

followed by one or more occurrences of the string modifier command **height** enclosed by curly braces `{ }`.

The definition of the string modifier commands will now be given.

**Height**

The **height** the **Height** string modifier calculates for the amend point is given by:

(a) if the absolute flag is not set, the height of the hinge point, otherwise zero.

plus

(b) the interpolated height for the user given heights at the start and end chainages

plus

(c) the interpolated height for the user given cross falls at the start and end chainage.

That is, if the absolute flag is not set:

```plaintext
new height = hinge height + (interpolated height) + (interpolated xfall) x (offset distance)
```

If the absolute flag is set:

```plaintext
new height = (interpolated height) + (interpolated xfall) x (offset distance)
```

The format of the **Height** string modifier is

```
height amend_str ref_str hinge_str st_ch end_ch ch_int st_xfall end_xfall st_ht end_ht absolute
```

where

- **amend_str** name of a **12d Model** string to take the hinge point out to. The format of the string name is “model_name->string_name”.
- **ref_str** name of reference string. The format of the string name is “model_name->string_name”.
- **hinge_str** name of hinge string. The format of the string name is “model_name->string_name”.
- **st_ch** start chainage for the modifier
- **end_ch** end chainage for the modifier
- **ch_int** interval between chainage points - can be the word **null**
- **st_xfall** xfall to be used at the start modifier chainage, **st_ch**
- **end_xfall** xfall to be used at the end modifier chainage, **end_ch**.
- **st_ht** height to be used at the start modifier chainage, **st_ch**
- **end_ht** height to be used at the end modifier chainage, **end_ch**.
- **absolute** optional - if it exists, include the height of the hinge string

**Height and Two Strings**

The **height** the **Height 2x** string modifier calculates for the amend point is given by:

(a) the height of the hinge point

plus
(b) the offset distance multiplied by the cross fall between two user selected strings.

\[
\text{new height} = \text{hinge height} + (\text{xfall between string 1 and string 2}) \times \text{(offset distance)}
\]

The format of the \text{Height 2x} string modifier is

\[
\text{height amend_str ref_str hinge_str st_ch end_ch ch_int xfall_str1 xfall_str2}
\]

where

- \text{amend_str} name of a 12d Model string to take the hinge point out to. The format of the string name is “model_name->string_name”.
- \text{ref_str} name of reference string. The format of the string name is “model_name->string_name”.
- \text{hinge_str} name of hinge string. The format of the string name is “model_name->string_name”.
- \text{st_ch} start chainage for the modifier
- \text{end_ch} end chainage for the modifier
- \text{ch_int} interval between chainage points - can be the word \text{null}
- \text{xfall_str_1} name of first string to calculate cross fall between. The format of the string name is “model_name->string_name”.
- \text{xfall_str_2} name of second string to calculate cross fall between. The format of the string name is “model_name->string_name”.

Go to the next section 21.10.1.16 \text{Substitutions in the Modifiers and Templates File} or back to 21.10.1 \text{Text Format of the MTF File}
21.10.1.16 Substitutions in the Modifiers and Templates File

The many template variables are special variables standing for information about the reference string used in the Apply MTF operation.

The many template variables are only evaluated when the many template file is used in an Apply MTF operation and provide a mechanism to generalize the many template file.

The many template file also recognizes the CCCP preprocessor rules including #include, #define, #if etc.

**Many Template Variables**

The list of the many template variables is:

- $tangent_curve_n: chainage of the tangent curve point for the nth HIP
- $tangent_spiral_n: tangent spiral
- $curve_spiral_n: curve spiral
- $spiral_curve_n: spiral curve
- $spiral_spiral_n: spiral curve
- $spiral_tangent_n: spiral tangent
- $curve_tangent_n: curve tangent
- $start_spiral_n: length of the start spiral on the nth HIP point
- $end_spiral_n: length of the end spiral
- $radius_n: absolute radius of the curve
- $signed_radius_n: signed radius of the curve
- $vertical_tangent_curve_n: chainage of the tangent curve point for the nth VIP
- $vertical_spiral_n: chainage of the tangent spiral point for the nth VIP
- $vertical_sag_n: chainage of the sag point for the nth HIP
- $vertical_crest_n: crest
- $vertical_crest_sag_n: crest or sag

For example,

- $tangent_spiral_3: get the chainage for the tangent spiral on HIP 3.

The variables can be used in expressions with the arithmetic operations +, -, *, and / as long as the expression is surrounded by round brackets ( ).

For example, in the width command:

```
width E ($tangent_spiral_2 - 50) ($tangent_spiral_2 + 50) 3 5 absolute
```

the expression ($tangent_spiral_2 - 50) will yield the chainage of fifty metres before the tangent spiral point of the second HIP point.

The variables can also be used in #define's and #include's according to the following CCCP rules.

(a) **#define** NAME Expansion of NAME

   if the #define is longer than one line, the backslash character `\` is added to the end of each line that has another line of the #define following to indicate that the #define continues to the next line.

(b) **#define** can be used to define a block of things with more than one argument

   For example,
#define SUPER(name,ip,xf1,xf2)  
  xfall name START_TAPER(ip) xf1 xf2 absolute \ 
  xfall name FIXED_TAPER(ip) xf2 xf2 absolute \ 
  xfall name END_TAPER(ip) xf2 xf1 absolute 

means that SUPER("EB",3,-3.0,3.0) will be expanded to the three lines:

```c
xfall "EB" START_TAPER(3) -3.0 3.0 absolute
xfall "EB" FIXED_TAPER(3) 3.0 3.0 absolute
xfall "EB" END_TAPER(3) 3.0 -3.0 absolute
```

Note that \ is used to indicate that the #define continues to the next line.

(c) \( (\text{if} (\text{express}) \{ \text{expression1} \} \text{ else } \{ \text{expression 2} \}) \) is an expression \text{express}, which evaluates to

- if \text{express} is true, then the value of the expression is \text{expression1}
- otherwise \text{expression 2}.

(d) \text{word##p}
is equivalent to \text{wordp}

(e) \#include \text{file_name}

A number of #defines can be placed in a file and included in the mtf by using the #include.

As an example combining the above rules, the meaning of

```
LEADING_TAPER_START(2)
```
given by the following $define:

```
#define LEADING_TAPER_START(ip)    (if($radius_##ip < 75) {$tangent_spiral_##ip - 50} else {$tangent_spiral_##ip - 75})
```

is

- if the radius of the second HIP is less than 75, then set LEADING_TAPER_START(2) to the chainage of the tangent spiral point of the second HIP point, less fifty metres,
- otherwise LEADING_TAPER_START(2) is set to the chainage of the tangent spiral point of the second HIP point, less seventy five metres.

A more complicated example now follows which shows how #defines can be used to easily apply super-elevation according to rules involving leading and trailing spirals.

```c
// ---------------------------------------------------
#define LEADING_TAPER_START(ip)    (if($radius_##ip < 75) {$tangent_spiral_##ip - 50} else {$tangent_spiral_##ip - 75})
// Note: LEADING_TAPER_START evaluates to a chainage.
#define LEADING_TAPER_END(ip)      (if($radius_##ip < 75) {$tangent_spiral_##ip + 10} else {$tangent_spiral_##ip + 25})
// Note: LEADING_TAPER_END evaluates to a chainage.
#define TRAILING_TAPER_START(ip)   (if($radius_##ip < 75) {$spiral_tangent_##ip - 10} else {$spiral_tangent_##ip - 25})
// Note: TRAILING_TAPER_START evaluates to a chainage.
#define TRAILING_TAPER_END(ip)     (if($radius_##ip < 75) {$spiral_tangent_##ip + 50} else {$spiral_tangent_##ip + 75})
// Note: TRAILING_TAPER_END evaluates to a chainage.
```
#define START_TAPER(ip) LEADING_TAPER_START(ip)\ LEADING_TAPER_END(ip)

// Note: START_TAPER evaluates to two chainages:  chainage1  chainage2.
#define FIXED_TAPER(ip) LEADING_TAPER_END(ip)\ TRAILING_TAPER_START(ip)

// Note: FIXED_TAPER evaluates to two chainages:  chainage1  chainage2.
#define END_TAPER(ip)   TRAILING_TAPER_START(ip)\ TRAILING_TAPER_END(ip)

// Note: TRAILING_TAPER evaluates to two chainages:  chainage1  chainage2.
#define SUPER(name,ip,x1,x2) \ 
  xfall name START_TAPER(ip) x1 x2 absolute \ 
  xfall name FIXED_TAPER(ip) x2 x2 absolute \ 
  xfall name END_TAPER(ip)   x2 x1 absolute

With the above #defines, SUPER evaluates to three lines of xfall MTF Modifiers which rotates cross-fall, keeps it constant and then counter-rotates the cross-fall about leading and trailing spirals for an HIP point.

For example,

SUPER(EB,2,-3,3)

would give expand to the following three lines of xfall commands for link EB which will rotate xfall from -3 to 3, hold it at 3 and then rotate it back form 3 to -3, all about the leading and trailing spirals for horizontal intersection point number two:

xfall EB begin_chainage_for_start_taper end_chainage_for_start_taper 3 3 absolute
xfall EB begin_chainage_for_fixed_taper end_chainage_for_fixed_taper_ch 3 3 absolute
xfall EB begin_chainage_for_end_taper end_chainage_for_end_taper 3 -3 absolute

The above definitions of SUPER could be placed in a file, say

f:\12d\12dmodel\library\super_mtf.def

and then simply included into a mtf file using the a #include:

#include "f:\12d\12dmodel\library\super_mtf.def"

Examples of Substitutions in the Modifiers and Templates File

The following example shows how #defines can be used to easily apply super-elevation according to rules involving leading and trailing spirals.

The definition of SUPER is given in the file, f:\12d\12dmodel\library\super_mtf.def, which is simply included in the mtf file using a #include.

    // ----------------------------------------------------------------
    // include the file containing the definition of SUPER
    // ----------------------------------------------------------------
    #include "f:\12d\12dmodel\library\super_mtf.def"
// apply templates left and right and then modifier them
// -----------------------------------------------------------------

left_side = {
    -999999 std
    999999
}

right_side = {
    -999999 std
    999999
}

specials = {
}

hinge_modifier = {
}

left_side_modifier = {
    // linearly widen the link EB by 12 metres and bring it back
    // in again.
    width EB ($tangent_spiral_2 - 50) ($tangent_spiral_2 + 50) 0 12
    width EB ($tangent_spiral_2 + 50) ($spiral_tangent_7 - 50) 12 12
    width EB ($spiral_tangent_7 - 50) ($spiral_tangent_7 + 50) 12 0

    // define superelevation
    SUPER(EB,2,-3,3)
    SUPER(EB,4,-3,3)
    SUPER(EB,5,-3,3)
    SUPER(EB,6,-3,3)
}

right_side_modifier = {
    SUPER(EB,3,-3,3)
    SUPER(EB,7,-3,3)
}

stripping = {
}

//boxing_file = "yourfile.bf"
left_boxing = {
}
right_boxing = {
}
string_modifiers = {
}
//section_width = 10000.0
21.10.2 Text Format of the Boxing File

The interactive editor for creating the Boxing Definitions in the Boxing file has been given in the previous sections 21.7.2 Edit Boxing File.

This section will describe the text layout of the text boxing file.

Boxing is defined by a series of commands going from left to right across the points of a cross section. (Cross sections are generated as 4d strings by options such as apply and cuts).

Named and unnamed points across a 4d string representing a cross section

The definitions of boxing cross sections are set up in a file ending in .bf (called the boxing file) and any number of boxing definitions can be placed in the boxing file as long as each boxing definition is given a unique name.

In the boxing file, a Boxing Definition with name boxing_name is set out as

```
boxing  boxing_name  {  
   boxing commands  
}
```

The boxing commands apply from the offset specified at the beginning of that command (start offset for the command) to the start offset of the next command in the file (like chainages and templates in the Apply MTF file). Hence the end offset for a command is the start offset of the following command in the file.

For example, in the sequence

```
offset1,  command1  
offset2,  command2  
```

command1 goes from offset1 (the start offset for command1) to offset2 (the end offset for command1).

The offsets can be fixed values or can be specified relative to a point name on the 4d string representing the x-section. One restriction is that all the points mentioned in a boxing definition, must be present in each x-section the boxing definition is applied to.

The notation used to specify an actual offset, or offset relative to a point name is

```
offset_value  
```

or

```
"point_name"  
```

or

```
"point_name" +/- offset_value  
```

and means in the first case

take the specified offset value (offset_value can be positive or negative).

and for the other two relative cases

take the offset at the string or 4d point called point_name and add offset_value to it (offset_value can be positive of negative).

Hence the offset can be specified as either a value or given relative to point_name (relative offset). For convenience, the offset will be denoted by rel_off.
The major advantage of defining boxing in terms of point names is that whenever the points are modified using MTF Modifiers, the boxing across the section is also automatically modified.

Since the offset part of a command can consist of text plus or minus a number, commas are used to separate each field of the command.

A boxing definition may be used in either a left_boxing or right_boxing mtf command (see the section, creating boxing), however unlike the case for templates, the boxing definition is applied to the point names going from left to right regardless of whether the boxing definition is used on the left or the right.

In practice, the definitions for left and right boxing are usually different because of the necessity of having unique point names across the entire cross section.

Vertical Walls
If a boxing definition creates two different height values at the one offset (i.e. a wall), then extra offset points are automatically inserted into the boxing x-section (at 0.1 mm from the previous point) so that no points are on top of each other.

So in effect a vertical wall is created but since no points are created that are directly above each other, the data can be triangulated.

The commands in the boxing definition are:
- see 21.10.2.1 Text Format - Boxing Copy
- see 21.10.2.2 Text Format - Boxing Copy with Height Adjustment
- see 21.10.2.4 Text Format - Boxing Line
- see 21.10.2.5 Text Format - Boxing Xfall
- see 21.10.2.6 Text Format - Boxing Xfall1
- see 21.10.2.9 Text Format - Boxing End
- see 21.10.2.10 Text Format - Boxing Right_Xfall
- see 21.10.2.11 Text Format - Boxing Right_slope
- see 21.10.2.12 Text Format - Boxing Right_copy
- see 21.10.2.13 Text Format - Boxing Left_Xfall
- see 21.10.2.14 Text Format - Boxing Left_slope
- see 21.10.2.15 Text Format - Boxing Left_copy
- see 21.10.2.16 Text Format - Boxing Definitions Example

21.10.2.1 Text Format - Boxing Copy

rel_off,              copy

This copies the links (or parts of links) from the start offset rel_off to the offset on the next line, keeping the present crossfall and height of each link.

For the boxing panel that creates this boxing command, see 21.7.2.2.1 Boxing Copy.
21.10.2.2 Text Format - Boxing Copy with Height Adjustment

\texttt{rel\_off, \ copy, \ delta\_height}

This copies the links (or parts of links) from the start offset \texttt{rel\_off} to the offset on the next line, keeping the present slope of each link but adjusting the height of each link by \texttt{delta\_height}.

For the boxing panel that creates this boxing command, see Section 21.7.2.2.1 Boxing Copy.

21.10.2.3 Text Format - Boxing Vertex

For the boxing panel that creates this boxing command, see Section 21.7.2.2.2 Boxing Vertex.

21.10.2.4 Text Format - Boxing Line

\textbf{Line Through Two Given Points}

\texttt{rel\_off, \ line, \ rel\_off\_1, \ delta\_height\_1, \ rel\_off\_2, \ delta\_height\_2}

This creates a link from the start offset \texttt{rel\_off} to the offset on the next line, with a
(a) slope given by two points
(b) start height given by projecting to the start offset, the line through the two points.

The first point defining the line has an offset \texttt{rel\_off\_1} and a height given by the height of the design x-section at offset \texttt{rel\_off\_1} adjusted by \texttt{delta\_height\_1}.

The second point defining the line has an offset \texttt{rel\_off\_2} and a height given by the height of the design x-section at offset \texttt{rel\_off\_2} adjusted by \texttt{delta\_height\_2}.

The typed format of the \texttt{line} commands created by this panel is (all on one line):
\texttt{point\_name + point\_offset, line, point\_1\_name + point\_1\_offset, delta\_height\_1, point\_2\_name + point\_2\_offset, delta\_height\_2}
21.10.2.5 Text Format - Boxing Xfall

**Line Through a Given Point with a Given Crossfall**

rel_off, xfall, rel_off_1, delta_height_1, xfall_value

This creates a link from the start offset to the offset on the next line, with a

(a) user given xfall

(b) start height given by projecting to the start offset, the line with a given xfall and going through a given point.

The point defining the line has an offset rel_off_1 and a height given by the height of the design x-section at offset rel_off_1 adjusted by delta_height_1.

The typed formats of the xfall commands created by this panel is:

point_name + point_offset, xfall, control_name + control_offset, control_height, xfall

The crossfall of the line is given by xfall_value

rel_off, xfall, rel_off_1, delta_height_1, xfall_value

next_off, ...

For the boxing panel that creates this boxing command, see 21.7.2.4 Boxing Xfall - line through a point with a given crossfall.
21.10.2.6 Text Format - Boxing Xfall1

Line Through a Given Point with Crossfall Taken from a Point
rel_off, xfall1, rel_off_1, delta_height_1, rel_off_2, delta_xfall

This creates a link from the start offset rel_off to the offset on the next line, with a
(a) xfall which is the xfall at a given offset plus an addition given xfall
and
(b) start height given by projecting to the start offset, the line with the given xfall and going
through a given point.

The point defining the line has offset rel_off_1 and a height given by the height of the design
x-section at offset rel_off_1 adjusted by delta_height_1

The typed formats of the xfall1 commands created by this panel is:
point_name + point_offset, xfall1, control_name + control_offset, control_height,
xfall_name + xfall_offset, xfall_delta

The xfall of the line is delta_xfall added to the xfall on the design x-section at the offset rel_off_2

For the boxing panel that creates this boxing command, see 21.7.2.2.5 Boxing Xfall 1 - line
through a point with a crossfall taken from a point.

21.10.2.7 Text Format - Boxing Intersect

For the boxing panel that creates this boxing command, see 21.7.2.2.7 Boxing Intersect -
Intersection of Two Lines.

21.10.2.8 Text Format - Boxing Xfall Point

For the boxing panel that creates this boxing command, see 21.7.2.2.9 Boxing Xfall Point.

21.10.2.9 Text Format - Boxing End
rel_off, end

The typed format of the line commands created by this panel is:
point_name + point_offset,  end

This command is used to give an end offset for any of the above commands when no command follows to use for the end offset. That is, the offset rel_off is used as the end offset for the previous command.

end doesn't begin another command and none of the above commands can follow an end command.

All of the above boxing commands are known as standard commands. Hence the end command is the last standard command.

For the boxing panel that creates this boxing command, see 21.7.2.16 Boxing End.

21.10.2.10 Text Format - Boxing Right_Xfall

Batter off Right End of Boxing with Crossfall Taken from a Point

The right_xfall command has two versions - providing a fixed cross fall or using the crossfall from part of the design x-section.

right_xfall rel_off,      delta_xfall
right_xfall xfall_value

The typed formats of the right_xfall commands created by this panel is:

right_xfall,  xfall_name + xfall_offset, xfall_delta

For the first case, the right_xfall command batters off the right end of the boxing using the xfall from the design section at a given offset rel_off plus an additional given xfall delta_xfall, until the design section is intersected. The intersection point is used as the next point in the boxing. Hence the xfall of the batter is delta_xfall added to the xfall on the design x-section at the offset rel_off.

For the second case, the right_xfall command batters off to the right end of the boxing at the given xfall xfall_value until the design section is intersected. The intersection point is used as the next point in the boxing.

In the right_xfall command, the xfall is percent cross-fall and a positive xfall is up and negative down.

For the boxing panel that creates this boxing command, see 21.7.2.18 Boxing Right Side Interface Xfall from Point.
21.10.2.11 Text Format - Boxing Right_slope

**Batter Off the Right End of Boxing with a Given Slope**

right_slope slope_value

The `right_slope` commands batter off to the right end of the boxing at the given slope `slope_value` until the design section is intersected. The intersection point is used as the next point in the boxing. In this command, a positive slope is up and negative down.

For the boxing panel that creates this boxing command, see 21.7.2.2.18 Boxing Right Side Interface Xfall from Point.

21.10.2.12 Text Format - Boxing Right_copy

**Copy from the Last Boxing Point to the end of Design Section**

right_copy value

If value is non-zero, the `right_copy` command copies from the last boxing point to the last point on the design section. Hence the `right_copy` command is used to continue the boxing section from the intersection point with the design section to the end of the design section (a full width boxing section).

**Note**

The `right_xfall` command takes precedence over the `right_slope` command. That is, if both commands exist then only the `right_xfall` command is used.

For the boxing panel that creates this boxing command, see 21.7.2.2.18 Boxing Right Side Interface Xfall from Point.

21.10.2.13 Text Format - Boxing Left_Xfall

**Batter off Left End of Boxing with Crossfall Taken from a Point**

left_xfall rel_off, delta_xfall

left_xfall xfall_value

The typed formats of the `left_xfall` commands created by this panel is:

left_xfall, xfall_name + xfall_offset, xfall_delta

The `left_xfall` is identical to the `right_xfall` command except that it is applied at the beginning of the boxing definition and batter off to the left rather than to the right.

In the `left_xfall` command, the `xfall` is percent cross-fall and a positive `xfall` is up and negative down.

For the boxing panel that creates this boxing command, see 21.7.2.2.17 Boxing Left Side Interface Xfall from Point.

21.10.2.14 Text Format - Boxing Left_slope
Batter Off the Left End of Boxing with a Given Slope

left_slope  slope_value

The left_slope is identical to the right_slope command except that it is applied at the beginning of
the boxing definition and batters off to the left rather than to the right. In this command, a positive
slope is up and negative down.

The left_slope and left_copy are identical to the right_slope and right_copy except that they are
applied at the beginning of the boxing definition and batter off and copy to the left rather than to
the right. In this command, a positive slope is up and negative down.

The left_copy command must come before the left_slope command but they both come after all
of the standard commands.

Note
The left_xfall command takes precedence over the left_slope command. That is, if both
commands exist then only the left_xfall command is used.

For the boxing panel that creates this boxing command, see 21.7.2.17 Boxing Left Side
Interface Xfall from Point.

21.10.2.15 Text Format - Boxing Left_copy

Copy from the Start of Design Section to the First Boxing Point

left_copy  value

The left_copy is identical to the right_copy except that it is applied at the beginning of the boxing
definition and copies to the left rather than to the right.

If value is non-zero, the left_copy command copies from the last boxing point to the last point on
the design section. Hence the left_copy command is used to continue the boxing section from
the first boxing point to the start of the design section (a full width boxing section).

Note
The left_xfall, left_slope, left_copy, right_xfall, right_slope and right_copy commands should
come after all of the standard commands.

When a boxing definition is applied on the left side, any right_xfall, right_slope or right_copy is
ignored. Similarly, when a boxing definition is applied on the right side, any left_xfall, left_slope or
left_copy is ignored.

Hence a boxing definition can have a left_xfall, left_slope, left_copy and a right_xfall, right_slope,
right_copy but which set is used depends on whether the boxing definition is used on the left or
the right.

When the boxing panel is used to create the boxing, only one boxing definition is needed and all
of the right_xfall, right_slope, right_copy, left_xfall, left_slope and left_copy commands are used.

For the boxing panel that creates this boxing command, see 21.7.2.17 Boxing Left Side
Interface Xfall from Point.
21.10.2.16 Text Format - Boxing Definitions Example

boxing “1” {
    “Linterface”, copy // line 1
    “Lpath2”, copy, -0.075 // line 2
    “Lpath1”, copy // line 3
    “Lbok” - 0.15, xfall, “Llok”, -0.3, 0 // line 4
    “Llok”, copy, -0.3 // line 5
    “Rlok”, xfall, “Rlok”, -0.3, 0 // line 6
    “Rbok” + 0.15, copy // line 7
    “Rpath1”, copy -0.095 // line 8
    “Rpath2”, copy // line 9
    “Rinterface”, end // line 10
}

Description
Line 1    copy from “Linterface” to “Lpath2”
Line 2    copy and drop by 0.075 from “Lpath 2” to “Lpath 1”
Line 3    copy from “Lpath1” to 0.15 before “Lbok”
Line 4    go from 0.15 before “Lbok” to “Llok” at depth 0.3 below “Llok”, with cross fall 0
Line 5    copy and drop by 0.3 from “Llok” to “Rlok”
Line 6    go from “Rlok” to 0.15 past “Rbok” at depth 0.3 below “Rlok”, with cross fall 0
Line 7    copy from 0.15 past “Rbok” to “Rpath1”
Line 8    copy and drop by 0.095 from “Rpath1” to “Rpath2”
Line 9    copy from “Rpath2” to “Rinterface”

boxing “left narrow” { // boxing defined from just before lkerb to m001
    “lkerb” - 0.7 , copy
    “m001” - 1.0, copy , -0.6
    “m001”, end
}
boxing “left” {
    // boxing defined from the left start of the section to m001 (the centreline say)
    “lkerb”,    copy,    -0.6
    “m001”,    end
    left_slope  5.0
    left_copy   1
}
boxing “right” {
    // boxing defined from m001 to the far right of the section
    “m001”,    copy,    0.6
    “rkerb”,    end
    right_slope 5.0
    right_copy  1
}
boxing “full” {
    // a full width boxing - defines the entire boxing going from left to right
    “lkerb”,    copy,    -0.6
    “rkerb”,    end
    left_slope  5.0
    left_copy   1
    right_slope -5.0
    right_copy  1
}

For more information on how Boxing works in 12d Model, please go to the section 21.4 Smart Chainages.
### 21.11 Superseded MTF Commands

These MTF Modifier options were superseded by the commands in 12d Model 11 that did not care how the links were originally defined.

#### 21.11.0.1 Fixed Link - Modify Width or Height - Superseded

This option has been superseded in V11 by the Fixed Link modifier, Modify Link. See 21.2.2.2.4 Fixed - Modify Link.

The **Width** modifier is used to modify the width of fixed links originally defined by width (width and height or width and xfall).

The **Height** modifier is used to modify the height of fixed links originally defined by height (height and width or height and xfall).

Selecting width and height brings up the Fixed - Modify Width and Fixed - Modify Height panels respectively.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link name</td>
<td>input</td>
<td>select name menu</td>
<td></td>
</tr>
<tr>
<td>Start/End mode</td>
<td>choice box</td>
<td>Start (ref)/End (ref)</td>
<td></td>
</tr>
</tbody>
</table>
defines the start/end chainages for modifying the link.

**Interval**

**Input**

*If non blank*, the interval to use to create cross sections and strings over the given chainage range. 
*If blank*, the **Section separation** value from the **Apply MTF** panel is used.

**Start/End width/height**

**Input**

**Measures menu**

*Start/end width/height for modifying the template link.*

**Extra start/end**

**Tick box**

*If ticked*, add an extra x-section 0.1 mm **before** the start/end chainage.

**Absolute**

**Tick box**

*If ticked*, the width/height is set to the values given in the **start** and **end value** fields.  
*If not ticked*, the values given in the **start** and **end value** fields are added to the existing widths/heights.

**Cubic**

**Tick box**

*If ticked*, the width/height is varied as a reverse cubic between the start and end chainages. 
*If not ticked*, the width/height is varied linearly between the start and end chainages.

**Comment**

**Input**

*Comment to add to the end of the line. In the file, the comment will be preceded by //.*

**Active**

**Tick box**

*If ticked*, use this modifier. 
*If not ticked*, don't use this modifier.

**OK**

**Button**

**OK** stores the values in the fields and removes the panel **BUT no recal**c is done.

**Apply**

**Button**

**Apply** stores the values and leaves the panel on the screen. 

*If the MTF is being used in an **Apply MTF** and **Auto recal**c is ticked in the MTF, then whenever the **Apply** button is clicked, a recal of the associated **Apply MTF** for the MTF is done.*

Continue to the next section **21.11.0.2 Fixed Link - Modify Xfall - Superseded** or go to the replacement options **21.2.2.2 Fixed Link Modifiers** or **21.2.2 Left and Right MTF Modifiers**.
21.11.0.2 Fixed Link - Modify Xfall - Superseded

This option has been superseded in V11 by the Fixed Link modifier, Modify Link. See 21.2.2.2.4 Fixed - Modify Link.

The Xfall modifier is used to modify the cross fall of fixed links originally defined by cross fall (xfall and width or xfall and height). Selecting Xfall brings up the Fixed - Modify Xfall panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link name</td>
<td>input</td>
<td>select name menu</td>
<td></td>
</tr>
<tr>
<td></td>
<td>name of the link to modify.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Start/End mode</td>
<td>choice box</td>
<td>Start (ref)/End (ref)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>defines the start/end chainages for modifying the link.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interval</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if non blank, the interval to use to create cross sections and strings over the given chainage range. If blank, the Section separation value from the Apply MTF panel is used.</td>

<td>tick box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
if **ticked**, add an extra x-section 0.1 mm **before** the start/end chainage.

**Absolute** tick box **tick**

if **ticked**, the xfall is set to the values given in the **start** and **end** xfall fields.
if **not ticked**, the values given in the **start** and **end** xfall fields are added to the existing xfall.

**Cubic and Rotate tick boxes:**

Only none or one of **Cubic** and **Rotate** can be set to **tick**.
The **default** is none - that is, **neither is ticked** and in the default case, the crossfall is varied **linearly with respect to crossfall** between the start and end chainages.

**Cubic** tick box

if **ticked**, the crossfall is varied as a reverse cubic between the start and end chainages.

**Rotate** tick box

if **ticked**, the xfall is varied **linearly with respect to the angle**, between the start and end chainages.

**Comment** input

comment to add to the end of the line. In the file, the comment will be preceded by //.

**Active** tick box **tick**

if **ticked**, use this modifier.
if **not ticked**, don’t use this modifier.

**OK** button

**OK** stores the values in the fields and removes the panel BUT no **recalc** is done.

**Apply** button

**Apply** stores the values and leaves the panel on the screen.

If the **MTF** is being used in an **Apply MTF** and **Auto recalc** is ticked in the MTF, then whenever the **Apply** button is clicked, a **recalc** of the associated **Apply MTF** for the MTF is done.

Continue to the next section [21.11.0.3 Fixed Link - Modify Xfall by CRC Formula - Superseded](#) or go to the replacement options [21.2.2 Fixed Link Modifiers](#) or [21.2.2 Left and Right MTF Modifiers](#).
21.11.0.3 Fixed Link - Modify Xfall by CRC Formula - Superseded

This option has been superseded in V11 by the Fixed Link modifier, Modify Link. See 21.2.2.2.4 Fixed - Modify Link.

The Xfall CRC modifier is used to modify the cross fall of fixed links originally defined by xfall and uses the circular reverse curve formula to modify the cross fall.

Selecting Xfall CRC brings up the Fixed - Modify Xfall Circular Reverse Curve panel

![Fixed - Modify XFall Circular Reverse Curve Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>

if ticked, use this modifier.  
if not ticked, don’t use this modifier.

OK  
button  
OK stores the values in the fields and removes the panel BUT no recalcs is done.

Apply  
button  
Apply stores the values and leaves the panel on the screen.

If the MTF is being used in an Apply MTF and Auto recalcs is ticked in the MTF, then whenever the Apply button is clicked, a recalcs of the associated Apply MTF for the MTF is done.

Continue to the next section 21.11.0.4 Fixed Link - From Link - Superseded or go to the replacement options 21.2.2.2 Fixed Link Modifiers or 21.2.2 Left and Right MTF Modifiers.
21.11.0.4 Fixed Link - From Link - Superseded

The fixed from Link walk-right brings up the fixed from Link menu with options to take the width, xfall or height from another link.

For Width/Height/Xfall from link, go to the next section Fixed Link - Take Width, Height or Xfall from another Link

Fixed Link - Take Width, Height or Xfall from another Link

Width from Link
The Width from link modifier is used to modify the width of fixed links originally defined by width (width and height or width and xfall) to be the same width as another link. That is, the width of the link is a copy of the width of another link.

Height from Link
The Height from link modifier is used to modify the height of fixed links originally defined by height (height and xfall or height and width) to be the same height as another link. That is, the height of the link is a copy of the height of another link.

Xfall from Link
The Xfall from link modifier is used to modify the cross fall of fixed links originally defined by xfall (xfall and height or xfall and width) to be the same xfall as another link. That is, the cross fall of the link is a copy of the cross fall of another link. The link to copy cross fall from can be defined in terms of cross fall or slope. If the link to copy is defined by slope, then the cross fall is calculated to match the slope.

Selecting the Width from link, Height from link or Xfall from link option brings up the Fixed - Modify Width from Link, Fixed- Modify Height from Link and Fixed- Modify Xfall from Link panels respectively.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

If there is more then one link name then the names must be separated by spaces. If the link name includes a space, then the name must be enclosed in the quotes " (eg "EB 1").

When the Start mode is Start (ref), or Typed and the chainage is blank, the modification begins at the low dropped chainage of the selected string.

When the End mode is End (ref), or Typed and the chainage is blank, the modification ends at the high dropped chainage of the selected string.
comment to add to the end of the line. In the file, the comment will be preceded by //</.

Active tick box tick
if ticked, use this modifier.
if not ticked, don’t use this modifier.

OK button
OK stores the values in the fields and removes the panel BUT no recalc is done.

Apply button
Apply stores the values and leaves the panel on the screen.

If the MTF is being used in an Apply MTF and Auto recalc is ticked in the MTF, then whenever the Apply button is clicked, a recalc of the associated Apply MTF for the MTF is done.
Fixed Link - Calculate Width, Height or Xfall to a String

**Width to String:**
For a fixed link defined by `width` and `height` or `width` and `xfall`, Width to string calculates the width of the link as the width from the start point of the link, to the the selected string. The `xfall` or `height` is taken from the link. The option will give an error for a link defined by `height` and `xfall`.

**Height to String:**
For a fixed link defined by `height` and `width` or `height` and `xfall`, Height to string calculates the height of the link as the difference in the height at the start point of the link, and the height at the selected string. The `xfall` or `width` is taken from the link. The option will give an error for a link defined by `width` and `xfall`.

![Diagram of Width to String](image)

![Diagram of Height to String](image)
Superseded MTF Commands

Xfall to String:
For a fixed link defined by xfall and width or xfall and height, Xfall to string calculates the xfall of the link as the xfall from the start point of the link to the selected string. The width or height is taken from the link. The option will give an error for a link defined by width and height.

Note:
Using two of the above modifiers together and with the same string will place the end point of the link on the selected string. For example for a modifier defined by width and xfall, using width to string and a xfall to string with the same string will place the end of the link on that string.

But the To string option will do the same thing in one command. See Fixed Link - Modify To String.

Selecting the width to string, height to string or xfall to string option brings up the Fixed - Modify Width
to String, Fixed - Modify Height to String and Fixed - Modify Xfall to String panels respectively.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

</table>

If the **MTF** is being used in an **Apply MTF** and **Auto recalc** is ticked in the **MTF**, then whenever the **Apply** button is clicked, a **recalc** of the associated **Apply MTF** for the **MTF** is done.

Continue to the next section **21.11.0.6 Fixed Link - to Tin - Superseded** or go to the replacement options **21.2.2.2 Fixed Link Modifiers** or **21.2.2 Left and Right MTF Modifiers**.
21.11.0.6 Fixed Link - to Tin - Superseded

The fixed to tin walk-right brings up the fixed to Tin menu with options to calculate the width, xfall or height to get to a given tin.

For Width/Height/Xfall to tin, go to the next section Fixed Link - Modify Width, Height or Xfall to Sit on User Tin.
Fixed Link - Modify Width, Height or Xfall to Sit on User Tin

**Width to Tin**

For a fixed link defined by *width* and *height* or *width* and *xfall*, Width to tin calculates the *width* of the link as the width required so that the link will sit on the user given tin at the *height/xfall given in the link*. The option gives an error for a link defined by *height* and *xfall*.

**Height to Tin**

For a fixed link defined by *height* and *width* or *height* and *xfall*, the Height to tin calculates the *height* of the link as the difference in the height of the start point of the link, and the height that is required so that the link will sit on the user tin at the *width/xfall given in the link*. The option gives an error for a link defined by *width* and *xfall*.
Section View

For a fixed link defined by \textit{xfall and width} or \textit{xfall and height}, \textit{Xfall to Tin} calculates the \textit{xfall} of the link as the \textit{xfall} required so that the link will sit on the user tin at the \textit{width/height given in the link}. The option gives an error for a link defined by \textit{width} and \textit{height}.

\textbf{Xfall to Tin}

For a fixed link defined by \textit{xfall and width} or \textit{xfall and height}, \textit{Xfall to Tin} calculates the \textit{xfall} of the link as the \textit{xfall} required so that the link will sit on the user tin at the \textit{width/height given in the link}. The option gives an error for a link defined by \textit{width} and \textit{height}.

Selecting \textit{Width to Tin}, \textit{Height to Tin}, or \textit{Xfall to Tin} brings up the \textit{Fixed - Modify Width to Tin}, \textit{Fixed - Modify Height to Tin} and \textit{Fixed - Modify Xfall to Tin} panels respectively.
The fields and buttons used in this panel have the following functions.

Continue to the next section 21.11.0.7 Fixed Link - to RL - Superseded or go to the replacement options 21.2.2.2 Fixed Link Modifiers or 21.2.2 Left and Right MTF Modifiers.
21.11.0.7 Fixed Link - to RL - Superseded

The fixed to RL walk-right brings up the fixed to RL menu with options to calculate the width, xfall or height to get to a given RL.

For Width/Height/Xfall to tin, go to the next section Fixed Link - Modify Width, Height or Xfall to Get to an RL

Fixed Link - Modify Width, Height or Xfall to Get to an RL

**Width to RL**
The Modify Width to RL, only applies to links defined by *Width and Xfall* NOT Width and Height or Xfall and Height.

For a fixed link defined by *width* and *xfall*, Modify Width to RL calculates the **width** required for the link to end at the given RL using the xfall given in the link.

The Modify Width to RL gives an error for a link defined by *width* and height or *xfall* and height.

**Height to RL**
The Modify Height to RL, only applies to links defined by *Width and Height* and Height NOT Width and Xfall.

For a fixed link defined by *height* and *width*, the Modify Height to RL calculates the **height** required for the link as the difference in height of the start point of the link and the given RL.
For a fixed link defined by height and xfall, the **Modify Height to RL** calculates the height required for the link to end at the given RL using the xfall given in the link. That is, the difference in the height of the start point of the link, and the height that is required so that the link will sit on the RL at the given xfall.

The **Modify Height to RL** gives an error for a link defined by width and xfall.

**Xfall to RL**

The **Modify Xfall to Get an RL**, only applies to links defined by Xfall and Width, NOT Xfall and Height or Width and Height.

For a fixed link defined by xfall and width, **Modify Xfall to RL** calculates the xfall of the link required for the link to end at the given RL using the width given in the link.

The **Modify Xfall to RL** gives an error for a link defined by xfall and height, or width and height.
Selecting Width to RL, Height to RL, or Xfall to RL brings up the Fixed - Modify Width to RL, Fixed - Modify Height to RL and Fixed - Modify Xfall to RL panels respectively.
The fields and buttons used in this panel have the following functions.

|                   |          | if not ticked, don’t use this modifier. |

**OK** button

**OK** stores the values in the fields and removes the panel BUT no recalc is done.
Apply button

Apply stores the values and leaves the panel on the screen.

If the MTF is being used in an Apply MTF and Auto recalc is ticked in the MTF, then whenever the Apply button is clicked, a recalc of the associated Apply MTF for the MTF is done.

Continue to the next section 21.11.0.8 Fixed Link - to Two Strings - Superseded or go to the replacement options 21.2.2.2 Fixed Link Modifiers or 21.2.2 Left and Right MTF Modifiers.
21.11.0.8 Fixed Link - to Two Strings - Superseded

The fixed to 2 strings walk-right brings up the fixed to 2 Strings menu with options to calculate the width, xfall or height from two given strings.

For Width/Height/Xfall to 2 Strings, go to the next section Fixed Link - Width, Height or Xfall between Two Strings

Fixed Link - Width, Height or Xfall between Two Strings

Width Between Two Strings

For a fixed link defined by width and height or width and xfall, Width to 2 strings sets the width for a link to be the width between two existing 12d Model strings,

The option will give an error for a link defined by height and xfall.

Height Between Two Strings

For a fixed link defined by height and width or height and xfall, Height to 2 strings sets the height for the link to be the height between two existing 12d Model strings,
The option will give an error for a link defined by \textit{width} and \textit{xfall}.

\begin{center}
\begin{tikzpicture}
\begin{scope}[scale=0.5]
\draw[->,thick] (0,0) -- (0,6); \node at (0,7) {string 1};
\draw[->,thick] (7,0) -- (7,6); \node at (7,7) {string 2};
\draw[->,thick] (0,0) -- (7,7);
\draw[thick] (0,0) -- (2,2);

Comment input

comment to add to the end of the line. In the file, the comment will be preceded by //.

Active tick box tick

if ticked, use this modifier.
if not ticked, don’t use this modifier.

OK button

**OK** stores the values in the fields and removes the panel BUT no recalc is done.

Apply button

**Apply** stores the values and leaves the panel on the screen.

If the MTF is being used in an **Apply MTF** and Auto recalc is ticked in the MTF, then whenever the **Apply** button is clicked, a recalc of the associated **Apply MTF** for the MTF is done.

22 Drainage and Sewer

Position of menu: Design -> Drainage-Sewer

The Drainage-Sewer option is used to place drainage and sewer networks within a subdivision, along highways and culverts for cross drainage. Pumps may also be included in the network. The network is placed in three dimensions including manholes (maintenance holes), and for sewer work, lot controls and house connections can be defined. A 12d drainage string is used for all of these options.

If used in conjunction with the services on a section view, interference with neighbouring pipe strings can be taken into consideration when placing the network.

Note that the drainage string and plots capabilities are only available with the drainage and sewer options, and the sewer extensions (property control, house controls and Melbourne Water plots) are only available with the sewer option.

The drainage string is based on a polyline string so that arcs can exist between manholes (maintenance holes). The manholes may be placed anywhere along the polyline but generally manholes are located at the polyline indices.

The use of the drainage string for drainage is only a subset of its use for sewer so the steps for the sewer will be given since they cover drainage as well.

The sewer process consists of a number of steps (the drainage process does not use steps 2 and 3):

1. creating the drainage or sewer network
2. vertical alignment, pipe cover and utility clash checking using the Drainage Network Editor
3. checking that residential blocks are controlled by the sewer network
4. creating the house connections for the sewer
5. network design using custom routines, spread sheets or advanced network analysis packages via the Drainage Network Editor
6. producing Drainage Plots (plan and long section) and Reports (material quantity reports, excavation volumes and manhole construction reports)

These steps are described in the rest of this chapter.

The Drainage walk-right menu is laid out to reflect the standard sequence of placing drainage and wastewater pipes, i.e. creating, editing and plotting.

22.1 Drainage Strings

A drainage string consists of a series of manholes (maintenance holes) at user selected (x,y,z) positions. The manholes can be joined by either straight or curved pipes.

Manholes may be any type of drainage structure and are represented by circles or rectangles. Drainage inlets, pump wet wells, gross pollutant traps, soak away pit, open channel changes in direction are all examples of manholes. The manholes have cover, grate and sump levels as well as wall and bottom thicknesses.

Pipes are the conduits connecting the manholes. Round pipes, box culverts, trapazoidal channels, pump rising mains, basin links, weirs and orifices are all examples of pipes.

Like all 12d Model strings, the drainage string has an implied direction, starting at the first manhole and going in the direction towards the next manhole in the drainage string. This order is normally determined by the creation order (or string order) of the manholes.

The chainage of the drainage string starts at the first manhole and then increases along the direction of the drainage string.

In 12d Model, drainage strings have a property indicating

(a) the most upstream manhole is entered as the first point of the string and hence the water flows in the direction of ascending string chainage. The flow direction is said to be in ascending chainage.

or

(b) the most downstream manhole is entered as the first point of the string and hence the water flows in the direction of descending chainage. The flow direction is said to be in descending chainage.

When a drainage string with flow direction in ascending order is profiled in a section view, the left hand side of a manhole is normally upstream and the right hand side of a manhole downstream.

It is recommended that drainage strings are entered with the flow direction in ascending chainage so that the minimum grade and cover can be satisfied as the drainage string is being placed.

That is, if the drainage string flow is in ascending chainage direction, then as manholes are appended, minimum cover and minimum grade can be automatically maintained. In all cases the invert levels can be recalculated using the Drainage Network Editor.
22.1.1 Pipes

A pipe is automatically created when a second or additional manhole is added to a drainage string. The properties of the pipe follow:

22.1.1.1 Type

22.1.1.2 Size (diameter, width, top width and natural channel shapes (dynamic only).

22.1.1.3 Inverts Levels

22.1.1.4 Wall Thickness

22.1.1.5 Minimum cover limit

22.1.1.6 Length

The pipe length by default is set to manhole centre to manhole centre. This length is displayed in the DNE and on the section view (Toggle->Grades) when the drainage string is profiled.

The pipe length maybe be also be calculated from the inside edge of the drainage manhole by using pit connections points enabled in the Drainage Network Editor on the Global Tab.

22.1.1.7 Grade

The pipe grade is calculated from the length and invert properties discussed above. This grade is displayed on the section view (Toggle->Grades) when the drainage string is profiled. It is shown as % or 1 in via Section View Menu View => Settings =>Grade annot

Please continue to the next section Networks and Junctions.
22.2 Networks and Junctions

In 12d Model, a drainage network consists of one or more drainage strings in the same model. Consequently, all the drainage strings in the same model are considered to be part of the same drainage network. It is suggested that all drainage strings in a network be entered with the same flow direction.

If two drainage strings from the same model have a manhole at exactly the same (x,y) location, then 12d Model assumes that the co-incident manholes are the same manhole and that the situation represents a junction. Most junction manholes are at the ends of the drainage strings. A junction may have a maximum of one manhole that is not at the end of the drainage string.

When water flows into a drainage string (from a branch drainage string) it is referred to as a trunk line. A trunk line may be a branch for another downstream trunk line.

Also for a network, if all the drainage strings are entered with the flow direction in ascending chainage, not only can minimum cover and minimum grade be maintained as manholes are appended, but if the branches are laid down before the trunk, then as you connect each branch to the trunk, the invert level for the trunk will be set to below the invert level of the branch line (less the default drop for the manholes). In all cases the invert levels for the entire network be recalculated using the Drainage Network Editor.

Please continue to the next section Drainage Definitions - Manholes and Pipes.
22.3 Drainage Definitions - Manholes and Pipes

A file of pipe and manhole (maintenance hole) definitions is used to create pipe and manhole (maintenance hole) types to allow tailoring for a particular project. The manhole or pipe type is one method to set many of the objects properties such as inlet capacity, thickness and roughness along with the objects user defined attributes.

When 12d Model starts up, it checks to see if an environment variable called DRAINAGE_4D exists and if it does, then the file it points to is used to provide the available types of manholes (maintenance holes) and pits.

If the environment variable is not set, then 12d Model searches for a file called drainage.4d in the standard 12d Model search sequence for set up files.

The drainage definitions file format is a text format and consists of one or more pipe and manhole definitions. Each definition in the file begins with the key word Pipe or Manhole, followed by the pipe or manhole type and then curly braces { }. The order that the definitions appear in the file determines the order they appear in the drop down lists inside 12d Model.

IMPORTANT: the file is only read when 12d Model starts up. When the file is changed while, 12d Model is running, you must restart 12d Model for the changes to become active. If any syntax errors have been made editing the file, the line number will be displayed in the output window. The error generally slightly above this line. The most common errors are missing curly braces { } and forgetting quotes around entries containing spaces.

A minimal example of a drainage definitions file is:

```
// -------------------------------------------------------------
// drainage.4d 1/6/96
// Used to define the types of Pipes and Manholes
// -------------------------------------------------------------
Pipe   "PVC"   { }
Pipe   "VC"   { }
Pipe   "PVC Extra Heavy"   { }
Pipe   "Plastic"  { }
Manhole   "CONC COVER"  { }
Manhole "Gatic"   { }
Manhole   "Rubber"   { }
```

Notes
1. spaces in text - any text string that includes spaces or only numbers, must be enclosed in double quotes "".
2. comments - anything after // until the end of the line is ignored.
3. blank lines - blank lines are ignored
4. Duplicate definitions are not allowed.

Please continue to the next section Drainage Definitions - Manhole Types.
22.3.1 Drainage Definitions - Manhole Types

Manhole types may be used to set the following manhole properties via the DNE.

- manhole diameter, length/width and thickness
- manhole description, notes, group, ku/kw method, ku/kw values, rational engine design freeboard,
- manhole level modes for cover level, grate level, survey setout level and sump levels,
- survey setout xy modes and road chainage modes
- user defined manhole attributes

Each definition (manhole block) in the file begins with the key word **Manhole**, followed by the manhole type and then curly braces `{ }`. The order that the definitions appear in the file determines the order they appear in the drop down lists inside **12d Model**.

The minimum requirement for a pit type definition is

```
Manhole "type name" {
}
```

The type name must be unique and the braces {} cannot be () or [].

Optional manhole commands may be placed inside the braces. These commands include may include **Manhole Editor Commands**, **Manhole Drainage Network Editor Commands** and Manhole Calculation Commands.

22.3.1.1 Manhole Editor Commands

These optional commands change the properties of the manhole objects. Changes to these commands will used in creating new drainage strings and the **Drainage Network Editor** will prompt you to update the object if these settings are different to the strings current settings. A list of these commands follows

- **mhdiam**  x.x  set the manhole as circular (internal diameter in base units)
- **mhsize**  x.x y.y  set the manhole as rectangular (over rides mhdiam) length and width in base units
- **mthickness**  
  - **diam_thickness**  x.xxx a.aaa b.bbb c.ccc d.ddd

  - **x.xxx**  nominal diameter choices will appear in the DNE->Pipe->Diameter drop down
  - **a.aaa**  optional front thickness (base units) 0.000 if omitted
  - **b.bbb**  optional back thickness (base units) front thickness if omitted
  - **c.ccc**  optional left thickness in direction of chainage (base units) front thickness if omitted
  - **d.ddd**  optional right thickness in direction of chainage (base units) front thickness if omitted

22.3.1.2 Manhole Level Modes

There are several modes that may be used to calculate x,y,and z values for the manholes. A description of each follows.

- **FS tin**  the manhole centre x,y location is used to obtain the level from the drainage finished surface tin
- **NS tin**  the manhole centre x,y location is used to obtain the level from the drainage natural surface tin
- **Setout string**  the manhole centre x,y location is dropped perpendicular onto the setout string. The x,y
Drainage Definitions - Manholes and Pipes

or z value is then obtained from this string. If this string is missing then the pit x,y location or finished surface tin level is used instead.

Centre string the manhole centre x,y location is dropped perpendicular onto the road centre string and the chainage value is obtained. If this string is missing an error message will be created in the output window.

Sz + Setout string the manhole centre x,y location is dropped perpendicular onto the setout string. The Sz value for the manhole is then added to the z value obtained from this string. If this string is missing the Sz value is added to the finished surface tin level at the pit centre x,y location.

Manual the x,y,z or chainage value is manually entered by the user.

Cover RL the z level is set the the Cover RL level (after it has been recalculated.

Max Obvert the maximum obvert level from off the conduits connected to this manhole is used.

Floating sump the manhole sump level is set to the lowest invert of all the conduits connected to this manhole + the sump offset

22.3.1.3 Manhole Drainage Network Editor Commands

These optional commands store user defined data on the manholes or change the calculation modes available in the Drainage Network Editor. The set pit details button in the editor will recalculate these for all manholes in the network. A list of these commands follows

mhdesc "description" creates a pit text attribute "pit type description" and is used in the drainage pit schedule report.

mhnotes "note" creates a pit text attribute "pit type remarks" and is used in the drainage pit schedule report.

mhgroup "group" routines that select manholes will select from a manhole belonging to the same group

attribute_integer "attribute name1" x x is an integer value (no decimal, stored exactly by computers

attribute_real "attribute name2" x.xxx x is a real value (used to store numbers with decimals or very large or very small numbers

attribute_text "attribute name3" "text" text is a series of words or numbers not intended for calculations

Note: If a non-special attribute name is set for some, but not all manhole types, that attribute will be deleted on all manholes with types where the attribute is not defined.

The following special attribute commands create/modify an attribute as described above but these attributes also control calculations performed by the set pit details button on the Drainage Network Editor. The DNE fields will be locked when these attributes are defined for the selected pit type. If these attribute are not defined for the selected pit type the DNE field will not be locked and remain unchanged.

attribute_integer "cover rl mode" x DNE field ->Pit=>Main=>Cover RL mode

Mode x
FS tin 0
Setout string 1
Manual 2
NS tin 3
Max Obvert 4
Sz + setout string 8

The following example of a channel ip point is given below. The setout modes are set, the cover and grate level modes are set and the ku (losses) are set. Finally, the inlet capacity is set to an on-grade pit with 200% inlet capacity so that even in a major storm with a choke factor of 0.5 it will
still have 100% inlet capacity.

Manhole "CHNL auto" {

  mhdesc  "channel hip-vip"
  attribute_text "lplot description1"  "OPEN CHANNEL"

  mhsize  0.0
  mhdiam  0.0
  attribute_integer "setout xy mode" 0 // centre of the channel

  attribute_integer "grate rl mode" 4 // max obvert - top of the channel
  attribute_integer "ku method" 0 // direct
  attribute_real    "ku" 0.0 // zero unless interested in bend losses

  cap_config G

  cap_percent 200 // if a choke factor of 0.5 is applied then it will still have 100% inlet capacity
}

// attribute_real    "design freeboard" Pipe=>Design=>Freeboard limit at US pit

22.3.1.4 Manhole Drainage Analysis Inlet Capacity Commands

Manhole inlet configuration and bypass pit entries determine if these inlet capacity commands are used. Both may be set in the Drainage Network Editor.

22.3.1.4.1 cap_config

The inlet configuration may be set via the following command

  cap_config x
  Mode x
  Manhole m
  Ongrade g
  Sag s

Inlet Configuration = manhole - no water will enter the pit through the grate. Commands not used.

Inlet configuration = on grade or sag

  Bypass pit not set - 100% of the approach flow will enter the pit. Commands not used.
  Bypass pit is entered. The following commands define the stormwater inlet capacity characteristics.
22.3.1.4.2 Inlet Capacity Equation

The inlet capacity equation is built up with optional components (single polynomial + curve polynomial + curve coordinates). Generally, only one of the components is used for each manhole type but they may all be used if desired.

\[
\text{inlet capacity} = \text{inlet efficiency} \times \text{inlet multiplier} \times \left( \text{single polynomial} + \text{curve multiplier} \times \text{curve polynomial} + \text{curve coordinates} \right)
\]

An inlet efficiency (choke factor) is specified in the Drainage Network Editor. An inlet efficiency (choke factor) of 0 would stop all water from entering the inlet. The inlet multiplier is specified with a cap_multi parameter.

**Multipliers**

\[
\text{cap_multi} \times x\times \text{inside a cap_curve_grade block or cap_curve_sag block, the curve inlet capacity is multiplied by this value outside a cap_curve_grade or cap_curve_sag, the total inlet capacity is multiplied by this value}
\]

**Single Polynomial**

The inlet capacity for an inlet may be specified by a single polynomial equation based on the approach flow. This is the most simplistic method and generally used for percentage capture or fixed capture rates.

\[
\text{inlet capacity} = \text{cap_fixed} + \text{cap_percent} \times 0.01 \times Q_a + \text{cap_coeff} \times Q_a^{\text{cap_power}}
\]

**Example**

This example creates an inlet with a fixed inlet capacity of 0.010 (cms or cfs).

Manhole "fixed inlet capacity" {
\[
\text{cap_fixed} 0.010
\]}

**Default values**

\[
\begin{align*}
\text{cap_multi} &= 1.0 \\
\text{cap_fixed} &= 0.0 \\
\text{cap_percent} &= 0.0 \\
\text{cap_coeff} &= 0.0 \\
\text{cap_power} &= 1.0
\end{align*}
\]

**Curve Polynomial**

For on-grade inlets, the polynomial parameters may change with road grade and cross fall threshold values. The formula is the same for cap_fixed, cap_percent, cap_coef and cap_power. Note that each curve may have its own curve multiplier specified with a cap_multi parameter (discussed below). Some hydraulic model tests have their on grade inlet results converted to polynomial equations.

**Example**

This example creates an inlet where the inlet capacity polynomials have been determined for 2 road grades (1% and 3%). Note that the road_grade 0.0 command is used for the 1% road grade. Since this is the flattest road grade curve we have calculated we will start using it at a road grade of 0%.

Note that the second curve "NJ G3" will be used when the road grade reaches 2.5. The threshold value where 12d should change to the next curve is generally slight less than the road grade from the source.
Manhole "On grade pit type NJ" {
    cap_config G
    
    cap_curve_grade  "NJ 1G" {
        road_grade  0
        cap_coeff  0.215
        cap_power  0.67
    }
    
    cap_curve_grade  "NJ 3G" {
        road_grade  2.5
        cap_coeff  0.24
        cap_power  0.673
    }
}

Curve Coordinates (On grade and SAG)

For on-grade and sag inlets, the inlet capacity may be determined by entering coordinates along
the inlet capacity curve. These coordinates are usually obtained from hydraulic model studies or
analytical methods such as HEC-22.

For on grade inlets, the coordinates are Qapproach and Qin, and the curves may change with
road grade and cross fall threshold values. The inlet capacity curves are never extrapolated.

Example

    Manhole "Ongrade coordinates" {
        cap_config G
        
        cap_curve_grade "0.5G" {
            road_grade  0
            coord 0.000 0.000
            coord 0.060 0.060
            coord 0.140 0.112
            coord 0.260 0.174
            coord 0.430 0.244
            coord 0.500 0.270
        }
        
        cap_curve_grade "1G" {
            road_grade  0.75
            coord 0.000 0.000
            coord 0.060 0.060
            coord 0.140 0.108
            coord 0.260 0.164
            coord 0.430 0.227
            coord 0.500 0.248
        }
    }

For sag inlets, the coordinates are Depth (base units) and Qin, and there is only one curve. Each
curve has a curve multiplier specified with a cap_multi parameter (discussed below).
Example

Manhole "SAG coordinates" {
    cap_config S
    cap_curve_sag "SAG" {
        coord 0.000 0.040
        coord 0.045 0.101
        coord 0.070 0.151
        coord 0.095 0.245
        coord 0.120 0.302
        coord 0.170 0.347
        coord 0.220 0.371
        coord 0.270 0.391
    }
}

22.3.1.4.3 Polynomial Inlet Capacity Commands

The following commands are used to set the parameters in the following polynomial equation

\[
\text{inlet capacity} = \text{cap_fixed} + \text{cap_percent} \times 0.01 \times Qa + \text{cap_coeff} \times Qa^\text{cap_power}
\]

- **cap_fixed**: x.x cms or cfs
- **cap_percent**: x.x percentage (0 to 100)
- **cap_coeff**: x.x multiplier
- **cap_power**: x.x exponent

22.3.1.4.4 Inlet Curve Block Commands

Inlet curve blocks may be specified for both on-grade or sag inlets. Inside the curve block you may include the Polynomial Inlet Capacity Commands and Coordinate Inlet Capacity Commands.

\[
cap_curve_grade "unique name for the pit type" {
    road_grade x.xx
    road_xfall x.xx
}
\]

Inside the cap_curve_grade block the road grade and road crossfall threshold values (percent) may be set. The road grade and crossfall are calculated by the Drainage Network Editor. When the 12d analysis engine selects the inlet curve, all curves with the same road_xfall are grouped together and then within the crossfall group the road_grade curves is selected. The inlet curve with the maximum grade threshold that is less than or equal to the road grade is selected.

Rules for 'cap_curve_grade' entries:
- Only applicable to on-grade pits.
- All cap_curve_grade names must be unique within a Manhole block.
- If both 'road_grade' and 'road_xfall' entries are omitted, only one cap_curve_grade entry is allowed within a pit.
- The cap_curve_grade 'coord' entries (if used) must be in order of increasing Qa.

\[
cap_curve_sag "unique name for the pit type" {
}
\]
Rules for 'cap_curve_sag' entries:
  - Only applicable to sag pits.
  - Only one cap_curve_sag entry is allowed within a pit, and it must have a valid name.

22.3.1.4.5 Coordinate Inlet Capacity Commands

The coord command must be used inside the cap_curve_grade or cap_curve_sag grouping.
coord x.xx y.yy
x.xx must be in increasing order.

For cap_curve_grade group, the coord command has the parameters Qapproach and Qin.
For cap_curve_sag group, the coord command has the parameters Depth and Qin.

Please continue to the next section Drainage Definitions - Pipe Types.
22.3.2 Drainage Definitions - Pipe Types

Pipe types may be used to set the following pipe properties via the DNE:

- pipe nominal/actual diameters and thickness
- roughness method and value
- rational method design mode and design percent depth
- minimum pipe height for the rational design engine
- user defined pipe attributes

Each definition (pipe block) in the file begins with the key word **Pipe**, followed by the pipe type and then curly braces `{ }`. The order that the definitions appear in the file determines the order they appear in the drop down lists inside 12d Model.

The minimum requirement for a pipe type definition is

```
Pipe "name" {
}
```

The name must be unique and the braces {} cannot be () or [].

Example:

```
Pipe "CHNL GRASS PROPOSED" {  //Open Channel created below the tin. cover set in cover file to 0.0
  roughness_n 0.040
  attribute_integer "design size mode" 3  // open channel mode
}
```

22.3.2.1 Pipe Drainage Network Editor Commands

22.3.2.1.1 Pipe Thickness

```
pipethickness {
  diam_thickness x.xxx y.yyy a.aaa b.bbb c.ccc d.ddd
}
```

- x.xxx nominal diameter choices will appear in the DNE->Pipe->Diameter drop down field
- y.yyy internal diameter (base units) will be entered into the DNE->Pipe->Diameter field
- a.aaa optional top thickness (base units) 0.000 if omitted
- b.bbb optional bottom thickness (base units) top thickness if omitted
- c.ccc optional left thickness in direction of chainage (base units) top thickness if omitted
- d.ddd optional right thickness in direction of chainage (base units) top thickness if omitted

22.3.2.1.2 Pipe Attributes

```
attribute_integer "attribute name1" x x is an integer value (no decimal, stored exactly by computers
attribute_real "attribute name2" x.xxx x is a real value (used to store numbers with decimals or very large or very small numbers
attribute_text "attribute name3" "text" text is a series of words or numbers not intended for calculations
```

The following special attribute commands create/modify an attribute as described above but
these attributes also control calculations performed by the set pit details button on the **Drainage Network Editor**. The DNE fields will be locked when these attributes are defined for the selected pipe type. If these attribute are not defined for the selected pipe type the DNE field will not be locked and remain unchanged.

**roughness_n** \( x.xx > \) DNE field \( \rightarrow \) Pipe \( \rightarrow \) Main \( \rightarrow \) Roughness
DNE field \( \rightarrow \) Pipe \( \rightarrow \) Main \( \rightarrow \) Roughness type (set to Manning)

**roughness_k** \( x.xx \) DNE field \( \rightarrow \) Pipe \( \rightarrow \) Main \( \rightarrow \) Roughness
Colebrook k roughness value in millimetres
DNE field \( \rightarrow \) Pipe \( \rightarrow \) Main \( \rightarrow \) Roughness type (set to Colebrook)

**attribute_real** \( x.xx \) DNE field \( \rightarrow \) Pipe \( \rightarrow \) Design \( \rightarrow \) Min pipe height
min height in base units

**attribute_integer** "design size mode" \( x \) DNE field \( \rightarrow \) Pipe \( \rightarrow \) Design \( \rightarrow \) Design mode

<table>

Pipe \( \rightarrow \) Design \( \rightarrow \) Flow-depth at pipe entrance

Please continue to the next section **Defaults**
22.4 Defaults

Position of menu:  Design => Drainage-Sewer => Defaults

The defaults menu sets default tin, manhole (maintenance hole) information, drainage pipe information, property control (sewer module only) and house connection (sewer module only) defaults which are all used when defining drainage networks.

The Defaults walk-right menu is

![Defaults Menu](image)

For the option *Tins (fs)*, please continue to the section *Tins (fs).*

*Manholes*, please continue to the section *Manholes (Maintenance Holes).*

*Pipes*, please continue to the section *Pipes.*

*Property controls*, please continue to the section *Property Controls.*

*House connections*, please continue to the chapter *House Connections.*
22.4.1 Tin (fs)

Position of option on menu:  Design => Drainage-Sewer => Defaults => Tin (fs)

On selecting the Tin (fs) option, the Drainage Tin Defaults panel is displayed.

This panel is for setting the default finished surface tin in the Create Drainage Strings panel which is used for creating a new drainage string.

For the drainage string, the finished surface tin is used as the surface that manholes automatically sit on when z float is set on, and for defining cover when placing controls and connections.
22.4.2 Manholes (Maintenance Holes)

Position of option on menu: Design => Drainage-Sewer => Defaults => Manholes

On selecting the Manholes option, the Drainage Manhole Defaults panel is displayed.

These defaults are used when creating a manhole in a drainage string. The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diameter</td>
<td>input</td>
<td>1.1</td>

<tr>
<td></td>
<td></td>
<td>set the drainage manhole defaults to the values in the above fields.</td>
<td></td>
</tr>
</tbody>
</table>
22.4.3 Pipes

Position of option on menu: Design => Drainage-Sewer => Defaults => Pipes

On selecting the Pipes option, the Drainage Pipes Defaults panel is displayed.

This panel is for setting the default drainage pipe diameter, grade, cover and type. These defaults are used when creating a pipe in a drainage string.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diameter</td>
<td>input</td>
<td>0.1</td>
<td></td>
</tr>
</tbody>
</table>

_default diameter of the pipe._

| Minimum grade      | input    | 1.0      |        |

_the minimum grade (measured as 1: value) used when laying down the pipe._

| Minimum cover      | input    | 1.0      |        |

_the minimum cover, measured in world units from the surface to the top of the pipe (obvert); used when laying down the pipe._

| Type               | input    | PVC      | PVC, VC, PVC X/HEAVY |

_the default type of the pipe_

Set button

_set the drainage pipe defaults to the values in the above fields._

**IMPORTANT NOTE.**

If the drainage string is laid down in the direction of flow (and hence the flow direction is in ascending chainage), then the minimum grade and minimum cover along the pipe are maintained as the drainage string is created. Otherwise the minimum grade and cover cannot be maintained.

Cover for the pipe segment can also be calculated and/or set afterwards by the pipe=>cover option in the drainage string editor.

Minimum cover and minimum grade for the pipe segment to the end of the line can be set afterwards by the pipe=>default grading option in the drainage string editor.
22.4.4 Property Controls

**Position of option on menu:** Design => Drainage-Sewer => Defaults => Property Controls

On selecting the Property controls option, the Drainage Property Control Defaults panel is displayed.

On a section view, the Profile => One substring and Profile => Many substrings options will profile the property control. Note that the centre (axis) of the property control is drawn on the section view, not the invert (bottom) or the obvert (top).

![Drainage Property Control Defaults Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diameter</td>
<td>input</td>
<td>0.1</td>

<td>input</td>
<td>60</td>
<td></td>
</tr>
<tr>
<td>Cover</td>
<td>input</td>
<td>1.0</td>
<td></td>
</tr>
<tr>
<td>Colour</td>
<td>input</td>
<td>cyan</td>
<td>available colours</td>
</tr>
<tr>
<td>Name</td>
<td>input</td>
<td>Lot</td>
<td></td>
</tr>
</tbody>
</table>

Set button

set the property control defaults to the values in the above fields.

- **Diameter**
  - default diameter of the property control.

- **Grade 1v in**
  - grade (units are "1v in" given value) to use for the property control

- **Cover**
  - cover measured from the surface to the top of the property control (world units) to be maintained from the end of the property control in the house block to the drainage string.

- **Colour**
  - colour to use to draw the property control

- **Name**
  - name for the property control - usually the lot number
22.4.5 House Connections

Position of option on menu:  Design => Drainage-Sewer => Defaults => House connections

On selecting the House connections option, the Drainage House Connection Defaults panel is displayed.

![Drainage House Connection Defaults panel]

This panel is for setting the default information used for connections from the drainage pipe to the house blocks.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tin (fs)</td>

Please continue to the next section Create.
22.5 Create

**Position of menu:** Design => Drainage-Sewer => Create

The Create walk-right menu is

![Drainage Create](image)

For Create, please see [Create Drainage String](#).
Create from strings, please see [Create from Strings](#).
Create from pts and lines, please see [Create from Points and Lines](#).
Create culvert, please see [Create Culvert Change](#).
Create spaced along string, please see [Create Drainage Spaced Along String](#).
Create/Read template, please see [Create/Read Drainage Template](#).
Create drainage.4d, please see [Create drainage.4d](#).
Create hydrographs from peaks, please see [Create Hydrographs from Peaks](#).
22.5.1 Create Drainage String

Position of option on menu:  Design => Drainage-Sewer => Create => Create

This section of documentation is a work in progress and will be updated in subsequent releases.

The Create option is used to produce new drainage strings and networks. If a drainage string already exists, the Editor option is used to modify it.

On selecting the Create option, the Create Drainage String panel is displayed.

To create a new drainage string, the name, colour, model and style of the new string are entered into the appropriate fields, plus the finished surface triangulation that the manholes are normally flush with, the natural surface triangulation, and the Create button selected.

The new fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Model</td>
<td>model box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Colour</td>
<td>colour box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Flow direction</td>
<td>input</td>
<td>ascending chainage</td>
<td>descending chainage</td>
</tr>
<tr>
<td>Tin (fs)</td>
<td>input</td>
<td>drainage=&gt;defaults=&gt;tin available tins</td>
<td>the finished surface tin. If manholes are &quot;floating&quot;, the top of the manhole is automatically place on the tin surface (&quot;floated&quot; on the surface).</td>
</tr>
<tr>
<td>Tin (ns)</td>
<td>input</td>
<td>available tins</td>
<td>the natural surface tin used in longsection plots.</td>
</tr>
<tr>
<td>Purpose</td>
<td>choice box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use pit connection points</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Many strings tick box
Create button

The **Create Drainage String** panel is then removed and the **Drainage Edit** menu and **Drainage Edit Info** panel fired up.

As for a 3d string, to create a new drainage string with some of the **same** name, colour, model and style as an existing string (not necessarily a drainage), the **Same as** button is chosen and the appropriate string selected.

The **Drainage Edit** menu contains all the available options for editing a drainage string and its associated block controls and house connections. The **Drainage Edit Info** panel contains information areas. The **Drainage Edit** menu and **Drainage Edit Info** panel are

To create a new drainage string, the user selects the **Append** option from the **Edits** walk right menu on the **Drainage Edit** menu.

Since the **Drainage Edit** menu and **Drainage Edit Info** panel are the same as those used when editing a drainage string, the options will be discussed under the drainage **Edit** option.

For documentation on editing Drainage string, please continue to the next section **String Editor**.
For drainage utilities and import/export see **More Drainage**

### 22.6 String Editor

**Position of option on menu:** Design => Drainage-Sewer => String editor

This is the same option as **Editor** from the **Strings** walk-right menu on the **12d Model** menu.

The string editor is used to modify any **12d Model** strings. After selecting the **Editor** option, the **Edit String** panel is placed on the screen to record any error messages.
The option is already in the **pick** mode (the **pick & edit** button only needs to be selected if the pick was cancelled) and the user simply picks and accepts the string to be edited.

From the picked string’s type, the editor is able to determine the edits that apply to the string and list them in the string’s **edit** menu.

If a drainage string is selected, the **Drainage Edit** menu and **Drainage Edit** panel (as shown in the previous section) are placed on the screen.

The individual edit operations for a drainage string will now be discussed in detail.

Please continue to the next section **Drainage Edit**.
22.6.1 Create from Strings

Position of option on menu:  Design => Drainage-Sewer => Create => Create from strings

12d will convert the super strings into 12d drainage strings. The default pipe, pit and tin data will be used to set the levels for the network. Do not use the other string convert commands found on the menu system.

See Also

Drainage overview

On selecting the Create from strings option, the Convert to Drainage Strings panel is displayed.

![Image of Convert to Drainage Strings panel]

The fields and buttons used in this panel have the following functions:

<table>

</tr>
</tbody>
</table>
|                                        | Removes the panel from the screen.
Important notes:

The imported strings must all be drawn in the same direction. Either all in the direction the water flows or all opposite the direction of flow.

Pits are created at all vertices on the strings.

Trunk lines must have a vertex where the branch lines join.

String names can be used to control the order in which the drainage lines are numbered. These names will be transferred to the 12d drainage strings. Later, the string names can be changed in the Drainage Network Editor.

Pits can always be renamed in 12d after the import is complete.

The drainage lines must have string names to use the Set Pit Names feature on the network editor.
22.6.2 Create from Points and Lines

Position of option on menu:  Design => Drainage-Sewer => Create => Create from pts and lines

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting the Create from pts and lines option, the Drainage Create from Ptd and Lines panel is displayed.

22.6.7 Create Hydrographs from Peaks

Position of option on menu: Design => Drainage-Sewer => Create => Create hydrographs from peaks

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting the Create hydrographs from peaks option, the Drainage Set Pipe Type panel is displayed.

![Drainage set pipe type panel](Image)

The fields and buttons used in this panel have the following functions:

22.6.8 Drainage IO Defaults
22.7 Drainage Network Editor

Position of option on menu: Design => Drainage-Sewer => Network editor

The drainage network editor enables the user to edit all of the drainage strings in a model (a network). The global and default settings may be stored and loaded via . There are five main tabs and plus function buttons on the bottom of the panel.

Using the Drainage Network Editor

Recommended order to use the tabs and Buttons.
(This is not required but it will lead you through the process in an systematic method.)

<table>
<thead>
<tr>

</table>

For information on specific tasks see the following sections,

- **Manhole Setout Settings**
  - Road Design File for Pit Setout - x, y, level, road chainage and setout offset

- **Hydrology Settings**
  - Catchment Areas
  - Checking the Automatic Catchment Linking
  - Coefficients of Runoff
  - Percent Impervious
  - Times of Concentration Methods
  - Tc Path Strings

- **Hydraulic Design Settings**
  - Pipe Friction Method
  - Pipe Friction Values and Freeboard Limit
  - Setout to Grate Offset
  - Pit Losses Ku, and Direct Flow
  - Outlet and Tailwater Conditions

- **Pipe Design Parameters**
- **Bypass Flow Settings**

On selecting the Drainage network editor option, the Drainage network editor panel is displayed.
22.7.1 Global Tab

Design values for the hydrology and hydraulics calculations are set either globally (one value for the entire network) or via Defaults for the manholes or pipes. Defaults values may be overridden by explicit settings found on the catchment, pits or pipes tab. Explicit manhole/pipe settings need only be specified if the default value is not desired.

There are 4 sub tabs. See Main tab, Utility Models tab, Notes tab and Display tab.

22.7.1.1 Main tab

Universal data Group

- **Units** - Metric or US. Catchment areas in ha/acres and rainfall-infiltration-storage in mm/in
- **Viscosity** - Used with Colebrook-White energy loss calculations
- **TUFLOW file** - with the dynamic drainage analysis and TUFLOW modules this specifies the TUFLOW tcf file to be used for the 2d storm analysis.
- **Att group (minor)** - results from the storm analysis (minor event ) may be contained within this pit/pipe attribute group
- **Att group (major)** - results from the storm analysis (major event ) may be contained within this pit/pipe attribute group
- **Use pit connection pts** - when not selected, pipes connect at the centre of the manhole. When selected the pipes connect at the pit connection points. See Pit Connection Points for more details.
- **Finished surface tin** - used for determining pipe cover and surface levels for the manholes.
- **Natural surface tin** - specified so that it can be included on the drainage longsection plots
- **Clear attributes** - when selected all pit/pipe attributes will be deleted before the Apply/AutoApply saves the data currently in the panel.
Catchment data Group

see Coefficients of Runoff

For Global pipe data see Pipe Friction Method.
22.7.2 Pit Connection Points

Pit Connection points allow the pipes connected to the pit to join at locations other than the inside perimeter of the pit wall. This feature is off by default and may be enabled on the DNE->Global->Main tab.

All pits have their connection point initially set to Points. This setting is found on the DNE->Pits->Setout tab.

Pit Connection Point Modes

Pit connection points may be moved via Strings->Points Edit->Move (except for Centre mode described below). The other modes constrain the movement of the connection points. If a pipe is manually moved to a new connection point, it will be locked to the connection point and will not move if the pit or neighbouring pit is moved (see exceptions below).

Centre (rectangle and circular) - This mode is the same as having the Use connection points turned off. The connection points will be located on the inside perimeter of the pit wall with the centre line of the pipe intersecting the centre of the pit. In this mode the connection points may not be adjusted.

Points (rectangle) - A connection point is created at the mid point of each internal side of the pit. This may be changed for a Pit type by using the con_points command in the drainage.4d file. In this mode the pipe ends will snap to the connection points. It is possible to place more than one pipe on the same connection point (the elevation of the pipes is not checked for clashes).

Points (circular) - The connection point may be moved anywhere around the pit internal wall as there are no connection points on the circular pits. Again, it is possible to place more than one pipe on the same connection location (the elevation of the pipes is not checked for clashes).

If the manhole centre is moved the connection point locks are removed.

Perimeter (rectangular and circular) - Same as Points (circular) above.

Unrestricted (rectangular and circular) - There are no constraints on the location of the pit connection points. This mode is intended for irregular shapes such as GPT structures and...
stormwater basins.

22.7.2.1 Utility Models tab

The utility models tab is used to specify the following data:

- Catchment polygons, the catchment slope strings, catchment labelling data
- Bypass flow strings
- Road setout strings, road centre line strings and crossfall/grade offsets
- Service/utility models and the allowable clearances
- Additional details
  - Catchments Areas
  - Bypass flow
  - Manhole setout via setout strings
  - Service and Utility Clashes

22.7.2.2 Display tab
The display tab is used to specify the following data:

22.7.2.3 Notes tab

The notes tab is used to specify the following data:
22.7.3 Defaults tab

The values on the defaults tabs are used unless the values are explicitly set on the Main Catchment, Pit and Pipe tabs.

22.7.3.1 Catchment subtab

The Catchment subtab is used to specify the following data:

- Catchment Areas
- Percent Impervious
- Times of Concentration Methods
- Coefficients of Runoff

22.7.3.2 Pits subtab

The Pits subtab is used to specify the following data:
Manhole Setout Settings
Pit Losses Ku, and Direct Flow
Setout to Grate Offset

22.7.3.3 Pipes subtab

The Pipes subtab is used to specify the following data:
Pipe Friction Method
Pipe Friction Values and Freeboard Limit
Pit Losses Ku, and Direct Flow
Pipe Design Parameters
22.7.4 Catchment tab

The Catchment tab is used to specify the following data:

- **Impervious**
  - Tc method
  - Length
  - Slope (%)
  - Retardance
  - Tc (minor)
  - Tc (major)

- **Pervious**
  - Tc method
  - Length
  - Slope (%)
  - Retardance
  - Tc (minor)
  - Tc (major)
  - C (minor)
  - C (major)
  - Vcg/Sor

The pit tab has the explicit settings for the values entered on the Defaults catchment tab. When these fields are blank the default value is used. Three catchment sets are available. Typically the user will use one set for different types of catchment areas. For example: Set 1-Road area, Set 2-Lots, Set 3-Parks.

All 3 sets use the same default values except the percent impervious which has a separate default for each set.

[Catchment Areas](#)
22.7.5 Pit tab

The Pit tab is used to specify the following data:

The pit tab has the explicit settings for the values entered on the Defaults pit tab. When these fields are blank the default value is used.

- Manhole Setout Settings
- Pit Losses Ku, and Direct Flow
- Setout to Grate Offset
- Outlet and Tailwater Conditions
- Pipe Design Parameters
- Bypass Flow Settings
22.7.5.1 Setout subtab
22.7.5.2 Bypass subtab

[Image of the Drainage Network Editor interface with the Bypass subtab selected]
22.7.5.3 Bypass Shape subtab
22.7.5.4 Basin subtab
22.7.5.5 Inflow subtab
22.7.5.6 Notes subtab
22.7.6 Pipe tab

The Pipe tab is used to specify the following data:

![Drainage Network Editor](image)

The pipe tab has the explicit settings for the values entered on the Defaults pipe tab. When these fields are blank the default value is used. It has 2 sub tabs.

Pipe:Main subtab

- Pipe sizes, Max pipe height and Multiple Pipes and Box Culverts

22.7.6.1 Design subtab
Pipe Friction Values and Freeboard Limit
Pipe Friction Method
Pipe Friction Values and Freeboard Limit
Pipe Design Parameters

22.7.6.2 Channels subtab
22.7.6.3 Notes subtab
22.7.6.4 Set Catchments

This selection links the catchment strings to the manholes and recalculates the areas. For SAG pits the catchments strings from all 3 sets are draped onto the design surface to locate the lowest overflow point. This level is used for the ponding depth. Information messages are written to the output window during this process.

See Set Catchments

22.7.6.5 Regrade Pipes

This option resets the pipe invert levels using the pipe design parameters. Information, warning and problem messages will be displayed in the output window. These messages will include pipe cover warnings, service crossing data and invert alignment messages. The user may place too many restraints using the regrade options results in no feasible solutions to the grading. These messages will also be shown.

22.7.6.6 Set Pit Details

This option resets the following manhole values: cover level. If activated the following are also set: road design string, setout x,y and z, road centre line chainage and offset, the manhole
symbol rotation, the road grade and crossfall, the bypass pit,

22.7.6.7 Set Pit Names

**Tin for pit cover level** tin box

*The new drainage manhole cover level will be set to the tin level at the manhole centre (optional)*

22.7.6.8 Plot

This plotting option will create a drainage plan and/or long section using the ppf files entered. The ppf editors can be launched from this panel by selecting the More Information folder icon beside the ppf field.

See [Using Drainage Network Plot Button]

22.7.6.9 Import/Export

22.7.6.10 String Editor

22.7.6.11 Set Catchments
See [Drainage Export and Import to Design Software](#)
22.7.7 Drainage Network Design

See Also Using [Drainage Design in 12d Drainage Design](#)

On selecting the Storm Analysis button, the Drainage Network Design panel is displayed.

22.7.8 Flood Extents Tab

![22.7.8 Flood Extents Tab Image]
22.7.9 Dynamic Settings Tab
22.7.10 Drainage Edit

On picking a drainage string when in the string Editor option, or by selecting Create in the Create Drainage String panel, the Drainage Edit menu and panel are placed on the screen.

The edit is cancelled by selecting the Quit. No changes to the string are recorded and the Drainage Edit option terminates.

The edit is finished and the changes recorded when the Finish is chosen. The Drainage Edit option then terminates.

When either button is selected, a Yes-No-Cancel panel is displayed and the user must confirm the selection.

The Drainage Edit Info panel is principally used to display information and messages during the creation and editing of the drainage string. It is toggled on and off by Info on the Drainage Edit menu.

The main message area indicates the purpose of the mouse buttons at each step.

Message area 1 displays the current Drainage Edit option and message area 4 indicate the next step in the edit option.

Message areas 2 and 3 are used to display information about the string as the cursor is moved near the drainage string and the drainage manholes.

Each of the options in the Drainage Edit menu will now be described.

For the option Drainage properties, please continue to the section Edits.

Edits, please continue to the section Edits.
Advanced Edits, please continue to the section Advanced Edits.
Manhole, please continue to the section Manhole (Maintenance Hole).
Pipe, please continue to the section Pipe.
Controls, please continue to the section House Connections.
Connections, please continue to the chapter House Connections.
Utilities, please continue to the chapter Utilities.
Z float, please continue to the chapter Z Float.

22.7.10.1 Edits
The options in the Edits menu are used for placing the initial manholes of a new drainage string, editing a new drainage string once the initial manholes are placed or editing an existing drainage string.

The Edits walk-right menu is

![Edits menu](image)

22.7.10.1.1 Append, Append+Radius

The Append, Append+Radius operations for a drainage string are similar to the Append options for a polyline string except that manholes are also automatically placed at each added point.

**Note** - a manhole can be removed from the point afterwards using the Manhole=>Remove option. The point will still be there but without a manhole on it.

If the Append + Radius option selected, then before each point is appended, an enter radius typed-input box is placed on the screen.

The enter radius typed-input box looks like

![Enter radius](image)

The radius is entered into the typed-input box, terminated with <enter>. The entered value is taken as the radius of the arc to the next drainage string point and the arc will be drawn correctly as the cursor is moved to the next point.

A radius value of 0 is taken to mean no arc.

If z Float is set to tick, then the top of the manhole is automatically placed on the terrain given in the tin field for the drainage string.

If height snap is toggled on in the Snaps menu, the height will be displayed as a new height entered but the new height will only be used if z Float is turned off for the manhole.

Each manhole in the string is connected by a drainage pipe. The diameter, type and cover at each end of the drainage pipe are taken from the Drainage Pipe Defaults panel.

The Append options are terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.1.2 Move

If used in a plan view, the Move option is used to move the (x,y) position of a manhole.

If used in a section view, the Move option can be used to change the height of the top of any manhole or the height of either end of the drainage pipe connecting adjacent manholes in the drainage string.

After the Move option is chosen, the user selects either a manhole in a plan view or the top of a manhole or a pipe end in a section view.
If a manhole is selected from a plan view, then the plan position of the selected manhole will move with the cursor. The new position for the top of the manhole can be chosen by either cursor selection or typed input in exactly the same way as for moving a point on a 3d string.

If the top of a manhole or the end of a pipe connecting adjacent manholes is chosen in a section view, then only the height of the selected point can be modified. That is, if a point is selected in a section view, then it is constrained to move in the z-direction only.

The Move option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.1.3 Insert

The Insert option is designed to place a new manhole between two adjacent manholes (note that the inserted manhole does not have to be on the line joining the two adjacent manholes).

To insert a new manhole, the two adjacent manholes are chosen by selecting the line connecting the two manholes. Once the line is selected, the new manhole is assumed to be at the current cursor position. As the cursor is moved, the drainage string is redrawn reflecting the changing position of the inserted manhole.

The Insert option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.1.4 Between

The Between option is similar to the Insert option except that the inserted manhole does have to be on the line joining the two adjacent manholes. To accomplish this, the cursor position is projected onto the manhole-manhole line to give the new manhole position.

Note - once the manhole is placed, it is no longer constrained to be on the one straight or arc joining adjacent manholes. If this is required, then the manhole is placed using the Manhole=>Add option.

The Between option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.1.5 Delete

The Delete option is used to delete manholes/and or points from the drainage string.

The manhole/point to be deleted is selected with the cursor and when the selection is accepted (MB), it is deleted.

Once a manhole/point has been deleted, the delete option is still current and can be repeated without re-selecting the Delete option.

The string, minus the deleted manhole/point, is redrawn after each deletion.

The Delete option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.1.6 Extend

The Extend option is used to move a manhole/point along the line joining the manhole/point to one of its adjacent manhole/point.

That is, the bearing of the manhole/point-manhole/point line is kept constant and the manhole/point moved along that line either towards or away from its neighbouring manhole/point.

Extending, like moving a manhole/point, is a two step process.

Step (a) - selecting the manhole/point-manhole/point line and the manhole/point to be moved along that line
Step (b) - selecting the final position for the manhole

Both steps are identical to extending an point in a polyline string.

Once the extend is completed, the extend option is still current and can be repeated without re-
selecting the extend option.

The **Extend** option is terminated by selecting **Cancel** from the **Pick Ops** menu, or by selecting **Quit**, **Finish**, or a new option from the **Drainage Edit** menu.

**Note** - Extend can be used on the end manholes of the drainage string

**22.7.10.1.7 Height**

The **Height** option is used to modify the height (z value) of the top of any manhole, or the height of the ends of the pipes connecting adjacent manholes in the drainage string.

The top of the manhole can be selected in either a plan or a section view. The pipe ends can only be selected in a section view.

After the **Height** option is chosen, the user must select the manhole top or pipe end that is going to have its height modified.

Once the manhole or pipe end has been selected, an **New height** typed-input box is displayed on the screen with the items current height (z value) in it.

![New height](image)

The required height is entered into the typed-input box, terminated with <enter>. The entered value is taken as the height of the manhole or pipe and the string redrawn with the new height at that point. The typed-input box then disappears.

The **Height** option is terminated by selecting **Quit**, **Finish**, or a new option from the **Drainage Edit** menu.

**22.7.10.1.8 Radius**

Selecting **Radius** brings up the **Change Radius** panel which is used to modify the radius of any arc/line joining adjacent manhole points.

![Change Radius](image)

After selecting the **Radius** option, the user selects the arc/straight to be modified and the current arc radius and bulge setting will be displayed in the **Change Radius** panel.

New values can then be entered and the arc modified by selecting the **Set** button.

If the radius is positive, the arc is drawn from the start point to the next point on the polyline in a clockwise direction. If the radius is negative, the arc is drawn from the start point to the next point on the polyline in a counter-clockwise direction.

For a given radius (positive or negative), there are two possible cases for the arc- one where the arc is less than a semi-circle, the other when the arc is greater than a semi-circle.

If bulge is turned on, the larger arc is used. The default is bulge turned off.
22.7.10.2 Advanced Edits

The options in the Advanced Edits menu are used for placing the adding manholes at locations other than a vertex and removing these manholes.

The Advanced Edits walk-right menu is

![Advanced Edits Menu]

22.7.10.2.1 Insert MH (no vertex)

The Insert MH (no vertex) operation for a drainage adds a manhole on the existing string. When either of the 2 adjacent manholes with a vertex are moved, this manhole will move as well.

22.7.10.2.2 Remove MH (no vertex)

The Remove MH (no vertex) operation for a drainage removes a manhole on the existing string. If the manhole is on a vertex the vertex remains in the horizontal geometry but does not affect the vertical geometry.
22.7.10.3 Manhole (Maintenance Hole)

The options in the Manhole menu are used to modify information about individual manholes in the drainage string.

The Manhole walk-right menu is

![Manhole Menu]

22.7.10.3.1 Add

The add option is similar to the Edits=>Between option in that a new manhole is created that must be on the line or arc between two adjacent manholes.

However, once the manhole is placed, it is always constrained to be on the one straight or arc joining its adjacent manholes.

To add a new manhole, the two adjacent manholes are chosen by selecting the line connecting the two manholes. Once the line is selected, the new manhole is assumed to be at the current cursor position. As the cursor is moved, the drainage string is redrawn reflecting the changing position of the inserted manhole.

The add option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.3.2 Remove

The Remove option is used to remove manholes from the drainage string but unlike the Edits=>Delete option, the underlying point on the drainage string remains. Hence only the manhole is deleted, but not the polyline point underneath.

The manhole to be removed is selected with the cursor and when the selection is accepted (MB), it is removed.

Once a manhole has been removed, the Remove option is still current and can be repeated without re-selecting the Remove option.

The string, minus the deleted manhole/point, is redrawn after each removal.

The Remove option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.3.3 Name

The Name option is used to change a manhole's label.

After selecting the option, the mouse is used to pick the manhole to have a name change.

Once a manhole has been selected, an Enter text typed-input box is displayed on the screen containing the selected manhole's name.
The new name is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The Name option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

**NOTE** - if the name of the manhole is EOL or eol then the diameter of the manhole is forced to zero.

### 22.7.10.3.4 Diameter

The Diameter option is used to change a manhole's diameter.

After selecting the option, the mouse is used to pick the manhole to have its diameter modified.

Once a manhole has been selected, an Enter value typed-input box is placed on the screen displaying the selected manhole's current diameter.

The new diameter is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The Diameter option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

### 22.7.10.3.5 Type

The Type option is used to change the type of the cover (lid) placed on a manhole.

After selecting the option, the mouse is used to pick the manhole to have its cover type modified.

Once a manhole has been selected, a Manhole type typed-input box is displayed on the screen containing the selected manhole's cover type.

The list of common covers for the manhole can be obtained by clicking the [+] in the Manhole type input box and getting a menu of valid cover types.

The new cover type is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The Type option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

### 22.7.10.3.6 Drop

The Drop option is used to change the vertical distance between the bottom of the pipes on either side of a manhole, i.e., the difference in the invert levels of the pipe.

Since the drop in simply the difference in vertical distance between two pipes on either side of a manhole, the actual value of the drop can be changed by moving either of the pipes up or down the manhole.

After selecting the option, the end of the pipe to be moved is selected with the mouse.
Once the pipe end been selected, an enter value typed-input box is displayed containing the drop across the manhole that the pipe end connects into.

The new drop type is entered into the typed-input box, terminated with <enter>. If the end of the pipe was on the upstream side of the manhole (normally the right hand side of a manhole in a section view), the end of the pipe will be moved upward until the drop across the manhole equals the entered value.

If the end of the pipe was on the downstream side of the manhole (normally the left hand side of a manhole in a section view), the end of the pipe will be moved down until the drop across the manhole equals the entered value.

The typed-input box then disappears.

The Drop option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.3.7 Z Float

A floating manhole takes the z-value for the top of the manhole from the tin selected for the drainage string. Hence as a floating manhole moves around in a plan view, the top of manhole will automatically change to suit the new z-value of the drainage string tin.

Selecting Z float brings up the Manhole Z Float panel which is used to change a manhole from floating to non-floating and vice-versa.

After selecting the Z Float option, the user selects the manhole to be modified and the current floating z status is displayed in the Manhole Z Float panel.

The tick box can then be changed and the manhole modified by then selecting the Set button.

22.7.10.3.8 Road Name

A road name can be set for a manhole of the line. Selecting Road name brings up the Manhole Road Name panel which is used to give and change a road name for a manhole.
The option is running as soon as the panel is on the screen and the user is asked to selected a manhole.

<Select manhole> [picks]|[Menu]

When the manhole is selected, any existing road name and the manhole number is placed in the road name and vertex no. fields respectively of the Manhole Road Name panel.

A new road name is then typed into the road name panel field and the Set button selected to record the road name with the manhole.

### 22.7.10.3.9 Road Chainage

A road chainage can be set for a manhole of the line.

Selecting Road ch brings up the Manhole Road Chainage panel which is used to give and change a road chainage for a manhole.

The option is running as soon as the panel is on the screen and the user is asked to selected a manhole.

<Select manhole> [picks]|[Menu]

When the manhole is selected, any existing road chainage and the manhole number is placed in the road chainage and vertex no. fields respectively of the Manhole Road Chainage panel.

A new road chainage is then typed into the road chainage panel field and the Set button selected to record the road chainage with the manhole.

### 22.7.10.3.10 Outfall Height

When a drainage string is created, the furthest downstream is often an outfall and the height of the outfall known.

When the furthest downstream manhole is considered to be an outfall, the Outfall ht option is used to set and change the outfall height. Once set, the outfall height is taken to be the height at the bottom of the furthest downstream manhole.

If this option is not used, the outfall height is left undefined.

After selecting the option, an enter value typed-input box is displayed on the screen containing the existing outfall height or null if no outfall height has been set.

The new outfall height is entered into the typed-input box, terminated with <enter>.

The height of the bottom of the furthest downstream manhole in the drainage string is then set to the given height and the typed-input box removed.

The Outfall ht option automatically terminates after use.

**Note:**

For a drainage string with flow direction in ascending chainage, the furthest downstream manhole is the last manhole.

For a drainage string with flow direction in descending chainage, the furthest downstream manhole is the first manhole.
flow direction in ascending chainage

flow direction in descending chainage

last pit or manhole

the Outfall height

first pit or manhole

the outfall height
22.7.10.4 Pipe

The options in the Pipe menu are used to modify information about the pipes joining adjacent manholes in the drainage string.

The Pipe walk-right menu is

```
Pipe
Move
Name
Cover
Diameter
Type
Colour
Grade
Grade to end
Default grading
```

22.7.10.4.1 Move

The Move option is used to move a pipe connecting two manholes whilst keeping the grade of the pipe constant.

After selecting the option, the mouse is used to pick the pipe to be moved.

Once a pipe has been selected, the pipe will be moved up or down so that the cursor remains on the pipe (or on the extension of the pipe if the cursor is on the other side of the manholes at either end of the pipe). The grade of the pipe is kept constant.

The manholes at either end of the pipe will also be extended if necessary so that the pipe still connects into the adjacent manholes.

The Move option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.4.2 Name

The Name option is used to change a pipe's label.

After selecting the option, the mouse is used to pick the pipe to have a name change.

Once a pipe has been selected, an Enter text typed-input box is displayed on the screen containing the selected pipe's name.

```
Enter text
```

The new name is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The Name option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.4.3 Cover

The Cover option is used to place the selected pipe so that minimum cover is maintained along the top of the pipe (obvert) with respect to the finished surface tin (tin (fs)).

After selecting the option, the pipe to set the cover for is selected with the mouse.

Once a pipe has been selected, an Enter value typed-input box is displayed on the screen.
containing the existing cover.

The new cover is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears and the pipe is adjusted so that the specified cover is maintained for the full length of the pipe at the pipes existing grade.

The **Cover** option is terminated by selecting **Cancel** from the **Pick Ops** menu, or by selecting **Quit**, **Finish**, or a new option from the **Drainage Edit** menu.

### 22.7.10.4.4 Diameter

The **Diameter** option is used to change a drainage pipe's diameter.

After selecting the option, the mouse is used to pick the pipe to be modified.

Once a drainage pipe has been selected, an Enter value typed-input box is placed on the screen displaying the selected pipe's current diameter.

The new diameter is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The **Diameter** option is terminated by selecting **Cancel** from the **Pick Ops** menu, or by selecting **Quit**, **Finish**, or a new option from the **Drainage Edit** menu.

### 22.7.10.4.5 Type

The **Type** option is used to change the type of material that the pipe is made of.

After selecting the option, the mouse is used to pick the pipe to have its material type modified.

Once a pipe has been selected, a Pipe type typed-input box is placed on the screen displaying the selected pipes material type.

The list of common materials for the pipe can be obtained by clicking B3 in the type input box and getting a menu of valid material types.

The new material type is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The **Type** option is terminated by selecting **Cancel** from the **Pick Ops** menu, or by selecting **Quit**, **Finish**, or a new option from the **Drainage Edit** menu.

### 22.7.10.4.6 Grade

The **Grade** option is used to specify an exact grade for a drainage pipe. The value for the grade is entered using typed input and is in the units "1v in".

In this option, the new grade is given to a pipe by keeping one end fixed and raising or lowering the other end by the amount required to give the pipe the new grade.

After the **Grade** option is selected, the pipe whose grade is to be modified is selected **at the end that is going to be moved**.

Once the pipe end has been selected, an enter value typed-input box is displayed on the screen
containing the current grade of the pipe. The new grade is entered into the typed-input box, terminated with <enter>.

The selected end of the drainage pipe is then moved up or down so that the pipe has the new grade.

If necessary, the manhole at the moved end of the pipe will be lengthened so that the pipe still connects into the adjacent manholes.

The Grade option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.4.7 Grade to End

The Grade to end option is used to specify a fixed grade for all the drainage pipes from a selected pipe to the low chainage end (beginning) of the line. That is, it grades from right to left on a long section of the drainage string.

The value for the grade is entered using typed input and is in the units "1v in".

This option was originally written for pipes with flow direction in descending chainage direction which is the reason why it works from the selected pipe back towards the beginning of the line.

Hence Grade to end should only be run on pipes with flow in descending chainage direction. If the flow is in ascending chainage direction, use the reverse string option (string=>strings edit=>reverse) before using this option, and then reverse the string again after the option is run. Note that the Default grading option looks at maintaining minimum grade and minimum cover for flow in either ascending or descending chainage direction and supersedes Grade to end.

In this option, the new grade is given to a pipe by keeping the high chainage end of the selected pipe fixed and raising or lowering the low chainage end by the amount required to give the pipe the new grade. The minimum cover is over ridden during this process. If necessary, the bottom of the manhole will be lowered so that the pipe still connects into its adjacent manholes.

The next lower chainage pipe is then dropped through the default drop and given the new grade. The drop is measured from the lowest pipe invert of all pipes in the network entering the manhole.

This process is repeated until the low chainage end (beginning) of the line is reached.

After the Grade to end option is selected, the first pipe whose grade is to be modified is selected.

Once the pipe end has been selected, an enter value typed-input box is displayed on the screen containing the current grade of the selected pipe. The new grade is entered into the typed-input box, terminated with <enter>. The option then does the grading.

The Grade to end option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

22.7.10.4.8 Default Grading

The Default grading option starts at the given pipe and then works to the end of the line when the flow direction is in ascending chainage, or the beginning of the line when the flow direction is in descending chainage. The Default grading option maintains minimum grade and minimum cover.
Default grading is not designed to optimise the placement of the pipes but provides one solution preserving minimum grade and cover.
22.7.10.5 Property Controls

Property, block or lot controls are trial connections from a sewer line (drainage string) to a user specified plan point.

The property controls are used as checks that selected house blocks can be serviced by the sewer line. That is, they are used to test if the house block is under the control of the sewer line.

For the trial connection, once the cover (measured from the finished surface to the top of the property connection line) that the property connection must maintain and the grade are specified, the position and depth that the trial property connection must have at the sewer line can be calculated, and where the height of the centre line of the property control when it reaches the sewer line is displayed in any section view containing a profile of the sewer line.

If the calculated depth of the trial property connection at the sewer line (drainage string) is below the sewer pipe, then no such connection would be feasible and the house block would not be totally controlled by the sewer line.

On a section view, the Profile => One substring and Profile => Many substrings options will profile the property control. Note that the centre line (axis) of the property control is drawn on the section view, not the invert (bottom) or the obvert (top).

NOTE - property controls are only accessible by the Sewer module.

The options in the Controls menu are used to place and modify the trial connections. The Controls walk-right menu is

22.7.10.5.1 Add

The Add option is used to create a new trial control line going from a selected drainage pipe to a user specified plan position (the free end of the connection).

After selecting the option, the mouse is used to pick the plan position of the connection point on the drainage pipe, and then the points defining the path to the plan position of the free end of the trial connection.

After the free end has been selected, the property name typed-input box is displayed on the screen so that a label for the control can be entered (this usually consists of the lot number).

When the property name box is placed on the screen, it will already have some text in it. This text comes from the name field in the Drainage Property Control Defaults panel.

A z-value equal to the drainage tin value minus the default control cover depth is automatically given to the free end of the control. The default control grade is then used to define z-values.
along the trial path (ensuring that the default control cover depth is always observed) to give a z-
value back at the drainage pipe (the connection height of the control).

A cross at the calculated connection height is displayed whenever the drainage string is profiled
on a section view.

The colour for the new control is taken from the Drainage Property Control Defaults panel.

The Add option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Fin-
ish, or a new option from the Drainage Edit menu.

22.7.10.5.2 Include

The Include option is used to make a control out of an existing polyline string.

The polyline string must start at the connection point on the drainage string and end at the free
end (use Strings=>Strings Edit=>Reverse if the string’s direction is incorrect).

After selecting the option, the mouse is used to pick the polyline string and its plan position is
copied and used to define a new control.

A z-value equal to the default drainage tin at that point, minus the default control cover depth is
automatically given to the free end of the new control. The default control grade is then used to
define z-values along the trial path (ensuring that the default control cover depth is always
observed) to give a z-value back at the drainage pipe.

The Include option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit,
Finish, or a new option from the Drainage Edit menu.

22.7.10.5.3 Delete

The Delete option is used to delete a control.

After selecting the option, the mouse is used to pick the block control to be deleted.

Once a block control has been selected, it will deleted and removed from the screen.

The Delete option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit,
Finish, or a new option from the Drainage Edit menu.

22.7.10.5.4 Name

The Name option is used to change the Property name of a control.

After selecting the option, the mouse is used to pick the control that will have a name change.

Once a control has been selected, an enter text typed- input box is displayed on the screen con-
taining the selected control’s name.

The new name is entered into the typed-input box, terminated with <enter>. The typed-input box
then disappears.

The Name option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit,
Finish, or a new option from the Drainage Edit menu.

22.7.10.5.5 Diameter

The Diameter option is used to change the diameter of a control.

After selecting the option, the mouse is used to pick the control that will have its diameter
modified.
Once a control has been selected, an Enter value typed-input box is placed on the screen displaying the selected control's current diameter.

![Enter value input box](image)

The new diameter is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.

The Diameter option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

### 22.7.10.5.6 Cover

The Cover option is used to change the distance that the control is below the tin (fs) for the drainage string.

After selecting the option, the cursor is used to pick the control whose cover will be modified.

Once a control has been selected, an Enter value typed-input box is placed on the screen displaying the selected block control's current cover.

![Enter value input box](image)

The new cover is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears and the new connection height using the new cover calculated.

The Cover option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

### 22.7.10.5.7 Grade

The Grade option is used to change the grade of a control (units "1v in").

After selecting the option, the mouse is used to pick the control whose grade will be modified.

Once a control has been selected, an enter value typed-input box is placed on the screen displaying the selected control's grade.

The new grade is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears and the new connection height using the new grade calculated.

The Grade option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.

### 22.7.10.5.8 Boundary

The Boundary option is used to specify a boundary trap depth which is used as a final drop at the drainage pipe end of the control.

After selecting the option, the mouse is used to pick the control whose boundary depth will be modified.

Once a control has been selected, an Enter value typed-input box is placed on the screen displaying the selected boundary depth.

![Enter value input box](image)

The new boundary trap depth is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears and the new connection height using the new boundary trap depth is calculated.

The Boundary option is terminated by selecting Cancel from the Pick Ops menu, or by selecting Quit, Finish, or a new option from the Drainage Edit menu.
22.7.10.5.9 Calc all

The Calc all option is used to re-calculate the connection heights for all controls of the drainage line.

The calculation uses the plan layout of the control, the control's cover, grade and boundary trap depth and the default tin for the drainage line.

The Calc bc's option automatically terminates after use.

22.7.10.5.10 Delete All

The Delete all option is used to remove all the controls defined for the drainage line being edited.

The Delete all option automatically terminates after use.
22.7.10.6 House Connections

The Connections option is used to create the connections from the sewer line (drainage string) to the house blocks in a subdivision.

When placing a house connection, the user indicates the two corners of the frontage of the block to allow the cross-fall of the block to be calculated and allow the frontage to be used in positioning the house connection.

When placing house connections, a section view is used to automatically display the connection to facilitate checking the type of connection used and any obstructions that may need to be avoided.

NOTES
1. House connections are only accessible by the Sewer module.
2. All house connection calculations do not take into account any thickness of pipe, joint sizes or actual entry points into the sewer. Hence they are approximate only and should only ever be used as a guide. Any quantities calculations should allow for a suitable margin of error.

The Connections walk-right menu is

The process for creating a house connection will now be described in detail.

22.7.10.6.1 Create from Controls

The Create from Controls option is used to create a new house connection from existing controls or modify an existing house connection.

After selecting the Create from Controls option, the Default House Connections panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>
| Mode              | input| update all| remove existing first,
update new, update all |

if remove existing first, all the existing connections are deleted before new ones are created from the controls.
if update new, connections are only created from controls with names different from any existing connection.
if update all, connections are created from all controls.
**Factor of safety**

Input: 0.15

The connection height for the control is adjusted by this depth from the control connection depth.

**Create** button

After selecting **Create**, the connections are created from the selected controls.
22.7.10.6.2 Create/Edit

The Create/edit option is used to create a new house connection or modify an existing house connection.

After selecting the Create/edit option, the House Connections panel is displayed.

Creating A House Connection

Step 1 Select Create

To create a new house connection, the Create button is selected from the House Connections menu.

If either the default drainage tin or section view have not be defined, the Drainage House Connection Basic Defaults panel will be placed on the screen after the Create button is selected.
The missing values need to be filled in and the Set selected. This information is needed so that the house connections can be drawn up in a section view as soon as they are created.

**Step 2** Selecting the Sewer (drainage) Pipe to Connect to

The user is then asked to select the sewer pipe to connect into.

**Step 3** Selecting the House Lot Frontage

Next the user indicates the two frontage points for the house block.

**Step 4** Positioning the House Connection on the Sewer Pipe

From the two frontage points and the default drainage tin, the program calculates the crossfall for the block frontage.

The crossfall is displayed in the name of the enter distance up line typed-input box which is now placed on the screen. The distance up line is the distance along the frontage that the house connection will be placed.
Depending on the crossfall, a default value for the distance up line is displayed. If the ground crossfall is greater than 1%, the lot mid point is the suggested connection location. For crossfalls less than 1%, the connection is located 3m off the lowest lot boundary.

A pop-up also exists for placing the connection point at the distance 2.0, 3.0, 5.0 along the frontage, the mid point of the frontage, and the distances 2.0, 3.0 and 5.0 from the other end of the frontage.

The distance up line value is entered into the typed-input box, terminated with <enter>. The typed-input box is then removed from the screen.

**Step 5: Defining the House Connection Type**

Next the **House Connection Edit** panel is placed on the screen.

Most of the values in the field come from the drainage house connection defaults.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chainage up line</td>
<td>input/output</td>
<td>chainage of connection</td>
<td>the chainage on the sewer string where the house connection is attached to the sewer line.</td>
</tr>
<tr>
<td>Lot name</td>
<td>input</td>
<td>from drainage defaults</td>
<td>name of the house block</td>
</tr>
<tr>
<td>HCB #</td>
<td>input</td>
<td>PVC, PVC X/HEAVY, VC</td>
<td>a user supplied house connection branch (HCB) number</td>
</tr>
<tr>
<td>Material</td>
<td>input</td>
<td>from drainage defaults</td>
<td>the material used for the house connection.</td>
</tr>
<tr>
<td>Bush required</td>
<td>input</td>
<td>no bush, PVC to VC</td>
<td>the type of bush used</td>
</tr>
<tr>
<td>Connection type</td>
<td>input</td>
<td>A, A Special, B, C, OB, Special jump up</td>
<td>the type of connection used. Go to the section House Connection Types for a description of each connection type</td>
</tr>
<tr>
<td>Connection side</td>
<td>input</td>
<td>right side, left side</td>
<td>the side of the line to make the connection</td>
</tr>
<tr>
<td>Connection length</td>
<td>input</td>
<td>from drainage defaults</td>
<td>length of pipe for the house connection</td>
</tr>
<tr>
<td>Connection level</td>
<td>input</td>
<td>calculated</td>
<td>height of the house connection. When this is first displayed, it is calculated using the invert level of the sewer pipe where the house connection is attached, the house connection type and connection length (if required by the house connection type), the default house connection grade, the default house connection cover and the surface level at the end of the house connection.</td>
</tr>
</tbody>
</table>

Try button
using the parameters in the panel fields, create the house connection. Also calculate a section along the house connection and draw it in the drainage default section view.

Finish button
end the option, remove the panel.

Step 5 Continued
After entering the appropriate values in the House Connection Edit panel and then selecting the Try button, the house connection will created.

To help check the house connection parameters, a section along the house connection will automatically be calculated and displayed in the section view given in the drainage defaults panel. Any tins or models on the section view will be included in the section.

Step 6 Modifying the Connection
If any of the fields in the House Connection Edit panel are changed, selecting the Try button will modify the house connection and redraw the section in the default drainage section view.

Editing A House Connection
To edit an existing house connection, the Edit button is selected from the House Connections menu and then the appropriate house connection selected.
The **House Connection Edit** panel will then be placed on the screen with the details of the selected house connection.

If any of the fields in the **House Connection Edit** panel are changed, the **Try** is used button to modify the house connection and redraw the section in the default drainage section view.

### 22.7.10.6.3 Delete

The **Delete** option is used to delete a connection.

After selecting the option, the mouse is used to pick the house connection to be deleted.

Once a house connection has been selected and accepted, it is deleted and removed from the screen.

The **Delete** option is terminated by selecting **Cancel** from the **Pick Ops** menu, by selecting a new option from the **Drainage Edit** menu.

### 22.7.10.6.4 Delete all

The **Delete all** option is used to delete all connections.

After selecting the option, all the connections are deleted and the option terminates.
22.7.10.7 Utilities

The options in the Utilities menu are used to modify default drainage tin, the name, colour, style and start chainage of the drainage string, and the size, angle, and offsets used when displaying the text for the names of all the manholes.

The Drainage Utilities walk-right menu is

![Drainage Utilities Menu]

22.7.10.7.1 Tin (fs)

The Tin (fs) option changes the default finished surface tin (tin (fs)) for the drainage string.

After selecting the option, the FS Tin for Drainage panel is displayed.

![FS Tin for Drainage Panel]

The existing default tin is displayed in the tin panel field. If a new tin is required, simply enter the new tin name into the tin (fs) field and select the Set button.

22.7.10.7.2 Tin (ns)

The Tin (ns) option changes the default natural surface tin (tin (ns)) for the drainage string.

After selecting the option, the NS Tin for Drainage panel is displayed.

![NS Tin for Drainage Panel]

The existing default tin is displayed in the tin (ns) panel field. If a new tin is required, simply enter the new tin name into the tin field and select the Set button.

22.7.10.7.3 Angle

The Angle option changes the angle of the text for manhole labels.

After selecting the option, an enter angle typed-input box is displayed on the screen containing the
current text angle.
The new angle is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.
The Angle option then terminates.

22.7.10.7.4 Size
The Size option is used to change the size of the text for manhole labels.
After selecting the option, an enter value typed-input box is displayed on the screen containing the current text size.
The new size is entered into the typed-input box, terminated with <enter>. The typed-input box then disappears.
The Size option then terminates.

22.7.10.7.5 Properties
The Properties option brings up the Drainage String Properties panel for the current drainage string.

![Drainage String Properties Panel](image)

Any of the data in the panel fields can be modified and then set for the drainage string by selecting the OK or Apply button.

22.7.10.8 Z Float
The status of Z Float is used each time a new manhole is created.
If Z Float is set to tick, then the top of the manhole is set to z float which means that automatically sits on the default drainage tin.
If Z Float is not set to tick, then the top of the manhole is given a set z value when it is created.
The z float status of the manhole can be changed after it has been created by using the Drainage Edit=>Manhole=>Z Float option.
22.7.11 Utility String Editor

Position of option on menu:  Design => Drainage-Sewer => Utility String Editor

This editor is used to edit properties of the strings used by the DNE. Properties always change at an existing vertex.

**Cross Section Strings (Manning’s n)** - set the left and right bank n values. the centre n value is assigned by the DNE.

**Flooded Width Values on Bypass Flow Strings** - the default setting of the bypass flow strings when used to calculate flooded widths in the Drainage Analysis. Changes are in effect until the end of the string or it has been re specified at vertex at a higher chainage.

Vertex labels are created whenever properties are set (Texstyle is required).

**Usage**

First the string is selected at the vertex where the values are to be assigned. Next select the purpose of the string (cross section or bypass) to unlock the appropriate fields. A textstyle favourite is required as the vertex is labelled with the assigned values. Enter the values into the fields and then select Set to set the values as vertex attributes and create the label as a vertex annotation.

On selecting the Utility String Editor option, the Drainage Utility String Editor panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Vertex index</strong></td>
<td>vertex</td>
<td>selected vertex</td>
<td></td>
</tr>
</tbody>
</table>

*Once the string is selected use this to move between vertices*

| **Style for Vertex Labels** | textstyle favourite | textstyles |                         |

*A label is created on the vertex using this textstyle favourite*

| **Left bank**               | Input         |  |  |

*manning’s n value, to delete clear and select set*

| **Right bank**              | Input         |  |  |
mannings \(n\) value, to delete clear and select set

**Max Flooded with**Input

*This changes the threshold where warning bars are created during flooded width calculations. It remains in effect till the next change or the end of the bypass flow string.*

**Qdc percentage**Input

*This changes the percentage of the \(Q_{direct} + Q_{catchment}\) that is used to interpolate the discharges during flooded width calculations. It is generally set on the first vertex past upstream pit and remains in effect till the next change or the end of the bypass flow string. The flow changes from the bypass flow at the upstream pit to this value/100*(\(Q_{direct} + Q_{catchment}\)).*

**Manning’s \(n\)** Input

*This changes the Manning’s \(n\) value used for during flooded width calculations. It remains in effect till the next change or the end of the bypass flow string.*

**Pick** button

*Use this button to select the string. Select near the vertex you want to assign the values to.*

**Set** button

*Create the attributes and the label on the vertex.*

**Finish** button

*Removes the panel from the screen.*

**Help** button

*Launches the 12d help*

---

In the example above, The Qdc is set to 80% at the eastern end of the catchment. The Qdc is set to 2% for the water overtopping the road. The 18% of the area is not considered large enough to do the flooded width calculation for. If desired, another bypass flow string approaching from the east could be drawn but the final bypass string to the west (direction during bypass should
remain).
22.7.12 Rainfall File ppf Editor

Position of option on menu:  Design => Drainage-Sewer => Rainfall editor

On selecting the Rainfall editor option, the Rainfall File Editor panel is displayed.

Data is entered using one (or more if desired) input methods and then saved by entering a Meteorology file name and selecting Write. The standard 12d system file search paths are used (project folder, user library folder and then library folder).
22.7.12.0.1 IFD Tables

IFD tables are often available from meteorological services. The table input format follows. The first row is used to define up to 9 return periods and the following rows list the rainfall intensities for the duration entered in the first column.

Hint: to increase the size of the grid control select another method, ARR 1987 for example, and then select IFD table again.
22.7.12.0.2 Australian Rainfall and Runoff 1987 Method

The rainfall intensities and other factors from Volume 2 of ARR 1987 are entered in this table.

22.7.12.0.3 Australian Rainfall and Runoff 1977 Method

The seven coefficients for each return period from ARR 1977 are entered in this table.
22.7.12.1 Rainfall Temporal Patterns

Temporal patterns are referred to as storms in dynamic drainage. Several example hydro files are included in the 12d library. These examples have the temporal patterns for the minor and major storms in the 8 zones of Australia.

Temporal patterns are not required for the SCS NZ method as the standard 24 hour temporal pattern from TP108 is built into the 12d analysis engine.

The Run storm, Zone filter, From ARI and To ARI columns are used determine which storms are analysed (run). The Run storm column must be checked for that temporal pattern to be analysed. Many storms may be selected.

The Zone filter is optional. Entering a value here will allow the selected storms to be further filtered. A Zone filter field (accepts wild card characters) is found on the DNE Global tab that is used to determine which of the selected storms (paragraph above) are analysed.

The ARI field on the Run panel is used with the From ARI and To ARI columns. The value on the run panel must be within the From-To range for the storm to be analysed.
The **Duration** column determines the total length of the storm. This value divided by the **Interval** must be a whole number and this number determines the number of % values to be entered to the right of the **Interval column**. The total of the percentage must equal 100.

### 22.7.12.2 Horton Losses

The pervious portion of the catchments used in the **ILSAX 2** analysis will have a loss type defined describing the soil type. The loss type is defined in the DNE Default->catchment and catchment tabs.

These soil types use the classifications of Terstriep and Stall (1974), based on the system developed by the U.S. Department of Agriculture. The default values entered from the library represent the soil types of

1. Type A - low runoff potential, high infiltration rates (consists of sand and gravel
2. Type B - moderate infiltration rates and moderately well-drained
3. Type C - slow infiltration rates (may have layers that impede downward movement of water)
4. Type D - high runoff potential, very slow infiltration rates (consists of clays with a permanent high water table and a high swelling potential)

Numbers are assigned to each soil type to allow interpolation between the defined soil types. When interpolated values are used they must be included in the list (2.5 and 3.5 for example). Interpolated values do not need loss data entered. If loss data is entered for the interpolated names then this data will be used rather than an interpolation occurring. If any loss data is entered then all of the values must be entered.

Four preset AMC points are defined in the rainfall file to mark AMC conditions ranging from dry (AMC1) to saturated (AMC4). The required data for each line is the **Initial loss rate**, **Final loss rate**, **decay rate** and 4 antecedent moisture conditions (AMCs). The AMC values are entered in depth of rainfall (mm) they represent the total rainfall prior to the start of the temporal pattern.

The AMC point numbers are set once for all catchments on the DNE Global tab. Value between 1 and 4 (decimal value are permitted) are entered for the minor and major events.

### 22.7.12.3 SCS NZ Losses (Initial Abstraction and Curve Numbers)

The SCS NZ method uses Initial abstraction (Ia) and the curve number (CN) to determine the losses for the catchments. Names are given to the SCS curve numbers in the rainfall file. These names and Ia (entered as storage values) and selected in the DNE catchment data.

A curve number of 0 results in zero runoff while a CN=100 results in 100% runoff. **TP 108** recommends the selection of the curve number by identifying 1) the soil type and 2) the land use. **A CN=98 an Ia=0 are recommended for impervious areas.**
22.7.13 String split/join

Position of option on menu: Design => Drainage-Sewer => String split/join

This option must be used on drainage strings instead of the standard split or join commands. On selecting the String split/join option, the String split/join panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>US string name</td>
<td>The upstream section of the split string is assigned this name.</td>
<td>input</td>

</tbody>
</table>
22.7.14 Adjust Pit Locations

Position of option on menu:  Design => Drainage-Sewer => Adjust Pit Locations

Key Points
1. Pits are moved perpendicular to the road string.
2. The string to be moved to must be closer than the search distance or it will not be moved.

On selecting the Adjust pit locations option, the Adjust Pit Locations panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>function</td>
<td></td>
<td></td>
</tr>
<tr>
<td>This function will re adjust the drainage pits</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Drainage model</td>
<td>model</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The drainage model to have the pits moved.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use road strings</td>
<td>tick</td>
<td></td>
<td></td>
</tr>
<tr>
<td>When selected, a DNE road string is checked for each pit. When found, the pit will be moved perpendicular to this string at the Road string offset distance. If the road string is not found, the layout string will be searched for using the Max layout search distance. If not selected the only the layout strings with an offset of zero will be used.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Pit type offset file</td>
<td>file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The grid data below is stored in this file when the Process button is selected.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Pit type</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Only used when Use road strings is selected. Each pit scans for its pit type in the Pit type column. When found, the pit is placed at the Road string offset distance from the road string.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Road string offset input

Only used when Use road strings is selected. The pit is placed at the Road string offset distance from the road string. Positive is away from the road centreline and negative is towards the centreline. When no Road string offset is set via the pit type, the offset value is zero.

Data Source of Pit Layout Strings sourcemodel

Used when Use road strings is NOT selected or when no road string is found. As road strings are often in several models, so the filter option is usually the best. Select a view with the road string models and then use the string info tab and name field (* wild card can be used) to select the strings to move to.

Max Layout Search Distance real 1.0

Only used for layout strings. Road strings do not have a search distance. If the closest string in the pit layout strings is farther than this distance the pit will not be moved.

Run button

This moves the pits horizontally. Undo is available.

Finish button

Removes the panel from the screen.
22.7.15 Dynamic Culvert Design

Position of option on menu:  Design => Drainage-Sewer => Dynamic Culvert

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting the Dynamic Culvert option, the Drainage Dynamic Culvert Design panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

22.7.16 Extract Sewer Property Controls

Position of option on menu:  Design => Drainage-Sewer => Extract Sewer Property Controls

The sewer property control strings are a sub string of the drainage string and therefore may only be profiled using a right mouse click of the profile button. To include these control strings on plots or export to other packages they need to be converted to super strings.

On selecting the Extract Sewer Property Controls option, the Extract Sewer Property Controls panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drainage model</td>
<td>mode box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Model for property controls</td>

</tr>
<tr>
<td>Finish</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

All drainage strings in this model will have their property controls strings duplicated as super strings.

The super strings for the property controls are placed in this model.

The super strings will have the constant pipe dimension set to the control diameter.

Create the super strings representing the property controls.

Remove the panel from the screen.
22.8 Reports

Position of menu:  Design => Drainage-Sewer => Reports

Reports menu contains an option to report on the property controls for the drainage strings and an option produce network quantities.

The Reports walk-right menu is

![Drainage Reports]

For the option Network quantities, please continue to the section Drainage Network Quantities.

Network report, please continue to the section Network Report.

Property control, please continue to the section Property Controls.

Excavation quantities, please continue to the section Excavation Quantities.

Pit schedules, please continue to the section Pit Schedules.

Barwon quantities, please continue to the section Barwon Quantities.

Barwon HC’s, please continue to the section Barwon House Connections.

Barwon design checks, please continue to the section Barwon Design Checks.

Barwon services reports, please continue to the section Barwon Services Report.
22.8.1 Drainage Network Quantities

Position of option on menu:  Design => Drainage => Reports=> Network Quantities

The Network quantities report contains information about the manholes and pipes that make up the selected drainage strings. Configuration files allow the user to specify the depth ranges and sizes of pipes to report on.

This option creates quantity tables for manholes, pipes and house connections.

The manholes/pipes/house connections are summarised by user defined depths and types.

See Also
Drainage overview

Key points
1. Items are counted/totalled by depth and optionally type.
2. The routine will not "double count" items even if the ranges overlap.
3. Types are case sensitive, types with spaces in the name must be enclosed in quotes and the wild card * may be used.
4. Use vertically offset tins and "banded" depth ranges to get quantities under roads, foot paths, etc. This is discussed later in detail.
5. Erase count file fields if the items are not to be counted.

On selecting the Network quantities option, the Drainage quantities panel is displayed.

The fields and buttons used in this panel have the following functions.
<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data String Source</strong></td>

<td>Report unused ranges</td>
<td>tick box</td>
<td></td>
<td>the depth ranges for the pit/pipe/house connections are defined in the *.4d files. Selecting this option will cause the depth ranges in the file to be printed even if there are no pit/pipe/house connections in these depth ranges (zero quantity values will be shown).</td>
</tr>
<tr>
<td>Report types</td>
<td>tick box</td>
<td></td>
<td>Selecting this option will cause the pit/pipe/house connection types used in the model types to be listed (even if quantities are not requested in the *.4d files). Since this is a complete of the type used in the model, the list informs the user what types have not been included in the quantity calculation.</td>
</tr>
<tr>
<td>Count</td>
<td>button</td>
<td></td>
<td>executes the option.</td>
</tr>
<tr>
<td>Finish</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
removes the dialogue from the screen

The *.4d files listed above are contained in the 12d library directory. Each line is the file performs a count (count lines). No items are counted twice. Therefore, if an item is counted its type and then a count line is found the wild card is used for the type, the type already counted will not be included in the count.

The format for a count line is three or four values (space delimited) per line. Size is optional.

```
<type (from drainage.4d)> <size> <starting depth> <ending depth>
```

Notes:

All types with spaces in the name must be enclosed in quotes. The wild card * may be used.

The size is optional and if omitted the all sizes will be counted in this group (do not use the * for a wild card).

The starting depth and ending depth are required for all count lines.

Quantities Under Roads and Footpaths

By creating super tins with vertically offset sections, quantities under roads, footpaths, etc. can be determined. For example.

Offset your road design tin up by 1000m (Tins->Utility->Translate/Copy) and then use the depth range 1000-1999 for pipes under roads.

Create a tin from the footpaths only, null by angle length with a small length to remove the road and then offset it vertically by 2000m. The depth range 2000-2999 is not the quantities under the footpath.

Sample count lines

```
// sum concrete cover manholes is various ranges

"CONC COVER"  0.0  1.6
"CONC COVER"  1.5  3.0
"CONC COVER"  3.0 999.9  // this is expected to be zero
"CONC COVER" -999.0 0.0  // trap errors

// any that are not Concrete cover will be counted here

* 0.0 1.6
* 1.6 3.0
* 3.0 999.9
```
### Manhole Quantities

<table>
<thead>
<tr>

<td>3.00</td>
<td>0</td>
<td>0.000</td>
</tr>
<tr>
<td>*</td>
<td>3.00</td>
<td>999.9</td>
<td>0</td>
<td>0.000</td>
</tr>
</tbody>
</table>

total length = 18.016

### Types Used

- **CONC COVER**

### Diameters Used

- 1.100

---

Since the **Report unused ranges** tick box was selected, these lines were printed even though there were no pits in the data ranges.

This data results from selecting the **Report types** tick box.

Sample count lines for pipes follow.

```plaintext
// sum class 2 pipes by diameter and for various ranges

// count 375
2 0.375 0.0 2.0
2 0.375 2.0 5.0
2 0.375 5.0 999.

// count 450
2 0.450 0.0 2.0
2 0.450 2.0 5.0
2 0.450 5.0 999.

// count 525
2 0.525 0.0 2.0
2 0.525 2.0 5.0
2 0.525 5.0 999.

// count pipe sizes that were missed
2 * 0.0 2.0
2 * 2.0 5.0
2 * 5.0 999.

// count all other missed pipes
* 0.0 999.
```
22.8.2 Network Report

After selecting the Network report option, the Report on Selected Items panel is displayed.

This is the same as the option Reports => Co-ord/ Brd-dst on the main menu.

For the given model, it prints out the string information for each string in the model.

If a sewer network model is given, each sewer string in the network model is reported on.

For further information, go to Coordinates or Bearing-Distance Report.
22.8.3 Excavation Quantities

Position of option on menu: Design => Drainage-Sewer => Reports => Excavation quantities

This routine uses 12d templates to calculate the excavation volume for all of the drainage strings in a model. An option to create section for a tin on top of the pipe is also available so that the drainage long sections can include hatching between the obvert of the pipe and the design tin under roads. Templates with names set to the pipe diameters (times 1000) are used for the calculations, thus trench shapes can be customised and over excavation for bedding materials can be included. Net area calculations to exclude pipe area are not supported.

Key points
1. One template for each pipe size (mm)
2. If obvert templates are used, add the prefix “obvert “ to the pipe size
3. Carefully consider the tin selected.

A template must exist for each pipe size in the model (pipe size x 1000). For example a 0.3m pipe will require a template to exist named 300. A 0.5ft pipe would require a template named 500. A sample template library is included in the 12d library in the file pipe_template.tpl. The templates are run along the strings and the total volumes are reported. Volumes for each strings are given in the report file.

If a tin is created from these strings then volumes by depth can be determined using Design=>Volumes=>Exact=>Tin to tin

On selecting the Excavation quantities option, the Drainage Excavation Quantities panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Use obvert templates</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Model to contain all of the pit and pipe network to be worked on.

Strings generated from the templates will be stored in this model.
Sections model

Sections generated from the templates will be stored in this model.

Report name

Cut and fill volumes will be sent to this report.

Ground Surface Tin

Tins from which the volumes will be calculated.

Separation

distance between the sections

Sections colour

Sections generated from the templates will be assigned this colour (strings colours are defined in the templates).

Clean section/strings model

Delete the strings in these models before processing.

Stop section at edge of pit

Template are run from pit centre to centre if this is not selected. The templates stop at the edge of the pit if selected. This is often selected with the following option Use obvert templates.

Use obvert templates

Templates must be named with the prefix “obvert”. i.e. obvert 300. The template is still run along the invert of the pipe but the user now has a section “set” of templates that can be used to create a tin on top of the pipe as well as below.

An example report file follows.

```plaintext
--- BEGIN APPLY TEMPLATE REPORT ---

apply template to string report -

</tr>
</tbody>
</table>
Notes:
The columns of data may be separated by spaces or a tab. (tab is used for spreadsheet transfers). The internal width and length data are retrieved from the drainage.4d file for the pit type specified. If you want a longer description for the pit then the type used inside 12d this can also be entered in the drainage.4d file. The remarks for each pit are entered as user defined pit attribute named remarks and may be set using the attribute editor (on the drainage menu) or via a spreadsheet.

</tbody>
</table>

Notes
The Set pit details must be run at least once to before printing the report. If the pits are moved or the designed strings changed then this option must be rerun.

The easting northing data obtained for the road design string option is obtained by dropping the
pit centre perpendicular onto the selected road design string. This data is stored as pit attributes setout x and setout y. It is calculated when the Set Pit Detail is selected in the Drainage Network Editor.
22.8.5 Property Controls

**Position of menu:** Design => Drainage-Sewer => Reports => Property Controls

The property controls report contains information about all the property controls for the selected drainage strings, and if required, denote the critical property control for a lot.

On selecting Property controls, the **Property Controls Report** panel is displayed.

![Property Controls Report Panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

</tbody>
</table>
22.8.6 Barwon Quantities

The report generated from this option includes:

- the lengths of each pipe type for each line and the total length for each pipe type for all pipes in the network.
- the quantity of concrete used for the manholes in the network.
- the number and type of house connections in the network, including caps, bends and bushes.

After selecting the Barwon quantities option, the Sewer Network Quantities Report panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

</tbody>
</table>
22.8.7 Barwon House Connections

**Position of menu:** Design => Drainage-Sewer => Reports => House connections

The house connections report contains information about all the house connections for the selected drainage (sewer) strings.

The house connection report includes for each house connection (branch) the:
- name of the sewer line
- downstream manhole for the house connection
- lot name
- house connection number and type
- chainage of the house connection
- the invert level at the end of the house connection (IL branch)
- the invert level of the house connection at the sewer pipe (IL sewer)
- the drop over the house connection (branch depth)

On selecting House connections, the **Sewer House Connections Report** panel is displayed.

![Sewer House Connections Report panel]

22.8.8 Barwon Design Checks

The report generated from this option includes the design checks:

- Network validations (checks that there are strings, no closed loops)
- Manholes don't have negative drops
- Other sewer lines connecting in don't have negative drops
- Sewers flow downhill with a minimum grade
- Manholes are not too close together (i.e. on top of each other)
- A minimum cover for each sewer line
- Block controls are above the pipe invert level

After selecting the Design checks option, the Sewer Design Checks Report panel is displayed.

![Sewer Design Checks Report Panel]

22.8.9 Barwon Services Report

For each sewer string in the network, this option generates a report which includes the
- section through any tins on the section view
- name and model of any services in the corridor defined by the section view
- co-ordinates and chainages of the parts of the service in the corridor, and the chainage and offset for
each of the point of the parts projected onto the sewer centre-line.
- clearance at the point where any service goes under or over the sewer string.

After selecting the Services report option, the Sewer Services Report panel is displayed

The fields and buttons used in this panel have the following functions.

22.9 Drainage Plots

**Position of menu:** Design => Drainage-Sewer => Plots

Currently the Plots menu contains an option to produce a long section including any HGL values, flows and user defined attributes read in from other sources, and a second option to output the network to Melbourne Water’s sewer format.

The Plots walk-right menu is

![Drainage Network Plots](image)

The options Longsections and Melbourne Water will now be described in more detail.

For the option Set Current Storm, please continue to the section Set Current Storm.
Long sections, please continue to the section Drainage Longsections.
Melbourne Water, please continue to the section Melbourne Water.
Plan annotations, please continue to the section Plot Annotations.
Long plot cut labels and manholes, please continue to the section Long Plot

Cut Labels and Manholes.
22.9.1 Set Current Storm

Position of menu:  Design => Drainage-Sewer => Plots => Set Current Storm

This section of documentation is a work in progress and will be updated in subsequent releases.
Selecting Set Current Storm brings up the Set Current Storm panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

</tbody>
</table>
22.9.2 Drainage Longsections

Position of menu:  Design => Drainage-Sewer => Plots => Longsections

The Longsections option is used to generate the longsection plots for all lines in a drainage network.

Given the plot sheet size and the horizontal and vertical scales, the longsections for the drainage lines are plotted starting at the top of the sheet and moving across the sheet. Once one row is full, if there is room the plot moves down the page and begins a new row. When a plot sheet is full, a new plot sheet is automatically begun.

Hence the drainage lines are plotted one after another on one or more plotter sheets.

The drainage lines are plotted in string name alphabetical order.

The drainage longsection plot includes
- the manholes, drainage pipe and any house connections
- the height of the finished surface at the manhole
- manhole names and cover types
- distances between manholes
- the invert depth of the pipe on either side of a manhole
- the grades and types of the pipes
- any services in the corridor - including their name, invert level and distance from the nearest downstream manhole
- if the information exists, the velocity, flow, HGL values and diagram

After selecting the Longsections option, the New Plot Drainage Network panel is displayed.

The drainage long section plot is tailored by using the plot parameter file (.ppf file) given in the plot parameters field. A default .ppf file is set by pointing to it with the environment variable DRAINAGE_PPF_4D path name of default .ppf file

In the path name to the default .ppf file, $LIB is used to stand for the library folder set by LIB_4D. For example, "$LIB/drainage.ppf" is the file drainage.ppf in the library area.

The title button on the bottom of this panel controls the use of a title block file and the plotting of a border and two lines of title. If the Title button is selected, the drainage plot title panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>

</table>
**Sheet size wd ht (mm)**
- **input**
  - available sheet sizes
  - the width and height values (separated by space) or the name of a user defined sheet size.

**X origin (mm)**
- **input**
  - the x position on the plot sheet for the bottom left hand corner of the longsection plots. Same as left_margin in the plot parameter file.

**Y origin (mm)**
- **input**
  - the y position on the plot sheet for the bottom left hand corner of the longsection plots. Same as bottom_margin in the plot parameter file.

**Text style**
- **input**
  - 1
  - available text styles
  - the default text style to use in the longsection plot.

**Plot ht (mm)**
- **input**
  - the maximum allowable height for a longsection plot for a drainage line. Datum breaks are applied to any part of the longsection that will not fit into the plot ht.

**Box text size (mm)**
- **input**
  - 3
  - size (in millimetres) to plot the chainages, heights etc. in the boxes in the plots of the drainage longsections.

**Box colour**
- **input**
  - cyan
  - available colours
  - colour used for the text and the boxes.

**Velocity**
- **tick box**
  - if tick, the velocity values for the pipes are drawn on the longsection plot.

**Flow**
- **tick box**
  - if tick, the flow values for the pipes are drawn on the longsection plot.

**Centre CH.**
- **tick box**
  - if tick, the road centre line chainages are drawn on the longsection plot.

**HGL vals**
- **tick box**
  - if tick, the HGL values for the pipes are drawn on the longsection plot.

**HGL diag**
- **tick box**
  - if tick, lines joining the HGL values for the pipes are drawn on the longsection plot.

**Drain No.**
- **tick box**
  - if tick, the drainage line names are drawn on the longsection plot.

**Plot**
- **button**
  - plot the drainage longsections for the drainage lines in the model given in the network model field.

The fields and buttons in the **title** tab are

**Use title file**
- **tick box**
  - if tick, a user defined title block file is used.

**Standard Title**
- **tick box**
  - if tick, the standard 12d Model border and two lines of title are placed on the bottom of the plot.

**Title file**
- **input**
  - *.tf
  - if non-blank and use title file is set to tick, then the file given in this field is used to generate a user defined title block for the plot.

**Title line 1/2**
- **input**
  - first/second line of title information
22.9.2.1 Drainage Longsection Plot Parameter File

The Longsections plot option is used to make special long section plots for a network of drainage strings.

Some of the look of the drainage long section plot can be controlled from the plot drainage network panel itself, however a wider selection of control parameters is available by using a drainage long plot, plot parameter file.

The drainage long section plot parameters are placed in a file with ending .ppf. Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line. Anything on a line after a double forward slash //</code> is considered to be a comment.

The set of all parameters for the drainage long section plot is enclosed within a set of curly brackets { } with the header

```
drainage_long_plot "plot set name"
```

before the curly brackets.

That is,

```
drainage_long_plot "plot set name" {
  plot parameters
  one per line
}
```

If there is more than one drainage_long_plot parameter set in the file, only the first set is used. There may also be parameter sets for other plot types such as section_x_plot in the same file. The other sets will be ignored when doing a drainage long section plot.

The plot parameters are documented in following groups:

For the Plot Sheet layout, please continue to the section **Plot Sheet Layout**.

Labelling the drainage string name, please continue to the section **Labelling the Drainage String Name on the Plot**.

Boxes area, please continue to the section **Boxes Area**.

Chainages and uprights, please continue to the section **Chainages and Uprights**.

Staggering, please continue to the section **Staggering of Chainages and Uprights**.

Below datum area, please continue to the section **Below Datum Area**.

Arrows area, please continue to the section **Arrow Areas**.

Grade arrows parameters, please continue to the section **Parameters for the Arrows for Grades of the Pipes**.

Pipe diameter arrows parameters, please continue to the section **Parameters for the Arrows for Diameters of the Pipes**.

Pipe velocity arrows parameters, please continue to the section **Parameters for the Arrows for Velocity in the Pipes**.

Pipe flow arrows parameters, please continue to the section **Parameters for the Arrows for Flow in the Pipes**.
Drainage line name arrows parameters, please continue to the section Parameters for the Arrows giving the Drainage Line Name.
User defined pipe arrows parameters, please continue to the section Parameters for the Arrows for User Defined Pipe Attributes.
Graph area parameters, please continue to the section Graph Area.
Top area parameters, please continue to the section Top Area.
Bubbles area parameters, please continue to the section Manhole name, Manhole Types and Surrounding Bubbles.
Change of direction parameters, please continue to the section Change of Direction Through Pits and Junctions.
Symbols at manhole parameters, please continue to the section Symbols at Manholes.
House connection parameters, please continue to the section Labelling House Connections.
Symbols at Property controls parameters, please continue to the section Symbols at Property Controls.
Property controls parameters, please continue to the section Labelling Property Controls.
Hatching cut and fill parameters, please continue to the section Hatching Cut and Fill Areas.
Labelling cuts parameters, please continue to the section Labelling Cuts of Drainage Through Strings in a Model.
Title block parameters, please continue to the section Title Block Information.
Panel modifying parameters, please continue to the section Parameters that Modify Fields In the Plot Drainage Network Panel.

22.9.2.1.1 Plot Sheet Layout
The plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```
sheet_size text // sheet name, or
"mm mm" // sheet size: width height
```

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D file // file of plotter sheets sizes
```

The plotting area is restricted to within the plot sheet by giving the margins

```
left_margin mm
right_margin mm
top_margin mm
bottom_margin mm
```

The drainage long section plot will break an individual plot up if it doesn't fit across the sheet. There can be one or more rows of plot on the same sheet.

The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

When a sheet is full, a follow on sheet is created.

As soon as one drainage string is completed, the next drainage string in the network model is plotted beginning on the same row as the previous drainage string and with a horizontal gap of size horizontal_plot_gap between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

The position of the left hand bottom corner of the first plot in the bottom row is given by the parameters, x_origin and y_origin which are the same as left_margin and bottom_margin respectively.
If there are two or more rows of plots, the position of the first plot in each row is given by adding multiples of the `plot_height` to the `y_origin` (bottom_margin).

- **network_model**: text // model of drainage strings
- **x_origin**: mm // Position of the left hand bottom, same as `left_margin`.
- **y_origin**: mm // corner of first plot in the bottom row, same as `bottom_margin`.
- **only_one_line**: 0 // more than one row on a sheet
- **plot_height**: mm // total height of a plot row. It includes the `vertical_plot_gap`.
- **horizontal_plot_gap**: mm // gap between plots on same row
- **vertical_plot_gap**: mm // gap between rows of plots, also the size of the top area

The drainage long plot itself consists of eleven areas. From the bottom up, they are drainage string name, boxes, below datum, arrow 1, bottom stagger, arrow 2, graph, arrow 3, top stagger, arrow 4, top.

The **drainage string name area** is where the name of the drainage string can be plotted.

The **boxes area** is where the chainages and various values for the drainage strings are labelled.

The **below datum area** is a region between the boxes area and the datum line.

The **arrow 1 area** is for drawing arrows where the arrows go between the staggered uprights and below the graph area. The datum line is at the bottom of the arrow 1 area.

The **bottom stagger area** is where the upright line staggers occur before going up from the boxes area to the graph area.
The **arrow 2 area** is for drawing arrows below the graph but where the arrows go between non-staggered uprights.

The **graph area** is the area where the actual plots of the strings are drawn.

The **arrow 3 area** is for drawing arrows above the graph area and where the arrows go between non-staggered uprights.

The **top stagger area** is where the upright line staggers occur above the graph area.

The **arrow 4 area** is for drawing arrows where the arrows go between the staggered uprights and above the graph area.

The **top area** is an annotation area above the arrow 4 area and is used for bubbles, manhole names (pit names), junctions, deflection angles, etc.

The areas and the information in them will now be described in more detail.
22.9.2.1.2 Labelling the Drainage String Name on the Plot

The plot can be labelled with the name of the drainage string under the boxes area. The name is made up of concatenation the text strings:

\[
\text{plot}\_\text{name}\_\text{pre}\_\text{text} \quad \text{drainage-string-name} \quad \text{plot}\_\text{name}\_\text{post}\_\text{text}
\]

The plot name is positioned under the boxes.

- plot\_name\_mode 0 // don't use the drainage string name
- plot\_name\_mode 1 // use the drainage string name in the // label

- plot\_name\_pre\_text text
- plot\_name\_post\_text text
- plot\_name\_textstyle textstyle
- plot\_name\_text\_size mm
- plot\_name\_text\_colour colour
- plot\_name\_x mm
- plot\_name\_y mm

The plot\_name\_x is measured from the beginning of the height boxes.
The default for plot\_name\_x is centred on the values area.
The plot\_name\_y is measured from the bottom of the box area with positive being down.

Example of Labelling Drainage String Name

<table>

<tr>
<td>plot_name_y</td>
<td>30</td>
</tr>
</tbody>
</table>
22.9.2.1.3 Boxes Area

Many of the drainage string values (invert levels and depth, hgl values, natural and finished surface, etc.) can be labelled in the boxes area at the bottom of the drainage long section plot.

Each type of information is plotted in a row made up of a title, and the actual values given at the chainage of each pit in the drainage string.

Each row of information is surrounded by lines to form a box, and the stacked boxes form the boxes area at the bottom of the drainage plot.

The title for the information, is drawn in the title area of the boxes area and the values are drawn in the values area of the boxes area.

Consequently the boxes area is made up of rows of text consisting of:

    title               followed by the values along the drainage string.

The titles area for the left plot in the bottom row starts at the co-ordinate \((x_{\text{origin}},y_{\text{origin}})\) and each row is begun by adding the distance \(\text{plot}\_\text{height}\) to the \(y_{\text{origin}}\) (see previous section).

The width of the title area is given by the box_width parameter and the height of each box is given by box_height.

\[
\begin{align*}
\text{box\_width} & \quad \text{mm} \\
\text{box\_height} & \quad \text{mm}
\end{align*}
\]

The colour of the box line work is given by:

\[
\begin{align*}
\text{box\_colour} & \quad \text{colour}
\end{align*}
\]

A default text size and colour can be specified for the title text and the values, or sizes, colours and text styles can be given for each individual box (given later in this section).

\[
\begin{align*}
\text{title\_box\_text\_size} & \quad \text{mm} \\
\text{title\_box\_text\_colour} & \quad \text{colour} \\
\text{box\_text\_size} & \quad \text{mm} \\
\text{box\_text\_colour} & \quad \text{colour}
\end{align*}
\]

The values text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (box_text_left_justify).

The values text can be on the left, right or centred on the uprights and is given by the parameter box_text_side.

The width of the values area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing (see next section).
The default order of the boxes from the bottom up is
0. drainage string chainages
1. road centre line chainages - user choice
2. natural surface heights - user choice
3. finished surface heights - user choice
4. before pit and after pit invert levels
5. before pit and after pit hgl values - user choice
6. before pit and after pit depth to inverts - user choice

There are parameters to change the order for 1-6. *Drainage string chainages* is fixed at the bottom (box 0) but what is in the boxes above box 0 is can be set by the box_n parameters:

```plaintext
box_n  number_from_list
```
// the n’th box above the drainage string
// chainages will contain given item number
// form the list.

For example, to have *finished surface heights* in the first box the drainage string chainages, use:

```plaintext
box_1 3 // the (1) will be replaced by (3)
```

The boxes (1), (2), (3) and (5) can be suppressed by the parameters

```plaintext
draw_centre_chainage  0/1 // 0 = don't have centre line chainages
```
The definition of depth to invert and whether box (6) is suppressed or not, are given by the parameter depth_mode:

- **depth_mode 0** // don’t draw depth to invert values
- **depth_mode 1** // draw depth to invert values to fs tin for drainage string
- **depth_mode 2** // draw depth to invert values to top of manhole for drainage string
- **depth_mode 3** // draw depth to invert values to ns tin for drainage string

The default for the number of decimal places used in the values in the boxes is:

- **number_of_decimals** integer // default number of decimal places

The text, size, colour and textstyle for the title text and values text for each box can be set by

### (0) Drainage String Chainages

- **plot_title_chainage_name** text // first line of title for chainages box
- **plot_title_chainage_name_2** text // second line of title for chainages box
- **chainage_title_colour** colour // colour of title
- **chainage_title_text_size** mm // size of title
- **chainage_title_textstyle** textstyle // textstyle of title
- **chainage_text_colour** colour // colour of values
- **chainage_text_size** mm // size of values
- **chainage_textstyle** textstyle // textstyle of values
- **chainage_decimals** integer // number of decimal places in chainage

### (1) Road Centreline Chainages

- **plot_title_centre_chainage_name** text // title for road centre
- **plot_title_centre_chainage_name_2** text // second line of title for road
- **chainage_title_colour_cl** colour // colour of title in cl box
- **chainage_title_text_size_cl** mm // size of title in cl box
- **chainage_title_textstyle_cl** textstyle // textstyle of title in cl box
- **chainage_text_colour_cl** colour // colour of cl values
- **chainage_text_size_cl** mm // size of values in cl box
- **chainage_textstyle_cl** textstyle // textstyle of values in cl box
- **chainage_cl_decimals** integer // number of decimal places in chainage cl

### (2) Natural Surface Values

- **plot_title_surface_name** text // title for the drainage ns values box
- **plot_title_surface_name_2** text // second line of title for drainage ns values
- **ns_title_colour** colour // colour of text
- **ns_title_text_size** mm // size of title in ns box
- **ns_title_textstyle** textstyle // textstyle of title
- **ns_text_colour** colour // colour of ns values
- **ns_text_size** mm // size of values

The text, size, colour and textstyle for the title text and values text for each box can be set by...
(3) finished surface values

- `plot_title_finished_name` (text): title for the drainage fs values box
- `plot_title_name_2` (text): second line of title for drainage fs values
- `fs_title_colour` (colour): colour of text
- `fs_title_text_size` (text): textsize for title
- `fs_text_colour` (colour): colour of ns values
- `fs_text_size` (mm): size of values
- `fs_textstyle` (text): textstyle of values
- `fs_decimals` (integer): number of decimal places in ns

(4) invert levels

- `plot_title_invert_name` (text): title for the invert levels box
- `plot_title_name_2` (text): second line of title for the invert levels box
- `il_title_colour` (colour): colour of text
- `il_title_text_size` (text): textstyle for title
- `il_text_colour` (colour): colour of il values
- `il_text_size` (mm): size of values
- `il_textstyle` (text): textstyle of values
- `il_decimals` (integer): number of decimal places in il

(5) hgl values

- `plot_title_hgl_name` (text): title for hgl values box
- `plot_title_name_2` (text): second line of title for hgl values box
- `hgl_title_colour` (colour): colour of text
- `hgl_title_text_size` (text): textstyle for title
- `hgl_text_colour` (colour): colour of hgl values
- `hgl_text_size` (mm): size of values
- `hgl_textstyle` (text): textstyle of values
- `hgl_decimals` (integer): number of decimal places in hgl

(6) depths

- `plot_title_depth_name` (text): title for depth of inverts box
- `plot_title_depth_name_2` (text): second line of title for depth of inverts box
- `depth_title_colour` (colour): colour of text
- `depth_title_text_size` (text): textstyle for title
- `depth_text_colour` (colour): colour of depth values
- `depth_text_size` (mm): size of values
- `depth_textstyle` (text): textstyle of values
- `depth_decimals` (integer): number of decimal places in depth
Drawing the Boxes

The bottom line from the boxes can be drawn or not drawn:

chainage_box_mode = 0  // don’t draw the bottom line
chainage_box_mode = 1  // draw all the box line work - default

draw_box_mode = 0  // don’t draw the title area box
draw_box_mode = 1  // draw the title area box, no lines - default
draw_box_mode = 2  // draw title box area with lines
22.9.2.1.4 Chainages and Uprights

The chainage box contains drainage string chainages for
(a) the chainages of each pit in the drainage string
(b) the chainages on the drainage string where any strings in models on the section view are cut by the drainage string (crossing services)

For a **pit**, the invert levels, depths, finished and natural surface levels, and hgl of pipes at a pit can all be labelled at the chainage of the pit.

For a **crossing service**, the level of the crossing service and the chainage on the drainage string where the crossing occurs are labelled.

**Note** - crossing services can also be labelled using cuts of drainage line through strings. However, this does not create a chainage in the chainage box.

Uprights, or leader lines, can be drawn from the chainage values at the bottom of the boxes to the top of the pit in the graph area, and from the top of the boxes to the top area.

Using the parameters `uprights_top_mode` and `uprights_bottom_mode`, it is possible to suppress the drawing from the top of the pit to the top area, and also from the top of the boxes to the bottom of the boxes.

```
uprights_top_mode = 0  // stop at top of pit
uprights_top_mode = 1  // go to top area (default)
uprights_bottom_mode = 0 // stop at top of boxes
uprights_bottom_mode = 1 // go to bottom of boxes (default)
```

Also uprights can be drawn from the chainage values bottom of the boxes to the crossing service in the graph area.
The chainage values at the uprights for the pits can be running chainage along the drainage string, pipe length chainages (i.e. the chainage starts at zero for each pipe) or both.

chainage_mode

0 //pipe length chainage
1 // running chainage
2 // both pipe length and running

If the chainage_mode includes "pipe length chainage" (modes 0 and 2), the pipe length can either be labelled with a 0.0 chainage at the start pit for the pipe and the pipe length at the end pit, or just have the length centred between the two pits.

centre_pipe_length

0 // default - 0 at start pit, length at end pit
1 // centre pipe length

The chainage values for the crossing services can be running chainage along the drainage string, chainage length from the previous pit (i.e. the chainage starts at zero at the previous pit) or both.

service_chainage_mode

0 //pipe length chainage
1 // running chainage
2 // both pipe length and running

The colour of the uprights for the pits and crossing services are given by:

manhole_line_colour colour // colour of uprights to the pits
service_line_colour colour // colour of upright to the crossing

// services

The crossing services are labelled with the drainage string chainage of the crossing point, the invert level of the service at the crossing and the name of the service which is made up of:

service diameter name of service invert level at the service at the crossing.

The service label is drawn the distance service_name_y below the crossing point:

service_name_y mm // def 1, distance of label below crossing point

The colours, text styles and sizes of the service information is specified by:

service_ch_text_colour colour // colour of services ch text
service_ch_text_size mm // size of services ch text
service_ch_textstyle mm // textstyle of services ch text

service_il_text_colour colour // colour of services il text
service_il_text_size mm // size of services il text
service_il_textstyle mm // textstyle of services il text

service_name_text_colour colour // colour of services name
service_name_text_size mm // size of services name
service_name_textstyle mm // textstyle of services name
service_name_decimals integer // number of decimal is il in name

A finished surface value or top of manhole value can also be written vertically along the uprights.
Whether the value is finished surface level or top of manhole level, the values position, size, colour, etc. is controlled by the parameters:

- **draw_fs_vertical**: 0 // don't draw fs vertical values
  1 // always draw values
  2 // only draw values when different -see // draw_fs_vertical_mode

- **draw_fs_vertical_mode**: 0 // the fs value is the value from the fs tin
  // for the drainage string.
  // When draw_fs_vertical is 1,
  // always draw the fs value.
  // When draw_fs_vertical is 2,
  // only draw fs value when it is
  // different from the top of manhole value
  1 // the fs value is the top of manhole
  // for the drainage string.
  // When draw_fs_vertical is 1,
  // always draw the fs value.
  // When draw_fs_vertical is 2,
  // only draw fs value when it is
  // different from the value of the fs tin.

<table>
<thead>
<tr>
<th>draw_fs_vertical</th>
<th>draw_fs_vertical_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

- **fs_vertical_pre_text**: text // text before the vertical fs value
- **fs_vertical_post_text**: text // text after the vertical fs value
- **fs_vertical_decimals**: integer // number of decimals in vertical fs
- **fs_vertical_colour**: colour // colour of the vertical fs text
- **fs_vertical_size**: mm // size of the vertical fs text
- **fs_vertical_textstyle**: textstyle // textstyle of the vertical fs
- **fs_vertical_x**: mm // x adjustment to position of text
- **fs_vertical_y**: mm // y adjustment to position of text
22.9.2.1.5 Staggering of Chainages and Uprights

If the text values are placed at the real chainage positions at the bottom of the plot, text over writing can easily occur if the chainages are very close together.

To prevent such over writing, the text can be staggered.

That is, if the text is going to over write a previous text value, the next text value is actually moved along until there is no over writing.

Since the text is no longer at the correct chainage position, the uprights to the pits and services start at the text position and then bend back to the correct chainage position on the plot. The region where the bending occurs is called the stagger area.

For the drainage plot, there is an area below the graph where the uprights bend backwards from the staggered text position to the real chainage position (bottom stagger area).

And there is a second area above the graph where the uprights bend forwards from the real chainage position to the staggered text position (top stagger area).

Hence annotation above the top stagger area will line up with the staggered values below the bottom stagger area.

The stagger area below the graph area is defined by

- `stagger_height_1` mm // distance from the top of arrow_area_1 to the start of the staggers
- `stagger_height_2` mm // distance over which stagger occurs
- `stagger_gap_bottom` mm // distance from end of staggers to the bottom of arrow_area_2

The stagger area above the graph area is defined

- `stagger_gap_top` mm // distance from the top of arrow_area_3 to the start of the staggers
- `stagger_height_3` mm // distance over which stagger occurs
- `stagger_height_4` mm // distance from end of staggers to the bottom of arrow_area_4

The distance to be left for text to avoid over writing is:

- `horizontal_text_gap` mm // minimum distance to leave for text after pit values
- `service_text_gap` mm // minimum distance to leave for text after service values

When staggering occurs, it is possible for the values area to be longer than the graph area.
Drainage long section plot stagger areas
22.9.2.1.6 Below Datum Area

The **below datum area** is the region between the boxes area and the arrow_1 area. The datum line is drawn at the top of the below datum area.

The size of the below datum area is

\[
\text{datum\_gap} \quad \text{mm} \quad // \text{height of the below datum area}
\]

---

The datum value is placed above the datum line, preceded by a datum name on the left hand side of the title area.

Since the datum value is automatically calculated to try and fit the plot vertically into the graph area, the datum value can change along the plot. When a datum change occurs, the new datum value is written on the datum line at the relevant chainage position.

The datum name, text size, colour and position are controlled by:

- \text{datum\_name} \quad \text{text} \quad // \text{datum title}
- \text{datum\_title\_x} \quad \text{mm} \quad // \text{distance to write name from lhs}
- \text{datum\_title\_y} \quad \text{mm} \quad // \text{distance above datum line}
- \text{datum\_title\_textstyle} \quad \text{textstyle} \quad // \text{textstyle of name}
- \text{datum\_title\_text\_size} \quad \text{mm} \quad // \text{text size}
- \text{datum\_title\_colour} \quad \text{colour} \quad // \text{text colour}

The datum value, number of decimal places, text size, colour and position are controlled by:

- \text{datum\_decimals} \quad \text{integer} \quad // \text{number of decimal places in datum value}
- \text{datum\_x} \quad \text{mm} \quad // \text{x dist. to write value from manhole}
- \text{datum\_y} \quad \text{mm} \quad // \text{y dist. to write value above datum line}
- \text{datum\_text\_size} \quad \text{mm} \quad // \text{size of datum value}
- \text{datum\_textstyle} \quad \text{textstyle} \quad // \text{textstyle for datum}
- \text{datum\_text\_colour} \quad \text{colour} \quad // \text{colour of the datum text and line}
22.9.2.1.7 Arrow Areas

Apart from information labelled in the boxes and top areas, the drainage long section plot can place arrows between pits for other information such as:

(a) pipe grade or slope
(b) pipe diameter
(c) velocity
(d) flow
(e) drainage line name
(f) user defined pipe attributes

A specific arrow area is defined for each set of arrows.

The **arrow areas** are designed for drawing and labelling arrows between pits.

All the values refer to pipes connecting adjacent pits and the relevant pipe is indicated by drawing an arrow between the uprights from the chainage text to the pits.

Because staggering of the chainage text can occur, the position of the uprights to draw the arrows between can vary depending on whether the arrow is above or below a stagger area.

Hence, there are four arrow areas:

- **arrow area 1** which is below the graph and the bottom stagger area. The arrows go between the *staggered* chainage positions of the pits.

The datum line is at the bottom of arrow 1 area.

- **arrow area 2** which below the graph but above the bottom stagger area. Hence the arrows go between the non-*staggered* chainage positions of the pits.

- **arrow area 3** which is above the graph but below the top stagger area. The arrows go between the non-*staggered* chainage positions of the pits.

- **arrow area 4** is above the graph and the top stagger area. The arrows go between the *staggered* chainage positions of the pits.

The heights of the four areas (which can be zero) are defined by:

- `arrow_area_1 mm` // height of arrow_1 area
- `arrow_area_2 mm` // height of arrow_2 area
- `arrow_area_3 mm` // height of arrow_3 area
- `arrow_area_4 mm` // height of arrow_4 area

![Diagram showing arrow areas and their definitions](image-url)
The parameters for controlling the arrows between manholes and associated text for the values of pipe slope, pipe diameter, flow, velocity, drainage line name and user defined pipe attributes are now given.

Each set of parameters has an arrow_mode with the following values:

```plaintext
..._arrow_mode
0 // no arrow
1 // arrow
2 // line
3 // line with uprights at ends
4 // uprights, no line
5 // line with downrights
6 // downrights, no line
7 // line with up and downrights at ends
8 // up and downrights, no line
```

![Diagram showing different arrow modes](attachment:image.png)
22.9.2.1.8 Parameters for the Arrows for Grades of the Pipes

Parameters specifying the arrow area used and the position of the arrows.

- **draw_pipe_grade**: 0 // don’t draw pipe grade
  1 // draw pipe grade
- **pipe_grade_arrow_area**: m // the arrow area for the arrows
  m = 1,2,3 or 4
- **pipe_grade_y**: mm // distance that the arrow is above the
  // bottom of the arrow area.

For the arrow, the value of the grade can be specified as either **1 in** or **percent** grade:

- **percentage_grade**: 0 // the value is a "1 in" grade
  1 // the value is a percent grade

Parameters for the title text on the left hand side of the plot:

- **pipe_grade_title**: text //title on the left hand side of the arrow
- **pipe_grade_title_textstyle**: textstyle // textstyle of the title
- **pipe_grade_title_text_size**: mm // size of the title
- **pipe_grade_title_text_colour**: colour // colour of the title
- **pipe_grade_title_offset**: mm //distance to raise or lower the text
  // from the arrow position
- **pipe_grade_title_x**: mm // distance from the left hand side of the
  // plot

Parameters for the arrow type:

- **pipe_grade_arrow_mode**: 0 // no arrow
  1 // arrow
  2 // line
  3 // line with up and downrights at ends
  4 // up and downrights, no line
  5 // line with downrights
  6 // downrights, no line
  7 // line with up and downrights at ends
  8 // up and downrights, no line
- **pipe_grade_arrow_colour**: colour // colour of the arrow
- **pipe_grade_arrow_size**: mm // height of the arrow
- **pipe_grade_arrow_gap**: 0 // no gap in arrow
  1 // leave gap in arrow for text

Parameters for the text on the arrow:

- **pipe_grade_arrow_pre_text**: text // text before the arrows text
- **pipe_grade_arrow_post_text**: text // text after the arrows text
- **pipe_grade_arrow_decimals**: integer // The number of decimal places used
  // when writing out the pipe grade
  // If > 0, all trailing zeros after the
  // decimal place are removed.
  // If < 0, the absolute value is taken as
  // the number of decimal places and no
  // trailing zeros are removed after the
  // decimal point.
- **pipe_grade_arrow_textstyle**: textstyle // textstyle of arrow text
- **pipe_grade_arrow_text_size**: mm // size of the text
- **pipe_grade_arrow_text_colour**: colour // colour of the text
- **pipe_grade_arrow_text_offset**: mm // distance to raise or lower the text
  // from the arrow position
22.9.2.1.9 Parameters for the Arrows for Diameters of the Pipes

The diameter of the drainage pipes can be plotted between each pit.

Inside 12d Model, the pipe diameter is given a world units (usually metres), but on the diameter arrow, the diameter is multiplied by 1000 and written out as an integer value. This is normally millimetres.

For diameters entered in feet and the plot diameter to be in inches, the following parameter should be set

\[ \text{pipe\_diameter\_scale\_factor} = 12. \]  // default is 1000.

Parameters specifying the arrow area used and the position of the pipe diameter arrows:

- \( \text{draw\_pipe\_diameter} \): 0 // don’t draw pipe diameter
  1 // draw pipe diameter
- \( \text{pipe\_diameter\_arrow\_area} \): \( m \) // the arrow area for the arrows
  \( m = 1,2,3 \) or 4
- \( \text{pipe\_diameter\_y} \): mm // distance that the arrow is above the
  bottom of the arrow area.

Parameters for the title text on the left hand side of the plot:

- \( \text{pipe\_diameter\_title} \): \text
  // title on the left hand side of the arrow
- \( \text{pipe\_diameter\_title\_textstyle} \): \( \textstyle \)
  // textstyle of the title
- \( \text{pipe\_diameter\_title\_text\_size} \): mm // size of the title
- \( \text{pipe\_diameter\_title\_text\_colour} \): \( \text{colour} \)
  // colour of the title
- \( \text{pipe\_diameter\_title\_offset} \): mm // distance to raise or lower the text
  from the arrow position
- \( \text{pipe\_diameter\_title\_x} \): mm // distance from the left hand side of the
  plot

Parameters for the arrow type:

- \( \text{pipe\_diameter\_arrow\_mode} \): 0 // no arrow
  1 // arrow
  2 // line
  3 // line with uprights at ends
  4 // uprights, no line
  5 // line with downrights
  6 // downrights, no line
  7 // line with up and downrights at ends
  8 // up and downrights, no line
- \( \text{pipe\_diameter\_arrow\_colour} \): \text{colour} // colour of the arrow
- \( \text{pipe\_diameter\_arrow\_size} \): mm // height of the arrow
- \( \text{pipe\_diameter\_arrow\_gap} \): 0 // no gap in arrow
  1 // leave gap in arrow for text

Parameters for the text on the arrow:

- \( \text{pipe\_diameter\_arrow\_pre\_text} \): \text // text before the arrows text
- \( \text{pipe\_diameter\_arrow\_post\_text} \): \text // text after the arrows text

On the arrow, the pipe type can be also plotted after the \( \text{pipe\_diameter\_arrow\_post\_text} \):

- \( \text{pipe\_type\_mode} \): 0 // don’t include the pipe type
  1 // include the pipe type after the
  \( \text{post\_text} \)
- \( \text{pipe\_diameter\_arrow\_textstyle} \): \( \textstyle \)
  // textstyle of arrow text
- \( \text{pipe\_diameter\_arrow\_text\_size} \): mm // size of the text
- \( \text{pipe\_diameter\_arrow\_text\_colour} \): \( \text{colour} \)
  // colour of the text
- \( \text{pipe\_diameter\_arrow\_text\_offset} \): mm // distance to raise or lower the text
  from the arrow position
22.9.2.1.10 Parameters for the Arrows for Velocity in the Pipes

Parameters specifying the arrow area used and the position of the arrows.

<table>
<thead>

22.9.2.11 Parameters for the Arrows for Flow in the Pipes

Parameters specifying the arrow area used and the position of the arrows.

- **draw_pipe_flow**
  - 0 // don’t draw pipe flow
  - 1 // draw pipe flow

- **pipe_flow_arrow_area**
  - m // the arrow area for the arrows
    - m = 1, 2, 3, or 4

- **pipe_flow_y**
  - mm // distance that the arrow is above the
    - bottom of the arrow area.

Parameters for the title text on the left hand side of the plot:

- **pipe_flow_title**
  - text // title on the left hand side of the arrow

- **pipe_flow_title_textstyle**
  - textstyle // textstyle of the title

- **pipe_flow_title_text_size**
  - mm // size of the title

- **pipe_flow_title_text_colour**
  - colour // colour of the title

- **pipe_flow_title_offset**
  - mm // distance to raise or lower the text
    - from the arrow position

- **pipe_flow_title_x**
  - mm // distance from the left hand side of
    - the plot

Parameters for the arrow type:

- **pipe_flow_arrow_mode**
  - 0 // no arrow
  - 1 // arrow
  - 2 // line
  - 3 // line with uprights at ends
  - 4 // uprights, no line
  - 5 // line with downrights
  - 6 // downrights, no line
  - 7 // line with up and downrights at ends
  - 8 // up and downrights, no line

- **pipe_flow_arrow_colour**
  - colour // colour of the arrow

- **pipe_flow_arrow_size**
  - mm // height of the arrow

- **pipe_flow_arrow_gap**
  - 0 // no gap in arrow
  - 1 // leave gap in arrow for text

Parameters for the text on the arrow:

- **pipe_flow_arrow_pre_text**
  - text // text before the arrows text

- **pipe_flow_arrow_post_text**
  - text // text after the arrows text

- **pipe_flow_arrow_decimals**
  - integer // The number of decimal places used
    - when writing out the pipe flow
    - If > 0, all trailing zeros after the
      - decimal place are removed.
    - If < 0, the absolute value is taken as
      - the number of decimal places and no
        - trailing zeros are removed after the
          - decimal point.

- **pipe_flow_arrow_textstyle**
  - textstyle // textstyle of arrow text

- **pipe_flow_arrow_text_size**
  - mm // size of the text

- **pipe_flow_arrow_text_colour**
  - colour // colour of the text

- **pipe_flow_arrow_text_offset**
  - mm // distance to raise or lower the text
    - from the arrow position
### 22.9.2.1.12 Parameters for the Arrows giving the Drainage Line Name

Parameters specifying the arrow area used and the position of the arrows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>draw_drainage_line</td>
<td>0</td>
<td>// don’t draw drainage line arrow</td>

<td>m</td>
<td>// the arrow area for the arrows</td>
</tr>
<tr>
<td></td>
<td></td>
<td>// m = 1,2,3 or 4</td>
</tr>
<tr>
<td>drainage_line_y</td>
<td>mm</td>
<td>// distance that the arrow is above the bottom of the arrow area.</td>
</tr>
</tbody>
</table>

Parameters for the title text on the left hand side of the plot:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drainage_line_title</td>
<td>text</td>
<td>// title on the left hand side of the arrow</td>
</tr>
<tr>
<td>drainage_line_title_textstyle</td>
<td>textstyle</td>
<td>// textstyle of the title</td>
</tr>
<tr>
<td>drainage_line_title_text_size</td>
<td>mm</td>
<td>// size of the title</td>
</tr>
<tr>
<td>drainage_line_title_colour</td>
<td>colour</td>
<td>// colour of the title</td>
</tr>
<tr>
<td>drainage_line_title_offset</td>
<td>mm</td>
<td>// distance to raise or lower the text</td>
</tr>
<tr>
<td></td>
<td></td>
<td>// from the arrow position</td>
</tr>
<tr>

22.9.2.1.13 Parameters for the Arrows for User Defined Pipe Attributes

There can be up to twenty sets of parameters which are used to define arrows for user defined attributes on the pipes.

Each user defined attribute is referred to by a given user name and it is this user name that is specified by a parameter and links the set of parameters to the information in the drainage string.

Note: user defined attributes on drainage pipes are usually set by special macros.

The parameters for the n'th set (n=1,2, 20) are:

Parameters specifying the pipe attribute used for this set of arrows and the arrow area used.

- `draw_pipe_attr_n`: 0 // don’t draw nth set of arrows
  1 // draw the nth set of arrows
- `pipe_attr_n_name`: text // the name of the attribute to be labelled
  // on the n’th set of arrows
- `pipe_attr_n_arrow_area`: m // the arrow area for the arrows
  // m = 1,2,3 or 4
- `pipe_attr_n_y`: mm // distance that the arrow is above the
  // bottom of the arrow area.

Parameters for the title text on the left hand side of the plot:

- `pipe_attr_n_title`: text // title on the left hand side of the arrow
- `pipe_attr_n_title_textstyle`: textstyle // textstyle of the nth attribute’s title
- `pipe_attr_n_title_text_size`: mm // size of the nth attribute’s title
- `pipe_attr_n_title_colour`: colour // colour of the nth attribute’s title
- `pipe_attr_n_title_offset`: mm // distance to raise or lower the text
  // from the nth arrow position
- `pipe_attr_n_title_x`: mm // distance from the left hand side of the
  // plot

Parameters for the arrow type:

- `pipe_attr_n_arrow_mode`: 0 // no arrow
  1 // arrow
  2 // line
  3 // line with uprights at ends
  4 // uprights, no line
  5 // line with downrights
  6 // downrights, no line
  7 // line with up and downrights at ends
  8 // up and downrights, no line
- `pipe_attr_n_arrow_colour`: colour // colour of the nth arrow
- `pipe_attr_n_arrow_size`: mm // height of the nth arrow
- `pipe_attr_n_arrow_gap`: 0 // no gap in arrow
  1 // leave gap in arrow for text

Parameters for the text on the arrow:

- `pipe_attr_n_arrow_pre_text`: text // text before the arrows text
- `pipe_attr_n_arrow_post_text`: text // text after the arrows text
- `pipe_attr_n_arrow_decimals`: integer // Only if the attribute is a real number.
  // The number of decimal places used
  // when writing out the value of the
  // attribute.
  // If > 0, all trailing zeros after the
  // decimal place are removed.
  // If < 0, the absolute value is taken as
  // the number of decimal places and no
  // trailing zeros are removed after the
  // decimal point.

// form the nth attribute’s arrow position
22.9.2.1.14 Graph Area

The **graph area** is the area where the actual plots of the drainage strings are drawn. The length of the graph area is determined by the length of the drainage string to be plotted, the horizontal scale (given by scale) of the plot and the sheet width.

```plaintext
scale value // 1:value - horizontal scale
// The vertical scale is determined by the
// horizontal scale and the vertical
// exaggeration for the section view.
```

The vertical exaggeration is taken from the section view specified for the plot by the parameter:

```plaintext
view_name text
```

The tins to be sectioned through by the drainage strings and any service models and corridor settings for the graph area are also taken from the specified section view.

The height of the graph is **calculated** by subtracting the height of the other nine boxes from the plot height.

If the plot will not fit horizontally into a row on the sheet, then the plot will be broken at an appropriate pit and the plot continued on another row.

Datum breaks at pits are used to try and fit the plot vertically into the graph area but if the plot still cannot fit, then it will be truncated at the bottom.

The types of strings that can be drawn in the graph area of the drainage long section plot are:

(a) drainage string  the strings from the network model
(b) tins           sections of the drainage string through any tins on the section view.
(c) hgl           hydraulic grade line values from the drainage string
(d) services      parts of strings from any models on the section view that cut the corridor for the section view.

Whether to draw the hydraulic grade line is controlled by:

```plaintext
draw_hgl_diag 0/1 // 1 = draw hydraulic grade line
```

The **colour** of the strings in the plot is the actual string colour for case (a) and (d), the colour of the tin used for the section in case (b) and user specified colour for (c).

```plaintext
hgl_colour colour
```

---

- **Arrow area 1**
- **Below datum area**

---

**drainage long section plot**
22.9.2.1.15 Top Area

The top area is an annotation area above the arrow_4_area at the top of the plot.
It can be used for pit names, pit types, line names, junctions and deflection angles through pits.
The height of the top area is given by

\[
\text{vertical_plot_gap} \quad \text{mm} \quad \text{// size of the top area. If it is not large enough, the text will over write the plot in the row above.}
\]

A line can be drawn at the bottom of the top area:

\[
\text{draw_top_line} \quad 0/1 \quad \text{// 1= draw line at bottom of top area}
\]

\[
\text{// (i.e. top of arrow_4_area)}
\]
22.9.2.1.16 Manhole name, Manhole Types and Surrounding Bubbles

The drainage string name, the manhole name (pit number) and manhole type (pit type) can be drawn on the drainage long section plot, with or without a bubble around it.

The bubble text is made up of

```
line_name / pit_name  pit_type
```

where the bits actually used are controlled by

- `draw_line_name` 0/1 // 1 = include line name. The "/" is only included if the line_name is drawn.
- `draw_pit_name` 0/1 // 1 = include pit_name
- `draw_pit_type` 0/1 // 1 = include pit type

The size, colour and text style of the bubble text is given by:

- `bubble_text_size` mm // size of text in bubble def angled_text_size
- `bubble_text_colour` colour // colour of text def angled_text_colour
- `bubble_textstyle` textstyle // textstyle for text def angled_text_textstyle
- `bubble_text_x` mm // horizontal distance from the default position (at the pit or in top area)
- `bubble_text_y` mm // vertical distance from the default position (at the pit or in top area)
- `bubble_pre_text` text // default ""
- `bubble_post_text` text // default ""
- `bubble_text_angle` value // default 0
- `bubble_text_justify` value // the default is centre justified

A bubble is drawn of radius `bubble_radius` is drawn around the bubble text.

If `bubble_radius` is zero, then no bubble is drawn.

If the `bubble_radius` is zero, the bubble text is still drawn but without the enclosing bubble.

```
bubble_radius  mm // if non-zero a bubble of this radius is drawn around the text
bubble_colour  colour // colour of bubbles
```

The "bubble" can be drawn as two semi-circles and two straight lines

```
bubble_length  mm // length of the straight line in between the semi-circles
```

The bubble text (and bubble) can be positioned at the bottom of the top area, or can be placed a fixed distance above the top of the corresponding manhole.

If the bubble text is drawn at the bottom of the top area, the upright is automatically drawn up to the bubble text.

If the bubble text is drawn above the pit, it is positioned by the `distance_above_pit` parameter plus the top stagger distances, `stagger_gap_top`, `stagger_height_3` and `stagger_height_4`.

This is necessary because the bubble text may need to be staggered.

```
draw_text_at_pit  0 // draw bubble and/or text in the top
```
// area.
1
// draw it above the pit

distance_above_pit
mm
// distance to add to the top stagger area
// heights to draw the bubble above the
// pit.

uprights_top_mode
0/1
// 1 = draw line from pit to bubble. Used to be
// draw_line_to_text
22.9.2.17 Change of Direction Through Pits and Junctions

If there is a change of direction of the pipes of the plotted drainage string going through the pit, the deflection angle (in degrees, minutes and seconds) is drawn above the bubble text.

The deflection angle text is made up:

angled_pre_text  deflection angle  angled_post_text

Also any junctions at a pit in the plotted drainage string can be labelled with the name of the drainage strings coming into the pit, and the angle of the pipes at the junction.

Hence the junction text is made up of two lines:

junction_pre_text  line_name  junction_post_text
junction_angle_pre_text  junction_angle  junction_angle_post_text

If bubbles are drawn, the deflection angle and junction name and angle are drawn at the distance angled_text_offset above the bubble and with the distance angled_text_gap between the lines of information.

If bubbles are not drawn, the bubble text and the deflection angle and junction name and angle is placed the distance angled_text_offset above bottom of the top area. Each line of text is separated by the distance angled_text_gap.

The deflection angle and junction name and angle are drawn at an angle of angled_text_angle.

angled_text_offset  mm  // distance of text above bubble text
angled_text_gap  mm  // distance between text to the right
angled_text_angle  value  // angle of text

The pre and post text, colour, size and text style for the deflection angle of the drainage string pipes going through the pit are controlled by:

angled_pre_text  text  // default " "
angled_post_text  text  // default " "
angled_text_colour  colour  // colour of deflection angle text
angled_text_size  mm  // size of deflection angle text
angled_textstyle  textstyle  // textstyle of deflection angle text
The junction drainage string name can be included/not included in the first line of junction information:

```
junction_name_mode  0 // don’t include the junction string name
                      1 // default - use junction string name
```

The pre and post text, colour, size and text style for the junction name and the angle that the junction makes at the pit are controlled by:

```
junction_pre_text    text  // default "JUNCTION "
junction_post_text   text  // default " 
junction_text_colour  colour  // colour of junction name text
junction_text_size    mm    // size of junction name text
junction_textstyle   textstyle  // textstyle for junction name text
junction_angle_pre_text text  // default " 
junction_angle_post_text text  // default " 
junction_angle_text_colour  colour  // colour of junction angle text
junction_angle_text_size    mm    // size of junction angle text
junction_angle_textstyle   textstyle  // textstyle for junction angle text
```
22.9.2.18 Symbols at Manholes

Manholes can be labelled with symbols which depend on the manhole type. There can be up to twenty (20) sets of manhole symbols.

\[
\begin{align*}
\text{manhole\_symbol\_n\_type} & \quad mh\_type \\
& \quad // \text{manhole type to have symbols} \\
\text{manhole\_symbol\_n\_mode} & \quad 0 \\
& \quad // \text{cross} \\
& \quad 1 \\
& \quad // \text{up from centre of box} \\
& \quad 2 \\
& \quad // \text{up and down from centre of box} \\
& \quad 3 \\
& \quad // \text{square} \\
& \quad 4 \\
& \quad // \text{triangle, base at bottom} \\
& \quad 5 \\
& \quad // \text{circle} \\
& \quad 6 \\
& \quad // \text{use a 12d symbol}
\end{align*}
\]

\[
\begin{align*}
\text{manhole\_symbol\_n\_position} & \quad 1 \\
& \quad // \text{at top of manhole - default} \\
& \quad 3 \\
& \quad // \text{above top of boxes} \\
& \quad 4 \\
& \quad // \text{above highest point} \\
& \quad 100 \\
& \quad // \text{to primary string} \\
& \quad 101 \\
& \quad // \text{to first found tin}
\end{align*}
\]

\[
\begin{align*}
\text{manhole\_symbol\_n\_size} & \quad \text{mm} \\
& \quad // \text{size} \\
\text{manhole\_symbol\_n\_x} & \quad \text{mm} \\
& \quad // \text{x adjustment to position - default 0} \\
\text{manhole\_symbol\_n\_y} & \quad \text{mm} \\
& \quad // \text{y adjustment to position - default is 0} \\
\text{manhole\_symbol\_n\_style} & \quad \text{text} \\
& \quad // \text{the name of the linestyle (symbol)} \\
\text{manhole\_symbol\_n\_angle} & \quad \text{value} \\
& \quad // \text{default value is 0} \\
\text{manhole\_symbol\_n\_colour} & \quad \text{colour} \\
& \quad //
\end{align*}
\]

For example:

\[
\begin{align*}
\text{manhole\_symbol\_1\_type} & \quad "\text{CONC COVER}" \\
& \quad // \text{manhole type to use} \\
\text{manhole\_symbol\_1\_position} & \quad 1 \\
& \quad // \text{on top of manhole} \\
\text{manhole\_symbol\_1\_mode} & \quad 6 \\
& \quad // \text{use 12d symbol} \\
\text{manhole\_symbol\_1\_style} & \quad "\text{shrub}" \\
& \quad // \text{name of 12d symbol} \\
\text{manhole\_symbol\_1\_size} & \quad 1 \\
\text{manhole\_symbol\_1\_x} & \quad 0 \\
\text{manhole\_symbol\_1\_y} & \quad 0
\end{align*}
\]

22.9.2.19 Labelling House Connections

**NOTE** - house connections are only accessible by the Sewer module.

The house connections can be drawn from the pipe to the house connection level, with a line across the top (a T). The full width the T can be specified by the user.

\[
\begin{align*}
\text{draw\_house\_connections} & \quad \text{yes/no} \\
\text{house\_connection\_width} & \quad \text{value}
\end{align*}
\]

The lot name for the house connection and the connection type can be labelled above the house connection. The house connection label is made up as:

\[
\begin{align*}
\text{connection\_pre\_text} & \quad \text{lot\_name} & \quad \text{connection\_mid\_text} & \quad \text{connection\_type} & \quad \text{connection\_post\_text}
\end{align*}
\]

where lot\_name and connection\_type are stored with the house connection on the drainage
The parameters controlling the drawing of the house connection label are

- **house_connection_mode**: 0 // don’t label the house connection
  1 // label the house connection with name
     // and type(default)
  2 // label the house connection with name only
- **connection_pre_text**: text // default " "
- **connection_mid_text**: text // default " "
- **connection_post_text**: text // default " "
- **connection_text_colour**: colour // colour of connection label
- **connection_text_size**: mm // size of connection label
- **connection_textstyle**: textstyle // textstyle connection label
- **connection_text_x**: mm // x adjustment to position of text - def 0
- **connection_text_y**: mm // y adjustment to position of text - def 0
- **connection_text_justify**: text // default is Bottom_left
- **connection_text_angle**: value // default vertical 90
- **connection_text_position**: 1 // above point height value
  3 // above top of boxes
  4 // above highest point
  100 // to primary string
  101 // to first found tin

**Label connection type:**

(this is used when the house_connection_mode is turned off, only the connection type is labelled)

- **house_connection_type_mode**: 0 // default, don’t label connection type
  1 // label connection type
- **connection_type_text_x**: mm // x adjustment to position of text - def 0
- **connection_type_text_y**: mm // y adjustment to position of text - def 0
- **connection_type_pre_text**: text // text before type - def " "
- **connection_type_post_text**: text // text after type - def " "
- **connection_type_text_style**: text // def box_text_size
- **connection_type_text_colour**: colour // def box_text_colour
- **connection_type_textstyle**: text //
- **connection_type_text_justify**: text //
- **connection_type_text_angle**: value // def vertical 90
- **connection_type_text_position**: 1 // above point height value - default
  3 // above top of boxes
  4 // above highest point
  100 // to primary string
  101 // to first found tin

**Label the distance from the down stream pit to the house connection**

- **house_connection_ds_pit_mode**: 0 // default, don’t label chainage
  1 // label from down stream
  2 // label from up stream
  3 // label from left
  4 // label from right
- **connection_ds_pit_text_x**: mm // x adjustment to position of text
- **connection_ds_pit_text_y**: mm // y adjustment to position of text
- **connection_ds_pit_text_style**: text // ("" ) text before type
- **connection_ds_pit_text_post**: text // ("" ) text after type
- **connection_ds_pit_text_size**: mm // def box_text_size
- **connection_ds_pit_text_colour**: colour //def (box_text_colour
- **connection_ds_pit_textstyle**: text //
connection_ds_pit_text_justify = text // default Bottom_Left
connection_ds_pit_text_angle = value // default is vertical (90)
connection_ds_pit_text_position = 1 // above point height value - default
connection_ds_pit_text_position = 3 // above top of boxes
connection_ds_pit_text_position = 4 // above highest point
connection_ds_pit_text_position = 100 // to primary string
connection_ds_pit_text_position = 101 // to first found tin
connection_ds_pit_decimals = value // def number_of_decimals

Label the connection depth from the finished surface:

house_connection_depth_mode = 1 //default, label house connection depth
house_connection_depth_mode = 0 // don’t label house connection depth
connection_depth_text_x = mm // x adjustment to position of text - def 0
connection_depth_text_y = mm // y adjustment to position of text - def 0
connection_depth_pre_text = text // text before type - def " "
connection_depth_post_text = text // text after type - def " "
connection_depth_text_size = mm // default box_text_size
connection_depth_text_colour = colour // default box_text_colour
connection_depth_textstyle = text //
connection_depth_text_justify = text // default Bottom_left
connection_depth_text_angle = value // def is vertical (90)
connection_depth_text_position = 1 // above point height value - default
connection_depth_text_position = 3 // above top of boxes
connection_depth_text_position = 4 // above highest point
connection_depth_text_position = 100 // to primary string
connection_depth_text_position = 101 // to first found tin
connection_depth_decimals = value // default number_of_decimals

Label the finished surface:

house_connection_fs_mode = 1 //default, label house connection finished
house_connection_fs_mode = 0 // don’t label house con finished surface
connection_fs_text_x = mm // x adjustment to position of text - def 0
connection_fs_text_y = mm // y adjustment to position of text - def 0
connection_fs_pre_text = text // text before type - def " "
connection_fs_post_text = text // text after type - def " "
connection_fs_text_size = mm // default box_text_size
connection_fs_text_colour = colour // default box_text_colour
connection_fs_textstyle = text //
connection_fs_text_justify = text // default Bottom_left
connection_fs_text_angle = value // def is vertical (90)
connection_fs_text_position = 1 // above point height value - default
connection_fs_text_position = 3 // above top of boxes
connection_fs_text_position = 4 // above highest point
connection_fs_text_position = 100 // to primary string
connection_fs_text_position = 101 // to first found tin
connection_fs_decimals = value // default number_of_decimals

The invert level of the house connection can also be plotted. The house connection invert level label is made up as:

The invert level of the house connection can also be plotted. The house connection invert level label is made up as:

\[ \text{invert level} \text{ label} = \]
connection_il_pre_text  connection_invert_level  connection_il_post_text

The parameters controlling the drawing of the house connection invert level label are:

- **house_connection_il_mode**
  - 1 // default, label the house connection il
  - 0 // don’t label the house connection il

- **connection_il_text_position**
  - 1 // above point height value - default
  - 3 // above top of boxes
  - 4 // above highest point
  - 100 // to primary string
  - 101 // to first found tin

- **connection_il_text_x** mm // x adjustment to position of text - def 0
- **connection_il_text_y** mm // y adjustment to position of text - def 0
- **connection_text_gap** mm // distance from connection label and il label
- **connection_il_decimals** integer // def -3, number of decimal places in il value
  - >0 drop trailing zeros after decimal point
  - < 0 keep trailing zeros

- **connection_il_pre_text** text // default " ", text before type
- **connection_il_post_text** text // default " ", text after type
- **connection_il_text_colour** colour // colour of connection il - def box_text_colour
- **connection_il_text_size** mm // size of connection il - def box_text_size
- **connection_il_textstyle** textstyle // textstyle connection il
- **connection_il_text_justify** text //
- **connection_il_text_angle** value // (vertical 90)

---

**22.9.2.1.20 Symbols at Property Controls**

**NOTE** - property controls and house connections are only accessible by the **Sewer module**.

The position of the property controls can be drawn as circles (which will display as an oval depending on the vertical exaggeration) with the diameter of the property control.

- **draw_property_controls** yes/no

The position of the property control can also be indicated by placing a symbol at the property control.

The position of the property control at the drainage string can be labelled with symbols. There
can be up to twenty (20) sets of property control symbols.

- **property_control_symbol_n_mode**: 0 // cross
- 1 // up from centre of box
- 2 // up and down from centre of box
- 3 // square
- 4 // triangle, base at bottom
- 5 // circle
- 6 // use a 12d symbol

For example:

- `property_control_symbol_1_position` 0 // at bottom (invert) of property control
- `property_control_symbol_1_mode` 6 // use 12d symbol
- `property_control_symbol_1__style` "shrub" // name of 12d symbol
- `property_control_symbol_1_size` 1
- `property_control_symbol_1_x` 0
- `property_control_symbol_1_y` 0

### 22.9.2.1.21 Labelling Property Controls

**NOTE** - property controls and house connections are only accessible by the **Sewer module**.

The property control can be labelled with its name where the property control is at the drainage string. The property control name label is made up as:

- **property_control_pre_text**
- **property_control_name**
- **property_control_pre_post_text**

where **property_control_name** is the stored with the property control on the drainage string.

The parameters controlling the labelling the property control are

- **property_control_mode**: 0 // don’t label the property control with name
- 1 // label the property control with name
- **property_control_pre_text**
- **property_control_post_text**
- **property_control_text_colour**
- **property_control_text_size**
- **property_control_textstyle**
- **property_control_text_x**
- **property_control_text_y**
- **property_control_text_justify** // default is Bottom_left
Chapter 22  Drainage and Sewer

Drainage Plots

property_control_text_angle  value  // default vertical 90
property_control_text_position  1  // above pc centre height value
3  // above top of boxes
4  // above highest point
100  // to primary string
101  // to first found tin

Label the distance from the downstream pit to the property control:

property_control_ds_pit_mode  0  // default, don’t label chainage
1  // label from downstream
2  // label from upstream
3  // label from left
4  // label from right

property_control_ds_pit_text_x  mm  // x adjustment to position of text
property_control_ds_pit_text_y  mm  // y adjustment to position of text
property_control_ds_pit_pre_text  text  // ("" ) text before type
property_control_ds_pit_post_text  text  // ("" ) text after type
property_control_ds_pit_text_size  mm  // def box_text_size
property_control_ds_pit_text_colour  colour  // def (box_text_colour
property_control_ds_pit_textstyle  text  //
property_control_ds_pit_text_justify  text  // default Bottom_Left
property_control_ds_pit_text_angle  value  // default is vertical (90)
property_control_ds_pit_text_position  1  // above pc centre height value - default
3  // above top of boxes
4  // above highest point
100  // to primary string
101  // to first found tin

property_control_ds_pit_decimals  value  // def number_of_decimals

Label the depth from the finished surface to the invert level of the property control:

property_control_depth_mode  1  // default, label property control depth
0  // don’t label pc depth

property_control_depth_text_x  mm  // x adjustment to position of text - def 0
property_control_depth_text_y  mm  // y adjustment to position of text - def 0
property_control_depth_pre_text  text  // text before type - def " "
property_control_depth_post_text  text  // text after type - def " "
property_control_depth_text_size  mm  // def box_text_size
property_control_depth_text_colour  colour  // def box_text_colour
property_control_depth_textstyle  text  //
property_control_depth_justify  text  // default Bottom_Left
property_control_depth_angle  value  // default is vertical (90)
property_control_depth_position  1  // above pc centre height value - default
3  // above top of boxes
4  // above highest point
100  // to primary string
101  // to first found tin

property_control_depth_decimals  value  // def number_of_decimals

Label the finished surface:

property_control_fs_mode  1  // default, label pc finished surface
0  // don’t label pc finished surface

property_control_fs_text_x  mm  // x adjustment to position of text - def 0
property_control_fs_text_y  mm  // y adjustment to position of text - def 0
property_control_fs_pre_text  text  // text before type - def " "
property_control_fs_post_text  text  // text after type - def " "
property_control_fs_text_size  mm  // def box_text_size
property_control_fs_text_colour  colour  // def box_text_colour

Drainage Plots
The invert level of the property control at the drainage string can also be plotted. The property control invert level label is made up as:

property_control_il_pre_text  property_control_invert_level  property_control_il_post_text

The parameters controlling the drawing of the property control invert level label are:

property_control_il_mode  1  // default, label the pc il
                          0  // don’t label the pc il
property_control_il_text_position  1  // above pc centre height value - default
                                    3  // above top of boxes
                                    4  // above highest point
                                    100 // to primary string
                                    101 // to first found tin
property_control_il_text_x  mm  // x adjustment to position of text - def 0
property_control_il_text_y  mm  // y adjustment to position of text - def 0
property_control_text_gap  mm  // distance from pc name label and il label
property_control_il_decimals  integer  // def -3, number of decimal places in il value
                                    // >0 drop trailing zeros after decimal point
                                    // < 0 keep trailing zeros
property_control_il_pre_text  text  // default " ", text before type
property_control_il_post_text  text  // default " ", text after type
property_control_il_text_colour  colour  // colour of pc il - def box_text_colour
property_control_il_text_size  mm  // size of pc il - def box_text_size
property_control_il_textstyle  textstyle  // textstyle pc il
property_control_il_text_justify  text  //
property_control_il_text_angle  value  // (vertical 90)
22.9.2.1.22 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

- **hatch_original_tin_n** (tin_name) // tin_name for original surface
- **hatch_new_tin_n** (tin_name) // tin_name for final surface
- **hatch_cut_separation_n** (mm) // distance between cut hatch lines
  - 0 // don't do cut hatching
- **hatch_cut_angle_n** (degrees) // angle in degrees of cut hatching
- **hatch_cut_colour_n** (colour) // colour of the cut hatching
- **hatch_cut_linestyle_n** (linestyle) // linestyle for cut hatching
- **hatch_cut_draw_sides_n** 1/0 // 1 = draw sides of cut regions
- **hatch_cut_draw_original_n** 1/0 // 1 = draw original tin in cut regions
- **hatch_cut_draw_new_n** 1/0 // 1 = draw new tin in cut regions
- **hatch_fill_separation_n** (mm) // distance between fill hatch line
  - 0 // don't do fill hatching
- **hatch_fill_angle_n** (degrees) // angle in degrees of fill hatching
- **hatch_fill_colour_n** (colour) // colour of the fill hatching
- **hatch_fill_linestyle_n** (linestyle) // linestyle for fill hatching
- **hatch_fill_draw_sides_n** 1/0 // 1 = draw sides of fill regions
- **hatch_fill_draw_original_n** 1/0 // 1 = draw original tin in fill regions
- **hatch_fill_draw_new_n** 1/0 // 1 = draw new tin in fill regions

**Notes**

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting hatch_cut_separation_n to 0.0.
fill hatching is turned off by setting hatch_fill_separation_n to 0.0.
22.9.2.1.23 Labelling Cuts of Drainage Through Strings in a Model

The cuts that the drainage string makes though any strings in user given models can be automatically labelled on the long section plots.

The height, chainage and name of the cut string can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the
(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

Text justification refers to the actual position and is given by

```
“top-left”  “top-centre”  “top-right”
“middle-left”  “middle-centre”  “middle-right”
“bottom-left”  “bottom-centre”  “bottom-right”
```

A choice of six special symbols and/or or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

```
+  |  |
```

Up to twenty five (25) separate models of strings can be cut and labelled.
22.9.2.1.24 Parameters for Labelling Where the Drainage Line Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the model which contains the strings, and then a name mask which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the n’th set (where n can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

- **cuts_n_model**
  - model_name // model of strings to be cut

The selection of the strings from the model model_name whose cut points are to be labelled is all the strings whose name satisfies the name mask cuts_n_mask:

- **cuts_n_mask**
  - name_mask // strings to check for cuts
  // and if a cut occurs,
  // parameters show how to
  // label the cut

where name_mask is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

- cuts_1_mask "ke*"
- cuts_1_mask "?bank*"

or, if both masks are required,

- cuts_1_mask "ke* ?bank*"

If cuts_n_mask is missing, then all strings in the model are used. This is equivalent to name_mask being ".*

All strings in the model cuts_n_model whose name satisfy the name mask cuts_n_mask are then checked for cuts with the drainage strings, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the n’th set.

The parameters for drawing a symbol at the cut points are

- **cuts_symbol_n_mode**
  - 0 // cross
  - 1 // up from centre of box
  - 2 // up and down from centre of box
  - 3 // square
  - 4 // triangle, base at bottom
  - 5 // circle
  - 6 // use a 12d symbol

If cuts_symbol_n_mode is 6, then the 12d symbol is given by

- **cuts_symbol_n_style**
  - plotsymbol // 12d symbol to draw at cut

**Important Note**

The plot symbol of name plotsymbol is defined in the file given by:
Drainage Plots

(a) the parameter `plot_symbols` in the ppf file

```
plot_symbols filename
```

**or if `plot_symbols` is not defined**, then

(b) in the file pointed to by the environment variable `PLOT_SYMBOLS_4D`

```
PLOT_SYMBOLS_4D filename // default plotsym.4d
```

**or if `PLOT_SYMBOLS_4D` is not defined**, then

(c) in the file `plotsym.4d`

which is searched for in the standard set up file sequence

**If none of the above files are defined**, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable `SYMBOLS_4D`

```
SYMBOLS_4D filename // default symbols.4d
```

or if the environment variable `SYMBOLS_4D` does not exist, in the file, `symbols.4d`

The position of the symbol or plot symbol is given by:

```
cuts_symbol_n_position 1 // above point height value
3 // above top of boxes
100 // to primary string
101-500 // to tin1 or tin2, etc.
```

The symbol can be adjusted by the parameters:

```
cuts_symbol_n_x mm // offset adjustment to position
cuts_symbol_n_y mm // height adjustment to position
cuts_symbol_n_angle degrees // rotation about point
cuts_symbol_n_colour colour // colour of symbol
```

and for all values of `cuts_symbol_n_mode `other than 6:

```
cuts_symbol_n_size mm // size of symbol, 0 don't draw
```

The value of the chainage of the cut string can be labelled using the parameters

```
cuts_chainage_n_position 1 // above cut strings height value
3 // above top of boxes
100 // to primary string
101-500 // to tin1 or tin2, etc.
```

```
cuts_chainage_n_x mm // chainage adjustment to position
cuts_chainage_n_y mm // height adjustment to position
cuts_chainage_n_angle degrees // rotation about point
cuts_chainage_n_size mm // size of text, 0 don't label
cuts_chainage_n_colour colour // colour of text
cuts_chainage_n_textstyle text // textstyle of text chainage
cuts_chainage_n_pre_text text // text before the chainage value
cuts_chainage_n_post_text text // text after the chainage value
cuts_chainage_n_justification justification // justification of the text
cuts_chainage_n_no_decimals integer // number of decimals in chainage
The value of a **height** at the chainage of the point can be calculated and labelled using the parameters

- `cuts_height_n_mode`  
  - `1` // use height of cut point itself  
  - `3` // use real world height of position  
  - `100` // above boxes  
  - `101-500` // height of primary string  
  - `101-500` // use height of to tin1 or tin2, etc.

- `cuts_height_n_position`  
  - `1` // at points position  
  - `3` // above top of boxes  
  - `100` // to primary string  
  - `101-500` // to tin1 or tin2, etc.

- `cuts_height_n_x`  
  - `mm` // chainage adjustment to position

- `cuts_height_n_y`  
  - `mm` // height adjustment to position

- `cuts_height_n_angle`  
  - `degrees` // rotation about point

- `cuts_height_n_size`  
  - `mm` // size of text, 0 don't label

- `cuts_height_n_colour`  
  - `colour` // colour of text

- `cuts_height_n_textstyle`  
  - `text` // textstyle of text height

- `cuts_height_n_pre_text`  
  - `text` // text before the height value

- `cuts_height_n_post_text`  
  - `text` // text after the height value

- `cuts_height_n_justification`  
  - `justification` // justification of the text

- `cuts_height_n_no_decimals`  
  - `integer` // number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters

- `cuts_label_n_position`  
  - `1` // above cut strings height value  
  - `3` // above top of boxes  
  - `100` // to primary string  
  - `101-500` // to tin1 or tin2, etc.

- `cuts_label_n_mode`  
  - `0` // don't include cut string name  
  - `1` // include cut string name in label

- `cuts_label_n_x`  
  - `mm` // chainage adjustment to position

- `cuts_label_n_y`  
  - `mm` // height adjustment to position

- `cuts_label_n_angle`  
  - `degrees` // rotation about point

- `cuts_label_n_size`  
  - `mm` // size of text, 0 don't label

- `cuts_label_n_colour`  
  - `colour` // colour of text

- `cuts_label_n_textstyle`  
  - `text` // textstyle of text label

- `cuts_label_n_pre_text`  
  - `text` // text before the string name

- `cuts_label_n_post_text`  
  - `text` // text after the string name

- `cuts_label_n_justification`  
  - `justification` // justification of the text
The cut point can be labelled with **chainage** of the cut point
**height** of the cut point
**height** of the x-section or tins at this offset
**name** of the string for the cut point

Any 12d symbol can be drawn at the cut point
the cut point
22.9.2.1.25 Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter plot_border.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_border</td>
<td>yes/no // yes plots a standard title block</td>
</tr>
<tr>
<td>title_1</td>
<td>text</td>
</tr>
<tr>
<td>title_2</td>
<td>text</td>
</tr>
<tr>
<td>title_text_size</td>
<td>value</td>
</tr>
<tr>
<td>title_colour</td>
<td>colour</td>
</tr>
</tbody>
</table>

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of chapter Advanced Plotting.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The plot_border parameter should also be set to no so that the standard title block is not also drawn.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>use_title_file</td>
<td>yes/no // yes draws the title block given in title_file</td>
</tr>
<tr>
<td>title_file</td>
<td>filename</td>
</tr>
<tr>
<td>plot_border</td>
<td>no // turn off standard title block</td>
</tr>
</tbody>
</table>

Some special plot parameters are used to pass information down to variables in a user defined title block.

For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_text_n</td>
<td>text</td>
</tr>
</tbody>
</table>

The special plot parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time_format</td>
<td>text // format for $time</td>
</tr>
<tr>
<td>user_text_n</td>
<td>text // where n = 1,2,... 1000</td>
</tr>
<tr>
<td>title_1</td>
<td>text // passed down to $title_1</td>
</tr>
<tr>
<td>title_2</td>
<td>text // passed down to $title_2</td>
</tr>
<tr>
<td>start_page_number</td>
<td>integer // used as the starting value for $page_number. If missing, $page_number starts at 1.</td>
</tr>
<tr>
<td>start_drawing_number</td>
<td>integer // added to $drawing_number in title block file. If missing, $drawing_number starts at 1.</td>
</tr>
<tr>
<td>drawing_number_prefix</td>
<td>text // passed down to $drawing_number_prefix</td>
</tr>
<tr>
<td>drawing_number_postfix</td>
<td>text // passed down to $drawing_number_postfix</td>
</tr>
</tbody>
</table>
### 22.9.2.1.26 Parameters that Modify Fields In the Plot Drainage Network Panel

A number of parameters match those in the plot drainage network panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for the parameter.

The plot parameters that also occur in the plot drainage network panel are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>network_model</td>
<td>text</td>
</tr>
<tr>
<td>scale</td>
<td>value</td>
</tr>
<tr>
<td>plotter_type</td>
<td>text</td>
</tr>
<tr>
<td>plot_stem</td>
<td>text</td>
</tr>
<tr>
<td>view_name</td>
<td>text</td>
</tr>
<tr>
<td>sheet_size</td>
<td>text or &quot;width height&quot;</td>
</tr>
<tr>
<td>plot_height</td>
<td>mm</td>
</tr>
<tr>
<td>x_origin</td>
<td>mm</td>
</tr>
<tr>
<td>y_origin</td>
<td>mm</td>
</tr>
<tr>
<td>global_textstyle</td>
<td>textstyle</td>
</tr>
<tr>
<td>box_text_size</td>
<td>mm</td>
</tr>
<tr>
<td>box_colour</td>
<td>colour</td>
</tr>
<tr>
<td>plot_border</td>
<td>yes/no</td>
</tr>
<tr>
<td>title_1</td>
<td>text</td>
</tr>
<tr>
<td>title_2</td>
<td>text</td>
</tr>
<tr>
<td>title_text_size</td>
<td>value</td>
</tr>
<tr>
<td>title_text_colour</td>
<td>colour</td>
</tr>
<tr>
<td>use_title_file</td>
<td>yes/no</td>
</tr>
<tr>
<td>title_file</td>
<td>filename</td>
</tr>
</tbody>
</table>
22.9.3 Melbourne Water

**Position of menu:** Design => Drainage-Sewer => Plots => Melbourne Water

The Melbourne Water option is used to generate the longsection plots for all lines in a drainage network to the Melbourne Water sewer standards.

Given the plot sheet size and the horizontal and vertical scales, the longsections for the drainage lines are plotted starting at the top of the sheet and moving across the sheet. Once one row is full, if there is room the plot moves down the page and begins a new row. When a plot sheet is full, a new plot sheet is automatically begun.

Hence the drainage lines are plotted one after another on one or more plotter sheets.

The drainage lines are plotted in string name alphabetical order.

The drainage longsection plot includes:

- the manholes, drainage pipe and any house connections
- the height of the natural surface at the manhole
- manhole names and cover types
- distances between manholes
- the invert depth of the pipe on either side of a manhole
- the grades and types of the pipes
- any services in the corridor - including their name, invert level and distance from the nearest downstream manhole

After selecting the Melbourne Water option, the Melb plot drainage network panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot parameters</td>
<td>input</td>
<td></td>
<td>file of plot parameters used for extra control of the long section plot.</td>
</tr>
<tr>
<td>Plotter type</td>
<td>input</td>
<td>hp</td>
<td>hp, dxf, postscript, etc.</td>
</tr>
<tr>
<td>Network model</td>
<td>input</td>
<td></td>
<td>the model containing all the drainage lines for the network.</td>
</tr>
<tr>
<td>Section view</td>
<td>input</td>
<td></td>
<td>the section view to be used to define the vertical exaggeration, corridor widths, tins to section through, services models to section, etc.</td>
</tr>
<tr>
<td>Plot file stem</td>
<td>input</td>
<td></td>
<td>since more than one plot page may be produced, the plot file names are constructed from the stem plus a plot page sequence number, followed by the appropriate plotter type ending.</td>
</tr>
<tr>
<td>Scale 1:</td>
<td>input</td>
<td></td>
<td>horizontal scale for plotting the drainage long section. The vertical exaggeration is taken from the section view given in the section view field.</td>
</tr>
<tr>
<td>Sheet size wd ht (mm)</td>
<td>input</td>
<td></td>
<td>available sheet sizes</td>
</tr>
<tr>
<td>X origin (mm)</td>
<td>input</td>
<td></td>
<td>the width and height values (separated by space) or the name of a user defined sheet size.</td>
</tr>
<tr>
<td>X origin (mm)</td>
<td>input</td>
<td></td>
<td>the x position on the plot sheet for the bottom left hand corner of the long section plots.</td>
</tr>
</tbody>
</table>
Y origin (mm)  input  
the y position on the plot sheet for the bottom left hand corner of the longsection plots.

Drainage line ht (mm)  input  boxes  boxes, centreline  
the maximum allowable height for a longsection plot for a drainage line. Datum breaks are applied to any part of the longsection that will not fit into the drainage line ht.

Box text size (mm)  input  3  
size (in millimetres) to plot the chainages, heights, etc. in the boxes in the plots of the drainage longsections

Box colour  input  cyan  available colours  
colour used for the text and the boxes.

Plot  button  
plot the drainage longsections for the drainage lines in the model given in the network model field.

The fields and buttons in title tab are:

Use title file  tick box  
if tick, a user defined title block file is used.

Standard Title  tick box  tick  
if tick, the standard 12d Model border and two lines of title are placed on the bottom of the plot

Title file  input *.tf  
if non-blank and use title file is set to tick, then the file given in this field is used to generate a user defined title block for the plot.

Title line 1/2  input  first/second line of title information

Title height (mm)  input  5  
height (in millimetres) to draw the characters in the two lines of title information.

Title colour  input  cyan  available colours  
colour used for the border and the title information.

Please continue to the next section Melbourne Water Plot Parameter File.

22.9.3.1 Melbourne Water Plot Parameter File

The Melbourne Water plot option is used to make special long section plots for a network of new drainage strings to Melbourne Water sewer standards. Some of the look of the long section plot can be controlled from the Melb plot drainage network panel itself, however a wider selection of control parameters is available by using a Melbourne Water long plot, plot parameter file. Because the Melbourne Water format is so fixed, most of the parameter have sensible default values and can be left out. However, for completeness, all the parameters are given.

The Melbourne Water Sewer (MWS) long section plot parameters are placed in a file with ending .ppf. Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the Melbourne Water sewer long section plot is enclosed within a
set of curly brackets \{ \} with the header

```plaintext
melb_water_sewer_long_plot "plot set name"
```

before the curly brackets.

That is,

```plaintext
melb_water_sewer_long_plot "plot set name" {
  plot parameters
  one per line
}
```

If there is more than one `melb_water_sewer_long_plot` parameter set in the file, only the first set is used.

There may also be parameter sets for other plot types such as `section_x_plot` in the same file. The other sets will be ignored when doing a Melbourne Water long section plot.

The plot parameters are documented in following groups:

For the **Plot Sheet layout**, please continue to the section **Plot Sheet Layout**.
- Chainages, staggering and uprights, please continue to the section **Chainages, Staggering and Uprights**.
- Boxes area, please continue to the section **Boxes Area**.
- Datum area, please continue to the section **Datum Value**.
- Arrows area, please continue to the section **Arrow Areas**.
- Graph area parameters, please continue to the section **Graph Area**.
- Top area parameters, please continue to the section **Top Area**.
- Manhole parameters, please continue to the section **Manholes**.
- Junctions parameters, please continue to the section **Junctions**.
- Services parameters, please continue to the section **Services**.
- Property controls and house connection parameters, please continue to the section **Property Controls and House Connections**.
- Symbols at manhole parameters, please continue to the section **Symbols at Manholes**.
- Hatching cut and fill parameters, please continue to the section **Hatching Cut and Fill Areas**.
- Labelling cuts parameters, please continue to the section **Labelling Cuts of Drainage Through Strings in a Model**.
- Title block parameters, please continue to the section **Title Block Information**.
- Panel modifying parameters, please continue to the section **Parameters that Modify Fields In the Melbourne Water Network Panel**.

### 22.9.3.1.1 Plot Sheet Layout

The plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```plaintext
sheet_size text // sheet name, or
"mm mm" // sheet: width height
```

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable

```plaintext
SHEET_SIZES_4D file // file of plotter sheets sizes
```

The Melbourne Water long section plot will break an individual plot up if it doesn't fit across the sheet. There can be one or more rows of plot on the same sheet.
The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

When a sheet is full, a follow on sheet is created.

As soon as one drainage string is completed, the next drainage string in the network model is plotted beginning on the same row as the previous drainage string and with a horizontal gap of size horizontal_plot_gap between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

The position of the left hand bottom corner of the first plot in the bottom row is given by the parameters, x_origin and y_origin.

If there are two or more rows of plots, the position of the first plot in each row is given by adding multiples of the plot_height to the y_origin.

network_model text // model of sewer strings
x_origin mm // Position of the left hand bottom
y_origin mm // corner of first plot in the bottom row.
only_one_line 0 // more than one row on a sheet
1 // only one row of plot on a sheet
plot_height mm // total height of a plot row.
// It includes the vertical_plot_gap.
horizontal_plot_gap mm // gap between plots on same row
vertical_plot_gap mm // gap between rows of plots

A textstyle can be specified which is used for all the text in the plot.

global_textstyle textstyle //used for all plot text

The Melbourne Water long plot itself consists of nine areas. From the bottom up, they are boxes, arrow 1, bottom stagger, arrow 2, graph, arrow 3, top stagger, arrow 4, top.

The boxes area is where the chainages and various values for the drainage strings are labelled. The arrow 1 area is for drawing arrows where the arrows go between the staggered uprights and below the graph area. The datum line is at the bottom of the arrow 1 area.

The bottom stagger area is where the upright line staggers occur before going up from the boxes area to the graph area.

The arrow 2 area is for drawing arrows below the graph but where the arrows go between non-staggered uprights.

The graph area is the area where the actual plots of the strings are drawn. The arrow 3 area is for drawing arrows above the graph area and where the arrows go between non-staggered uprights.

The top stagger area is where the upright line staggers occur above the graph area.

The arrow 4 area is for drawing arrows where the arrows go between the staggered uprights and above the graph area.

The top area is an annotation area above the arrow 4 area and is used for manhole names, junctions, deflection angles, etc.

Although the arrow areas exist, the Melbourne Water plot does not have any arrows in them.
22.9.3.1.2 Chainages, Staggering and Uprights

All of the labelling of the Melbourne Water sewer plot is done at the chainages of the manholes on the drainage line. For example, the invert levels, depths and natural surface of pipes at a manhole are all labelled at the chainage of the manhole.

The labels for these values are done at an angle of zero degrees rather than ninety degrees for the sewer plots.

Uprights, or leader lines, are drawn from the values at the bottom of the plot to the manhole in the graph area.

If the text values are placed at the real chainage positions at the bottom of the plot, text over writing can easily occur if the chainages are very close together.

To prevent such over writing, the text can be staggered. That is, if the text is going to over write a previous text value, the next text value is actually moved along until there is no over writing.

Since the text is no longer at the correct chainage position, the uprights to the manholes and services start at the text position and then bend back to the correct chainage position on the plot. The region where the bending occurs is called the stagger area.

For the Melbourne Water plot, there is an area below the graph where the uprights bend backwards from the staggered text position to the real chainage position (bottom stagger area). And there is a second area above the graph where the uprights bend forwards from the real chainage position to the staggered text position (top stagger area).

Hence annotation above the top stagger area will line up with the staggered values below the bottom stagger area.

The stagger area below the graph area is defined by

- \( \text{stagger\_height\_1 mm} \) // distance from the top of \( \text{arrow\_area\_1} \)
- \( \text{stagger\_height\_2 mm} \) // distance over which stagger occurs
- \( \text{stagger\_gap\_bottom mm} \) // distance from end of staggers to the bottom of \( \text{arrow\_area\_2} \)

The stagger area above the graph area is defined

- \( \text{stagger\_gap\_top mm} \) // distance from the top of \( \text{arrow\_area\_3} \)
- \( \text{stagger\_height\_3 mm} \) // distance over which stagger occurs
- \( \text{stagger\_height\_4 mm} \) // distance from end of staggers to the bottom of \( \text{arrow\_area\_4} \)

The distance to be left for text to avoid over writing is:

- \( \text{horizontal\_text\_gap mm} \) // minimum distance to leave for text after manhole values
- \( \text{services\_text\_gap mm} \) // minimum distance to leave for text after service values

When staggering occurs, it is possible for the values area to be longer than the graph area.

The colour of the uprights that are drawn from the text to the manholes is given by:

- \( \text{manhole\_line\_colour colour} \) // colour of uprights to the manholes
22.9.3.1.3 Boxes Area

The drainage string values invert level, depth to invert and surface level can be labelled in the Melbourne Water plot with one line of title, and the actual values given at the chainage of each manhole in the drainage string.

The title or label for the strings, is drawn in the labels area of the boxes area and the values are drawn in the values area of the boxes area.

Consequently the boxes area is made up of rows of text consisting of:

labels followed by the values along the string.

Thus the boxes area is built up as a series of individual boxes and the boxes area is made up of two areas side by side - the labels area and the values area.

The order of the boxes from the bottom up is

(a) chainage values 
(b) upstream and downstream depth to inverts 
(c) upstream and downstream invert levels 
(d) natural surface heights

The label text size and colour are specified by

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_title_text_size</td>
<td>size of label text in boxes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_text_colour</td>
<td>colour of label text in boxes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The width of the label box is given by the box_width parameter and the height of each box is given by box_height.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_width</td>
<td>width of the label boxes.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>box_height</td>
<td>height of each box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The label text for each box can be set by

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_title_chainage_name</td>
<td>label for chainages box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_surface_name</td>
<td>label for the sewer ns values</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_invert_name</td>
<td>label for the invert levels</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_depth_name</td>
<td>label for depth of inverts</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For the Melbourne Water plots, there are also additional parameters for special Melbourne Water labels. They are

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_title_item_name</td>
<td>label for item line</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_d_and_g_name</td>
<td>label for diameter and grade</td>
<td></td>
<td></td>
</tr>
<tr>
<td>plot_title_detail_name</td>
<td>label for detail line at top of plot</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The pipe type can also be included with the diameter and grade values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>label_pipe_type</td>
<td>yes/no</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The labels area for the left plot in the bottom row starts at the co-ordinate (x_origin,y_origin) and each row is begun by adding the distance plot_height to the y_origin.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>x_origin</td>
<td>x coord of bottom lh corner of bot row</td>
<td></td>
<td></td>
</tr>
<tr>
<td>y_origin</td>
<td>y coord of bottom lh corner of bot row</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The values area starts at the end of the label area.

As for the label boxes, the height of each individual box area is given by the box_height parameter.

The width of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_text_size</td>
<td>size of value text</td>
<td></td>
<td></td>
</tr>
<tr>
<td>box_text_colour</td>
<td>colour of values in boxes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The colour of the box line work is given by:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_colour</td>
<td>colour of the lines in the boxes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The total height of the boxes area is simply given by number of boxes drawn multiplied by the height of one box).

The total width of the boxes area is the width of the labels area plus the width of the values area which depends on the amount of staggering that occurs.

### 22.9.3.1.4 Datum Value

The datum value is placed above the top of the natural surface heights box.

Since the datum value is automatically calculated to try and fit the plot vertically into the graph area, the datum value can change along the plot. When a datum change occurs, the new datum value is written on the datum line at the relevant chainage position.

The datum name, text size and colour are controlled by:

- **datum_name**
  - text
  - // text to write before the datum value

- **datum_text_size**
  - mm
  - // size of datum text and value

- **datum_colour**
  - colour
  - // colour of the datum text and line

- **datum_value_pre_text**
  - text
  - // text before the datum value

- **datum_value_post_text**
  - text
  - // text after the datum value

  // (default " m")

- **datum_value_decimals**
  - integer
  - // number of decimal places in the datum value.

  // If > 0, trailing zeros are removed.

  // If < 0, the absolute value is taken as the number of decimal places and no trailing zeros are removed.

### 22.9.3.1.5 Arrow Areas

The **arrow areas** were designed for drawing arrows between manholes and labelling them with values such as pipe slope, pipe diameter, flow, velocity and drainage line name.

These are not required for the Melbourne Water sewer plot.

However, values can still be given to defined the sizes of the arrow areas.

There are four arrow areas:

- **arrow_1_area** which is below the graph and the bottom stagger area. The arrows go between the staggered positions of the manhole chainages.

- The datum line is at the bottom of the arrow 1 area.

- **arrow_2_area** which below the graph but above the bottom stagger area. Hence the arrows go between the non-staggered chainage positions of the manholes.

- **arrow_3_area** which is above the graph but below the top stagger area. The arrows go between the non-staggered chainage positions of the manholes.

- **arrow_4_area** is above the graph and the top stagger area. The arrows go between the staggered chainage positions of the manholes.

The heights of the four areas (which can be zero) are defined by:

- **arrow_area_1**
  - mm
  - // height of arrow_1 area

- **arrow_area_2**
  - mm
  - // height of arrow_2 area

- **arrow_area_3**
  - mm
  - // height of arrow_3 area

- **arrow_area_4**
  - mm
  - // height of arrow_4 area
22.9.3.1.6 Graph Area

The graph area is the area where the actual plots of the drainage strings are drawn.

The length of the graph area is determined by the length of the drainage string to be plotted, the horizontal scale (given by scale) of the plot and the sheet width.

```
// 1:value - horizontal scale
// The vertical scale is determined by the
// horizontal scale and the vertical
// exaggeration for the section view.
```

The vertical exaggeration is taken from the section view specified for the plot by the parameter:

```
view_name  text
```

The tins to be sectioned through by the sewer strings and any service models and corridor settings for the graph area are also taken from the specified section view.

The height of the graph is calculated by subtracting the height of the other nine boxes from the plot height.

If the plot will not fit horizontally into a row on the sheet, then the plot will be broken at an appropriate manhole and the plot continued on another row.

Datum breaks at manholes are used to try and fit the plot vertically into the graph area but if the plot still cannot fit, then it will be truncated at the bottom.

The types of strings that can be drawn in the graph area of the sewer long section plot are:

(a) drainage string the strings from the network model
(b) tins sections of the drainage string through any tins on the section view.
(c) services parts of strings from any models on the section view that cut the corridor for the section view.

The colour of the strings in the plot is the actual string colour for cases (a) and (c), and the colour of the tin used for the section in case (b).

22.9.3.1.7 Top Area

The top area is an annotation area above the arrow_4_area at the top of the plot.

It can be used for manhole names, manhole types, pegs, junctions and deflection angles through manholes.

The height of the top area is given by

```
vertical_plot_gap  mm
```

// size of the top area. If it is not large enough the text will over write the plot in the row above.
22.9.3.1.8 Manholes
The manhole name, manhole type, special manhole symbol and the change of direction of the pipes going through the manhole can all be displayed at the top of the plot.

The manhole name and type are drawn first, followed by the angle of any change of direction of the pipes going through the manhole (the angle is in degrees, minutes and seconds) and finally any junction information.

The text is drawn at the distance \texttt{angled\_text\_y\_offset} above the top of the plot, \texttt{angled\_text\_x\_offset} to the right of the manhole position and each piece of information is spaced horizontally by the distance \texttt{angled\_text\_gap} to the right of the manhole name if the \texttt{angled\_text\_angle} is zero, or the distance \texttt{angled\_text\_gap} below the previous text if \texttt{angled\_text\_angle} is non-zero.

The size of the manhole names and type is given by \texttt{angle\_text\_size} and the size of the change of direction angle is given by \texttt{manhole\_angle\_text\_size}.

The symbol at the manhole is controlled by the manhole name.

\begin{verbatim}
label\_manhole\_type \hspace{1em} yes/no  // include manhole type
angled\_text\_size \hspace{1em} mm  // size of manhole name text
manhole\_angle\_text\_size \hspace{1em} mm  // size of text for change of
\hspace{1em} angle through manhole
angled\_text\_x\_offset \hspace{1em} mm  // distance of text above top of the plot
angled\_text\_y\_offset \hspace{1em} mm  // distance of text to the right of manhole
angled\_text\_gap \hspace{1em} mm  // distance of text to the right of previous
\hspace{1em} text
angled\_text\_angle \hspace{1em} value  // angle of text
angled\_text\_colour \hspace{1em} colour  // colour of text
\end{verbatim}

The symbol at the manhole is controlled by the manhole name.

\begin{verbatim}
manhole\_symbol\_n\_size \hspace{1em} mm
manhole\_symbol\_n\_colour \hspace{1em} colour
manhole\_symbol\_n\_y \hspace{1em} mm  // distance above top line
manhole\_symbol\_n\_repeats \hspace{1em} integer  // draw the symbol this
\hspace{1em} // many times with a
\hspace{1em} // decreasing size)
manhole\_line\_colour \hspace{1em} colour  // colour of line through
\hspace{1em} // manhole
\end{verbatim}

22.9.3.1.9 Junctions
Any junctions at the manhole are also labelled with the name of the lines coming into the manhole.

The junction text is made up of two lines:

\begin{verbatim}
JUNCTION LINE \hspace{1em} line\_name
angle of the junction
\end{verbatim}

The junction text is at the same height as the manhole and angle text and at a distance \texttt{angled\_text\_gap} to the right of the manhole and angle text, or a previous junction label. The size of the text is given by

\begin{verbatim}
junction\_angle\_text\_size \hspace{1em} mm
\end{verbatim}

When a junction does occur, the incoming pipe is drawn at the correct position on the manhole of the main line.
22.9.3.1.10 Services

Any services in the corridor are drawn on the plot and if the service actually cuts the drainage string, then a line is drawn to the cut point and the line labelled with the service name. The name is drawn below the cut point and is right justified.

- `service_text_size mm` // size of the text for the service name
- `service_text_x_offset mm` // adjustment to the drawing position
- `service_text_y_offset mm` // for the service name
- `service_text_colour colour` // colour of the service name
- `service_line_colour colour` // colour of the line to the cut point

22.9.3.1.11 Property Controls and House Connections

The position of the property controls can be drawn on the plot and can have a user specified diameter.

- `draw_property_controls yes/no`
- `property_control_diameter value`

The house connections can be drawn from the pipe to the house connection level, with a line across the top (a T). The full width the T can be specified by the user.

- `draw_house_connections yes/no`
- `house_connection_width value`
22.9.3.1.12 Symbols at Manholes

Manholes can be labelled with symbols which depend on the manhole type. There can be up to twenty (20) sets of manhole symbols.

- **manhole_symbol_n_type**
  - `mh_type`
  - // manhole type to have symbols

- **manhole_symbol_n_mode**
  - `0`
  - // cross
  - `1`
  - // up from centre of box
  - `2`
  - // up and down from centre of box
  - `3`
  - // square
  - `4`
  - // triangle, base at bottom
  - `5`
  - // circle
  - `6`
  - // use a 12d symbol

- **manhole_symbol_n_position**
  - `1`
  - // at top of manhole - default
  - `3`
  - // above top of boxes
  - `4`
  - // above highest point
  - `100`
  - // to primary string
  - `101`
  - // to first found tin

- **manhole_symbol_n_size**
  - `mm`
  - // size

- **manhole_symbol_n_x**
  - `mm`
  - // x adjustment to position - default 0

- **manhole_symbol_n_y**
  - `mm`
  - // y adjustment to position - default is 0

- **manhole_symbol_n_style**
  - `text`
  - // the name of the 12d symbol

- **manhole_symbol_n_angle**
  - `value`
  - // default value is 0

- **manhole_symbol_n_colour**
  - `colour`
  - //

For example:

```plaintext
manhole_symbol_1_type "CONC COVER"  // manhole type to use
manhole_symbol_1_position 1  // on top of manhole
manhole_symbol_1_mode 6  // use 12d symbol
manhole_symbol_1__style "shrub"  // name of 12d symbol
manhole_symbol_1_size 1
manhole_symbol_1_x 0
manhole_symbol_1_y 0
```
22.9.3.1.13 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

- `hatch_original_tin_n`  `tin_name` // tin_name for original surface
- `hatch_new_tin_n`  `tin_name` // tin_name for final surface
- `hatch_cut_separation_n`  `mm` // distance between cut hatch lines
- `hatch_cut_angle_n`  `degrees` // angle in degrees of cut hatching
- `hatch_cut_colour_n`  `colour` // colour of the cut hatching
- `hatch_cut_linestyle_n`  `linestyle` // linestyle for cut hatching
- `hatch_cut_draw_sides_n`  `1/0` // 1 = draw sides of cut regions
- `hatch_cut_draw_original_n`  `1/0` // 1 = draw original tin in cut regions
- `hatch_cut_draw_new_n`  `1/0` // 1 = draw new tin in cut regions
- `hatch_fill_separation_n`  `mm` // distance between fill hatch line
- `hatch_fill_angle_n`  `degrees` // angle in degrees of fill hatching
- `hatch_fill_colour_n`  `colour` // colour of the fill hatching
- `hatch_fill_linestyle_n`  `linestyle` // linestyle for fill hatching
- `hatch_fill_draw_sides_n`  `1/0` // 1 = draw sides of fill regions
- `hatch_fill_draw_original_n`  `1/0` // 1 = draw original tin in fill regions
- `hatch_fill_draw_new_n`  `1/0` // 1 = draw new tin in fill regions

Notes

(a) cut is when the new tin is below the original tin.
    fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
    fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.
22.9.3.1.14 Labelling Cuts of Drainage Through Strings in a Model

The cuts that the drainage string makes though any strings in user given models can be automatically labelled on the long section plots.

The height, chainage and name of the cut string can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the
(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:
Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

Text justification refers to the actual position and is given by
- top-left
- middle-left
- bottom-left
- top-centre
- middle-centre
- bottom-centre
- top-right
- middle-right
- bottom-right

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.
22.9.3.1.15 Parameters for Labelling Where the Drainage Line Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the model which contains the strings, and then a name mask which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the n'th set (where n can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

\[
\text{cuts}_n \_ \text{model} \quad \text{model} \_ \text{name} \quad // \text{model of strings to be cut}
\]

The selection of the strings from the model model\_name whose cut points are to be labelled is all the strings whose name satisfies the name mask cuts\_n\_mask:

\[
\text{cuts}_n \_ \text{mask} \quad \text{name} \_ \text{mask} \quad // \text{strings to check for cuts}
\]

where name\_mask is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

- cuts\_1\_mask "ke*"
- cuts\_1\_mask "?bank*"
- or, if both masks are required, cuts\_1\_mask "ke* ?bank*"

If cuts\_n\_mask is missing, then all strings in the model are used. This is equivalent to name\_mask being ***.

All strings in the model cuts\_n\_model whose name satisfy the name mask cuts\_n\_mask are then checked for cuts with the drainage strings, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the n'th set.

The parameters for drawing a symbol at the cut points are

\[
\text{cuts}_n \_ \text{symbol}_n \_ \text{mode} \quad \text{cuts}_n \_ \text{symbol}_n \_ \text{style} \quad \text{plotsymbol} \quad // \text{12d symbol to draw at cut}
\]

0 1 2 3 4 5
predefined symbols for cut\_symbol\_n\_modes 0 to 5

If cuts\_symbol\_n\_mode is 6, then the 12d symbol is given by

- cuts\_symbol\_n\_style plotsymbol // 12d symbol to draw at cut

Important Note
The plot symbol of name plotsymbol is defined in the file given by:

(a) the parameter plot_symbols in the ppf file

\[ \text{plot_symbols filename} \]

or if plotSymbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D

\[ \text{PLOT_SYMBOLS_4D filename} \] // default plotsym.4d

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file plotsym.4d

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D

\[ \text{SYMBOLS_4D filename} \] // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, symbols.4d

The position of the symbol is given by:

\[ \text{cuts_symbol_n_position 1} \] // above point height value
\[ 3 \] // above top of boxes
\[ 100 \] // to primary string
\[ 101-500 \] // to tin1 or tin2, etc.

The symbol can be adjusted by the parameters:

\[ \text{cuts_symbol_n_x mm} \] // offset adjustment to position
\[ \text{cuts_symbol_n_y mm} \] // height adjustment to position
\[ \text{cuts_symbol_n_angle degrees} \] // rotation about point
\[ \text{cuts_symbol_n_colour colour} \] // colour of symbol

and for all values of cuts_symbol_n_mode other than 6:

\[ \text{cuts_symbol_n_size mm} \] // size of symbol, 0 don't draw

The value of the chainage of the cut string can be labelled using the parameters

\[ \text{cuts_chainage_n_position 1} \] // above cut strings height value
\[ 3 \] // above top of boxes
\[ 100 \] // to primary string
\[ 101-500 \] // to tin1 or tin2, etc.

\[ \text{cuts_chainage_n_x mm} \] // chainage adjustment to position
\[ \text{cuts_chainage_n_y mm} \] // height adjustment to position
\[ \text{cuts_chainage_n_angle degrees} \] // rotation about point
\[ \text{cuts_chainage_n_size mm} \] // size of text, 0 don't label
\[ \text{cuts_chainage_n_textstyle colour} \] // colour of text
\[ \text{cuts_chainage_n_textstyle text} \] // textstyle of text chainage
\[ \text{cuts_chainage_n_pre_text text} \] // text before the chainage value
\[ \text{cuts_chainage_n_post_text text} \] // text after the chainage value
\[ \text{cuts_chainage_n_justification justification} \] // justification of the text
\[ \text{cuts_chainage_n_no_decimals integer} \] // number of decimals in chainage
The value of a height at the chainage of the point can be calculated and labelled using the parameters:

- **cuts_height_n_mode**: 1 // use height of cut point itself
- **cuts_height_n_mode**: 3 // use real world height of position
  - above boxes
- **cuts_height_n_mode**: 100 // height of primary string
- **cuts_height_n_mode**: 101-500 // use height of to tin1 or tin2, etc.

- **cuts_height_n_position**: 1 // at points position
- **cuts_height_n_position**: 3 // above top of boxes
- **cuts_height_n_position**: 100 // to primary string
- **cuts_height_n_position**: 101-500 // to tin1 or tin2, etc.

- **cuts_height_n_x**: mm // chainage adjustment to position
- **cuts_height_n_y**: mm // height adjustment to position
- **cuts_height_n_angle**: degrees // rotation about point
- **cuts_height_n_size**: mm // size of text, 0 don't label
- **cuts_height_n_colour**: colour // colour of text
- **cuts_height_n_textstyle**: text // textstyle of text height
- **cuts_height_n_pre_text**: text // text before the height value
- **cuts_height_n_post_text**: text // text after the height value
- **cuts_height_n_justification**: justification // justification of the text
- **cuts_height_n_no_decimals**: integer // number of decimals in height

A label which can include the name of the cut string is drawn by using the parameters:

- **cuts_label_n_position**: 1 // above cut strings height value
- **cuts_label_n_position**: 3 // above top of boxes
- **cuts_label_n_position**: 100 // to primary string
- **cuts_label_n_position**: 101-500 // to tin1 or tin2, etc.

- **cuts_label_n_mode**: 0 // don't include cut string name
- **cuts_label_n_mode**: 1 // include cut string name in label

- **cuts_label_n_x**: mm // chainage adjustment to position
- **cuts_label_n_y**: mm // height adjustment to position
- **cuts_label_n_angle**: degrees // rotation about point
- **cuts_label_n_size**: mm // size of text, 0 don't label
- **cuts_label_n_colour**: colour // colour of text
- **cuts_label_n_textstyle**: text // textstyle of text label
- **cuts_label_n_pre_text**: text // text before the string name
- **cuts_label_n_post_text**: text // text after the string name
- **cuts_label_n_justification**: justification // justification of the text
The cut point can be labelled with:
- **chainage** of the cut point
- **height** of the cut point
- **height** of the x-section or tins at this offset
- **name** of the string for the cut point

User defined symbols can also be drawn at the cut point.

Point where the drainage cuts a string

22.9.3.1.16 Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

**Standard Title Block**

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter plot_border.

```
plot_border      yes/no // yes plots a standard title block
                 // default yes

  title_1    text
  title_2    text
  title_text_size  value
  title_colour   colour
```

**User Title Block**

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of chapter Advanced Plotting.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The plot_border parameter should also be set to no so that the standard title block is not also drawn.

```
use_title_file  yes/no // yes draws the title block given in title_file
                 // default no

title_file      filename

plot_border      no // turn off standard title block
```

Some special plot parameters are used to pass information down to variables in a user defined title block.

For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

```
user_text_n    text
```

The special plot parameters are:

```
time_format    text // format for $time
user_text_n    text // where n = 1,2,... 1000
                 // passed down to $user_text_n

title_1        text // passed down to $title_1
title_2        text // passed down to $title_2

start_page_number   integer // used as the starting value for
                     // $page_number. If missing,
                     // $page_number starts at 1.

start_drawing_number   integer // added to $drawing_number in title
                         // block file. If missing,
                         // $drawing_number starts at 1.

drawing_number_prefix  text // passed down to
                         // $drawing_number_prefix

drawing_number_postfix text // passed down to
                         // $drawing_number_postfix
```
22.9.3.1.17 Parameters that Modify Fields In the Melbourne Water Network Panel

A number of parameters match those in the New Melb Plot Drainage Network panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for the parameter.

The plot parameters that also occur in the Melb plot drainage network panel are:

- network_model text
- scale value
- plotter_type text
- plot_stem text
- view_name text
- sheet_size text or "width height"
- plot_height mm
- x_origin mm
- y_origin mm
- global_textstyle text/style
- box_text_size mm
- box_colour colour
- plot_border yes/no
- title_1 text
- title_2 text
- title_text_size value
- title_text_colour colour
- use_title_file yes/no
- title_file filename
22.9.4 Plot Annotations

See Drainage Long Plot PPF Editor.
22.9.5 Long Plot Cut Labels and Manholes

Position of menu: Design => Drainage-Sewer => Plots => Long plot cut labels and manholes

This section of documentation is a work in progress and will be updated in subsequent releases.

Selecting Long plot cut labels and manholes brings up the Create plot manholes and cut strings panel.

The fields and buttons used in this panel have the following functions.

22.10 More Drainage

Position of menu:  Design => Drainage-Sewer => More

The More Drainage menu items contain the drainage import export routines and tools that enhance the basic drainage functions on the Drainage Sewer menu.

The More Drainage walk-right menu is:

![More Drainage Menu](image)

Frequently Asked Questions (FAQ)

Drainage Overview

The following are the basic steps from creating a urban drainage network to producing your plan/drainage longsection drawings and pit layout table. The optional catchment area models and bypass flow model will be discussed afterwards.

- Set drainage defaults
- Draw the drainage strings
- Set zero chainage to downstream end of the pipe string (Reverse drainage strings) (optional)
- Automatically assign pit names
- Define catchment areas (optional)
- Define Pit/manhole Inlet Capacities via Overland flow strings (optional)
- Hydraulic/hydrology calcs via spreadsheets, Drains, RAT2000, PCdrain, XP SWMM or ILSAX
- Drainage longsection plots
- Pit layout/construction schedules
- Manhole and Pipe Table of Quantities (summarise by type, depth and size)
- Drainage line excavation volume calculations
- Roadway flooded width calculations
Drainage Export and Import to Design Software

Copy/Paste from spreadsheets
Running Drains
Running PCdrain (Windows)
Running Micro Drainage - Win DES
Running XPSWMM
Running RAT2000

22.10.0.1 Training Course Notes

Stormwater Part 1, Stormwater Part 2 and Dynamic Stormwater Design training course notes (Adobe PDF format for printing) and sample 12d data sets are available on the Installation DVD and the 12d User Forum. The training course moves through a worked example in detail. The course notes are also included below for your reference.

Stormwater Part 1
Stormwater Part 2
Dynamic Stormwater Design
22.10.1 Drainage FAQ

What is pipe capacity?

Pipe capacity is full pipe flow with no pressurisation. The capacity figure should be used to help designers know if the friction loss in the pipe is greater or less than the pipe slope.

Case 1: Flow less than capacity....friction slope is less than pipe slope. except for maybe for pit losses, surcharging is not a problem

Case 2: Flow greater than capacity....friction slope is MORE than pipe slope. You can do this for a short length of pipe but watch out for surcharging because you cannot keep it up for too long without flooding occurring!

Why do the obvert/invert levels not change when I import data via the "pit/pipes interface"?

On the interface panel there is an Options button that displays a panel with the "hold obverts on import" option. The default is off but if it is selected the pipe obverts will not change even if import data has new levels. Note that the invert levels will change is the pipe diameters change.

Can I manually enter catchment areas in the drainage design programs?

Yes. The catchment strings are optional in 12d. If no catchment string has been linked to a manholes and there has been no manhole "area" attribute a default area of 0.0001 will be sent. When results are imported back into 12d the total areas from the design package will be saved in the manhole "area" attribute.

How do I include/exclude the hydraulic grade line on drainage longsections?

First, there must be HGL results. These may come from the 12d rational drainage design, imported from another design package (including spreadsheets) or manually entered as manhole/pipe attributes. If HGL results exists then they may be viewed in the section view of the drainage line.

Second, the HGL results may be added to the drainage longsection drawings by editing the plot parameter file (ppf) as shown below.
22.10.2 Creating Drainage Strings

Drainage strings may be created in 12d in a number of ways.

1. Import 2d strings from other drawing packages and convert them to drainage string inside 12d.
2. Draw the string in 12d using a design tin to the manhole cover levels and pipe inverts.
3. Enter the details in a spreadsheet format and paste the spreadsheet into 12d.

Regardless of the method, take the time to set your defaults before you start. You can always change the data later.
22.10.3 Set Drainage Flow Direction

Position of option on menu: **Design => Drainage-Sewer => More => Set flow directions**

The routine changes the strings drainage flow direction to either **same as string direction** or **opposite to string direction**. This setting affects the pipe grading, network connectivity and hydraulic calculations.

On selecting the **Set flow directions** option, the **Set Drainage Flow Directions** panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source of drainage strings</td>
<td>source box</td>
<td>Select the desired drainage strings</td>
<td></td>
</tr>
<tr>
<td>Flow direction</td>
<td>choice box</td>
<td>same as string direction, opposite to string direction</td>
<td></td>
</tr>
</tbody>
</table>

*all drainage strings will have this flow direction set*

<table>
<thead>
<tr>
<th>Run</th>
<th>button</th>
<th>set flow directions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Finish</td>
<td>button</td>
<td>remove the panel from the screen</td>
</tr>
</tbody>
</table>
22.10.4 Create Network from Import

Position of option on menu:  Design => Drainage-Sewer => More => Create network from import

This routine creates drainage strings from existing MicroDrainage WinDes (sws and fws) and xpsoftware xpswmm (xpx) files.

On selecting the Create network from import option, the Create Network from Import panel is displayed.

![Create Network from Import Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>File type</td>
<td>choice box</td>
<td>SWS</td>
<td>SWS, xpswmm</td>
</tr>
<tr>
<td>Drainage model</td>
<td>model box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>File to import</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- File type: choice box
  - SWS (or FWS) for WinDes files, xpstorm files are the xpsoftware xpx files

- Drainage model: model box
  - the drainage strings created will be stored in this model.

- File to import: file box
  - select sws, fws or xpx file types

- Process: button
  - create import file and create strings

- Finish: button
  - remove the panel from the screen
22.10.5 Place Points

Position of option on menu: Design => Drainage-Sewer => More => Place points

This routine creates points along a string so that drainage pits can be placed at a fixed offset from an intersection. As this is a very common task it combines several standard 12d options into one step.

The user selects a point near where the pit it to be located. The routine finds the closest string on the working view that matches the String name filter and creates a temporary point on the string.

The Mode determines a reference point located on the string and a marker of length, distance, is created from the reference point towards the temporary point.

On selecting the Place points option, the Place point on string panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>choice box</td>
<td>From curve or end</td>
<td>From curve or end, From end, Nearest point</td>
</tr>
</tbody>
</table>

if From curve or end, the reference point is closest (by chainage) end of curve or end of string
if From end, the reference point is the closest (by chainage) end of the string is located
if Nearest point, the reference point is the closest vertex to the temporary point is located

Working view view box 1
strings on this view will be searched using the string name filter. The point model will also be added to this view.

String name filter input *
the closest string on the working view matching this filter will be selected

Distance input 1
the chainage distance from the reference point to the end of the marker (note that the marker is drawn as a straight line but the distance uses the chainage value).

Point Model model box drainage points
the marker points are placed in this model using the FLOW LINE linestyle

Pick point button
select a point near where the point marker is to be created. Only the x,y value is used from the selected point

Finish button

remove the panel from the screen
22.10.6 Drainage Pit and Pipe Locks

Position of option on menu:  Design => Drainage-Sewer => More => Pipe locks

The routine locks/unlocks (sets to manual) the pit and pipe levels in a drainage network model. A function is created so that the locks can easily be applied or removed. This is often used for existing networks or by designers wishing to set all levels manually.

On selecting the Pipe locks option, the Pit and pipe locks panel is displayed.

![Drainage Locks panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>function box</td>
<td>Pipe locks</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>A function can be created to lock and unlock the drainage string properties (via attributes)</td>
</tr>
<tr>
<td>Invert action</td>
<td>choice box</td>
<td>Lock</td>
<td>Lock, Unlock, None, Default</td>
</tr>
<tr>
<td>Size action</td>
<td>choice box</td>
<td>Lock</td>
<td>Lock, Unlock, None, Default</td>
</tr>
<tr>
<td>Cover action</td>
<td>choice box</td>
<td>Manual</td>
<td>Manual, None, Default</td>
</tr>
</tbody>
</table>

Sets the pipe invert lock flags for the DNE
- if Lock, the flag is enabled
- if Unlock, the flags are cleared
- if None, the flags are left unchanged
- if Default, the flags are cleared (same as unlock)

Sets the pipe diameter, width and top width lock flags for the DNE
- if Lock, the flag is enabled
- if Unlock, the flags are cleared
- if None, the flags are left unchanged
- if Default, the flags are cleared (same as unlock)

Sets the mode for the cover levels (manual is the equivalent of locked)
if Manual, the mode is set to manual,
if None, the mode if left unchanged,
if Default, the field is cleared and the default setting becomes active

Grate action choice box Manual Manual, None, Default

Sets the mode for the grate levels (manual is the equivalent of locked)
if Manual, the mode is set to manual,
if None, the mode if left unchanged,
if Default, the field is cleared and the default setting becomes active

Drainage model model box

existing strings in this model are processed

Process button

Applies and removes the locks as indicated

Finish button

remove the panel from the screen
22.10.7 Delete All Attributes in a Model

Position of option on menu: Design => Drainage-Sewer => More => Delete All Attributes in a Model

This routine deletes all of the model, string, pit and pipe attributes in the selected model.

On selecting the Delete All Attributes in a Model option, the Delete Attributes panel is displayed.

![Delete Attributes panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

More Drainage
22.10.8 Write Inlet Curves to Model

Position of option on menu:  Design => Drainage-Sewer => More => Write inlet curves to model

This routine reads the inlet capacity curves from the drainage.4d file and creates plot strings. This tool is an efficient way to review the inlet capacity data in the file.

On selecting the Write inlet curves to model, the Drainage Inlet Curves to Model panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

</tbody>
</table>
22.10.9 Creating a drainage.4d file from the Drains database dump

Position of option on menu:  Design => Drainage-Sewer => More => Drains to drainage.4d

On selecting the Drains to drainage.4d option, the Drains to drainage.4d panel is displayed.

Key Points

When you are finished, open the drainage.4d file and check the road grade and crossfall values for the ongrade curves!

1. If Drains is used to select the pit sizes then the 12d pit type must be the prefix of the Drains pit size (Pit Name road separators are used).

   If 12d is used to select the pit sizes to export to Drains, the Drains Pit Size and 12d Pit types have to match, exactly! The pit databases supplied by Drains often have road grade and/or crossfall attached to the end of the pit size. If pit sizes are to be sent from 12d, this must be removed! Find Prepare the Drains Pit Database for more details.

2. Select Copy Drains database (12d will search the usual locations for the Drains database).

3. Review the Drains pipe types and Drains pit families lists to ensure you have the correct database.

4. 12d pit groups are not used in Version 8.

5. Pit Name road separators can only be used if Drains is selecting the pit types. If 12d pit types are to be exported to Drains, this field should be left blank. If you change these entries you must press the enter key to update the 12d pit types list below.

6. Check the 12d pit types and if they are acceptable select Create drainage.4d.
The Details

YOU MUST RESTART 12D FOR THE NEW DRAINAGE.4D FILE TO BECOME ACTIVE!

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drains database file</td>
<td>file box</td>
<td>Drains Connection Data.txt</td>
<td></td>
</tr>
</tbody>
</table>

You must update this file from Drains before each use of this panel. Inside Drains select Project=>Overflow Route database. Then select OK and then YES. This will cause Drains to export the database to the file “Drains Connection Data.txt”.

Selecting Copy Drains database will cause the panel to search for the database dump in the folders C:\Program Files\Drains\Program and C:\Program Files\Drains\Demo\Program. If the Drains program is installed in another folder then you must browse for the file. The file will be read and the panel updated with either selection.

| Drainage.4d          | file box    | drainage.4d             |                      |

The drainage.4d will be created in the 12d working folder unless otherwise specified. It will only be used for 12d projects in this folder.

| Pit families         | choice box  | Drains pit families     |                      |

These are the Drains pit families that will be exported to the drainage.4d file. These will become the names on grade inlet capacity curves for all the pit sizes that belong to the family. The pit family name will be searched for words like grade, slope etc to try to determine the values for road grade and crossfall for the 12d capacity curves.

| Pipe type            | choice box  | Drains pipe types       |                      |

These are the Drains pipe types that will be exported to the drainage.4d file.

| Pit group separator  | input box   |                      |                      |

Pit groups are not used in Version 8. These characters will be used to remove the road grade crossfall data from the Pit families above. The data before this character will become the 12d pit groups. Press Enter or select Read Drains database to create a new list of 12d pit groups.

| 12d pit groups       | choice box  | 12d pit groups         |                      |

These are created from the Pit family list above by deleting all text after the Pit group separator.

Create drainage.4d button

Create a drainage.4d file.
22.10.10 Editing a drainage.4d file

Position of option on menu: Design => Drainage-Sewer => More => Edit drainage.4d

On selecting the Edit drainage.4d option, the Edit drainage.4d panel is displayed.

Select the Find button to search the 12d path for the current drainage.4d file. Select the More info button and then Edit to edit the file.
22.10.11 Drainage IO Defaults

22.10.11.1 Set zero chainage to downstream end of line (Reversing the strings)

Position of options on menu: Design => Drainage-Sewer => More => Reverse all strings

For drainage direction of flow see Reversing the strings

If desired, the reverse function may be used to move the zero chainage to the downstream end of the line. This should be done after entering all of the drainage strings and before naming the pits. From the main menu select Design=> Drainage-sewer => More => Reverse all strings

This will also change the drainage flow direction attribute from ascending chainage to descending chainage. Leave the Increment as 1.

22.10.12.1 Spreadsheet clipboard

Spreadsheets are an effective method to manage the numerous variables urban drainage designers create in the modelling process. Spreadsheet data can be transferred to and from 12d in tab delimited files and stored within 12d as “user definable attributes”. These attributes are linked to the pit and pipes within a network. Drainage long section plots can display the pipe attributes in the “arrows” data area and pit attributes in the bubbles area. Drainage plan drawing can also show these pit and pipe attributes.

Drainage strings will be created if they do not exist in the model but pits cannot be added to existing strings.

- Spreadsheet options

22.10.12.2 12d to spreadsheet transfers

This interface is accessed the Import/Export button on the Drainage Network Editor.
22.10.12.2.1 Options

The Spreadsheet Options section allows the user to define the amount of data exported.

1. Select Spreadsheet clipboard
2. Leave as clipboard.txt to send the data to the windows clipboard as well as this file.
3. Mapping files are the most current 12d technology. Leave this selected.

These options are not used for spreadsheet export.

4. Usually leave this off! Select to export the junction pit at the end of all drainage lines (very rarely needed).
5. You may also select to limit the output if desired. If you like using spreadsheets for data entry, the PCdrain data and ILSAX data formats are useful for adding data for the first time for either program.
6. Select Run to place the data on the clipboard.

All Data: All of the 12d drainage string data and the user defined attributes will be exported to the clipboard in a tab delimited format. The 12d data names and the user defined attribute names will...
appear at the top of the spreadsheets columns.

**ILSAX:** For the ILSAX program, the spreadsheet column headings will change depending on the pipe and catchment indicators (P2 card) and the inlet type (P3 card). Therefore, use the ILSAX pipe editor macro to set up one pit/catchment for the type of data you wish to enter. Now when you export the pipe network data the column headings will include the names of the relevant parameters.

**User defined below:** The **Customised list file name** is used to define the drainage values, their order and format you desire.

The **customised list file** is a text file where each line contains a drainage variable or a spreadsheet IO command (blank lines are ignored unless preceded by the header command). The spreadsheet IO commands are all lower case and listed below:

- **header** to define a line of text to be exported
- **blank** to leave a blank column in the output
- **pit data** the following attributes are for the pit.
- **downstream pit data** the following attributes are for the downstream pit.
- **upstream pit data** the following attributes are for the upstream pit(s).
- **pipe data** the following attributes are for the pit’s outlet pipe
- **downstream pipe data** the following attributes are for the downstream pipe(s)
- **upstream pipe data** the following attributes are for the upstream pipe(s)
- **variable name** a 12d drainage variable names
- **factor** the following variable is multiplied by this factor
- **decimals** the following variable will export with these decimal places

The simplest way to create your own customised tab delimited file is to set the **Preset Output** field to **All data** and leave the **customised list file name** field blank. Selecting **Set**, **Finish** and then **Copy** from the main dialogue. The data will be placed on the clipboard and a **customised list file**, named **output_list.txt** will be created containing the names of all of the drainage variables in the 12d model. Use a text editor to add/or delete the variable names, change their order and/or add spreadsheet IO commands. **Save the file with a new name!** The **output_list.txt** file is overwritten on every export.

A listing of a customised list file follows. Note the words in the header file have a “tab” between them so that they will be spaces across the spreadsheet columns.

```plaintext
header
Pipe Details
header
Name Length U/S IL D/S IL Slope(%) Class Dia I.D. Rough Pipe Is No. Pipes
pit data
*pit name
pipe data
*length
low ch invert
high ch invert
factor
100
*grade
pipe type
factor
1000
diameter
```

After creating your customised list file, select **Options** again and change the **Preset Output** field
to **User Defined below** and enter the new **customised list file** name that you saved above. Select **Set** then **Finish** and finally **Copy** to put the formatted data onto the clipboard.

The data can be pasted into a spreadsheet program for checking or additional formatting.

**CUSTOM FORMATED DATA MIGHT NOT BE PASTED BACK INTO 12d!**

The data must be in the “12d drainage spreadsheet” format to be read into 12d.

Caution with pit names in the form 1-1 or 1/1. Some spreadsheets will interpret these values as dates. If you use these formats for your pit names you will have to paste command them in once, format the columns that contain the pits names as text data and then paste the information in again.

One final word on using the copy/paste commands in the Microsoft Excel program. The Paste Special command using the “Skip Blanks” option will allow you to copy a large block of 12d data (with blanks in it) on top your data so that your data is preserved where it coincides with the blanks. To use this option paste the data into a blank spreadsheet and then select copy again. The Paste special option with “Skip Blanks” will now be available.

**22.10.12.2.2 Spreadsheet to 12d Update and Create**

This item is accessed from the **Import/Export** button on the **Drainage Network Editor**.

The following panel will appear.
Tab delimited, "12d drainage spreadsheet" format or "from to" format data must be on the clipboard in order to update a 12d drainage model or create a new model. These format are described below.

### 22.10.12.2.3 Updating an Existing Model

The data usually is generated by 12d using the Export option, pasted into a spreadsheet and then copied back to the clipboard so that 12d can be updated.

When 12d exports the drainage model to a spreadsheet it includes a column for the unique string identifier and a unique pit identifier (unique to the drainage model not the 12d project). The names of the strings and pits may be changed via the spreadsheet if these columns are present at import time.

If the pit id column is not present, 12d will search the drainage model for a matching pit name. When the pit is a junction between drainage lines, only the trunk line will be the data updated.

### 22.10.12.2.4 Creating a New Model

It is possible to create a new string or an entire drainage network using this format. However, pits cannot be added to an existing string. The entire drainage string must be created at once. Two
formats are available, the “from-to pit” format and the “12d drainage spreadsheet” format.

At present the network editor must select a drainage string to become active. Therefore, if you
are not adding strings to a network, you will have to great a drainage network with one “dummy”
pit. Select this one “dummy” pit to activate the editor. After importing the data and the new
drainage lines are created the “dummy” pit may be deleted.

12d drainage spreadsheet Format

The top left cell in the clipboard data must be the text “12d” to specify this format. The minimum
amount of data required to create a new string is the string name, pit name, x and y coordinates. You
can add as much additional data as you have available. This would include pipe diameters inverts
etc. The pils must be listed from upstream to downstream order. If the string is to join a trunk line,
the junction pit must be included for both the tributary and the trunk line.

An example file exists called new_network.txt is supplied in the library. Open this file in a
spreadsheet or a text editor and copy it to the clipboard. Set the I/O Action to Import and select
Run. The new drainage lines will exist in the model currently being edited.

From-to Pit Format

The top left cell in the clipboard data must be the text “from to” to specify this format. The minimum
amount of data required to create a new string is the upstream pit name **pit name), the
downstream pit name (*ds pit name) and the x(x location) and y(y location) coordinates of the
upstream pit. If the string is to join a trunk line, the junction pit must be included for both the tributary
and the trunk line.

An optional column for the pit cover elev (cover elev) may be specified. Once the network has been
created additional pipe and pit data may be added using the “12d drainage spreadsheet” format
described above.

An example file exists called new_from_to_network.txt is supplied in the library. It is shown below.
Open this file in a spreadsheet or a text editor and copy it to the clipboard. Enter a new model name
in the Drainage model field and select paste. The new drainage model will now exist.

</tbody>
</table>

**Duplicate Definitions**

Strings Variables such as “direction” are may be defined for numerous pits on the same string. Searching in a top down direction through the file, the last definition found for the string will be set.

Invert levels may be set via pipe data or pit data or combined. It is recommended that the user only use one method and not combine them. Both are exported so delete the ones you are not going to use. The variables are processed from left to right, so if duplicate definitions of an invert level or found the right most data will be set.

**The format definition**

1. Row 1, column 1 must contain either “12d”, or “from to”. Therefore, the first column must be a 12d drainage variable (cannot be a user defined attribute).

2. Row 1. The text <pit> at the top of the column indicates the column contains a user defined pit attribute and similarly <pipe> indicates a user defined pipe attribute.

3. Row 2. This row contains the names of the 12d drainage variable names and the pit/pipe attributes. All names are case sensitive so be careful where you use capital letters. A list of 12d drainage variables is found below.

Names beginning with an asterix (*) will not be processed (except pit/string names when unique identifiers are present in the data). 12d drainage variables names beginning with an asterix indicate that this data was calculated at export time and cannot be read back into 12d (for example, pipe length, pipe grade and deflection angle).

Prefixing an user defined attribute name with “DELETE ” (no quotes, note the space after the DELETE) will cause the attribute to be deleted from all pits/pipes within the model.
4. Row 3. The text in this row define the type of attribute to be stored within 12d. The only valid choices are:

   integer
   real
   text

   If you want to change an attribute type you must delete the attribute and create it again. If you simply change the attribute type in the third row then that attribute will not be updated.

5. Blank lines may be inserted as desired.

6. You are not required to fill in all of the cells in the spreadsheets. Blank cells are ignored (you must use a space to remove all data from text attributes (the space will not be stored).

7. Pipe names are included in the data so that they can be changed but they are not used to identify the pipe. Pipe data will always be assigned to the pipe following the pit in the direction of ascending chainage. If flow directions is ascending then the pipe data will be for the downstream pipe. If the flow direction is descending then the pipe data will apply to the upstream pipe.

22.10.12.4 12d Drainage Variable Names

<table>

22.10.13 Quick Check Lists for Drainage Design Software

The drainage design software packages each have their specific requirements regarding the manhole types, names and then method they use to model pit inlet capacities. The following section details the specific requirement for each package.

See Drains Version 2+ Requirements and Notes
See PCdrain Requirements
See Running RATHGL/RAT2000 and XP-SWMM
See Micro Drainage - WinDes Requirements

22.10.13.1 Drains Version 2+ Requirements and Notes

See also Drainage overview

Basic Check List
1. All manholes must have a unique name (Manhole names cannot begin with "O ")
2. The pipe type used in 12d must exist in the Drains pipe database

Overland flow with Inlet Capacity Check List
1. Make sure you are using Drains Version 2-5 clipboard data. Inside Drains select Project=>Pit database. The pit family selection should be available. (CAP1 etc. is Version 1).
2. All Overflow route shapes, pit families and pit types used in 12d must exist in the Drains pit database
3. Overland flow lines must be within 1.0 metres/feet of the manhole
22.10.14 Running Drains - Version 2+

Key Points

The Drains database (each project has its own) and the 12d database (drainage.4d) must be synchronised (More).

12d Version 8 needs you to create a new drainage.4d file to include the new inlet capacity curves (pit groups are no longer used).

For pits with a bypass pit and road grade defined (non ILLUDAS), 12d selects pit families for Drains in the following way:

The users selects the pit type (Drains pit size) in 12d and 12d selects the ongrade or sag curve from the drainage.4d file (see inlet capacity calculations). The names of these curves are the Drains pit families. If there are no curves for the pit type in the drainage.4d file then the Drains pit type is exported as ILLUDAS with no family or size data.

If the 12d pit type is **Headwall** then the pit will be exported as a headwall.

Catchment lengths, slopes and roughness values are NOT exported in the Drains Rational format. The default values for these parameters are NOT exported in the Drains ILSAX format but the explicit settings from the catchment panel are exported. If used, Drains requires length, slope and roughness for both impervious (paved) and pervious (grass). Supplementary values must entered in Drains.

Data is copied from 12d to the Windows clipboard and then pasted into Drains. 12d can not delete any objects in Drains, it can only add and update.

When updating 12d from Drains, always copy the DATA to 12d before the results. 12d will update the network but will not add or delete pits.

If a new pit is added in Drains, the user will have the option to create it in 12d. If it is created only the pit will be added and not the pipes.

Why Do I get ILLUDAS pits?

The bypass pit is blank. There must bypass pit for the water to go to. Bypass flow strings must pass within 1 pit diameter (beware pits with zero manhole diameters) and you can enter them manually.

The pit type selected has no capacity curves in the drainage.4d file. The curve names become the pit family for the export to Drains. No pit family means ILLUDAS.

If you are intentionally using a drainage.4d file with NO inlet capacity curves, the pit families you set in Drains will be remembered by 12d when you import back into 12d. The inlet capacity curves will not be required for your next export to Drains.

Drains Interface Overview

The Drains program performs the rational or ILSAX hydrology calculations as well as hydraulic grade line calculations that determine pipe sizes and pipe invert levels.

The data sent to Drains includes

- pit names and types, easting and northing data with surface levels
- finished surface profile along the centre line of the pipes

**Headwalls** and their levels

- optional - bypass inlets, road grades/crossfalls and **SAG Inlet Calculations** (ponding volumes and depths). Pit family selection using road grade and crossfall data.

- optional - composite catchment area create from three 12d areas per inlet (must alter the mapping file)

- catchment characteristics, k values and overland travel times

- pipe sizes, type and invert levels
Data is copied from 12d to the Windows clipboard and then pasted into Drains (Edit=>Paste data from spreadsheet). 12d can not delete any objects in Drains, it can only add and update.

The Drains menu selection Run=>Design is used to design the network. Once the drainage network has been designed in Drains the updated design data (Edit=>Copy data to spreadsheet) and/or the hydraulic results (Edit=>Copy results to spreadsheet) are sent back to 12d via the clipboard.

Always copy the DATA to 12d before the results as the results are deleted inside 12d with every update of the data!

Catchment Data

Drains has one catchment per inlet and therefore only 12d’s catchment set one is used in the interface. The 12d catchment is split a pervious (grass) area and an impervious (paved) area using the percent impervious fraction. The rational and ilsax spreadsheet export formats (selected in the import/export panel) are different.

The Rational format of the Drains interface does not export Drains “more detailed data”. The ilsax format does support the “more detailed data” format but the user must define the length, slope and roughness in the catchment panel. No 12d DNE default data will be exported. As 12d does not have a supplementary area this data will have to be entered into Drains. Gutter lengths and slopes are calculated from the upstream section of the longest overland flow path entering the inlet.

Supplementary data entered in Drains will be remembered in 12d for the next export. The grassed percentage for the next export is calculated as the $(100 - \%\text{impervious}\ - \%\text{supplementary})$.

Synchronising the Drains database and the drainage.4d file.

The 12d pipe types are always used to interface with Drains. Ongrade or SAG pits will be created for export to Drains if the 12d pit has a bypass pit, road grade and a pit type with inlet capacity curves. If all three are not present it will be exported as an ILLUDAS pit.

Every Drains file begins with a default database and Drains uses that database for the life of the project. This database must by synchronised with the drainage.4d file in 12d to ensure the Drains pit families, pit sizes, pipe types and overflow route types match. Therefore it is highly recommended that copy of the drainage.4d file be kept in the 12d working folder.

The Drains and 12d data must match as follows.

<table>
<thead>
<tr>
<th>Drains database</th>
<th>drainage.4d</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pipe type</td>
<td>Pipe type entries</td>
</tr>
</tbody>
</table>

Only if bypass flow is required

Drains database | drainage.4d |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Pit size</td>
<td>Pit type</td>
</tr>
<tr>
<td>Pit family</td>
<td>ongrade or sag curve names</td>
</tr>
<tr>
<td>Overland route database</td>
<td>default in mapping file</td>
</tr>
</tbody>
</table>

Note: If Drains is to be used to select the pit size then an exact match in pit types is not required. For this case the 12d pit type need only be the prefix of the Drains pit size.

The following 6 steps will help ensure 12d is synchronised with Drains. More details are given in the sections below.

1)Prepare the Drains Pit Database

IF 12d is to select the Drains Pit Size, then the Drains Pit Size and 12d Pit types have to match, exactly! If Drains is used to determine the pit size then you may skip this step.

More Drainage
The pit databases supplied by Drains often have road grade and/or crossfall attached to the end of the pit size. **THIS EXTRA DATA MUST BE REMOVED!**

For example, in Drains database you may find the following

<table>
<thead>
<tr>
<th>Pit family</th>
<th>Pit size</th>
</tr>
</thead>
<tbody>
<tr>
<td>NSW RTA SA Inlet, 3% crossfall, 1% grade</td>
<td>SA1 (Type 2) - 1% longitudinal grade</td>
</tr>
<tr>
<td>and</td>
<td></td>
</tr>
<tr>
<td>NSW RTA SA Inlet, 3% crossfall, 3% grade</td>
<td>SA1 (Type 2) - 3% longitudinal grade</td>
</tr>
</tbody>
</table>

The pit size for both is the same, SA1, but 12d can not tell this because of all the extra data at the end. In Drains, simply remove the extra information so that they are both **SA1**. If the network already exists in Drains, then Drains will automatically change the names of the sizes you have already selected. No time lost here.

Once you have changed the Drains pit size names, you are ready to use the **Drains to drainage.4d** routine to create a drainage.4d file that is synchronised with Drains.

2) Export the Drains database from your Drains file

Inside Drains Open your drains file or begin with a blank file. Select **Project=>Overflow Route database**. Then select **OK** and then **YES**. This will cause Drains to export the database to the file "Drains Connection Data.txt" and store it in the folder with the Drains program.

3) Create a drainage.4d file from the Drains file

From the 12d menu select **Design->Drainage-Sewer->More->Drains to drainage.4d**.

Select **Copy Drains database** to copy the file to the 12d working folder.

select **Create drainage.4d**. The Drains database dump file is copied to the 12d working folder and a drainage.4d file is created in the 12d working folder. **More details below.**

4) Edit the drainage.4d file

From the 12d menu select **Design->Drainage-Sewer->More->Edit drainage.4d**. Select **Find** then edit from the file **more info** button. Set the road grade and crossfalls for the 12d pit groups. **More details below.**

5) Restart 12d

From the 12d menu select **Project->Restart**.

6) Set the Overflow shape, Update Pit and Pipe types (Optional)

If the network has already been created using pit and pipe types that no longer exist in the drainage.4d file, they will have to be updated before the export to Drains can occur. You may update them using the drainage network editor (one at a time) or you may set all of the pit and pipes types to **one value** using this routine. Later you may change them individually using the **Drainage network editor**

This routine will also set a default overflow route shape for export (values can be modified in the Drains program if desired).

From the 12d menu select **Design->Drainage-Sewer->More->Drainage io defaults**. **More details below.**

Drains to drainage.4d file

Position of option on menu: **Design =>Drainage-Sewer =>More=>Drains to drainage.4d**

On selecting the **Drains to drainage.4d** option, the **Drains to drainage.4d** panel is displayed.
Key Points

When you are finished, open the drainage.4d file and check the road grade and crossfall values for the ongrade curves!

If Drains is used to select the pit sizes then the 12d pit type must be the prefix of the Drains pit size (Pit Name road separators are used).

If 12d is used to select the pit sizes to export to Drains, the Drains Pit Size and 12d Pit types have to match, exactly! The pit databases supplied by Drains often have road grade and/or crossfall attached to the end of the pit size. If pit sizes are to be sent from 12d, this must be removed! Find Prepare the Drains Pit Database for more details.

Select Copy Drains database (12d will search the usual locations for the Drains database).

Review the Drains pipe types and Drains pit families lists to ensure you have the correct database.

12d pit groups are not used in Version 8.

Pit Name road separators can only be used if Drains is selecting the pit types. If 12d pit types are to be exported to Drains, this field should be left blank. If you change these entries you must press the enter key to update the 12d pit types list below.

Check the 12d pit types and if they are acceptable select Create drainage.4d.

The Details

YOU MUST RESTART 12D FOR THE NEW DRAINAGE.4D FILE TO BECOME ACTIVE!

Field DescriptionType Defaults Pop-Up
Drains database filefile box Drains Connection Data.txt

You must update this file from Drains before each use of this panel. Inside Drains select Project=>Overflow Route database. Then select OK and then YES. This will cause Drains to export the database to the file “Drains Connection Data.txt”.

Selecting Copy Drains database will cause the panel to search for the database dump in the folders C:\Program Files\Drains\Program and C:\Program Files\Drains\Demo\Program. If
the Drains program is installed in another folder then you must browse for the file. The file will be read and the panel updated with either selection.

**Drainage.4d** file box  drainage.4d

The drainage.4d will be created in the 12d working folder unless otherwise specified. It will only be used for 12d projects in this folder.

**Pit families** choice box  Drains pit families

These are the Drains pit families that will be exported to the drainage.4d file. These will become the names on grade inlet capacity curves for all the pit sizes that belong to the family. The pit family name will be searched for words like `grade`, `slope` etc to try to determine the values for road grade and crossfall for the 12d capacity curves.

**Pipe type** choice box  Drains pipe types

These are the Drains pipe types that will be exported to the drainage.4d file.

**Pit group separator** input box

Pit groups are not used in Version 8. These characters will be used to remove the road grade crossfall data from the **Pit families** above. The data before this character will become the **12d pit groups**. Press **Enter** or select **Read Drains database** to create a new list of **12d pit groups**.

**12d pit groups** choice box  12d pit groups

These are created from the Pit family list above by deleting all text after the **Pit group separator**.

**Create drainage.4d** button

Create a drainage.4d file.

**Editing the Drainage.4d file**

Position of option on menu:  Design => Drainage-Sewer => More => Edit drainage.4d

On selecting the Edit drainage.4d option, the Edit drainage.4d panel is displayed.

Select the **Find** button to search the 12d path for the current drainage.4d file. Select the **More info** button and then **Edit** to edit the file.

The drainage.4d file contains Manhole and Pipe commands. 12d also uses the Manhole commands to specify a pit group by using the prefix "group". Details follow.

**Headwalls**

The pit type “Headwall” (case sensitive for Drains) is reserved for the inlet headwall for a conduit. Drains does not use this for an outlet headwall.

If the inlet type is On Grade or there is no bypass pit, the grate level is exported as the Drains surface level. If the Inlet type is marked as a SAG pit then the surface level will be calculated from the low point on the catchment string (catchment set #1). Also see **SAG Inlet Calculations**.

**Pit Families**

Version 2+ of the Drains clipboard interface uses a **pit family** to describe the kerb shape and optionally, the name include the road crossfall and/or grade attached as a suffix.

An example pit group is the drainage.4d file is shown below. 12d uses the road grade and/or the road crossfall to select which pit family should be sent to Drains. In this example the road crossfall would not be used in selecting the pit family.

It is up to the user to decide the grade when the next pit family should be used. In this case the threshold value for the gutter grade is set midway between the published values of the inlet curves. For example at a gutter grade of 2% 12d starts sending the **NSW RTA Pits - 3% slope**
pit family.
The pit families listed on the right must match exactly with those in the Drains pit database.

Pit Types and Pit Sizes
Each Drains pit family has several pit sizes. The Drains pit sizes link to the 12d pit types and therefore all Drains pit sizes should exist in the 12d drainage.4d file.

The pit size will be read back from Drains into 12d as the pit type so that it can be placed on the drainage long sections and pit schedules. If no matching pit type is found in 12d then a character will be dropped off the end of the Drains pit size and 12d will be searched for the new shorter pit type. This will be repeated till a match is found (or there are no more characters in the Drains pit size).

Pipe Types
The pipe type selected in 12d must exist in the pipe database inside Drains. Simple “2” for class 2 or “RCP” do not exist in Drains.

Setting the Overflow Route, the Pit and Pipe types
Position of option on menu: Design => Drainage-Sewer => More => Drainage IO Defaults

On selecting the Drainage IO Defaults option, the Drainage IO Defaults panel is displayed.

The routine changes ALL of your pit and pipe types in a model to a single value. If you have changed your drainage.4d file after creating you drainage network, the pit and pipe types you originally selected may no longer be valid (i.e. in the drainage.4d file).

Field DescriptionType Defaults Pop-Up
Design Programchoice Drains Drains, PCdrain
Drainage modelfile
12d pipe types choice values from drainage.4d
12d manhole types choice values from drainage.4d
Default pit group choice values from drainage.4d
Default road shape
Drains database file C:\Program Files\Drains\Program
Drains pipe types Database not loaded
Drains Overflow Route Shapes Database not loaded

Set all pipe types will set all pipes in the model to this value
12d pit types  choice values from drainage.4d

**Set all pit types** will set all pits in the model to this value

Default pit groups choice values from drainage.4d

pit definitions in the drainage.4d file that have group as a prefix are included.

Default road shape choice values from drainage.4d
type the desired name or if using Drains select the desired shape from the **Drains Overflow route shapes**.

Drains Tab

Drains database file

pressing enter in this field will start a search for the Drains database dump. The search path is the specified folder, C:\Program Files\Drains\Program then C:\Program Files\Drains\Demo\Program. If the file is found the choice fields below are populated. **It is highly recommended that this file be in the 12d working folder.**

Drains pipe types choice I values from Drains file

the pipe types are retrieved from the last Drains database dump. Changing this value will update the **12 pipe types** above.

Drains Overflow Route Shapes choice values from Drains file

the overflow route shapes are retrieved from the last Drains database dump. Changing this value will update the **Default road shape** above.

Set all pipe types button

all pipe types in model are set to this value

Set all pit types button

all pit types in model are set to this value

Set defaults button

the defaults for the **Drains Overflow Route Shapes** and **12d pit group** are set

Finish button

removes the panel

Drains Version 2+ Requirements

Pit Names

The 12d pit names cannot be more than 9 characters long. 12d uses 2 additional characters to the pit name at export time create names for the pipes, overflow routes and catchments. For example pit “A-1” will have a bypass route “F A-1”, a catchment “C A-1” and a downstream pipe “P A-1”.

Bypass Flow (Overland Flow Routes)

There are 3 requirements for Drains bypass flow (bypass pit, pit inlet capacity curve and road grade/crossfall).

Select a **pit type** that has ongrade or sag inlet capacity curves defined in the drainage.4d file. The Drains and 12d databases must be in sync.

Bypass strings in the **Bypass route model** specified (Network editor->Global->Utility Models->Bypass flow model. For more details see Bypass Flow.

Road grade and crossfall calculated (Network editor->Global->Utility Models->Road design file)
The overland flow strings are not allowed to pass through the outlet pit on the network.

SAG Inlet Calculations

SAG inlets are inlets where the water ponds at the surface rather than flowing past. If a SAG inlet
has a catchment string the overflow depth and volume are calculated. The catchment string from Set #1 is draped onto the design tin and the lowest point in found on the draped string (stored as a 12d pit attribute overflow level. The storage volume inside the string up to this point is measured and stored as a 12d pit attribute overflow volume from level. and are subtracted from the to determine

The Max Ponding Depth = overflow level - grate level

If the manual flag is selected for the "sag pit pond depth", 12d will NOT calculate the value but will use the value entered by the user. 12d will check if a volume has been calculated before or imported from Drains. If the volume exists then it is exported. If it does not exist, this ponding depth will be used calculate the ponding level (depth + grate level). The ponding level will be used to calculate a ponding volume from the design tin and the catchment boundary.

If you want to manually delete this volume and force 12d to recalc to volume using the user defined level, delete the pit attribute, "overflow volume from level". To delete the attribute use Strings->Properties->Attributes, select the pit, go to the pit tab, right mouse select the row with this attribute and select delete).

Results

Drains exports the maximum data from all of the rainfall events analysed. Therefore, ensure you analyse only the rainfall events desired before coping the results to the clipboard. To verify the data that is being sent to 12d, copy the data into a spreadsheet so you can view it there first. The pit sizes selected in Drains will be stored in 12d as the pit type. Therefore the pit sizes in Drains should exist as pit types in the drainage.4d file. If pit families are changed in Drains the pit group in 12d will be updated by search for the pit family in the drainage.4d file.

12d to Drains

Setup your drainage network models and ensure they have been assigned pit names.

Copy the data to the clipboard

From the Drainage network editor select the Import/Export button.

The following interfaces dialogues will appear.
More Drainage

From within the Drains program select **Edit => Paste data from spreadsheet**. If you paste the data into a Drains project that has a hydrological model and rainfall data already defined the project will be ready to run.

Use the Drains Run=> Standard design to design your pipe sizes and invert levels. The Run=> Advanced Design will select the size of the pits as well.

**Drains to 12d Update**

The following steps are required to update the 12d model with the Drains hydraulic results and changes to the pipe sizes and inverts.

To update the pipes and invert levels in 12d, select **Edit -> Copy Data to Spreadsheet** from the Drains menu.

From within the 12d Drainage network editor select **Import/Export**.
IMPORTANT: THE DATA MUST BE PASTED BEFORE THE RESULTS!

12d erases the hydraulic and hydrology data when the physical data is updated. Therefore, always paste the data before the results.

Drains Mapping File

The rational format and the ilsax format have separate mapping files.

The Drains spreadsheet format consists of sections starting with a header, then the data area and ending with a blank line. The mapping file defines the format of the section headers and the format of the data within the sections.

Select Import

This will ignore the invert levels read from Drains and the current pipe obverts will remain fixed.

Plan and long section drawings may be created at the import time so that you can see the results on the drawings.

Select Run to update the drainage model. To see the changes in the section views you will have to select Regen on the section view toolbar.

To return to the network editor select Edit.
The headers in the mapping file define the exact text to be exported in the Drains section headers. During an import the first 4 columns of the Drains header are compared to the headers in the mapping file to determine which section is being read. The data format line is then used to decode the the data.
22.10.15 PCdrain Requirements

See also Drainage overview

Basic Check List
1. All manholes must have a unique name
2. Only one outlet allowed in the drainage model
3. First export should have “Export default catchment/pit/overland parameters” selected
4. Pit types in used in 12d must exist in the PCdrain Inlet gully file selected.

Overland flow with Inlet Capacity Check List
1. A gutter profile named “4d” must exist in PCdrain before the interchange file is read. This gutter profile may be created in PCdrain from the menu selection Data=>Gutter profiles then New.
2. Overland flow lines must be within 1.0 metres/feet of the manhole

Data is exchanged to and from PCdrain via the interchange (*.int) file. Gutter profiles and inlet type must be specified in PCdrain before the interchange file is read into PCdrain.

The data sent to PCdrain includes
- pit names and types, easting and northing data with surface levels
- pipe deflection angles at pits
- finished surface profile along the centre line of the pipes
- optional - crossing services - level, size and location along the pipes
- optional - bypass inlets, road grades and SAG inlet ponding depths
- optional - up to 2 catchment areas per inlet
- optional - default catchment characteristics, k values and overland travel times
- optional - pipe sizes and invert levels

22.10.15.1 PCdrain Requirements

Pit names
The pit name from 12d is assigned to both the structure and catchment name in PCdrain. These names cannot exceed 7 characters.

Pit type
The 12d pit type is transferred to the structure type in PCdrain. These names must match those specified in the PCdrain Inlet charts selected (Data=>Inlet charts). Select the desired inlet charts BEFORE importing the interchange file.

12d pit types with an “S” in the name are treated by 12d and PCdrain as a SAG inlet pit. 12d will strip off all characters after the “S” before adding the ponding depth. If a catchment string in set #1 is available for the SAG pit then the ponding depth will be calculated. The 12d pit type will remain unchanged. A typical example would be a pit type “ITC” with the sag tick box on would become “ITC0.100” if a ponding depth of 0.1 was calculated.

Bypass Flow
When a catchment string is specified for the pit, the maximum depth before bypass flow commences is calculated. The lowest point on the catchment string is determined by draping it
onto the drainage strings tin. The maximum depth before bypass is calculated pit setout level less the setout to grate offset less the lowest point on the catchment string.

PCdrain differentiates between pits (no surface inflow) and gully pits via the 12d pit type. The bypass flow strings can only be drawn within 1 pit diameter of the gully pits. Keep the bypass flow strings away from the PCdrain pits.

**Catchments**

Again, since PCdrain differentiates between inlets and manholes (using the 12d pit type), ensure that catchments are only drawn for gully inlet and NOT manholes.

22.10.15.2 12d to PCdrain

1. Export the data to PCdrain selected via the Network editor

   Design=>Drainage-Sewer=>Drainage Network Editor

   After selecting the drainage network, select the **Import/Export** button and the following dialogue will appear.

   ![Image of Import/Export dialogue]

   Select the **Run** button and the interface file will be created.

2. Launch the PCdrain for Windows program. If you have a project set up with the design parameters, rainfall data, inlet charts and gutter profiles then open it now and skip to step 8. Otherwise continue with step 5.

3. The Design Parameters can be set as desired with the menu selection **Data=>Design Parameters**.

4. Select the rainfall data using the **Data=>Rainfall** menu selection.

5. Select the inlet charts using the **Data=>Inlet Charts** menu selection. The pit types specified in 12d must be included in these settings.

6. At least one gutter profile in PCdrain needs to be defined. These are set through the menu selection **Data=>Gutter Profiles**. The default gutter section name (**Road ID**) from 12d is **4d** and therefore it is recommended you create a profile with this name and your own description. If you have changed the profile names in 12d (through the spreadsheet interface or the Attribute editor) these new profile names will have to exist in PCdrain.

7. Save this file now so that you can retrieve it later if required. It can be used as a starting template for new jobs.

8. **File=>Import** from the menu. Select the file exported in step 1. The information from 12d may be viewed by selecting **Data=>Network** and then selecting the desired tabs.

9. The HGL level and the pipe elevation at the outlet should be set using the menu selection **Data=>Outlet**.

10. If you have not exported pipe data then the pipe size must be determined. Use the menu selection **Process=>Select Pipe Sizes**.

22.10.15.3 PCdrain to 12d

Export the results to 12d using the **File=>Export** menu selection. Note the name of the interchange file you are creating as you will need to enter it inside 12d.

<table>
<thead>
<tr>
<th>Impervious</th>
<th>12d</th>

</thead>
<tbody>
<tr>
<td>Impervious</td>
<td>Length</td>
<td>Length of gutter</td>
</tr>
<tr>
<td>Impervious</td>
<td>Slope</td>
<td>Grade of Gutter</td>
</tr>
</tbody>
</table>
Return to 12d and select **Import/Export** from the network editor and the following dialogue will appear,

- Select **PCdrain Int (Windows)** from the drop down list.
- Select the output file name you created in PCdrain.
- Select **Run** and the file will be read into 12d and the drainage network will be updated. To see the changes in a section view, select **Regen**.

A listing of the data imported is stored on the 12d output window.

Inlets that have been specified as SAG inlets will have the ponding depth removed from the end of the PCdrain structure type before the data is stored as the 12d pit type.

22.10.15.4 RAT2000 Requirements

See also [Drainage overview](#).

**Basic Check List**

1. All manholes must have a unique name (they become nodes in RAT2000)
2. Only one outlet allowed in the drainage model
3. First export should have “Export default catchment/pit/overland parameters” selected
4. First export should have “Export pipe diameters and Inverts” selected
5. Outlet conditions must be set in RAT2000.
6. Start-up data may be specified in the file `drainage startup.xpx` (the standard 12d system file path will be searched).

**Overland flow with Inlet Capacity Check List**

1. Overland flow lines must be within 1.0 metres/feet of the manhole
2. If inlet capacity curves are to be used then the curve name must match the 12d pit type with the road grade/crossfall data added.
23.0 Running RAT2000

Data is exchanged to and from RAT2000 via the interchange (*.xpx) file. The data exported from the 12d drainage model is appended to the xpx startup data specified in the file drainage startup.xpx (the standard 12d system file path will be searched). This file may be edited using a text editor or you may create your own default file by exporting your RAT2000 global data this file.

RAT2000 Requirements

Manhole names

All manholes will become nodes in RAT2000 and therefore they must have a unique name inside 12d.

Manhole Types

The manhole types are used to determine the pit inlet capacities if overland flow routes are selected. Fixed inlet capacities values may be set in the drainage.4d file while inlet capacities curves must be included in the drainage_startup.xpx file. The range of available curves for 12d to choose from are set in the drainage.4d file and the curves are determined using the pit type, road grade and road crossfall.

Pipe Types

Pipe types are not transferred to RAT2000.

Overland Flow

When an overland flow model is selected the pit inlet capacities and bypass routes are calculated.

23.1 12d to RAT2000

1. Export the data to RAT2000 by selecting

   **Design=>Drainage-Sewer=>More=>Pit/Pipe Design Interface**

The following dialogue will appear.
23.2 Updating an existing RAT2000 file

Adding new Nodes and Pipes

If new manholes and pipes have been added to 12d then these new entities will now be included in the xpx file and imported into the RAT2000 project. 12d identifies the nodes in XP by the node names. Therefore if nodes names are changed in either program then they must be manually changed in both programs.

If a manhole is to be inserted in an existing link then the existing link must be deleted in RAT2000 so that the new links and manholes may be created in the void.

**WARNING!** If the tick box *Export catchment/pit/overland flow default data* is selected for the update then any changes to these defaults in RAT2000 will be lost. Two options are available to the user.

**Option 1** - Preferred method if updating pipe lengths, invert levels for your design.
De select the tick box and export the data. The new node and links created in RAT2000 will not have all the defaults set but the existing nodes and links will not have revisions to defaults overwritten.

**Option 2** - Preferred method if you have created numerous new links and nodes.

Leave the tick box selected but export the RAT2000 to a temporary xpx file first. This will save the existing setting. After RAT2000 is launched and loaded with the new data, import your temporary xpx file you just created to restore the original data.

**Deleting Nodes and Pipes**

If a node or link is to be deleted then delete the entity from both 12d and RAT2000.

23.3 RAT2000 Results to update 12d

If RAT2000 is launched automatically using option 1 above then as soon as RAT2000 is exited an interface file is automatically created (using the same name as the import xpx file). This file will now be read back into 12d to update the pipe network and import hydraulic results for drainage longsection plots.

Return to 12d and select

   **Design=>Drainage-Sewer=>More=>Pit/Pipe Design Interface**

The following dialogue will appear,
23.3.0.1 XP SWMM Program Requirements

See also Drainage overview

Basic Check List

1. All manholes must have a unique name (they become nodes in XP SWMM)
2. Only one outlet allowed in the drainage model
3. First export should have “Export default catchment/pit/overland parameters” selected
4. First export should have “Export pipe diameters and Inverts” selected
5. Outlet conditions must be set in XP SWMM.
6. Start-up data (run times and hydrology data) may be specified in the file master_drainage.xp (the standard 12d system file path will be searched).
23.3.1 Running RATHGL/RAT2000 and XP-SWMM

The drainage design with all three of the XP software programs follows the same methodology. The process is substantially automated with the XP-SWMM program so that the XPX file is automatically read by XP-SWMM and automatically created when leaving XP-SWMM.

Drainage design with XP programs includes the following steps.

1. 12d creates an XPX file that is read by the XP programs.
2. The XP program is then run in the design mode to determine the pipe sizes and invert levels.
3. If bypass and overland flows are to be modelled then the inlet capacities need to be defined and then run the XP program in the Full Analysis Model.
4. The XP program creates an XPX file for 12d to import.

23.4 xpstorm and xpswmm bypass requirements

12d will select the inlet capacity curves for the xp programs when the following bypass settings are complete.
1. The 12d pit type determines the inlet capacity values or curves to be selected from.

2. The bypass pit must be defined for the pit. If the bypass pit follows the pipe network a xp-multi link with a natural channel is created. Otherwise a xp single link is created. The default xp natural shape is “Road Section”

3. The Ongrade/SAG pit on the Main tab determines whether depth or approach curves are exported to (details below).

4. If ongrade is selected then the 12d inlet capacity curves may be selected by road grade, crossfall, both or neither. (details below).

5. The 12d choke factors will be exported as the xp inlet efficiency factor \((1 - 12d \text{ choke})\)
The numbers below relate the same numbers in the 12d panels above.

1. Inlet capacity is turned on when 12d has a bypass inlet.
2. 12d **Ongrade** inlets export as **Rated by Approach Flow** and 12d **SAG** inlets export a **Rated By Approach Depth** with depth calculated by **Node Storage Characteristics**.
3. 12d **Inlet Capacity Curve names**

   Below is an extract from the drainage.4d file for Canberra rating curves.

   4. The minor/major selection is the 12d export panel determines the efficiency factors that are exported/

   Efficiency factor = 1.0 - 12d choke.
1. The manhole is the inlet type selected above.

2. cap_config G forces the inlet to be used as qa 12d ongrade inlet. An S would be SAG and an M a manhole.

3. The curve name indicated here is exported as the xp inlet capacity curve.

4. The curve name will be exported starting at road grade of 0. Since one curve has a road grade value all curves must have a road grade value and the user must have a road grade calculated on the 12d bypass tab.

23.5 12d to the XP Programs
The x,y pit layouts and the cover/surface levels are obtained from your drainage network while the catchment and overland flow data comes from the models specified in the drainage interface dialogue.

The steps required to transfer the data to the XP programs are as follows.
1. Setup your drainage network models.

2. To create the XPX file for XP programs start the Drainage Network Editor and select Import/Export

The following interfaces dialogues will appear.

Select XPSWMM or RAT HGL from the drop down list.
Enter the name of the xpx file to be created.

Select Export

Not used at this time.

Finally, Select the Run button to create the file.

If exporting to RAT-HGL the following dialogue will appear.

If you are using old versions of RAT-HGL (1996 or earlier) select use Local otherwise select 4D units (eastings and northings).

Select process.

3. The XP SWMM program will automatically startup and load the XPX file.

From within RAT-HGL, either select File => New and follow the input prompt or load a file that contains all of the pit inlet rating curves, hydrological and design data without a pipe network. Many users have such RAT-HGL files setup so as to streamline the design process.

The xpx file for RAT2000 will have the file startup.xpx added to it so that you may include all the startup global data that you require. The Fixed inlet capacities and rating curve names indicating road grade and crossfall may be set in the drainage.4d file. The format for these names is pit name-crossfall-road grade (ex SA2-3-4). These curves must exist in this file.

4. To read in the pipe file created above, select Special => Import Data and select the xpx data file. Warnings will be given stating that several fields are inactive. This is expected as more data is sent to RAT-HGL than is needed at this time. Select the Close Square on the Help title area and the pipe network and catchments should now appear on the screen.

5. If you want RAT-HGL to redesign you network, change the analysis mode to Design mode by
selecting **Special=>Job Control** and **Select Design mode**. Do not do this if you want to analyse the network you layed out in 12d (used for existing systems).

6. Select the rainfall events to design/analyse and the **LB** (twice) on **OK** to return to the layout. Now select the outlet and enter the starting tailwater levels.

7. Now you can run RAT-HGL (**Special =>Solve**).

### 23.6 XP Programs to 12d

Once you have your design finished, the following steps are required to update your 12d model. Your design may contain several return periods in the analysis (Rp1 to Rp7) but 12d reads only the results from Rp1. The following table is taken from the RATHGL output file (*.out extension) and the results indicated are read back into 12d via the xpx file.
In addition to the results, the following input data is read back into the 12d model so that it may be exported back to RATHGL in the future (if required). 100% of your RATHGL data is not included in the XPX formats and the contents of the XPX file will depend upon your design mode. Therefore, use caution if you read an XPX file into an existing RATHGL model and check your data once inside RATHGL.

1. From within RAT-HGL, produce an XPX file for 12d to read by selecting Special=>Export Data and following the default prompts.

2. From within 12d, select the Import/Export button on the Drainage Network Editor. The fol-
lowing panel will appear.

Select to select RATHGL or XP-SWMM.

Select the file name specified in step 1.

Select Import.

Select Run to update the drainage model and import hydraulic/hydrological results.
23.6.1 Running Micro Drainage - WinDes

See also Drainage overview

**Basic Check List**

1. All manholes must have a unique name (they become nodes)
2. Only one outlet allowed in the drainage model
3. First export should have “Export default catchment/pit/overland parameters” selected
4. First export should have “Export pipe diameters and Inverts” selected
5. Outlet conditions must be set in Win DES.

23.7 Micro Drainage - WinDes Requirements

**Pit - Pipe names**

The pipe names are used in the WinDes interface NOT the pit names. Therefore the pipes are often named separately to follow the WinDES required naming convention.

**12d string names**

The trunk line drainage string must be named “1” and then moving from upstream to down stream the branch line strings increase 2,3,4 etc. If the branch lines have sub branches then they are named in a similar upstream to downstream sequence. The sub branch string are named before moving downstream on the trunk line. If this string numbering system is not followed 12d will renumber the strings and request the user to run the drainage misc utilities to rename the pipes and pits.

**12d pipe names**

The trunk line pipe segments start at the upstream end at 1.000 and increase downstream (1.001, 1.002 etc). The assign pit names will automatically name the pits for you if you have followed the string naming convention discussed above. “Number of digits” must be set to 3 to ensure the leading zeros are used.
The panel below shows the naming convention.

![Drainage Network Editor: Set Pit Names](image)

**12d pit names**

The pit names may be set to any desired naming convention. Using the same names as the pipes makes the pit/pipe identification easier for the user but it is not required. As of April 2007 the maximum length is 8 characters but Windes is planning to remove this restriction.

The *.sws or *.fws files may be open directly inside WinDes.

**23.8 Global /default variable mapping**

The default 12d drainage mapping file maps the following Windes data
23.9 Additional Notes

Pipe Resizing

Pipes are automatically resized when opened in Windes and the sizes used are from the specified *.pip file (standard.pip by default).

When locked pipe sizes are sent to Windes the pipe sizes can be increased but not made smaller.

Pit Resizing

Pit diameters are automatically updated by Windes depending on the size of the attached pipes. This resizing is determined by the Windes file, standard.mhs.

23.10 Open channel drainage design.

Win Des can (hydraulically) model any shape of conduit. The conduits are given numbers between 1 and 100. 12d selects these conduits by setting the pipe type to WINDES (case sensitive) and pipe diameter to the WinDes conduit number divided by 1000. (examples 0.032 indicates WinDes conduit 32).

12d can create the conduit shape by applying a template to the drainage string. The user must create a template with the same name as the WinDes shape number (32 for example). The templates are created from the main menu

Design->Template->Create Edit

For more information about template design please refer to the 12d training manual.

Once the template has been created it is applied to the drainage string to create the cross sections and strings to represent the conduit shape.

From the main menu Design->Drainage-Sewer->User->Drainage Volume Calculations

For more information see Drainage line excavation volume calculations.
23.10.1 Drainage Excavation Quantities

Position of option on menu: Design => Drainage => Reports => Excavation Quantities

See Also
Drainage overview

This routine uses 12d templates to calculate the excavation volume for all of the drainage strings in a model. An option to create section for a tin on top of the pipe is also available so that the drainage long sections can include hatching between the obvert of the pipe and the design tin under roads.

Templates with names set to the pipe diameters (times 1000) are used for the calculations, thus trench shapes can be customised and over excavation for bedding materials can be included. Net area calculations to exclude pipe area are not supported.

Key points
1. One template for each pipe size (mm)
2. If obvert templates are used, add the prefix “obvert “ to the pipe size
3. Carefully consider the tin selected.

A template must exist for each pipe size in the model (pipe size x 1000). For example a 0.3m pipe will require a template to exist named 300. A 0.5ft pipe would require a template named 500. A sample template library is included in the 12d library in the file pipe_template.tpl.

The templates are run along the strings and the total volumes are reported. Volumes for each strings are given in the report file.

If a tin is created from these strings then volumes by depth can be determined using Design=>Volumes=>Exact=>Tin to tin

On selecting the Excavation quantities option, the Drainage Excavation Quantities panel is displayed.

The fields and buttons used in this panel have the following functions.
### Field Description | Type | Defaults | Pop-Up
---|---|---|---
**Drainage model** | input box |  |  
*Model to contain all of the pit and pipe network to be worked on.*

**Strings model** | model box |  |  
*Strings generated from the templates will be stored in this model*

**Sections model** | model box |  |  
*Sections generated from the templates will be stored in this model*

**Report name** | input box |  |  
*Cut and fill volumes will be sent to this report*

**Ground Surface Tin** | tin box |  |  
*Tins from which the volumes will be calculated*

**Separation** | real box |  |  
*Distance between the sections*

**Sections colour** | colour box |  |  
*Sections generated from the templates will be assigned this colour (strings colours are defined in the templates)*

**Clean section/strings model** | tick box |  |  
*Delete the strings in these models before processing.*

**Stop section at edge of pit** | tick box |  |  
*Template are run from pit centre to centre if this is not selected. The templates stop at the edge of the pit if selected. This is often selected with the following option Use obvert templates.*

**Use obvert templates** | tick box |  |  
*Templates must be named with the prefix “obvert”, i.e. obvert 300. The template is still run along the invert of the pipe but the user now has a section “set” of templates that can be used to create a tin on top of the pipe as well as below.*

An example report file follows.

**Excess of Cut over Fill:** 32.924
23.10.2 Attribute Editor

Position of option on menu: Design => Drainage => More => Top Ten attributes editor

Most of the detailed catchment data is stored within 12d as user defined attributes. These attributes are automatically created by 12d when required but you are free to change them or add more as desired. The attributes may be exported to a spreadsheet and edited and then imported back into 12d or edited inside 12d using this panel.

See Also

Drainage overview

Usage

From the menu select Design => Drainage => More => Top ten attribute editor

The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up
--- | --- | --- | ---
pick string | button | | 
used to pick the initial string in a model

string-pit-pipe | choice box | string,pit.pipe | 
select the type of attribute to be displayed. Pit and pipe attributes are only available for drainage strings.

attribute name | input box | | 
3 top 10 attributes lists are maintained (pit, pipe and string). The attributes that you can select from are all of the attributes that exist on all of the strings in the model. If the attribute does not exist for the
string/pit/pipe that you are displaying the data field will display Not found.

type  choice box  Text, Real, Integer

for existing attributes this will display Text, Real or Integer.
When defining a new attribute select the type of data to be stored in the attribute.

data  input box

the data stored in the attribute is displayed/edited/created in this field.

<= prev  button

move to next  string in the model
             pit on the string
             pipe on the string

next =>  button

move to next  string in the model
             pit on the string
             pipe on the string

process  button

updates the attributes displayed in the dialogue.

Notes:

First LB select Pick to select the string that contains the user attributes. All catchment data is stored with the pits in drainage strings. The strings will be highlighted in white when they are selected.

To access the pit attributes LB this field then select Pit. A circle will be drawn around the pit selected.

LB the Attribute Name field and then select from the list of existing user defined attributes. These attributes include all of the attributes in the model that the string exists in. They may not be defined for the string you are editing. If the string does not have that attribute defined not found will be displayed in the Data field.

To change the value for the attribute enter the new value in the data field. If the attribute does not exist, deleting the not found text and adding data will create it. The following message will be displayed whenever you are creating a new attribute.
23.10.3 Delete All Attributes in a Model

Position of option on menu: Design => Drainage => More => Delete all attributes in a model

See Also
Drainage overview

This option deletes all model, string, pit and pipe attributes in the model specified. This option allows the user to "start from scratch" while maintaining the drainage, catchment and bypass flow strings.

Usage
From the menu select Design => Drainage => More => delete all attributes in a model

![Delete Attributes dialog box]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model name</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*the model specified will have all of its attributes and all of the strings attributes deleted*

Process button

*Deletes all of the attributes*

Notes: THERE IS NO UNDO!
23.10.4 Flooded Width Flow Analysis and HEC-RAS

Position of option on menu: Design => Drainage-Sewer => Calc flooded widths

The Calculate Flooded width procedure creates cross sections along the bypass flow paths and then calculates the flooded width at each section using Manning’s normal depth calculations. A HEC-RAS project (same name as the bypass flow string) is also created for each line. The flooded width is indicated on each section as a blue line if it is less than a user defined width and a red line if the flooded width exceeds the limit. Details of the calculations such as the velocity, depth, wetted perimeter and slope can be exported to a spreadsheet for further analyse (velocity times depth calculations for example). The discharges imports from the urban stormwater design packages are shown in the following table.

<table>
<thead>
<tr>
<th>Design Program</th>
<th>Discharge Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCdrain</td>
<td>Minor ARI</td>
</tr>
<tr>
<td>Drains</td>
<td>Maximum flow event analysed</td>
</tr>
<tr>
<td>ILSAX</td>
<td>Maximum flow event analysed</td>
</tr>
<tr>
<td>RAT HGL</td>
<td>First return period analysed</td>
</tr>
</tbody>
</table>

The user defines the length of these sections and the interval at which they are to be spaced. 12d calculates the normal flow depth interpolating the pit approach and bypass flows from the hydrology models (ILSAX, Drains, PC Drains or RAT HGL). The cross sections are taken perpendicular to the flow line and the slope is for the normal depth calculations is determined using the distance along the flow line and the change in elevation between the two lowest points in the primary flow channel. The flow line need not intersect the low points on the section but the flow line does mark the primary flow channel. If the depth of the flow exceeds the banks of the primary channel, then all adjacent flow channels will be considered as active flow area.

On selecting the Calc flooded widths, the Drainage flooded width panel is displayed.
The fields and buttons used in this panel have the following functions.

**VxD warning colour**

*colour box* orange

Colour of the velocity x depth bars

**Process**

*button*

Clean output models, calculate flooded width and create HEC-RAS projects named from the string names.

**Finish**

*button*

remove the panel from the screen

### 23.11 Limitations where overland flow lines join

Where overland flow lines converge at an inlet, 12d does not know the flow split between the 2 approaching paths. Therefore, 12d uses the total flow from all lines as the flow at the inlet for each line. This may overestimate the flooded width along the flow lines at these points.

### 23.12 Limitations at SAG pits

The flow width are not shown adjacent the sag inlets. The depth of flow due to ponding and the approach flow coming from several directions may overestimated flooded width in these areas. Therefore not flood depths are calculated approaching SAG inlets.

**Summary Tables**

The hydraulic calculations and warning messages are stored as string attributes on the flooded width bars. If these attributes are exported to a spreadsheet via the clipboard a summary table my be created. To copy these attributes to the clipboard select

File IO->User->String attributes-properties to/from clipboard

The **string model** may be either the flooded width bars or the warning bars. Both models of strings contain attributes on the strings.

The prefix selection and prefix exclusion are filters for reducing the number attributes that are exported to the clipboard.
23.13 Cross Sections, Discharges and Warnings

The analyse flooded width will proceed along each flow path and identify every pit on the line. Cross sections will be constructed in the model with the length and interval entered in the input dialogue. These cross sections may be plotted using the main menu selection Plot=>Xplot=>Xplot. The Sort Sections must not be selected for these sections to be plotted.

Discharges will be determined for each cross section by linearly interpolating the discharge using distance between the pits. The bypass discharge (pit attribute - calculated bypass flow) will be taken from the upstream pit and the approach discharge (pit attribute - calculated approach flow) from the downstream pit.

The slope is calculated by subtracting the lowest points nearest to the centre line and dividing the cross section separation. The levee tolerance is NOT used for locating this point thus any rise in section moving away from the centre line marks the end of the low point search in that direction.

12d will give warning messages in the output window when it encounters the following conditions and these messages will be stored as string attributes on the flooded width strings. Descriptions of these messages follow.

**Inverts do not go downhill**

12d locates the lowest point (adjacent to the flow line without moving over a local crest) on each cross section to calculate the slope between the cross sections. This message indicates that the downstream minimum elevation is higher than the upstream minimum elevation.

Sometimes flow lines will go uphill. If you have specified an overflow from a SAG location then the flow line will go uphill until it crosses the overflow crest.

If the flow line is not supposed to be going uphill at this section, check to see where the flow line intersects the cross section located upstream of the one identified in the warning message. If it is in a local sag point that is not the lowest point on the section, move the flow line.

The program will use a slope of 0.5% to calculate a width at this location. This results in very wide flooded width sections to draw the user’s attention to the problem area.

**Vertical Walls Assumed at the Ends of the Cross Sections**

If the depth of flow exceeds the ground surface elevation at the ends of the cross section a warning message the warning message shown above is shown. The cross sections causing the warning follows.

The vertical wall is placed at cross section chainage –20. Note that the flow line is always at chainage 0.
23.13.1 Convert Drainage String to Polyline

Position of option on menu:  Design => Drainage => More=> Convert drainage string to polyline

See Also

Drainage overview

All drainage strings in the specified model are exported to a 12da file. When this 12da file is imported back into 12d Model the strings will be converted to polylines. Import the strings using

File_io=>Data Input=>12da/4da data

Specify a prefix for the model when it is read back in. Otherwise the strings will be placed in the same model as the originals.

Usage

From the menu select Design => Drainage => More=> Version 6=> Convert drainage string to polyline

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drainage model name</td>
<td></td>
<td></td>
<td></td>

<td>Drainage data,4da</td>
<td></td>
</tr>
</tbody>
</table>
**drainage model name**  
*input box*  
*Drainage model containing the drainage strings*

**12da file name**  
*input box*  
*drainage data.4da*  
*A temporary file that will hold the converted string data.*

**process**  
*button*  
*Exports the drainage strings and converts the file to polylines.*
23.13.2 Drainage.4d file

A sample pit entry in the drainage.4d file is as follows:
Enhancements have been made if exporting to the Drains program. See Pit Families and Pit Groups
The drainage.4d file controls many of the settings for the pit and pipes types inside 12d. This section details the format of the drainage.4d file. Changes to this file take effect only after 12dmodel has been restarted. If there are any errors in the drainage.4d file they will be listed in the output window at startup (just after the shp file listing). The error in the drainage.4d file is generally located just above the line indicated in the output window.

All text to the right of the // is ignored by 12d (comments). There are pit and pipe type definitions. Because of historic reasons the pit types are defined using a Manhole command.

Many of the settings in the drainage network editor (DNE) can be controlled by the pit types and the pipe types defined in the drainage.4d file. The special manhole attributes defined below control these fields.

The original drainage.4d file is found in the “program files\12d\12dmodel\10.00\set_ups” directory. Do NOT change this file. Copy it into your user folder “\12d\10.00\User” and edit it there. Files in the user directory are used by preference and they are never over written by a 12d update.

Two Point Dynamic Profiles

If at any time you want to obtain a temporary section view, 12d has a dynamic profiling capability (2 point profile). First, add your tin design model to the section view.

Next RB on the section view title area and then LB select 2 points. The following panel will appear.

Select Start_End pts to begin and then pick/accept a point on a Plan View Now as you move your cursor the section view will be dynamically updated (the dynamic box should be checked on and a surface tin model added to the section view). When you obtain the cross section you want LB select then accept (MB) the second point.

LB select Finish when done.
23.13.3 ILSAX Editors

Position of menu: Design => Drainage => More => ILSAX Editors

The ILSAX editors walk-right menu is

See ILSAX Pipe/Catchment Editor
See ILSAX Rainfall File Editor

23.13.3.1 ILSAX Pipe/Catchment Editor

Position of option on menu: Design => Drainage => More => ILSAX editor => ILSAX pipe editor

See Also
ILSAX Rainfall File Editor
Drainage overview

The ILSAX pipe data editor allows the user to edit pipe and catchment parameters. Most commonly used functions are supported but some of the less used functions are not included at this time. The same names have been used as those in the ILSAX drainage manual for easy reference.

Unlike the rainfall editor, all of the data in the pipe data editor is stored with the drainage string as user attributes. These user attributes can be changed using the editor (recommended for the novice user) or they may be output to a spreadsheet, changed and then read back into 12d.

CAUTION: If the drainage string is deleted then all of the attributes are deleted at the same time.

Usage

The ILSAX pipe data editor is accessed by selecting Design => Drainage-Sewer => More => ILSAX Editors => ILSAX Pipe file editor. The following dialogue will appear.

The panel to the left is only and example of what the editor panel may look like. This dialogue will change in size and complexity depending on the check boxes selected. The left side of the dialogue is reserved for pipe and pit data while the right side contains catchment data. The first step is to select the drainage string to be edited. Click on Pick drainage string and then select the drainage string from one of the views.

There are two ways to move between pits. The Prev pit and Next pit will move the user between the pits with the current pit name been shown in the Change pit name field. Do not use the Change pit name
field to move between pits. It will not work! This field is used to manually change the pit name. Entering the **pit number** and pressing **Enter** is the second method for selecting pits. This is a good way to move between pits on long drainage lines (from pit 20 to pit 1 for example).

The **pipe diameter** will change the diameter of the pipe leaving the pit in the direction of increasing chainage. Note that the invert level of the pipe will remain fixed as the obvert level changes.

The most common **Design mode** is 1 for design. This ignores the present pipe size and resizes the pipe as required.

When the **Inlet capacity** and **Bypass pit** tick boxes are checked, additional fields are added to the dialogue. These will be discussed in the section 5.0 above.

The **Catchment Detailed** and **Comprehensive** tick boxes also add additional fields to the dialogue. Again, the ILSAX drainage manual contains detailed descriptions of these parameters.
23.13.3.2 ILSAX Rainfall File Editor

Position of option on menu: Design => Drainage => More => ILSAX Editor => ILSAX rainfall file editor

The ILSAX rainfall file editor assists in the creation and editing of the ILSAX rainfall files. It is truly a file editor and no data is stored inside the 12d Model. Most common features of the ILSAX rainfall file are included but some have been omitted as they have been rarely used. The files can be created using the editor and then manually edited using a word processor if required.

See Also

ILSAX pipe editor
Drainage overview

Usage

This panel is accessed from the menu selection Design => Drainage => More => ILSAX editors => ILSAX rainfall file editor

The Rainfall file name must be specified before the Read or Write buttons will operate. If you want to create a file, fill in the Rainfall file name field and then LB select Write to save the data.

Intermediate Files and Separate Rain/pipe files must be ticked to have ILSAX run within 12d. The minimum value for Num Rainfall Events is 1.

The remaining data in the left column is the data for the ILSAX R3 and R4 cards and the data in the right column is the data for the ILSAX R2, R6, R6B and R8 cards. Please refer to the ILSAX manual for a description of these values. The fields are not in the same order as the ILSAX files but instead the fields at the top of the column are those changed most frequently between rainfall events.

The Prev Rainfall and Next Rainfall buttons select the rainfall events up to the number specified.
in Num rainfall events. If you wish to add or decrease the number of events analysed change the Num rainfall events value.

**CAUTION:** the Finish button does not perform a save so make sure you click **Write** before Finish.

The fields and buttons used in this panel are described in the ILSAX users manual.
23.13.4 PCdrain to 12d pit converter

Position of option on menu: Design => Drainage Sewer => More=>Create Pit type from PC Drain gully files

This option is used to read a PCdrain gully file and create the same pit type in the 12d drainage.4d file. The sag pits in the gully file have an “S” added as a suffix as they are imported. Important: 12d must be restarted to see the new pit types.

23.13.5 Calc pit overflow areas

Position of option on menu:  Design => Drainage Sewer => More=>Calc pit overflow areas

This option is used to graphically display the overflow storage volume at a sag pit. The following pit attributes must exist for the flood extents to be calculated.

- **overflow volume**: value greater than zero required.
- **sag pit**: must be equal to 1.
- **catchment model id**: set by labelling catchments
- **catchment string id**: set by labelling catchments

The maximum storage volume is read from the drainage pit attribute "overflow volume". This may be entered manually using the **Attribute Editor** or it will be created when data is read from the drainage design programs Drains or XP SWMM design programs.

This routine locates the lowest point on the catchment string by draping the string on the tin specified and adds the overflow limit specified to this value. This becomes the **overflow limit**.

The volume at this level is calculated and the compared to the overflow volume read from the user defined attribute. If the overflow volume is less than the volume in the catchment then the routine iterates to find the flood level for the overflow volume.

If the overflow volume is greater than the volume in the catchment, the results depend on the **Use overflow limit** tick box.

If the box is selected, the overflow limit (calculated above) is reported at the flood level in the catchment.

If the tick box is not selected, the routine iterates to find the flood level where the storage equals the overflow volume read. This option allows the user to see the maximum flood level should the catchment low point become blocked.

1.12d Model Drainage Modules and Work Flow

12d Model has a suite of drainage modules for stormwater design. This course covers the items listed below on this page except 24, 25 and 28.

1.1 Drainage Module

**Part A - Locate Structures and Connect the Pipe Network**

1. Obtain/create Survey data and design surfaces (TINs) for pipe and manhole levels,
2. Identify overland flow paths and drainage inlet structure locations,
3. Set drainage default for the pits and pipes (most common settings, they may be changed later).
4. Read a drainage model template file containing you default and global settings.
5. Create the drainage strings in 12d or convert strings from CAD.
6. Assign pit names using the DNE. This allows easy reference to the structures.
7. Change pit and pipe types where they are different from the default values
8. Link the drainage model to the road design models for an integrated design.
9. Check and adjust horizontal alignment of the pipes and pits.
10. Set the vertical alignment using the DNE (set pit details and regrade pipes).
11. Check for service clashes and adjust vertical as required.

**Part B - Hydrology and Hydraulic Data Preparation**

12. Set catchment areas, % impervious, C and tc values for hydrology,
13. Set grate levels, Ku methods (pit and culverts), pipe roughness etc for hydraulic design
14. Draw/create bypass flow paths if bypass/inlet capacity calcs are required.
15. user defined export and update interfaces with Drains, PCdrain, Micro drainage-WinDes, RAT2000 and XP SWMM/STORM.

**Part C - Design Documentation**

16. Print pit schedules and plan/long section drawings for construction,
17. Import and Export the network to spreadsheets,
18. Calculate network quantities (by depth ranges) for costing and system checks,
19. Calculate earthwork excavation volumes,
20. Repeat as required for design changes,
21. And of course peer review at various points of design,
22. Electronic models for survey setout.

1.2 Drainage Analysis Module

**Part D - Rational Hydrology, Surface Flow Calculations and Pipe Hydraulics**

23. Calculate rational hydrology peak discharges,
24. Normal depth surface flow hydraulics using channel sections cut from the ground surface. Results are shown in plan, section and 3d views (and reports) with warnings given for exceeding max widths, channel capacity and velocity x depth hazard conditions,
25. inlet capacities at sag and on grade locations determine bypass and pipe flows,
26. HG1 calculations use pipe and manhole losses (Ku/Kw). Pipe are sized using either freeboard or flow depth methods. This includes full culvert design with backwater and inlet control calculations.

27. Review results in plan drawings, long sections and printed reports,

28. Analysis of the major flood event and checks for surface flow and hazard conditions.

1.3 Dynamic Drainage Module - Unsteady flow analysis

This module uses ILSAX and SCS hydrology together with the solution of the unsteady flow equations to analyse the network. Inlet capacity charts are used to analyse surface and subsurface HG1 lines. Natural channel shapes and elevation-area curves for basin are created directly from the ground surface. User defined reports are created via the spreadsheet interface.

1.4 TUFLOW and Roadflow Modules

These modules use the TUFLOW engine (1D/2D hydrodynamic computational engine) for simulating free-surface water flow for urban waterways, rivers, floodplains, estuaries and coastlines. Using tools including 12d grid tins and the 12d TUFLOW control file editor the 12d, TUFLOW input data is created, edited and viewed all within 12d. This module may be combined with the dynamic drainage module for a coupled 1D/2D analysis to include pipes and culverts.
2.12d Model Stormwater Courses

In these documents, the generic term pit refers to manholes, inlets and catch basins. When the term manhole is used on the 12d menu system it refers to any type of pit.

2.1 Stormwater Design Part 1

These notes are for this course designed to cover creating drainage networks, rational method design and reporting.
- create a super tin for pipe cover and pit cover levels,
- set Defaults and layout a drainage network from CAD and in 12d,
- use the 12d Drainage Network Editor to assign names to the pit/pipes, avoid service clashes, grade pipes, align obverts, minimise depth and many other design tools,
- designate catchment areas and produce catchment plans,
- run the 12d storm rational hydrology and hydraulics engine,
- transfer data to and from electronic spreadsheets to enable the user to easily review the data and add user defined data to the 12d pipe network. This data may include such data as pipe bedding types and trench width,
- create a drainage template containing customised default design parameters,
- create pit setout schedules to export to spreadsheets or word processors for final formatting,
- produce long section drainage profiles including HGL data, flows, invert levels and service crossings,
- create plan drawings with pipe sizes, flows, pit symbols, linestyles for pipe sizes, design parameters for pit and pipes and user defined data,
- locate pits/manholes at exact chainage and offset locations.

2.2 Stormwater Design - Part 2

This course continues on with surface flow analysis, inlet capacity and bypass flow and customising the 12d drainage setup file (pit and pipe type database).
- customising the drainage.4d file Drainage Definitions - Manholes and Pipes,
- 12d storm analysis with inlet capacity calculations and bypass flow,
- flooded width analysis and flooding at SAG pits,
- drainage trench excavation volume calculations,
- pipe and pit quantity calculations/reports,
- open channel calculations,
- adjusting pit locations for changes in horiz road geometry
- analysing the major flood events,
- creating drainage symbols with grates and upstream side inlets,
- detailed drainage plan labelling and long sections with hatching under roads.

2.3 Stormwater Basin Design Hydraulics and Hydrology

- The course discusses unsteady flow hydraulics and their use in the design of storage basins and tanks.
3. Using the Course Notes

Areas marked in yellow (grey for black and white prints) are the exact steps required to complete the tasks. The numbers in the panels are the order to preform the tasks and they are always written to the right of the button, drop down or data field.

The additional text explains in more detail the tasks you are preforming.
4. Customising 12d Model Drainage

12d Drainage has a series of files that customise your drainage components and design process. These includes:

- drainage.4d (required)
  - manhole types and properties
  - pipe types and properties

- drainage model template
  - contains global and default settings for the drainage network. Including references to the following files.

- cover files
  - specify pipe cover for each pipe type

- grade file
  - specify pipe/channel slope by height

- drop file
  - specify drop across manholes by deflection angle

- catchment file
  - specify polygons for 3 land use types

- road design file
  - link manholes to strings to determine x,y,z coordinates

- services file
  - specify clearance tolerances for models of service crossing.

The drainage.4d file has been configured for the training version. However, when you start working on your projects you may want to customise the drainage module. More - Customising the drainage module

The drainage.4d file is the required drainage setup file that contains:

- manhole and inlets with wall thickness and inlet capacity curves for ongrade and sag conditions

- pipe types (RCP, Class 2 etc.) with nominal pipe diameters and wall thicknesses,

- user defined attributes lists to be assigned to the network via pit and pipe types.

- manhole and pipe type parameters are used to control settings in the DNE. This allows the user to set numerous properties by selecting only the pit or pipe type. More.
5. Survey data and design surfaces (TINs)

We will start a 12d project from the beginning by first creating the project and then reading in the survey and design data. The data can then be triangulated so that we have a final surface to measure pipe cover from and set structure cover levels to.

Start up the 12d model by selecting the 12d icon from your desktop.

The project selection panel will appear. The bottom corner of the panel is shown below.

1) **LB** to browse to the working folder indicated.
2) Type a project name for your work *Stormwater Part 1 all* for example.
3) Select **Proceed**.

Alternate Step 2. If you do not want to create the tin or roadway then select the existing project *Stormwater Part1* found in the courses\drainage folder. Skip to the section *Drainage Overland Flow Investigation* or go straight to *Read in a drainage model template*.

12d will first look in your working folder for any input data files and output files will be created here unless you specify another folder. 12d stores it’s data in a folder not a single file. Therefore, a folder named *Stormwater Part 1 all* will be created when you select **Proceed**.

12d model will load and you will see the following panel.
5.1 Importing the Raw Survey Data

You have created a new project into which we will import the survey data. From the main menu select:

File I/O->Data Input->12da/4da data

1) LB the folder icon to display the file list. Select the file existing survey.
2) LB Read to read the data
3) LB Finish to remove the panel

The data will appear on a new plan view.

Enter data as desired. This data is both for reference and can be included on your drawings.
Later these details can be changed via Project=>Management=Details Editor
5.2 Creating the existing Ground Surface

From the main menu select

Tins=>Create=> Triangulate data

Now we will display the z values for the survey data.

1) LB the toggle button
2) LB Z values

Use your mouse wheel to zoom in and read the z values. Press Ctrl and Middle mouse drag to pan

1) Type a name for the function to make it easy to recalculate later in new data arrives.
2) Type a new tin name then press Enter
3) Type grass2 instead of green. This will look better in the visualisation.
4) LB Remove Bubbles so that breaklines will attempt not to form triangles back onto themselves (if the breakline is a contour, this removes contour bubbles).

Preserve strings will make one side of a triangle follow the string thereby preserving the levels along the string.

Weed tin removes all duplicate points from the tin database.

The Cell method is a good speed enhancement for data that is in a grid type pattern.

Triangle data is used for string that form triangles (tins imported from other programs).
5.3 Viewing the Ground Surface Tin

The tin will be shown with the tin edges turned on. This is the default when you have all tin display modes turned off.

The tin will be stored in the model tin existing. A tin, like all 12d strings, must be stored in a model. 12d prefixes all its tins with tin for data management.
Display Contours
1) LB the toggle button
2) LB Tin contours.

The contours are displayed with their default colours and increment (1 unit).

Display Flow
1. LB the toggle button
2. LB Tin flow.
Flow arrows are now visible at the centre of every triangle.

To plot flow arrows, create them in a model using Tins->Tin analysis->Flow arrows

Change Contour Intervals and Colours
1) LB the View menu button
2) Walk right (do not LB select) on settings.
3) Walk right on Tins.
4) LB Contours

4) LB Contours

ShortCut! Press F11 to display the Menu shown in step 4
Change the Flow Arrow Length and Colour

Select the Menu button on the plan view tool bar and then walk right on.

Settings=>Tins=>Flow Arrows and the following dialog will appear. Remember to walk right!

5.4 Inquiring about Heights on the Surface

The elevation anywhere on the tin can be obtained by simply moving the pointer over the desired spot. To obtain the tin elevations select,

Tins=>Inquire=>Height

If you do not select a tin, the last tin added to the view will have its height displayed. You will see the data
in the panel change as you move the pointer around the screen. You may explicitly select a tin if another tin is desired.

Move the panel to the bottom right corner of the screen and leave it there.

5.5 Viewing the Surface Tin in a 3d Perspective

To create a 3d perspective view select

View=>New=>Perspective Open GL

1) Add the model tin existing to the view.
2) Toggle the contours on.
3) Toggle the shading on (note that the contours are no longer seen).
4) Use the Orbit control (planet on the toolbar) and zoom wheel to move around the view.

5.6 Reducing the number of points for the 12d Practice Version

We can delete the survey data to save space for those using the practice version of 12d. If you have a full version of 12d this is not required. From the main menu select.

Models=>Delete=>Delete a Model

and the following dialog will appear.

1) LB the model icon and select EXISTING SURVEY
2) LB Delete and then confirm each panel
3) LB Finish

The model is now in the 12d trash can (see bottom right corner of the 12d screen).

5.7 Importing the Road Design Centre lines

Repeat the process of importing 12da data.

File I/O->Data Input->12da/4da data
5.8 Using Create Roads

We are going to create the roadways from the road centre lines (vertical grading has already been done). First we will need the road templates that we will read from a templates file.

File IO=>Templates input

Now we are ready to create the road strings and design tin.

Design=>Roads=>Create=>Create Roads - Manager
1. LB **Function** and select the **create roads** function. This has all of the road design details included in it.

2. LB the **Create** button

3. LB the **Finish** button.

4. Add **tin design** onto the plan view.

To view the road strings, add on all of the **road ** models to view 3. To view the tin add on the **tin design** model. You can also add the **tin design** model onto the perspective view. **Important:** On the OpenGL perspective view, 12d will show the tin data with the greatest z values (when viewed from the top side). Rename view 3 to roads to help organise your work.
5.9 Creating a Super Tin from the Survey and Design Data.

The drainage fs tin may be used to set pipe invert, pit levels, sag catchment overflow points and catchment slopes for tc strings. Therefore, the tin often needs to include several tins combined into one tin. To create a tin that is the combination of the survey data and the road design data you will need to create a 12d super tin. From the main menu

Tins=>Create=>supertin

- The order of the tins is very important. Tin 1 is the first to be drawn then tin 2 is drawn. i.e. wherever tin 2 exists it will be used. If there is no tin 2 at a location then tin 1 will be used.

5.10 Changing the Colour of a Tin

To emphasise the super tin is just the tins “glued” together, we will change the colour of the existing tin and see how the super tin changes colour as well.
Toggle the **Tin solid** on and note the colours of the super tin.

Tins=>Colour=>Colour of tin
1. LB tin icon and select the **existing** tin
2. LB colour icon and select **dark green**
3. LB Colour
4. LB Finish
6. Drainage Overland Flow Investigation

Where a drainage designer chooses to start their design is depends a great deal on the project and the designer. Identifying overland flow routes, with the crest and sag points, is essential because it is on these routes that the inlets are to be placed. Inlet structures are then placed at the critical locations (sag points, flattening of grades, intersections, upstream of pedestrian crossings etc.). and then the spacing of additional inlets is determined by the size of the catchments. Finally, the pipe drainage system can be created linking the drainage structures.

Following is a list of 12d tools to identify surface flow routes:

- Change the Flow Arrow Length and Colour
- Downhill Strings
- Locating Crests and Sag Points
- Rain drop

6.1 Downhill Strings

Roads are generally designed with a flow path in the cross section shape. In this example the roadway has a dual crossfall with kerb and gutters. We will use the downhill strings option to locate all the invert strings, change their line style to a flow arrow, split them at their crest and sag points and ensure the chainage increases in the downhill direction.

From the main menu select

Design->Drainage-Sewer->Downhill strings

1. type Road*Strs (it is case sensitive). These are the models that contain all of the road strings. Road 1 Strs for example.
2. type *inv. The road string models have a linv and rinv string for the invert of the kerb and gutters.
3. type dr overland flow to create a model for the new strings
4. Select Run
5. add the model dr overland flow onto the roads view.

6.2 Locating Crests and Sag Points

This step will place tick marks at the crest and sag points of your kerb strings and label them with the levels.

Strings =>Label => Chainages
Add all of the models beginning with Road onto plan view 1.

1. Select the filter button
2. Select the View tab
3. Select the Roads view
4. Select the String Info tab
5. Type *inv to so that the linv and rinv strings will be selected.
6. Select Filter Select to select the inv strings to be labelled.
7. Select crests/sags from drop down list.
8. Enter a model to contain the text labels. A ,1 after the model name, requests that the model be added to view 1. This saves you adding the model to the view later to see the labels.

9. Select icon to define the text style.

10. Untick **Chainages**

11. Tick **Heights**

12. Select **Label**

13. Select **Marks** tab

14. Select the model used above for the tick marks.

15. **LB** to select **ticks centred** from the drop down list.

16. 10m marks stand out well on the screen.

17. Set colour to **yellow**

18. Select **Label** to create the labels.
6.3 Creating a Filter Favourite

![Image of Label Chainages on String]

1. Before closing the panels, create a filter favourite that can be used later. Select the Star button.

2. Select [Create].

3. Type drainage invert.

4. Select Create.

5. Select Finish. The favourite is now created for later use.

Select Finish to remove the panel.

Now add the model dr crests and sags onto the roads view.

6.4 Rain drop

The raindrop routine will create a line from a selected point and follow either up or down the tin.

From the main menu select

**Design->Drainage-Sewer->Rain drop**

Try selecting several points on the tin to see the flow lines that are created.
7. Setting Drainage Defaults (Initial Settings)

Before creating drainage strings in 12d we should set default values for the pit and pipes. These defaults are only used as initial settings for new manholes and pipes. This ensures that most of the pit and pipes will have the desired type, size etc and then we only need to modify the pit and pipes that are different to the default values. The defaults for the drainage network are accessed through three panels; pipe defaults, manhole defaults and Tin defaults.

7.1 Tin Default

The 12d drainage module is designed so that no levels need to be manually entered into the drainage system (although they can be and locked if desired). The primary source for these levels is a design tin but levels from design strings and polygons can be used as well.

Design => Drainage-Sewer => Defaults => Tin

The default TIN is used to set the initial manhole cover level and the pipe invert levels (via pipe cover or depth settings discussed later). Super tins may be used if you want to place manholes on both the existing and the design ground surface (see Creating a Super Tin from the Survey and Design Data).

1. LB the tin icon and select the combined tin.
2. LB the Set button
3. LB the Finish button.

If you place a pit outside the tin boundary:
1. then no elevation will be set for the top of the pit, (it can be set later manually or by linking it to a road design string).
2. Pipe invert levels cannot be set using the default cover. Pipe invert levels must be set manually as 12d cannot automatically determine cover levels without a TIN.
3. Finally, if you are exporting to an external drainage design program that accepts surface levels along the string, then an error message will be displayed at export time. The message will say that the surface level string is shorter than the pipe length.

7.2 Manhole (Pit) Defaults

Design => Drainage-Sewer => Defaults => Manholes

Notes on pit Diameters

The pit diameter/size is specified in metres/feet not mm/inches. The size of the pit is generally set in the drainage.4d file as either circular (mhdiam) or rectangular (mhsiz). If both commands are specified then the mhsiz command takes precedence. Plan drawings may use a symbol via the drainage plot annotations. The Diameter is used for:
1. for visual service clash identification in long section drawings,
2. to clip the pipe lines drawn in the plan annotations so that symbols can be inserted in the space created,
3. maximum distance the bypass flow strings can be drawn from an inlet centre.

The minimum drop will be used to set the invert level of the outlet pipe relative to the invert level of the inlet pipes. The drop should always be entered as a positive value. The DNE has many more options for aligning the pipe inverts at the pits. The drop may vary with the pipe deflection angle via the DNE->Defaults->Pipe->Drop file.

Setting the default name to New is a good reminder that you have not confirmed the pit type. Use the Set Pit Names function on the DNE to assign the pit names.

The pit type list is obtained from the drainage.4d file. Set this to the most common pit type and then later change the ones that are different using the DNE.

You must click the Set button to set the default values. Finish alone will not set the defaults.

7.3 Pipe Defaults

The pipe diameter is set in metres or feet not mm or inches. Set this to a common pipe diameter for your project then alter other pipes or change to box culverts in the DNE.

Pipe Thickness for Pipe Cover

When 12d set the pipe inverts it checks the minimum cover from the top of the pipe to the finished ground surface at the ends of the pipe. Pipe thickness is changed by pipe type as defined in the drainage.4d file.

Cover = surface level - thickness - diameter(height) - invert

If the grade of the pipe is less than the minimum grade, the grade of the pipe is increased. The DNE has a pipe grade file where the minimum grade may be changed via the pipe diameter.

Finally, 12d checks if there is anywhere along the pipe length that has less than the minimum cover. If there is such a low point in the design surface, the pipe is shifted vertically downwards to achieve the cover.
required. The **DNE** has a pipe cover file that will change the pipe cover via the pipe type. If the pipe type is not found in this file then this minimum cover will be used. Circular pipes have the cover checked along the centre line and box culverts along the centre line and edges.

When using the 12d editors to change the pipe diameters the invert levels will remain fixed and the obverts will change. The inverts may be reset using **Regrade Network** on the **network editor**.

The list of available pipe types is set in the **drainage.4d** file.

### 7.4 String Colour and pit Label Text Size/location (string defaults)

12d can automatically label the pits at a fixed offset from the pit using **view text** OR you can use the **network editor** **Plot** to create text labels that can be moved/rotated etc.

For view text, the default line colour and text size are set by selecting

**Project=>Management =>Defaults**

The following panel will appear.

```markdown
1. LB **colour** icon to set the default colour of the drainage string and man-hole labels.
2. Type the height of the text in pixels
3. LB the **Set** button. This will set the defaults for this project only.
4. LB the **Finish** button.
```

The manhole label textstyle and offset may be changed via the **DNE->Global->display tab**
Optionally, you may LB the Write button to set the defaults for other projects. The following panel will appear. Selecting Current folder will save ALL these defaults for projects in this working folder only. The defaults set in the user or setups directories will not be used if you select this option.

Selecting User folder will save your defaults so that all other 12d projects will use these defaults. This is the most common option (unless your network administrator has not given you write access to this folder (check Properties in windows explorer).

Select Write then Finish
8. Creating Drainage Strings

We are now going to create a culvert to cross road 3.

Key Points

1. Before creating the drainage strings, read in a drainage model template (Design->Drainage-Sewer->Create->Create/Read template) so that all of DNE settings will set. There is a sample one in the 12d library (drainage_template_QLD.12da). If you forget, do it later but READ A TEMPLATE FILE. We will create one at the end of this course.

2. You will be placing centre of the culvert headwall. The headwall centre is the selection point for the pit. Pipes can be connected this pit Use setout strings for construction setout points!

3. Drawing all drainage lines in the same direction may help you keep your drainage work organised. Either draw all string uphill to downhill (flow same as string direction) OR downhill to uphill (flow opposite to string direction). You can mix the flow directions if desired.

4. The Drainage Network Editor Regrade Pipes is the key to setting pipe invert levels! Use this after modifying the drainage plan layout as it will update all initial grading described below.

However, 12d will perform an initial grading as you draw the string. If you choose opposite to string direction then will need to select Pipe=>Default Grading then Grade to achieve this initial estimate. If you create branch lines before the trunk lines the initial grading will ensure the trunk line inverts remain below the branch line. Regardless, the DNE regrade pipes will sort the grading for all strings in the model.

8.1 Read in a drainage model template

A drainage model template contains your favourite global and default settings for the DNE. These settings are stored as model attributes and the template may be read before or after the drainage strings have been created. Caution: existing default and global setting may be overridden.

You can create your own templates as well. After you have completed a drainage job and all of your global and default settings are set, create a template to save in your user library.

From the main menu select

Design => Drainage-Sewer => Create => Create/Read template

1. Leave as Read.
2. Type drainage to create a new model for the drainage strings
3. LB the folder icon, then lib to locate drainage_template_QLD.12da
4. LB Process to create the model and import the default and global settings.

8.2 Creating the Drainage Strings in 12d

12d has a routine that creates a culvert very quickly. Design->Drainage-Sewer->Create->Culvert. It will also add a channel to the outlet as well! Try this, then the general method discussed below. The culvert is placed in a model culvert and the levels are all set to the manual mode.
A drainage string is created by selecting

**Design => Drainage-Sewer => Create->Create**

The initial manhole and pipe types will those set in **Setting Drainage Defaults (Initial Settings)**.

1. Type a string name (used for pit naming later).
2. Type a new model name for the network.
3. LB the **Colour** icon and select colour (optional).
4. Leave unless drawing in uphill direction.
5. From the default, leave as is.
6. Existing tin can be used for long section dwg levels.
7. Select if creating more than 1 string.
8. LB the **Create** button, the menu below will appear.

If you have already created a drainage string, click the **Same as** button and select the drainage string to obtain the panel values from that string. After selecting the string, change the string **Name**.

We are going to initially place our head walls on edge of the batters and then fine tune the location later.

To create your first manhole select

1. **Edits => Add/Append MH**. A +MH will appear with your pointer. Refer to the plan below for the headwall locations.
2. LB and accept for the upstream (east) and downstream (west) headwalls.
3. LB the **Finish** button after the last headwall is placed.
8.3 Change Pit and Pipe Types and Sizes

We will use the DNE to change the structures to inlet and outlet headwalls and the pipe to a box culvert.

The drainage network editor is accessed through the main menu by selecting

**Design=>Drainage-Sewer=>Network Editor**

The bottom section of the network editor panel is shown below. You can change tabs but no data can be entered in the panel until a drainage pit or pipe has been selected and accepted.

The action buttons on the drainage editor now become active.

The pit closest to the point selected is highlighted with a circle and an arrow shows the direction of flow and the pipe being edited (see image below). When the outlet is selected there is no arrow. If the arrow is in the wrong direction or the outlet is at the upstream end of the string see Flow in the Wrong Direction to correct this.
1. Select the **Pit** Tab

2. Note the **Pit type** is already **HW** as we set this as the default. The type may be used to set pit properties. See [Drainage Definitions - Manhole Types](#) in 12d help. If you did not set this as your default ([Manhole (Pit) Defaults](#)) then change it now.

3. Diameter/length is in the direction of the road once it is linked otherwise it is east-west. Width is 90 degrees to this, if width is blank the pit is circular.

4. Select **Apply** to see the changes.

---

1. Select the **Pipe** Tab

2. Change the **Pipe type** to **BC** (for box culvert). This may be used to set some of the pipe properties. See [Drainage Definitions - Pipe Types](#) in 12d help.

3. Change **Diam/height** to 0.375 and width to 0.600. If width is blank the pipe is circular.
A popup will appear indicating that the pipe thickness will be changed because the pipe type has a different thickness setting in the drainage. Select **Stop asking for this session** and then click **Update**.

8.4 Flow in the Wrong Direction

The direction of flow is used by 12d to determine which end of the string is the outlet and therefore the direction of decreasing invert elevations when regrading the string.

The direction of flow will be indicated with the arrow on the pit when using the **DNE**. No arrow will appear if the outlet is selected. If you find the arrow is pointing in the wrong direction there are 2 methods to access the flow directions.

**Method 1:** Use the **DNE** to select the string with the flow in the wrong direction and then select the **String Editor** button. From the menu select **Utility->Properties**. Change the **Flow direction** value to the other value. Select **OK** then **Save & Finish**. Now use the **Pick** button to select the drainage network again.

**Method 2:** Use the **Strings->Properties->String** option from the main menu. Select the string and then change the **Flow direction** value to the other value.
9. Drainage Strings Levels

The **DNE** quickly sets the levels for your drainage network. All the levels can be calculated by the **DNE** or locked with user specified values.

9.1 Pit Levels

Pits have 4 levels:

1. the cover level is used in plotting and pit depth calculations. This is also the maximum obvert level drawn for all connecting pipes.
2. the grate level is used for the freeboard measurements, the surcharge to bypass level and the reference level for pond flooding depths.
3. the setout level is used for survey setout to construct the pit.
4. the sump level (bottom of the pit) is used in plotting and for depth calculations. If set to floating mode, it is calculated from the lowest pipe invert connected to the pit plus the sump offset.

The grate level is the most important level in 12d hydraulics and will be discussed more in those sections.

9.2 Pipe Levels

Pipes have the upstream and downstream invert levels that can set by the minimum grade and cover criteria (see **Vertical Alignment - Pipes**). The invert drop across a pit can also be fixed or change with the deflection angle. At this time we are only concerned with the pipe cover and grade.

9.3 Section View of a Drainage String

Create a section view to profile the drainage string.

From the main menu select

View->Create->Section view

1. Type **Drainage**
2. Select the **Create** button
9.4 Set Pit Details

Selecting Set Pit Details will set the pit levels and setout coordinates for all of the pits in the network using either the default settings for the model or the explicit settings for the pit (if used). Other attributes are set as well but they will be discussed later. A prompt box appears asking you to confirm. Select Yes.
9.5 Regrade Pipes

Selecting the **Regrade Pipes** button sets the pipe inverts for all of the pipe in the network using either the default settings for the model or the explicit settings for the pipe (if used). A prompt box appears asking you to confirm. Select **Yes**. To toggle off/on the confirm request **RB Regrade Pipes**.

Minimum grade and cover are checked and trunk lines are lowered to accept incoming branch lines. Grade is calculated using either the pit centre to centre distance or the end of pipe to end of pipe distance (DNE- >Global **Use end to end pipe length**). Default pipe cover and grade are set on the **DNE Defaults-Pipe** tab and if not found there the **Drainage->Defaults-Pipe** settings are used.

Invert alignment is based on the pipe cover, the pipe minimum grade and the drop across the pit (see **Pipe Grade Modes**). The tin specified in the **Global-Main Finished Surface Tin** box is used for these calculations. Since every pipe that enters the pit may have a different drop mode, the drop mode is set on the downstream end of the pipe, NOT the pit.

If the inverts are locked on the **Pipe** tab then some the design criteria may not be able to be achieved. Messages in the output window will indicate these problems.

Now we will regrade the culvert checking the cover only under the roadway. First select the upstream (east) headwall.

1. Select the **Pipe** tab
2. Select the **Design** tab
3. Type **0.6** to over ride the default cover we set earlier (this is the minimum distance measured from the top of the pipe).
4. Type **2.5** for the Skip cover distances (US and DS). These distances are measured from the ends of the pipe. This will stop 12d from checking the cover in these areas.
5. Select **Regrade Pipe** to reset the inverts.

For circular pipes, the cover is checked along the centre line of the pipe. For box culverts the cover is also measured along the sides. The wall thickness is set via the pipe type and diameter from the drainage.4d file.
9.6 Setout Strings to Align the Headwalls with the Roadway

Now link the headwalls to the roadway so they are perpendicular to the batter slope.

![Diagram of drainage network editor with steps highlighted]

1. Select Global
2. Select Utility Models
3. Type road strings
4. Select the folder icon then Open

![Diagram of road design file with steps highlighted]

1. RB in the Road Strings Model cell and select Road 3 Strs model
   - type *bok so that the headwall will be linked to the closest lbok or rbok string.
   - type 10 as the max distance to search for a string
2. LB Write to save the file
3. Select Finish
4. Select Set Pit Details to create the links to the road strings.

Note: The obvert of the pipe will never be drawn above the grate levels. If the cover or grate level is below the pipe invert you will get an X pipe. Set pit details will recalculate the pit levels and Regrade pipe to set the inverts.
The culvert headwalls now align with the roadway instead of east-west.

Now confirm the manhole link to the road strings (setout strings).

9.7 Adjust Pipe Length

Now adjust the culvert length to an even number of pipe lengths.

DNE string links exist until you manually clear them or you delete the string.
OR you clear the link by RB on the manual pick and select Clear,
OR you clear all road string links via Global->Utility Models->Clear Road Links.
We have a good link so do not do this at this time.

From the main menu select

Design->Drainage-Sewer->More->Extend pipe/culvert
As the culvert appears to be too long we will shorten it to 10 standard lengths (half on both ends).

1. Pick and accept the culvert
2. Change **End to extend** to **high chainage**
3. Change **Standard length** to 2.46
4. Change **Gap length** to 0.010
5. Change **Num pipes** to 11 and press enter. The new length is displayed
6. Select **Process**
7. Select **Finish**

After selecting process, the section view will need updating. Also the pit cover levels are set to the pipe invert level. The next time you press **Set pit details** in the DNE they will be reset using the selected method.
10. Importing Drainage Layouts from AutoCAD

We are now going to import a pipe layout that was drawn in CAD along with the overland flow routes and catchment areas (These could have been created in 12d as well). When these were drawn the following rules were followed:

1. Strings are drawn where the pipes are NOT to setout x,y locations,
2. Polylines are used in AutoCAD,
3. Lines drawn from upstream to downstream (direction of flow),
4. A vertex was placed at every pit location.

To import the AutoCAD drawing, from the main menu select

File IO->Data Input=>DWG/DXF/DXB

1. Select 2012 support
2. LB the folder icon and select the drainage data.dwg file
3. Type a prefix for the models. It will help organise the layers from AutoCAD as every layer goes into a separate model in 12d. Specifying a prefix causes all of the layer names to be prefixed with this text and therefore kept together in the model list. The prefix used is dwg<space>.
4. Enter the null value 0 (no level in CAD value)
5. LB Read button. If you select the Read button more than once the data will be imported again and you will get duplicate, triplicate...etc data.
6. LB Finish

The models that have been created are,

dwg Catchs Future
dwg Catch Lots
dwg Catch Reserve
dwg Catch Roads
dwg network

dwg network is a drainage layout that we will use to locate the pits in our drainage design.

10.1 Checking the String Direction of CAD Network Strings

A quick way to check the direction of the strings imported from CAD is to change the linestyle to a style that indicates the direction.

From the main menu select,

Utilities->A-G->Change
10.2 Create the drainage strings from the CAD strings

Before creating the drainage strings, [Read in a drainage model template] so that all of DNE settings will be set. If you forget, do it later but [READ A TEMPLATE FILE]. If the drainage strings are going to be added to a model that already has the global and default settings set, these strings will use those model settings.

12d will convert the import strings into 12d drainage strings. The default pipe, pit and tin data will be used to set the levels for the network. Do not use the other string convert commands found on the menu system.

Most of the pits will be grated roadway side entry pits (AL2D). Set this pit type as the default.

Design => Drainage-Sewer => Defaults => Manholes

1. LB the Type drop down and select AL2D.
2. LB the Set button.
3. LB the Finish button.

Next from the menu select

Design => Drainage-Sewer => Create => Create from strings

The following panel will appear.
1. Select the existing \textit{dwg network} model
2. Select the \textit{combined} tin. The cover level for the manholes will be obtained at the manhole centres from this tin.
3. Leave as \textit{same as string direction}. The strings were drawn in the same direct as the flow in th CAD program.
4. Select the existing \textit{drainage} model. If this model was not created from the read drainage model template function then you could type the name now and the model would be created.
5. \textbf{Clean drainage model} when selected will delete all strings in the model before the new drainage strings are created.
6. \textbf{Process} create the drainage strings
7. \textbf{Finish} closes the panel

The imported strings must all be drawn in the same direction. Either all in the direction the water flows or all opposite the direction of flow.

- Pits are created at all vertices on the strings.
- Trunk lines must have a vertex where the branch lines join.

Delete the new plan that was created and observe the new drainage strings created (road view).
11. Horizontal Alignment and Drainage String Edits

11.1 Road design strings (centre line) for Adjust Pit Locations

During the design process, roadways are often moved slightly, requiring the pit location to be adjusted. Linking the inlets to the road design strings enables 12d to quickly adjust these locations and create a report of the pit requiring adjustment.

The Adjust Pit Locations routine will move the centre of the pit perpendicularly to a layout string or offset from a road setout string.

Layout strings do not need to be set up in advance but they do not allow for an offset.

Road design strings need to be setup in the DNE but allow an offset from the setout string that can vary with the pit type. Often large pits will be offset more into the footpath or roadway.

Road and layout strings can be used at the same time. If no road string is found, a layout string will be searched for.

In this example, we are going to use the road setout strings not layout strings. We have already linked the culvert headwalls to the road design strings on Road 3. We will now do the same for the roadway inlets so they will align with the roadway and we can offset the centre of the pit a fixed distance from the setout string. This will require a link to the road centre line as well. A positive offset is away from the centre line and negative towards the centre line.

Start the DNE and select the network.

1. Select Global
2. Select Utility Models
3. Select the folder icon then Open
To confirm that the inlets were linked to setout (*bok) and centre line strings,

1. RB in the Road Strings Model cell and select Road 2 Strs model
   type *bok so that the inlets will be linked to the closest lbok or rbok string.
   type 3 as the max distance to search for a string
2. press enter until row 3 is added
3. type * for Centre String ID.
   This wild card will allow a string with any name (blank will not work).
   type 10 as the max distance to search for a string
4. LB Write, then Replace to save the file
5. Select Finish then Set Pit Details to create the links to the road strings.
6. Regrade pipe to set the inverts.

11.2 Log Lines with the Drainage Network Editor

Double clicking on a log line in the Output window will take the DNE directly to the pit the message refers to!

Selecting Set Pit Details and messages are created in the Output Window for information and error checking. If the line of text begins with an exclamation mark it is a log line.
1. Double click on the word PROBLEM.

No road setout string has been found because we have not included the model Road 1 Strs in the Road strings file found on the Global->Utility Models tab of the DNE. The *bok strings in the Road 2 Strs and Road 3 Strs were more than the search distance away.

1. Note: the DNE (if open) moves to inlet NEW.
2. Select the Pit tab
3. Select the Setout tab.
4. Note that the Setout string field is blank

1. Add the new row and complete with the data as you have done before.
2. After Writing the file select Set Pit details.
3. Confirm that I-11 now has a setout string.
11.3 Adjust Pit Locations

Now we can offset the inlets from the bok setout strings. Close the DNE and then from the main menu select,

Design->Drainage-Sewer->Adjust pit locations

1. Select the model drainage.
2. Ensure Use road strings is selected.
3. RB and select AL2D pit type
4. Type 0.450 for the offset away from the road centre line
5. Layout strings and layout search distance are not being used at this time.
6. Select Process and redraw the plan view to see the new pit locations.
7. Select Finish

The message box indicates that 13 of the 18 pits were adjusted. Check the output window for a list of the pits that were adjusted. If no road string is found then the layout string is searched for. Since we did not use layout strings we get the warning messages for 3 of the pits. Note: You will not have pit names assigned yet (Set Pit names (and pipes)) so your names will be just NEW.

WARNING: Adjust Pit Locations - pit "I-07" found no perpendicular layout string within the specified search distance.
INFO: Adjust Pit Locations - pit "I-04" adjusted by 2.610 units.
WARNING: Adjust Pit Locations - pit "I-08" found no perpendicular layout string within the specified search distance.
INFO: Adjust Pit Locations - pit "I-05" adjusted by 2.610 units.
INFO: Adjust Pit Locations - pit "I-06" adjusted by 2.610 units.
INFO: Adjust Pit Locations - pit "I-07" adjusted by 2.610 units.
INFO: Adjust Pit Locations - pit "I-08" adjusted by 2.610 units.
WARNING: Adjust Pit Locations - pit "I-10" found no perpendicular layout string within the specified search distance.
INFO: Adjust Pit Locations - pit "I-09" adjusted by 2.610 units.
INFO: Adjust Pit Locations - pit "I-10" adjusted by 2.610 units.
WARNING: Adjust Pit Locations - pit "I-11" found no perpendicular layout string within the specified search distance.
WARNING: Adjust Pit Locations - pit "I-12" found no perpendicular layout string within the specified search distance.
### 11.4 Manual Horizontal Alignment - Moving, Adding and Deleting Pits

The most common functions for adjusting the horizontal alignment of manholes and pipes are found on the Strings->Points Edit menu.

The **Append, Between, Delete, Insert and Move** commands are the most common.

The **Move** command has extra options for moving junction pits. Selecting **All points with the same coordinate** will move all points on the view that are at the same x,y coordinate. The point selected will move first and the others will follow **after** the new location has been accepted. **Restrict to selected model** will stop data from other models at the same location from being moved.

The second option

**Strings->Edit**

... gives you all the same commands and more but requires you to select a string first and the edit commands will be restricted to the selected string.
12. Completing the Intersection Drainage Design

When placing inlets around an intersection, it is often required to place the centre of the inlet a specified distance from the curve so that the grate and/or the side inlet will be located on the straight section of kerb. If there is a pedestrian crossing, the inlet should be placed at a specified distance upstream to be clear of the crossing.

12.1 Placing Marker Points around the Intersection

The place points routine is a fast way to place inlet location markers at a specified location from the curved section of the kerb.

From the main menu select

Design->Drainage-Sewer->More->Place points

1. Select the Roads view as it contains the inv strings where we want the pipes.
2. Type *inv so the linv and rinv strings can be selected.
3. Type the distance from the end of the string or the start of curve where the pit is to be placed.
4. Select Pick point and then snap near where the pit is to be placed. The routine will find the closest *inv string and then search for the closest end or curve. It will then measure from the point towards your initial snap to create the marker (see magenta arrows below).
5. Repeat for the remaining 3 ends of the kerb returns.

12.2 Option 1 (Connection at Manhole in the Road)

The option below has been selected for you to complete so that it has 2 inlets and a manhole. Use the tools you have learnt thus far to create the drainage string and assign the pit names. Special care is required when creating a junction pit (10) shown below. There must be a pit on the trunk line where the branch line connects and there branch line must point snap onto the centre of the trunk line pit (see Junction Pits).
12.3 Option 2 (Connection pipe under the footpath)

Some road authorities prefer not to have a manhole in the intersection. Move the connection pit to the inlet to the west and delete the manhole.

A check list is on the following page once you have completed the layout.

12.4 Intersection Check List

1. Did you place the pipes in the correct location so that the correct cover could be measured?
2. When placing the manhole did you use the RB and Perpendicular to place the manhole?
3. Did you use Strings->Points Edit->Insert to add a pit to the trunk line at the junction location?
4. Did you assign a unique string number to the new string so that the set pit names routine would run?
5. Did you select Set Pit Details in the DNE to ensure the cover, grate and setout data was correctly calculated?
6. Did you check the output window for problem messages? Did you fix them?
7. Did you recalc the function \textit{Adjust pits} so that the inlets are 0.450 behind the bok string. Below are 2 other methods for placing pits that you may find useful.

12.5 Offsets from strings

As an alternative to the place points above you can use the snaps CAD to place the pits “on the fly”. Once the points move has been started use the RB and select \texttt{Snaps Cad=>Points=>Locate Offset}. Follow the prompts given in the message area (bottom left corner of the screen). You will need experience with the 12d “directional pick” to use this capability.

12.6 Placing pits at specific Easting Northing Locations

For locating pits at specific x, y coordinates, simply start typing the x coordinate instead of clicking onto a location. An input panel will appear for you to enter the x and y coordinate separated by a space.
13. Manholes - A Closer Look

A manhole is made up of 3 points; the centre of the manhole and the pit-pipe connection points. The pipe exists as the connection between two manholes. The pipe may have a horizontal radius but not vertical.

13.1 Pit-Pipe Connection Points

The default mode has the pipes align between the centres of the manholes. The pit-pipe connection points are at the intersection of the manhole interior wall and the centre of the pipe (see below).

These connection points may be moved by enabling Use pit connection points on the DNE->Global->Main tab. All pits have their connection point initially set to Points. This setting is found on the DNE->Pits->Setout tab.

Pit connection points may be moved via Strings->Points Edit->Move (except for Centre mode described below). If a pipe is manually moved to a new connection point, it will be locked to the connection point and will not move if the pit or neighbouring pit is moved.
13.1.1 Pit Connection Point Modes

**Centre** (rectangle and circular) - This mode is the same as having the **Use connection points** turned off. The connection points will be located on the inside perimeter of the pit wall with the centre line of the pipe intersecting the centre of the pit. In this mode, the connection points may not be adjusted.

**Points** (rectangle) - A connection point is created at the mid point of each internal side of the pit. This may be changed for a **Pit type** by using the **con_points** command in the drainage.4d file. In this mode, the pipe ends will snap to the connection points. It is possible to place more than one pipe on the same connection point (the elevation of the pipes is not checked for clashes).

**Points** (circular) - The connection point may be moved anywhere around the pit internal wall as there are no connection points on the circular pits. Again, it is possible to place more than one pipe on the same connection location (the elevation of the pipes are not checked for clashes). If the manhole centre is moved the connection point locks are removed.

**Perimeter** (rectangular and circular) - Same as **Points** (circular) above.

**Unrestricted** (rectangular and circular) - There are no constraints on the location of the pit connection points. This mode is intended for irregular shapes such as GPT structures and stormwater basins.

---

1. Close the DNE to unlock the drainage strings.
2. Use **Strings->Points Edit->Move** to move the junction pit you added to complete the intersection westward to the inlet.
3. Use **Strings->Points Edit->Move** to move the ends of the pipes as shown. Note that the pipes snap to the centre of the edges.
13.2 Junction Pits

Key Points

1. The branch line must **Point Snap** onto the centre of a pit on the trunk line.
2. Both strings must be in the same model.
3. The downstream end of the string (depends on flow direction) must join onto the trunk line.

When creating a junction, pit turn the point snap on and the line snap off (the F3 and F4 keys are convenient for this). Zoom into the pit so that you can snap the being moved onto the centre of the stationary pit.

Recall a pit contains three points; one at each pit pipe connection points and one at the pit centre. You want to snap onto at the pit centre for a junction pit. In the figure below, the blue line is being placed to join the white line. Note that the diamond indicates that there is a point snap as well as the information panel.
13.3 Drainage Section Views (downhill left to right OR right to left)

The long section views and the profile plots are running downhill from left to right. If you want them downhill from right to left use the reverse function.

To reverse only one string, from the main menu select Strings=>Points Edit=>Move to move the branch string pit the “downstream end” of the branch line must be the junction pit.

1. The centre of the pits did not align. Use Strings=>Points Edit=>Move to move the branch string pit the “downstream end” of the branch line must be the junction pit.

2. The branch string and the trunk string have not been created in the same drainage model. From the main menu select Strings=>Inquire (F2) and select the strings to check their models. If this is the problem, use Strings=>Edit=>Change and specify the correct drainage model (enter the model BEFORE picking the string) or Strings=>Edit=>Duplicate to duplicate one of the strings into the correct model.

If you cannot see your branch lines joining in the section view, check the following:

1. The centre of the pits did not align, Use Strings=>Points Edit=>Move to move the branch string pit the “downstream end” of the branch line must be the junction pit.

2. The branch string and the trunk string have not been created in the same drainage model. From the main menu select Strings=>Inquire (F2) and select the strings to check their models. If this is the problem, use Strings=>Edit=>Change and specify the correct drainage model (enter the model BEFORE picking the string) or Strings=>Edit=>Duplicate to duplicate one of the strings into the correct model.

13.3 Drainage Section Views (downhill left to right OR right to left)

The long section views and the profile plots are running downhill from left to right. If you want them downhill from right to left use the reverse function.

To reverse only one string, from the main menu select

Strings => Strings Edit => Reverse

and pick the drainage strings to reverse. This will also change the drainage flow direction attribute from same as string direction to opposite to string direction.

To reverse all of the strings in a model select the Reverse all strings option,

Design => Drainage-Sewer => More => Reverse all strings
13.4 Drainage Split and Join

In this example, we are going to **split** the string shown in white below at IN14 (your pit are still NEW) so that we can **join** the west end (IN14 to IN16) to the trunk line on the southern side of the road (cyan). This will allow us to produce a long section that will extend the full length of the road 2 to the headwall outlet.

Use the **String split/join** from the Drainage menu not the one on the **Strings->Strings edit**.

**Split Option**

The split must be done at a pit.
1. A new name for the upstream string (optional). Leave it blank.
2. A new name for the downstream string (optional) Leave it blank.
3. LB the **Split** button and then select the pit where the split is to occur. (IN14).

**Join Option**

This routine will add a new pipe between the 2 strings if required. When **Join US to DS** is selected, the properties and attributes of the upstream string and pit at the join will transfer to the new joined string. **Join DS to US** will cause the properties and attributes to come from the ds string. Upstream and downstream is determined by the flow direction.

1. Select the **Join US to DS** button.
2. Pick and accept the cyan drainage string, then the IN14 to IN16 string (follow the messages in the 12d message area).
14. Drainage Network Editor (DNE)

We have had a brief introduction to the DNE when we worked with the culvert. We will now look at many more of the DNE capabilities.

**Read in a drainage model template!** There is no need to set all of your global and default settings each time you start a new job. If we had not already read in a template we would do it now. Templates are a way to store all of your [Network Editor - Global, Default Settings and Explicit Settings](#).

The drainage network editor is used to automatically or manually change the properties of your drainage network. These abilities include:

- **Vertical Alignment - Manholes**
- **Set Pit names (and pipes)**
- **Service and Utility Clashes**

### Hydrology

- **Catchment Areas**
- **Catchment Areas and Percent Impervious**
- **Coefficients of Runoff**
- **Times of Concentration**
- **Tc Path Strings**
- **Bypass flow routes**

### Hydraulics

- **Cover RL, Grate RL, Setout RL and Sump RL modes.**
- **Culvert Hydraulics and Tailwater**
- **Pit Losses Ku, and Direct Flow**
- **Pipe Friction Method, Roughness Values and Direct pipe flow**
- **Design mode, Freeboard Limit and Flow-depth limit**
- **Pipe Size Design**
- **Pipe Design Parameters - Sizes, Invert alignment, Min Cover, Max Height**

The DNE also links your drainage model to your 12d design models.

---

The drainage network editor is accessed through the main menu by selecting

**Design=>Drainage-Sewer=>Network Editor**
The bottom section of the network editor panel is shown below. You can change tabs but no data can be entered in the panel until a drainage pit or pipe has been selected.

The pit closest to the point selected is highlighted with a circle and an arrow shows the direction of flow and the pipe being edited (see image below). When the outlet is selected there is no arrow. The option buttons on the drainage editor now become active.

1. Pick and accept a drainage string and the network will be loaded into the panel (only drainage strings may be picked).

The pit closest to the point selected is highlighted with a circle and an arrow shows the direction of flow and the pipe being edited (see image below). When the outlet is selected there is no arrow. The option buttons on the drainage editor now become active.

14.1 Update from drainage.4d

We have set our default diameter as 1m and default manhole as AL2D. In the drainage.4d file the AL2D manhole is defined having a diameter/length of 0.93m and a width of 0.85m. When you select one of the manholes the DNE finds the difference and asks you if you want to update the manhole diameter.

1. Select **Update from drainage.4d**. The manhole diameter will now be changed to 0.93 for this manhole.
2. If you select **Stop asking for this DNE session** first, you will not be prompted before the DNE updates the manhole data.
3. Selecting **Set Pit details** will update all manhole diameters in the network.

A surveyor who received a 12da file of the drainage network without the drainage.4d file would select **Keep stored data**.
14.2 Moving through the Drainage Network

There are 3 ways to change pits in the network editor. The Next-Previous (chainage NOT flow direction or east west) buttons will work if you are on the Defaults, Global or Results tabs. If the editor finds an error on a pit, it will take you to the error and you must correct the error before moving to the next pit.

Try all 3. The GoTo List will be interesting as we have not assigned pit names yet.

14.3 Auto-Apply, Auto-Pan, Auto-Profile and Auto-Redraw

To tell if these buttons are on or off you need to know your computer display settings. For Windows 7, the default is Blue for on.

With Auto-Apply (A) enabled, data is saved when any of the 15 lower buttons are pressed except Finish and Help.

Auto-Pan is always active and any plan view showing the active drainage network selected will always auto pan if the selected pit is not in the view.

With the Auto-Profile (P) enabled, the same will happen for the section view.

With Auto-Redraw (R) enabled, the editor will regenerate the section view when changes are made in the vertical. This saves selecting Regen on the section views.

14.4 Set Pit names (and pipes)

Pit names are used to identify and label the pits for access. The DNE Goto drop down and outlout window loglines (warning/problem messages) become much more meaningful. Storm analysis requires that unique pit names be set.
Use the DNE to manually change single pit names (in the Pit field) or quickly change all the names using the Set Pit Names button. The Set Pit Names button requires unique string names. To view string names on the plan view, go to the Plan View tool bar and select Toggle=>Names. If they do not appear see Displaying View Text.

Models->String Info table is a fast was to view all the string names in the model. Double clicking on the lines will launch an editor to change the string names. The DNE also sorts the strings based on these names and this controls the plotting order.

The string names may be changed in the String field when the Catchment, Pit or Pipe tabs are selected at the top of the DNE. The string names must be unique.

14.5 Set Pit Names using Pit Type

We can customise the pit name prefix, suffix, numbering sequence etc for each pit type. Currently all of the pits have the default pit type. We will now change the outlet pit type to HW and then rename the pits.

1. Select Set Pit Names and the following panel will appear.

1. Select Sequential Numbering to number the manholes starting at First Pit Number.
2. Change the Default naming parameters. Map pit numbers to letters causes the first pit to be A instead of 1. Min digits in pit numbers set to 2 causes 1 to be 01.
3. Run will update the quick text pit names on the plan view. Try other settings! You may find you want to change some of the string names back in the network editor.
4. Back to the Editor return to the main editor panel.

Reverse order starting numbering at the high chainage end of the string instead of the low chainage.
1. Move to the outlet using any of the 3 methods.
2. Change the Pit type to HW
3. LB Select Pit Names

1. Type the file name for the pit naming scheme. An example may be found in the library if desired.
2. LB the folder icon and select Open.
14.6 Change Pit Name Textstyle and Offset

The textstyle and offset for the pit name is set on the Global->Display tab of the DNE. It is always shown as pixel text size and cannot be changed to world.
1. Select the **Pit label textstyle** icon and then the **Arial 2 centre** favourite.

2. Type the new **Height (u)** as **12** pixels.

3. Select **Set**.

4. Select **Finish**.

5. Select **Apply** from the bottom of the DNE to see the new textstyles.
15. Vertical Alignment - Manholes

The diagram below shows the properties of a manhole. The RL levels may be set manually or calculated via the their associated mode and the **Set Pit Details** button. The **Grate RL** is used by 12d hydraulics when determining the freeboard level, bypass flows, inlet capacity values at sag inlets and depth of flooding at sag inlets.

The **Setout RL** is the level used by surveyors to setout the pit.

15.1 Cover RL, Grate RL, Setout RL and Sump RL modes

The default values for the RL modes are set on the **DNE->Defaults->Pits** tab.

<table>

</tbody>
</table>
These may be explicitly for an individual pit on the DNE->Pit->Main and Setout tabs

**RL Modes**

**Cover RL**  
Only available for Grade and Setout RL modes. z value will be the same as the cover RL.

**FS Tin**  
z value from the pit centre x,y location on the DNE->Global->Main->FS tin.

**NS Tin**  
z value from the pit centre x,y location on the DNE->Global->Main->NS tin.

**Setout String**  
z value from the string found by dropping the pit centre x,y location perpendicularly onto the setout string (DNE->Pit->Setout->Setout string) and then moving the distance DNE->Pit->Setout->Setout adjustment $S_{xy}$.

**$S_z + Setout String**  
z value as for the Setout String plus the value DNE->Pit->Setout->Setout adjustment $S_z$.

**Max Obvert**  
z value of the maximum pipe obvert of all the connecting pipes.

**DS Invert**  
z value

**Sump Invert**  
Only available for Setout RL. z value from DNE->Global->Main->Sump RL

**Manual**  
z value is entered in the RL field to the right of the mode (field becomes active when this is selected).

**floating**  
Only available for Sump RL mode. z value is of the minimum pipe invert of all connecting pipes plus the value DNE->Pit->Main->Sump offset

**RL modes for the entire model may be set via**

Design->Drainage-Sewer->More->Pipe Locks

This routine has lock modes for pipes as well.
16. Vertical Alignment - Pipes

The pipe invert levels may be set manually or calculated using the DNE->Regrade Pipes button.

Pipe invert mode may be set to locked for the entire model via Design->Drainage-Sewer->More->Pipe Locks

There are many controls to guide 12d in the setting of the pipe inverts and the user may over constrain the network so that no solution is possible. If the minimum cover, grade or drop criteria cannot meet the criteria you have set, a problem message will be in the output window.

16.1 Minimum Cover

The minimum cover can be set via the pipe type and the pipe cover file (optional). If the pipe type is not found in the pipe cover file then the Defaults-Pipes-Cover for the project is used.

16.2 Minimum Grade

Pipe grade has been traditionally measured based on the horizontal distance from pit centre to pit centre. However, this causes issues with surveyors when they use electronic models to set out the drainage pipes. All drainage pipes lengths can now be calculated from the horizontal distance between inside pit edges (or pit connection point for the unrestricted pit connection mode). The alternate pipe length results in a different pipe grade to be calculated in 12d. This option is set one the DNE->Global->Main Use Actual Pipe Lengths.
16.3 Pipe Grade Modes

**Minimum Depth** The cover sets the inverts at each end of the pipe and then the downstream invert is lowered if the minimum grade is not achieved.

**Minimum grade** The pipe is set to the min grade and then lowered to meet the cover requirements.

**Grade from DS** Warning! Minimum cover may not be maintained in this mode. Each pipe has its downstream (ds) invert level set via its **DS pipe alignment** mode. If the downstream pit is the outlet then the cover is used to set the invert level. The upstream invert is set using the minimum grade.

**Const Depth Channel** Warning! Minimum cover, minimum grade and pit alignments are not used in this mode. The obvert of the pipe is set to the finished tin level at the pit centre.

16.4 Downstream Alignment Modes

The amount of the drop is determined first from the **Drop file** and then if required from the manhole default settings for the project. How the drop value is applied is set via the **DS align mode**.

Inverts are moved down, if required, according to the setting in **DS align mode**.

**Min drop** ensures that the inverts drop a minimum of the drop but may be more.

**Min drop<DS-Dia** ensures that the inverts drop a minimum of the drop but may not be more than the downstream pipe diameter. This restricts the max drop so that the water jet will not completely impact the opposite wall of the pit.
**OL-OL Drop** uses the drop value for the obverts. If the downstream pipe is a smaller, then the drop will be applied to the inverts so that water will not be trapped in the pit. If the downstream pipe is larger then the obverts will be aligned as long as the min drop is maintained on the inverts.

**IL-IL Drop** uses the drop value for the inverts.

The **Drop file** contains the drops that change with the pipe deflection angle. A sample file is included in the library.

If only one drop value is to be used set the deflection angle to 180 degrees.

After setting the pit and pipe levels, add the model **tin combined** to the **Drainage** section view. The trunk profile will be similar to the following. Select the toggle button, to toggle on the grades (and pipe lengths).
To inquire about the cover on a pipe use the following option.

**Tins->Inquire->Depth from string**

1. LB to select the tin
2. LB to select the string.
3. Move the pointer in plan or section to monitor the data.

The DNE calculates cover from the top of the pipe NOT the obvert so cover may appear incorrect. Also for box culverts, cover is measured at the edges as well as the centre of the pipe. Finally for multiple pipes, each pipe is checked for cover.
17. Service and Utility Clashes

We will import some services from a 12da file. From the main menu select,

File I/O->Data Input->12da/4da data

1. LB the Folder icon
2. Select the service file
3. LB the Read button.
4. LB the Finish button.
5. Add the model services onto the plan and section views.

12d service clash routines notify the user of crossing services but not parallel services that are close to each other. The clearance values are vertical distances at the centre line of the drainage and service strings. The minimum clearance may be less than the vertical clearance if the drainage or services are on very steep slopes.

To view parallel services, add the services model onto a section view, profile a drainage string and then set the corridor value for the section view.

Settings->Corridor and then set the Width left and Width Right to the desired clearance. If the service can be seen then it is within the tolerance. 11 is used in this example only so that you can see the service on the other side of the road.

Use the Next and Prev button to switch drainage strings.
To obtain a report of all strings inside or crossing the drainage string profiled, select the View menu button then Utilities->Report

1. Select the Global tab
2. Select Utilities Model tab
3. Type services to create a new services file.
4. Select Open from the icon list.
In the **Service model** column RB to select the model. Enter **Minimum Clearance** for the services in this model. Include an extra amount for the thickness of the drainage pipe. If the service model contains other drainage/sewer strings you must add the thickness of these pipes as well.

If different clearances are required for different services then place the services in different models. Warnings will be issued when you **Regrade Pipes, Set Pit details, Import** or **Storm Analysis**. Cover levels or fixed inverts can be used to avoid the services.

To quickly move to the section view of the string, Double click on the message in the output window (note the red! mark). The **DNE** will move to the pipe and with auto profile button enables the section view will update to this string.

The most common method to avoid the clash is to increase the **Pipe cover limit** for this pipe segment so that the pipe is pushed down.

If the clash problem is above the pipe then the **Max pipe height** may be used and multiple pipes are selected.

This method is preferred over locking the inverts as this leaves more flexibility for aligning the inverts.

Often changing the **Grade mode** to **Min grade** on a branch line will raise the downstream invert. This may allow the entire trunk line to rise and thus reduce excavation costs. This is especially true if the service clash is near the upstream end of the pipe.
Once the invert levels have been reset by selecting Regrade pipes, the output window will indicate the final clearance.

After a pipe design run in Storm Analysis, details of the service clash data will again be listed in the output window.
18. Drainage Plan Plots

The drainage plan plots create detailed drawings with symbols for the pits, linestyles for the pipes and string names ready to export to the desired layers in CAD. Pipes levels are 3d and setout points ready for downloading to survey total stations are prepared.

18.1 Labelling the Pits and Pipes

Plan plots are used to label the pits and the pipes. Drainage Plan Annotations may be accessed from one of three locations. The third is the most common.

**Location 1:** From the plan toolbar

![Select the plot button and then Drainage plan](image)

Note (The following panel has been reduced in size).

![Drainage Plan Plot PPF Editor](image)

1. Select a ppf file from the library
2. **LB Read**
3. Select your drainage model
4. Type a model name for the new labels.
5. Select **Plot**
6. Select **Finish**

Now add the drainage labels model onto the plan view.

**Location 2:** The Plot Button on the Drainage Network Editor

The following panel will be displayed. This option can plot both the long section and plan at the same time. Select a ppf file from the library (drainage_design).
1. Enter a model for the plan annotations.
2. Select **Full clean model beforehand** if you have not manually moved any of your manhole labels.
3. Turn off the long section plot for now.
4. Select **Plot**.
5. Select **Back to Editor**
6. Now add the **Model for plan annotations** onto the plan view.
7. Note: if you rename the manholes you will need to replot these labels!

Note that **Full clean of model beforehand** was not selected. The drainage plan plot does a smart clean where it deletes and reprints text that has not been manually moved and updates text that has been moved.

The text properties can all be customised using the plot parameter file but this will be discussed later in the plotting section. These labels are **not** automatically updated when you change the names or pipe diameters. You must rerun the plot routine to update the labels.

**18.1.1 Turn off View Text Pit Labels**
To turn off the automatic view text pit labels for this view select **Toggle=>Text** and then walk right to select the drainage model. Do not click on **Text**, rather walk right. If you click **Text** you will toggle on/off all of your text on the view, not just the drainage model.
18.1.2 Moving Text

The labels created may be manually moved using the **CAD toolbar** but if the model is relabelled the text will return to its original location! Text moved via the **Drafting->Multi string translate** will remain in the moved position when **Smart Clean** is selected in the Plan Annotation panel.

Before selecting text turn on your **text snap**.

To move a single line of text use the **CAD** toolbar. Select the **Move text justify** button. To use this toolbar you must **DRAG** the **Create text** button to the right

and then release when the pointer is on the **Move Text Justify Point**.

To move a pre-defined **Group** of text select
Drafting->Multi string translate

Select **Group** and then pick and accept one of the text items in the group. Move it to its new location and accept.
19. Construction Setout

Pits are setout on the construction site using a variety of techniques. The DNE creates a construction setout point \((x,y,z)\) that can either be located at the pit centre or the pit centre can be dropped perpendicularly onto a design string for the xy location. The z value for the setout point has a number of modes as described below. Road centre line chainage may also be calculated.

In the diagram below the setout point is lip of kerb. The setout x,y location level z will be obtained from the setout string and the pipe will be shown at its proper position so that the pipe cover is calculated correctly.

Pipes are setout using the pit connection points and the invert levels.

Design->Drainage-Sewer->Convert to Pts and Lines will create 12d super strings with the pipe attributes on them.

Setout reports can be created and the drainage plan plot generates strings for the surveyor to download to the instruments.
19.1 Pit Setout (xy)

Setout xy mode - Pit centre is the centre point of the manhole (the intersection of the joining pipes). Often the setout point for a manhole or catch basin is not the centre of the manhole but rather a point on the kerb or back on the foot path. The setout string option will drop the centre point of the manhole onto the closest string in the Road design model list specified on the Global->Utility models tab.

Setout z mode options are listed in the panel. This levels are used in the pit schedules.

There are currently 9 modes for determining the pit setout levels.

Cover RL - this ensures the level is the same as the Cover RL (not available for Cover level).

FS tin -The level is obtained from the finished surface tin at the pit centre.

NS tin -The level is obtained from the existing surface tin at the pit centre.

Setout String - The pit centre is dropped perpendicular onto the setout string and the level is obtained from the elevation on the string.

Sz + Setout String an offset is added to the level from Setout string described above.

Max Obvert- all connecting pipes, usually open channels, are checked for the highest obvert.

DS Invert - the invert of the outlet pipe (there is only one).

Sump Invert - the lowest pipe invert plus the Sump offset.

Manual - The user must manually type in the cover levels (rarely used as a default).

Explicit settings for the setout strings and the auto calculated values are found on the Pit-Setout tab. If the manual mode is selected the Easting and Northing locations may be picked in plan view or typed into the input boxes.

19.2 Pit Setout (z) Level

The setout level defines the level to be printed in the pit setout tables and in the drainage longsection plots. The FS Tin selection obtains the level from the FS tin, specified on the Global-Main tab, at the centre point of the pit. The Setout String location obtains the z level from the setout string as described in the section above. Explicit settings and the auto calculated value are found on the Pit-Setout tab.

19.3 Road Centre Line Chainage

If Road chainage mode is set to Centre string, then the Centre String ID in the Road design file (shown above) is used to select the road string to measure the chainage and offset from. The values and explicit settings for the road chainage and offset are found on the Pit->Setout tab.

19.4 Pipe Setout

Pipe setout is along the centre line of pipes.
19.5 Plan Plots for Surveyors

Use the drainage plan plot routine to create survey setout point for each pit and strings for each pipe with the invert levels. If \textit{drainage\_setout} is not in your library, start with \textit{drainage\_inverts}.

1. Select \textit{drainage\_setout} ppf from the library
2. LB Read
3. LB Drainage Plan Plot branch
4. Select the existing \textit{drainage} model
5. ensure NOT selected
6. Select \textit{Pipes} branch and note Trim mode
7. Select Maintenance holes->MH setout points branch
8. Note: \textit{Draw setout points} is selected.
9. String names are sent to the survey instruments so select this.
10. Select Plot
11. Add \textit{drainage setout} model onto a plan view

19.6 Construction Manhole/Pit Schedules

Manhole/pit schedules or construction tables are generated in tab or space delimited formats.

This routine does not recalculate the setout locations. Similar to plotting, it prints the results of the last time the calculation were done (DNE->Set Pit Details).

Position of option on menu: Design => Drainage => Reports => Pit schedule

This routine prints the calculations from the last time Set Pit Details was selected in the Drainage Network Editor.

On selecting the Pit schedule option, the Manhole/Pit Schedule panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

<td>when selected, the column headings will be printed each drainage line</td>
</tr>
</tbody>
</table>

Process button
Create the pit report

Finish button
remove the panel from the screen

Notes:
The columns of data may be separated by spaces or a tab. (tab is used for spreadsheet transfers). The internal width and length data are retrieved from the drainage.4d file for the pit type specified. If you want a longer description for the pit then the type used inside 12d this can also be entered in the drainage.4d file. The remarks for each pit are entered as user defined pit attribute named remarks and may be set using the attribute editor (on the drainage menu) or via a spreadsheet.

Notes

The Set pit details must be run at least once to before printing the report. If the pits are moved or
the designed strings changed then this option must re rerun.

The easting northing data obtained for the road design string option is obtained by dropping the
pit centre perpendicular onto the selected road design string. This data is stored as pit attributes
setout x and setout y. It is calculated when the Set Pit Details is selected in the Drainage
Network editor.
20. DNE and Rational Hydrology

The rational methods uses the formula \( Q = CIA/360 \)

where

- \( A \) = catchment area (hectares)
- \( C \) = runoff coefficient
- \( I \) = rainfall intensity (mm/hr)
- 360 = conversion factor to \( m^3/s \) for area (ha) and rainfall (mm/hr)

The rainfall intensity requires the input/calculation of the time of concentration (tc) for the catchment and then a return period to be used in the IFD table (see 12d Rational Method Hydrology - Drainage Rainfall Editor).

The total area entered/measured may be split into impervious and pervious and analysed separately.

If you use a single composite C value for your catchments, enter a %impervious of zero and ignore the impervious settings.

Many authorities increase the C values for major storms. If you do not then enter the same C for minor and major. Similarly Tc values are sometimes reduced for major storms so you have the option to enter a minor and major C value. An example is provided below.

<table>
<thead>
<tr>
<th>Total Area</th>
<th>%imp</th>
<th>Cminor</th>
<th>Cmajor</th>
<th>Tc minor</th>
<th>Tc major</th>
</tr>
</thead>
<tbody>
<tr>
<td>Impervious</td>
<td>Area*%imp</td>
<td>0.9</td>
<td>0.92</td>
<td>5 min</td>
<td>5 min</td>
</tr>
<tr>
<td>Pervious</td>
<td>Area-imp area</td>
<td>0.3</td>
<td>0.31</td>
<td>10 min</td>
<td>10 min</td>
</tr>
</tbody>
</table>

20.1 Network Editor - Global, Default Settings and Explicit Settings

This section will discuss the Global, Defaults and explicit setting for the hydrology parameters. Design values for the hydrology and hydraulics calculations are set

- either globally (one value for the entire network)
- or via defaults.

Defaults values may be overridden by explicit settings found on the top level catchment, pits or pipes tabs. Explicit over ride catchment settings need only be specified if the default value is not desired. Only fill them in if you want to use a value different than the default. The tool tip will indicate the default values.

Default values must be entered for all of the fields for Set 1. Set 2 and Set 3 blank default values will use the defaults you have used in Set 1.

20.1.1 Catchment Areas and Percent Impervious

There is no default catchment area to apply to all catchments. You may type in the catchment area or create a string where 12d will measure the plan area (Drawing Catchment Strings in 12d).

The percent impervious will split the catchment area into the pervious and impervious sub catchments. Separate C and tc values are used for the pervious and impervious areas. The default percent impervious for the various sets are entered on the Defaults->Catchment Defaults and the explicit settings are on the Catchment tab. The percent impervious is used also used to determine the composite C value if using the ARR 1987 method for calculating runoff coefficients.
20.1.2 Coefficients of Runoff

Global Settings

Runoff C methods include **Direct**, **Direct * Fy**, **ARR 1987**, **QUDM 2007** and **ACT**.

**Direct**: There is a global impervious C value for minor and major storms. This can only be set once. The C values for the pervious areas may be changed for every catchment in your model.

**Direct * Fy**: For urban areas in Australia the flood frequency factors (fy) are constant for urban hydrology. You are required to enter the f10 values, the same value for minor and major. For rural areas the direct method is required.

**ARR 1987**: The composite C value is calculated using the 1hr-10yr intensity, the percent impervious, ARR frequency factors and the return period specified when hydrology runs are made. **You must enter the 1hr-10yr intensity value. No C values are entered if this method is used!**

**QUDM 2007**: Similar to the ARR 1987 method (except when the %impervious for the catchment = 0.0). The **Veg/Soil** type must be entered for the catchment via the default catchment tab.

Default Settings

![Diagram of Runoff C methods and settings](image)
Explicit Settings

20.1.3 Times of Concentration
There are several methods for entering times of concentration for the catchment areas (see list below). Since each catchment may use a different tc method, all of the tc parameter fields on the defaults tab are active and required. They must be filled in even if you do not plan on using that value.

1. **Direct method** requires minor and major tc values.

2. **Friend, Kinematic Wave, Bransby Williams** and **QDUM** methods require the retardance, length and slope of the catchments to be entered. Default values must be entered but the optional explicit settings for slope and length can be entered on the catchment tabs or a catchment characteristic strings may be drawn (see Catchment Tc path strings). The length of this string is used for the length parameter and the design tin is used with the string to calculate the slope using the equal area method.

3. Data for the remaining methods is entered in a similar fashion.

20.2 Catchment Areas

**Key Points**

1. You do not have to draw catchment strings. You can enter the catchment areas manually (ha or acres).
2. When drawing catchment polygons, start near the inlet for auto linking.
3. 3 catchment sets are available and all catchment polygons must be in these models.
5. Network Editor Set Catchment button links the polygons and calculates the areas
6. Once a string has been linked to a inlet, it will remain linked until it is deleted or the link has been cleared (Clear Catchment Links on the Globals->Utility Models tab).
8. Manholes (set via cap_config in drainage.4d or Inlet config on the Pit->Main tab cannot have linked catchments.
9. Use the CAD polygon tool for drawing catchments OR close the string for sag pits
10. You can disable the auto selection of a string via Right mouse on the pick button then select Clear.

The catchment strings may be drawn in a CAD package and then imported into 12d or drawn inside 12d. The strings may be easily drawn in 12d with the tin contours and/or flow arrows displayed in the plan view.

When a catchment string is created to define the area for an inlet then all other data entry types will be ignored and the area from the string will be used.

There are 3 sets of catchments and it is up to the user to decide how they are to be used. Each set has its own percent impervious. The most common is to use the sets as land use types (roads, lots and park land for example). Another frequently used option is to use set 1 for all the impervious areas and set 2 the pervious and set 3 for special areas. The 3 catchment sets are drawn in three different models.

If exporting to external drainage design programs, the package may not accept all three sets so check the interface notes before defining the catchments.

Set Catchments - Auto Linking

In each set/model, 12d will automatically link the catchment string to the inlet that is closest to vertex 1 on your catchment string. This is the preferred method. If this is not possible, then an inlet may be manually linked to a catchment string using the Catchment manual link. More on catchment links may be found in Catchment string links.

Also see Checking the Automatic Catchment Linking

Start the Drainage network editor and move to the Global Tab and then the Utility Models sub tab.
The **Auto-rename catchment polygons** will set the name of the catchment string to the pit name that it is linked to. If it is not linked to any inlet it will be named “not used”. The model can be checked for **not used** strings by selecting **Models->String Info Table**. The catchment will also be filled with the **Error colour** if a catchment string is not linked.

1. Type a filename for the catchment file
2. LB **More info** button and then select **Open**
3. RB to select the catchment model for set 1 (used in the **CAD control bar** above). Every inlet can have up to 3 catchments, row 1 is catchment set 1, row 2 for catchment set 2 and row 3 for catchment set 3. Often the sets are used as catchment types. for example
   Set 1 - Roads, Set 2 Lots and Set 3 Parks
4. Optional - RB to select a fill colour for the catchments
5. LB **Write** to save the file
6. LB **Finish**
7. Type a new model name for the catchment labels (optional)
8. LB **More info** button to select textstyle (required if **Labels model** is used)
Label Catchments

Finally select Set catchments. This will link the catchments to the inlets and label the catchments. Now add the mode-labels onto the plan view.

Adding the edges to the fills
To view the edges go to the View Menu button and select Settings->Faces
1. LB Draw Edges
2. LB Set
3. LB Finish

There are some cases where linking the closest inlet to vertex 1 is not feasible. In these cases you may manually link the inlet to a catchment.

20.3 Drawing Catchment Strings in 12d
There are 2 catchments on the south east side of the road that have not be drawn. Use the CAD polygon tool to draw the catchments
Before creating the catchment string set the CAD control bar data.
Type the name of a model for the catchment strings

Now to create the catchment string use the Create line string button on the CAD toolbar.

**DRAG** the Create line button and release at the Create Line String button.

The first point should always be placed near the inlet. 12d will assume that the catchment will drain to the inlet closest to this first point.

Draw the catchment strings with the accuracy you feel appropriate. Catchment strings for sag pit or drawn along a crest lines so take extra care near the crest low points where the water may overflow and bypass. Continue selecting and accepting the points on the catchment string and the press **ESC** to finish creating this string. You are now ready to create the next catchment string.

**Sag inlet catchments: DO NOT START AT THE INLET, just start nearer to this inlet than any other!** If you start at the inlet then move out to the crest of the catchment, the catchment overflow level cannot be determined from the catchment string.

**CAD tips**

Use the CAD toolbar eye dropper to load the properties from an existing catchment polygon.

Try CAD trace instead of CAD polygon to trace around edges of existing catchment areas. It is at the end of the CAD string fly out. Follow the directions in the 12d message area (bottom left of window).

Trace begins as normal string draw, select t to start the trace, pick the start point on a string then pick the end point of the trace, (if the trace is going the wrong way select f or b).

Now you can select another string to trace or select p to return to pick mode. select c to close and finish and you are off creating another catchment string.

Once the catchments are drawn they become linked to the drainage network in the **Drainage network editor**. We will label the catchment with the inlet name and area at the same time.
20.4 Splitting Catchment Strings to Insert an Inlet

The catchment for the northwest sag pit needs to be split into 2 catchments for the inlet labelled I-9.

We will use mostly CAD tools except for Strings->Strings edit->Split. The trick is to roll the mouse roller ball once whenever you need to redraw the screen.

1. Cad String->Close to close the string. (roller ball!)
2. Strings->Strings Edit->Split, select string at split point (string area will go solid white - accept) roller ball!
3. repeat for south side
4. CAD vertex->Append select the string away from the split point, roller ball and draw the new catchment boundary. Single ESC to finish this string.
5. CAD vertex->Append select the string away from the split point, roller ball and trace the new catchment boundary. Double ESC to finish this string and end appending

Catchment manual link

The manual links are used when the first point on the catchment string is closest to the wrong inlet. Note that the following restrictions still apply.

1. The string selected for catchment 1 must be in the model for set 1. To check if you have selected a valid string select the Set Catchments button.

2. If the catchment string has already been linked to another inlet (automatic or manual) then the new link will be created and the old link erased.

3. If you change the catchment model for one of the sets on the Network Editor->Global->Utility Models->catchments than all of the manual links in that set will be erased.
Verifying the Automatic Catchment Linking

The automatic inlet-catchment linking is easily checked by after selecting the Set Catchments button on the network editor by any or all of the following:

1. Specifying a Catchment labels model with Labels textstyle on the Global->Utility models tab and .
   The catchment is indicated when the inlet is selected using the network editor. Since there may be three catchments per inlet the catchment data last viewed in the editor is the catchment that is highlighted.

2. Selecting the Auto-rename catchment polygons on the Global->Utility Models tab will set the name of the catchment string to the pit name that it is linked to. If it is not linked to any inlet, it will be named “not used”. The model can be checked for not used strings by selecting Models->String Info Table.

3. The unlinked catchment strings will be filled with the Error colour on the Global->Utility models tab.

1. Change to the Catchment tab. Move to the desired inlet. I-9 in the plan above. The inlet will be circled in the plan view and its name shown in the Current Pit field.

2. LB Set 1 then LB the Catchment polygon button and pick the desired catchment string.
   NOTE! If you decide to enter a value and NOT use the selected string RB on the button and select Clear.
   If the Auto apply tick box is not selected then you will have to select the Apply button for the manual link to become active.

3. LB Set Catchments button. A prompt box appears asking you to confirm. Select Yes. To toggle off/on the confirm request RB Set Catchments. The measured catchment area will be shown in the Catchment area field using the units specified in the Global-Utility models-Units field.

4. Repeat these steps for the sag pit to the west.
Reseting All Catchment links to Start Over

There may be occasions where you will want to clear all of the catchment links and begin with a fresh start. Select **Clear Catchment Links** on Network Editor->Global->Utility Models.

### 20.5 Tc Path Strings

These strings are used to calculate the time of concentration for the impervious and pervious areas. For each catchment set, they are drawn in two models; one for the impervious paths and one for pervious paths. The models are specified using the **Catchment file** field on the network editor (Global->Utility model tab). The 3 rows in the catchment file correspond to the 3 catchments available for each inlet. Therefore it is possible to have a maximum of 6 Tc paths models!

**Key Points**

1. Each Catchment set may have 2 Tc paths models. Pervious and impervious paths are kept in separate models.
2. End the Tc path string near the inlet that it is to be linked to.
3. Enter the paths models via **Catchment file** field on the (Global->Utility model tab)
4. You must select a Tc method (explicit or implicit) via the **Defaults->Catchments** tab or the **Catchments Tabs**. Just specifying the models is NOT enough!
5. Select **Set Catchments** to perform the calculations of length and slope.

The tc strings can be drawn in the same way as the catchment strings but make sure that you change the model name first! The tc string model is then entered in either the impervious or pervious paths model columns (You could have up to 6 tc string models!).
20.5.1 Catchment slope (equal area)
The length of this string is used for the length parameter and the design tin is used with the string to calculate the slope using the equal area method. These strings are drawn from upstream to downstream, finishing nearest to the inlet they are to be linked to.

1. Change the Cad toolbar model to `dr Catch Reserve tc` and the line type to FLOW LINE
2. Use Cad line->Cad line to draw the flow path from the culvert inlet up to the top of the catchment.
3. Use Cad string->Reverse to that the string is in the same direction as the flow.

---

1. Change the Cad toolbar model to `dr Catch Reserve tc` and the line type to FLOW LINE
2. Use Cad line->Cad line to draw the flow path from the culvert inlet up to the top of the catchment.
The equal area slope is calculated when Set Catchments is selected. The slope string be profiled, with tin combined added to the view, to see the slope and the equal areas (see below) above and belong the tin.
21. Network Editor - Hydraulics

This section will discuss the hydraulic Global, Defaults and explicit settings for the hydraulic parameters. The explicit settings for the parameters described on the defaults tab will also be found on the Pit or Pipe tabs.

21.1 Grate Levels

Important! Get the Grate level correct! The freeboard is measured from this level and if you do bypass cals the water will bypass if the hgl reaches this level. If the grate level is at or below the obvert of the pipe then the pit cannot surcharge and the pipe cannot flow full (it is an open channel). The grate level should not exceed the cover level except for pressurised, bolt down manholes and culvert headwalls.

Special Structures

- **Bolt down manholes** will have the grate level above the cover level. The height above the cover will determine the hydraulic head required to "pop" the cover off and begin surcharging.

- **Headwalls** cover levels are often the top of the headwall structure and and the grate level is set to the highest point of the channel before bypass begins.

21.2 Outlet and Tailwater Conditions

The most downstream pit on each network requires tailwater conditions. Often the invert level on the downstream end of the last pipe also needs to have the invert level locked to either discharge into a waterway or join into an existing drainage system. When the most downstream pit is selected the following fields will become active on the DNE Pit-Main tab. If these field are not active and you think you are at the outlet see Flow in the Wrong Direction.

Minimum will use the least of the Critical or Normal depths. If a fixed level is available for the minor and/or major storms, these value may be entered here.

The Ko is the loss coefficient for the exit losses into the downstream system. A value of 1 is typical for discharging into a pond or creek, or a Ku value for the pipe configuration in the pit the network is joining.

21.3 Culvert Hydraulics and Tailwater

To set the tailwater conditions for the culvert we created at the beginning of the course, select the outlet...
In part 2 of the course we add an open channel to calculate a realistic tailwater for the culvert.

21.4 Pit Losses Ku, and Direct Flow

The $Q_{dg}$ (direct flow) (ems/cfs) is water flowing into the manhole. It is added to the approach flow and is subject to pit inlet capacity. This field will be disabled on the pit tab if the inlet type is set to a manhole.
The Pit loss Ku is used to model the energy losses through the pits and inlet control on culvert inlets. Three Ku methods are available, Direct (user entered), Ku,Kw via charts (may be negative), or Ku,Kw >0 via charts where all negative values are changed to zero. The remaining methods specify various headwall types for culverts. These will use inlet control curves and backwater energy loss coefficients.

Ku config has 4 options: Preferred, Good, Fair and Poor. The settings have no effect for 100% grate flow, straight through and 90° bends. For pipes with bends they determine the charts to use. The following are guidelines in selecting the Ku config.

- Preferred: water impacts the opposite wall where it exits
- Good: water impacts the side wall where it exits
- Fair: water impacts the side wall and exits on the end
- Poor: water impacts the opposite wall of the pit and exits on the side wall.

21.5 Introduction to 12d Ku/Kw Calculations

The following description is a very general overview of the Ku calculations in 12d. For a detailed description please see the 12d forum site http://forums.12dmodel.com/.

When 12d uses the Ku and Kw Charts, the values of upstream pipe angle, (Qgrate/Qoutlet), (Upstream diameter/outlet diameter) and (pit depth/outlet diameter) are calculated and used in the Ku/Kw charts. Three cases exist which determine which chart is used.

Case 1 - Pits with 100% Grate Flow

The angle between the ground approach flow and the exit pipe is measured. Charts, compiled from Sangster et al (1958) are used; G1 is used for angles less than 15 degrees (rare) and G2 for angles > 15 degrees. 12d’s names G1 and G2 can be referenced to other publications in the table below.

Case 2 - Pits with More than 50% Through Flow

12d has 10 charts (T1-T10) compiled from the Hare (1981) and cross referenced to the QUDM and ACTDS Charts. In general T10 charts have greater losses than T1 charts.

Case 3 - Pits with between 0 and 50% Through Flow

With the flow condition between grate flow and through flow, a K value interpolation is performed based on the percentage through flow.
21.6 Pipe Friction Method, Roughness Values and Direct pipe flow

The default roughness and pipe roughness method are set here (Colebrook (mm) or Manning).

Qdp (direct pipe flow is flow) at the upstream end of the pipe that is included in the pipe flow calculations but is not included in the upstream pit losses nor restricted by the pits inlet capacity.

The ranges for pipe peak velocities are used for checking purposes only. If the velocities are outside this range, warning messages will be given in the output window.

21.7 Design mode, Freeboard Limit and Flow-depth limit

The Design mode has 4 options.

Pressurised Pipe: Freeboard Design does not use partial depths in the pipes and pipe sizes selected by checking the pit freeboard.

Part-full Pipe: Freeboard Design is similar to option 1 except gradual varied flow and hydraulic jumps are calculated in the pipes. Critical depth is the minimum depth at the upstream end of the pipe.

Part-full Pipe: Flow-depth Design is the similar to option 2 except the pipe sizes are selected by checking the normal depth in the pipe against the Flow-depth limit. Freeboard is also checked in this mode and if required the pipe will increase in size.

Open Channel: Freeboard Design is similar to option 2 except depths at the upstream end of the pipe may be less than critical depth for steep pipes (supercritical flow at the entrance).

The Freeboard limit is used for all Design modes. The freeboard is measured down from the grate level (Cover RL plus Grate offset).

The Flow-depth limit at pipe entrance (%) is used in Design mode 3. If the flow depth in the pipe is
greater than this value the pipe size is increased.

21.8 Pipe Design Parameters - Sizes, Invert alignment, Min Cover, Max Height

The invert levels during design are controlled by the pipe sizes, max pipe height, min pipe cover and invert alignment mode.

21.9 Pipe sizes, Max pipe height and Multiple Pipes and Box Culverts

The 12d design engine will select pipe sizes from the file specified on the Drainage Network Design panel, Preferred pipes file field list. See selecting pipe sizes. However, the maximum pipe height allowed before multiple pipes are used and the selection of box culverts is set on the pipe->main and pipe >design tabs respectively.

Num of specifies the number of identical pipes. The pipe flow is divided by this value when calculating losses.

To specify a box section in your network, select the pipe and enter a width for the pipe.

A Top width is used for trapezoidal channels. Note that if the hgl exceeds the top of the channel it will have friction on the soffit just as a box culvert.

For box culverts, the design engine increases the widths and maintains the height through the available sizes. Once the maximum height has been reached, the next culvert height and minimum width is checked.
21.10 Pipe Size Design

On the **Pipe** tab the **Lock Pipe size** prevents the 12d design engine from resizing the pipe. **Min pipe height** can be set for each pipe segment (there is no default for this value).

![Pipe Design Tab](image)

Specifying a minimum pipe size may speed up 12d design. The starting value for pipe sizing will not be less than this value. That includes all downstream pipes as well. So if you know that the pipe needs to be this size or bigger, enter it here.

**Max pipe height** can be set for each pipe segment (there is no default for this value). If the 12d design engine requires a larger pipe, then multiple pipes will be selected.

21.11 Calculate Bypass flow routes

This option is required for pit inlet capacity calculations and is covered in the Stormwater Part 2 training. As an introduction, the bypass strings determine the downstream bypass inlet for each inlet. Inlet capacity is determined from commands in the drainage.4d file. Road grade and crossfall measurements require the inlet to be linked to a setout string and pond depth measurements require a link to catchment string.
22. Drainage Design in 12d Drainage Design

12d has a sophisticated rational method hydrology and hydraulic grade line pipe design engine. In addition it has the capability to export this data to several other popular drainage packages. Regardless of the design method selected, the drainage network in 12d is updated from the design so that drainage plans, long sections and pit schedules can be quickly produced.

22.1 12d Rational Method Hydrology - Drainage Rainfall Editor

The Drainage Rainfall Editor is used to input rainfall IFD data using several methods. The data is stored in hydro files (each file is for a specific location) that can be shared between 12d projects. The data is edited using an editor similar to those used for the plot parameter files (ppf). Seven methods for entering/calculating the rainfall intensities are shown in the panel below. From the main menu select, Design->Drainage-Sewer->Rainfall EditorData is entered using one (or more if desired) input methods and then saved by entering a Meteorology file name and selecting Write. The standard 12d system file search paths are used (project folder, user library folder and then library folder).

Select the folder icon and then walk right on the Lib item to display a list of sample files. Select a file the select Read. YOU MUST SELECT THE READ BUTTON!

22.1.1 IFD Tables

IFD tables are often available from meteorological services. The table input format follows. The first row is used to define up to 9 return periods and the following rows list the rainfall intensities for the duration entered in the first column.

Hint: to increase the size of the grid control select another method, ARR 1987 for example, and then select IFD table again.
22.1.2 Australian Rainfall and Runoff 1987 Method

The rainfall intensities and other factors from Volume 2 of ARR 1987 are entered in this table.
22.1.3 Australian Rainfall and Runoff 1977 Method
The seven coefficients for each return period from ARR 1977 are entered in this table.

22.2 Drainage Network Design
The Storm Analysis button on the Network Editor executes the 12d drainage design, plots the drainage long section and plan annotation and prepares the hydrology and hydraulic design tables.

From the Drainage Network Editor select Storm Analysis. The following design panel will appear.
Storm Analysis Factors

The valid ARI will depend on the method selected but you cannot extrapolate beyond your data. Select the folder icon on the Rainfall location file and then walk right on the Lib line to select one of the rainfall files in the 12d library. If the file has only one type of rainfall definition then the Rainfall method field will be completed. Otherwise select the Rainfall method desired.

Storm event type determines which set of design values (minor or major) will be used for this run. Pipe travel time method should be set to the authorities requirements.

Enable the 12d rational method engine partial area calculations by selecting the Partial area effects box.

Network Design Factors

Modify Pipe Sizes

These values control the values to be designed in the run. Consider bypass flows causes the engine to use the bypass flow routes and inlet capacity data from the drainage.4d file.

Ensure Pipe Q < Qcap will increase the pipe size if this criteria is violated.

Modify pipe inverts will allow the design engine to shift the inverts if required (usually pipe size changes).

If Modify pipe sizes is selected then a files containing the available pipe sizes must be supplied. The pipe sizes in this file are in the Units specified in the drainage network editor. To create a new file, enter the file name and then select the folder icon followed by the Edit line. The following panel will appear.
The Upsize only selection will stop pipes in the system from being reduced in the design. Regardless of this selection, the 12d design engine will not allow a smaller pipe to be selected in the downstream direction.

22.3 Pipe Sizes too Large?

A few comments on why you may have large pipes in your design.

If one pipe is sized large then 12d will not allow a smaller pipe downstream. So when pipes seem large, check the most upstream large pipe. HGL restraints will require you to look downstream of the large pipe.

Check List

1. High roughness values, accidentally setting roughness to Manning with a 0.6 roughness value (Colebrook)!
2. Grate levels not set correctly. Freeboard is measured from these levels.
3. Pipe min pipe cover set very close to freeboard.
4. Selecting Ensure Q<Qcap in the storm analysis dialogue. This is required by some authorities but can cause larger pipes in flat areas.
5. NOT selecting Modify pipe sizes in the storm analysis dialogue. 12d will not change the pipe size.
6. Selecting Only allow pipes to upsize in the storm analysis dialogue. 12d will not check if a smaller pipe will do.

Generate Results in Plan

This selection automatically runs the drainage plot annotation function. A Drainage plan ppf must be entered and samples are supplied in the 12d library. A Model for plan results is required if this option is selected. The Full clean model before hand tick box forces the model to be cleaned before the labels are created. When not selected a “Smart clean” is performed.

Generate Results in Long Section

This selection automatically runs the drainage long section plotter. A Drainage long section ppf is required and examples are found in the 12d library. A Model stem for long section results is required if this option is selected. In almost all cases the Clean model before hand tick box should be selected.
Generate hydrology report

The **hydrology report** may be formatted for inserting into a 12d model/text editor (formatted) or spreadsheet (comma or tab delimited). In almost all cases **Overwrite existing report file** will be selected.

22.4 The Run Button and HGL data on the Section View

When the Run button is selected the discharges are calculated, the HGL check is performed and the pipes sizes and inverts are designed (if selected). The plan and long section drawings will also be updated with the new data (if selected).

The HGL values will also be available on the 12d section views when profiling the drainage strings. The colour of the HGL line may be changed via the view’s menu button then **Settings >Drainage**.

22.5 Importing Text into a 12d model

Formatted text may be inserted into a 12d model by selecting
Drafting->Text and Tables->Create edit paragraph text

Change to File.
Select the folder icon and then pick the formatted text file. It will be displayed then select Set.
Next select the location in plan for the text.
The font selected must be a fixed space font or the data will not align properly.
Select the Font to display the following panel.

Enter a Text Model for the report.
The Text Style must be a fixed space font.
Select Set then Finish.
Now add the Text Model onto the

Generate hydraulic report

The hydraulic report may be formatted for inserting into a 12d model/text editor (formatted) or spreadsheet (comma or tab delimited). In almost all cases Overwrite existing report file will be selected.

If you want both the hydrology and hydraulic report in the same file, enter the same file name in both file fields but turn off the Overwrite existing report file for the hydraulic report.
22.5.1 Design Results
Results from the design runs are shown in several forms:
1. Hydrology and hydraulic reports
2. Drainage plan annotations
3. Drainage long sections
4. Hydraulic Grade line on the Section view
5. Output window data - Service/utility clashes
Samples of the hydrology and hydraulics report are shown below.

23. Create a Drainage Model Template (Saving Defaults and Globals)

A drainage model template contains your favourite global and default settings for the DNE. These settings are stored as model attributes and the template may be read before or after the drainage strings have been created. Caution: existing default and global setting may be overridden.

You can create your own templates as well. Now that you have completed a drainage job and all of your global and default settings are set, create a template to save in your user library.

From the main menu select

Design => Drainage-Sewer => Create => Create/Read template

1. Change to Write.
2. Select drainage for your existing network
3. LB the folder icon, then user_lib, type a name for the template the select Open
4. LB Process to create the drainage model template for your next project.
24. Drainage Data Input and Output to Spreadsheets

Spreadsheets are an effective method to manage the numerous variables urban drainage designers create in the modelling process. Spreadsheet data can be transferred to and from 12d in tab delimited files and stored within 12d as “user definable attributes”. These attributes are linked to the pit and pipes within a network. Drainage long section plots can display the pipe attributes in the “arrows” data area and pit attributes in the bubbles area. Drainage plan drawing can also show these pit and pipe attributes.

Drainage strings will be created if they do not exist in the model but pits cannot be added to existing strings.

See also

12d to spreadsheet transfers
Spreadsheet to 12d update and create
Spreadsheet options

24.1 12d to spreadsheet transfers

This interface is accessed the **Import/Export** button on the Drainage **Network Editor**.

1. Select Spreadsheet clipboard
2. Leave as **clipboard.txt** to send the data to the windows clipboard as well as this file.
3. Mapping files are the most current 12d technology. Leave this selected.
   These options are not used for spreadsheet export.
4. Usually leave this off! Select to export the junction pit at the end of all drainage lines (very rarely needed).
5. You may also select to limit the output if desired. If you like using spreadsheets for data entry, the PCdrain data and ILSAX data formats are useful for adding data for the first time for either program.
6. Select Run to place the data on the clipboard.
25. Long Section Plotting

Detailed description of the 12d drainage long section plotting may be found in the 12d Reference manual. The long section plots are customised using the drainage plot parameter files (drainppf). Title blocks, user defined text may be added and then plotted directly or to various file formats (dwg, dgn etc.). From the main menu

Design=>Drainage-Sewer=>Plots=>Longsections

See Also

Set Pit Details to set road chainage and name data

1. To access the drainppf files supplied select the icon and then walk right on Lib to select this drainppf file.
2. Select Read
3. Enter a new name for this drawing
4. select Write. This will save the setting we are about to make should you want to replot this long section.
5. This section view determines the additional models (such as services) to show plot. These are referred to as corridor models. The vertical exaggeration is also obtained from this view.

6. The network model field will be completed with the model of the string being profiled. If this is not your drainage network model then select it now.

7. When Plotter Type is set to model then plot file stem is the model name prefix for plots that will be created. The first sheet of plots will be in model plot1, the second in plot2 etc.
8. Select + on the Plot sheet layout branch and then select Other parameters.

9. The plot height determines how much room is left vertically for the actual plot. This specifies the total height of the plot. 12d then constructs the box area and arrow area on the bottom and then arrow area on the top. The amount left over is used for the long section itself.

To stop datum breaks from occurring increase this height, increase your plot scale or decrease your vertical exaggeration. If there is too much white space in the graph area then reduce this value.
10. The **Drainage plot** + **title block** + **User title info** allow you to enter the text for the title block.

11. The list displayed is retrieve from the **title file** selected above. Enter the data for the plot.

12. Select **Write** to save the changed to the local drainppf file you entered earlier.

13. Select **Plot** and the plots will be send to the **plot file stem** entered. These models may be added (one at a time) to a plan view to inspect them before plotting to paper or exporting to other drawing packages.
26. More Information

This section provides detailed description of items introduced previously in the training notes.

26.1 Linking to Strings in General

Many pit properties may be calculated from strings linked to the pit. The following rules apply to all strings linked via the DNE.

1. The selection of strings is limited to the models specified on the DNE->Utility Model tab.

2. When no link exists for the pit, the closest string matching the selection criteria will be chosen. If a link exists, then no new string will be searched for. Even if the search criteria changes or a closer string is created. The link must be deleted before new links are searched for.

3. The link will not be broken unless:
   - another string is manually selected
   - the link is manually Cleared with the RB on the manual string select
   - the string is deleted (manually or when a recalc is done on template applies),
   - the model links are reset on the DNE->Utility Model tab,
   - the model is removed from the DNE->Utility Model tab.

4. Once link is broken the calculated values will be kept unchanged, with the exception of bypass pits.

26.2 Catchment string links

Each catchment set has its own model of catchment strings and the sets are linked independently.

If the area (in ha) is present in the area field, no new string link be searched for.

Vertex number 1 on the catchment string determines which pit the string will link to. If vertex 1 of several catchment strings are closest to the same pit. Only the closest string will link and the remaining will not be used for any other pit.

After the catchment string link is created, the vertices are re arranged so that the vertex closest to the pit becomes vertex.

26.3 Road string links

Road strings have a name and maximum search distance criteria and there is no limit to how many pits link to a single road string. The closest string matching the string name criteria (in the road string file) and within the search distance will be selected. Note that once the string link is established, changing the criteria will NOT break the link.

26.4 Bypass string links

Pits marked with an Inlet type of Manhole on the DNE->Pit->Main tab ignore the bypass strings. Bypass strings must pass within 1 manhole diameter to be linked.
27. Training Check List

Network plan  - convert from strings
              - insert, append, delete and move pits

Network Vertical  - Set Pit Details and Regrade pipes
                  - Pipe alignment modes

Set Pit Names

Catchments  - draw, label, link and check
             - tc strings

Hydrology  - Area, Tc, C values with defaults

Hydraulics  - setout to grate
             - method (pipe full or HGL)
             - available pipe sizes and box culverts

Services  - over and under drainage pipes

Road strings  - rotate symbols
               - x,y and/or z for setout
               - road grade and crossfall for inlet capacity
               - road chainage from centre line

12d design engine  understanding the reports

Setout pit schedules  - easting, northing and road centre line

Drawings  Long Section plotting
            Plan drawings

Kerb Strings  - select by name
               - crests and sags

THE END
1.0 Stormwater Design Part 2- Introduction

The Stormwater Design Course Part 1 and this manual, the Stormwater Design Part, describe the functions and processes of the 12d drainage module. In these documents, the generic term pit refers manholes inlets, catch basin and manholes.

The Stormwater Design Course - Part 1 Notes contain:

- create a super tin for pipe cover and pit cover levels,
- set Defaults and layout a drainage network from CAD and in 12d,
- use the 12d Drainage Network Editor to assign names to the pit/pipes, avoid service clashes, grade pipes, align obverts, minimise depth and many other design tools,
- designate catchment areas and produce catchment plans,
- run the 12d storm rational hydrology and hydraulics engine,
- transfer data to and from electronic spreadsheets to enable the user to easily review the data and add user defined data to the 12d pipe network. This data may include such data as pipe bedding types and trench width,
- create a drainage template containing customised default design parameters,
- create pit setout schedules to export to spreadsheets or word processors for final formatting,
- produce long section drainage profiles including HGL data, flows, invert levels and service crossings,
- create plan drawings with pipe sizes, flows, pit symbols, linestyles for pipe sizes, design parameters for pit and pipes and user defined data,
- locate pits/manholes at exact chainage and offset locations.

This manual, the Stormwater Design Course - Part 2, is intended to describe the additional features of 12d Model drainage and discuss the customisation of the package. This will include

- customising the drainage.4d file Drainage Definitions - Manholes and Pipes,
- 12d storm analysis with inlet capacity calculations and bypass flow,
- flooded width analysis and flooding at SAG pits,
- drainage trench excavation volume calculations,
- pipe and pit quantity calculations/reports,
- open channel calculations,
- adjusting pit locations for changes in horiz road geometry
- analysing the major flood events,
- creating drainage symbols with grates and upstream side inlets,
- detailed drainage plan labelling and long sections with hatching under roads.
2.0 Starting with a Basic Drainage Network

In this document, the generic term pit refers to manholes, inlets, catch basin and manholes. When the term manhole is used on the 12d menu system it refers to any type of pit. Pit types, dimensions and inlet capacities of the pits are set in the Drainage.4d setup file/database.

These course notes assume that you have completed the Stormwater Design Course and that you have experience creating 12d Model drainage networks with catchments areas. You may continue this project or begin with a completed drainage design found in the folder \12d\10.00\Courses\Drainage_Analysis

The project name is Local Road Complete.

3.0 Setup Files and Their Locations

The drainage.4d setup/database file contains the pit and pipe types (RCP, Class 2 etc.). The drainage.4d setup/database file can also control many of the settings in the drainage network editor (DNE). Changing the pit/pipe type in the DNE will result in your favourite settings being applied thus minimising user input errors.

The pit types may optionally include:
- DNE field controls, including internal pit dimensions (diameter or length and width)
- pit wall thicknesses that vary with depth,
- pit connection points (locations where the pipes joint the pit),
- inlet capacities for sag and on grade inlet pits.
- detailed pit type descriptions to be inserted into your pit schedules
- user defined attributes.

The pipe types may optionally include:
- DNE field controls, including internal nominal and actual pipe sizes with wall thickness,
- user defined attributes.

For PCdrain and Drains users there are routines to read your gully pit/database files and create the Drainage.4d setup file/database.

The Drainage.4d setup file/database may be customised for any additional inlet capacity data you may have. REVIEW THIS DATA CAREFULLY!
4.0 Bypass Flow

Bypass flow strings are used to trigger the bypass calculations in the network editor and are used as a centre line for flooded width calculations.

The 12d storm analysis, and many of the design programs 12d exports to, allow for bypass flow. Bypass flow involves the calculation of pit inlet capacity for on-grade or sag inlets. These capacities are based on the pit type and may use either ponding depths (sag inlets) or on the road grade and/or crossfall upstream of the inlet (on grade inlets).

4.1 Key Points

1. Draw an bypass flow string in the direction of flow so that it passes within 1 pit diameter of an inlet. At sag locations the string should show the direction of flow during bypass conditions. When bypass flow strings join they must join within 1 pit diameter of an inlet (pits with inlet config set to Manhole are not considered inlets). If flooded with calculations are to calculated the string should located in the flow channel. Enter the model name in the Bypass flow model field on the Global->Utility Models tab.

Note: if there is no bypass flow string within 1 pit diameter then 100% of the approach flow will enter into the pit.

2. Many bypass strings may join at an inlet but only one bypass string should leave each inlet.

3. Set the pit type. (Pit Type on the Pit tab). With a bypass string within 1 pit diameter of the pit centre, no water will enter the pit unless the pit type has inlet capacity data defined in the Drainage.4d setup file/database.

4. Set the Inlet config on the Pit->Main tab (Manhole, On-grade or Sag pit). This selection will be disabled if cap_config parameter sets the inlet type in the Drainage.4d setup file/database. Manholes have no inlet capacity and are not considered inlets, on-grade inlets capture the water as it passes the inlet while SAG inlets trap the water flowing in from all directions (until the pond depth overflows at the low point of the catchment string).

5. On grade pits may require road grade and/or crossfall data for inlet capacity. They may be entered manually or calculated using the road strings. A setout string link is required to measure road grade. If road crossfall measurement is needed then the centre string is also required. These strings are specified using the Road design file on the Global->Utility Models tab (see Stormwater Part 1 manual).

6. Sag inlets require a pond depth either manually entered or calculated by 12d. Pond depth calculations require a link to a catchment string to locate the overflow point and correct grate level (Grate rl mode).

7. Press the Set Pit Details button. Road grades, crossfalls, pond depths and bypass pits will now be found on the Pit->Bypass tab of the Network Editor. Measurement markers are created in the construction drainage data model.

8. Bypass pits may be cleared using Clear Bypass Links on theGlobals->Utility Models tab

9. Storm Analysis must have Consider Bypass Flows selected on the Main tab.

10. Calculate overland flood extents is optional on the Flood Extents tab of Storm Analysis.
4.2 Creating Overland Flow Strings using Downhill Strings

The bypass flow string must be within 1 pit diameter of the drainage pit in be considered on the bypass flow path. If the bypass flow string is to be used for flooded width calculations in the future, the string must also be drawn in the main flow area of the cross section. At sag locations the bypass flow strings indicate the direction the water flows when it overtops the overflow point. This string usually goes uphill to this overflow point.

The downhill string function quickly creates bypass flow strings from road design strings. The remaining tasks will be the bypass flow at intersections and areas off the roadways.

This routine copies strings to a single model using a string name mask to select the strings from a collection of models (using a model name mask). These strings will have their name, line style and colour changed. The line style is usually FLOW LINE so that you may see the direction of the string (downhill). The strings are split at crests (identified using a levee tolerance). They may also optionally be split at drainage string inlet location to allow easy modification using the drainage utility string editor.

From the main menu select

**Design->Drainage-Sewer->Downhill strings**

1. type `Road*Strs` (it is case sensitive). These are the models that contain all of the road strings. `Road 1 Strs` for example.

2. type `*inv`. The road string models have a `linv` and `rinv` string for the invert of the kerb and gutters.

3. If the crest height on one side is less than this amount it will not be split.

4. Tick the box and select the drainage model. This will help with the drainage utility editor later.

5. type `dr overland flow` to create a model for the new strings

6. Select Run

7. add the model `dr overland flow` onto the roads view.

4.3 Creating Overland Flow Strings at Intersection and Sag Locations

Use the **CAD toolbar** to create the overland/bypass flow paths the flow crosses the road.
Starting at the upstream end. LB select an insertion point and MB or press return to accept the selection (the line style is shown after the point is accepted).

Do not stop drawing until you reach another sag or ongrade inlet (not a manhole). Overland flow lines often overlap as you see in the drawing above. If you stop short of the inlet, the bypass pit for the upstream inlet will be LOST.

Continue drawing until you reach the end of the flow path. Press ESC to finish drawing the string. Frequently you will draw an overland flow path uphill and away from a sag inlet. It will usually go through the low point on the catchment crest and then downhill to the next inlet. No do this where road 2 intersects road 1 (see below).
4.4 Creating Overland Flow Strings for Culverts

Culverts placed at sag location in the road will generally how the overflow across the crown of the road and the upstream headwall grate level will be set the sag low point elevation of the road crown. For headwalls, there usually is not grate so this becomes the reference elevation for bypass.

The culvert in our example is not at a sag in the roadways so the water will overflow the southern side of the channel, cross the footpath, and flow down the roadway. We need to set the grate level to the bypass level along this path.

To draw the string, start at the top of the catchment so that the **flooded width calculations** in the approach channel will use the correct flows. Finish at I-3!

You could use the **CAD string->Copy** option to copy the tc string that was drawn in the model **dr Catch Reserve tc** and then **CAD vertex->Append** to add onto the downstream end of the new string and then **CAD vertex->Move** to adjust where need.
There is a low point where the south side of the channel joins the road (see red arrow). This overflow area will need to have erosion protection and detailed grading. Let's assume that the overflow area is regraded with a crest RL30.1. The grate level needs to be set to this value.

4.5 Set Inlet type to Sag or On grade

12d supports Manhole, on-grade and SAG configurations. The inlet configuration is set on the Pit->Main. This setting can be locked to the Pit type in the Drainage.4d setup file/database using the cap_config command. The remaining bypass data is found on the Pit->Bypass tab.

Pits Inlet config setting:

- **Manholes** will not receive bypass flow and cannot have catchments assigned to them.
- **On-grade** pits are pits where the water will flow past the pit if not captured (velocity and momentum are important for these inlets). Approach flow, road grade and road crossfall generally determine the inlet capacity equations/curves.
- **Sag pits** are located at sag locations where the water will pond around the pit if there is not enough inlet capacity (generally the water will stop at these locations and flow into the inlet). There is only one inlet capacity curve/equation per inlet and the ponding depth is used to determine the inlet capacity.

To view the inlet capacity curves used in this project, try Viewing Inlet Capacity Curves.

In this example the pit types have been set to an on grade grated, side entry inlet. We will now change the pit types for the manhole and the sag inlets.

Not all sag locations on a roadway behave hydraulically like a sag inlet. In general the flow should approach the inlet and not bypass over it. Sometimes the inlet acts as a sag inlet at low flows but like an on grade at design flows.
4.6 Set Pit Details - Calculate the Bypass Flow Data

Once the first Key Points of bypass flow are complete, you are ready to calculate the bypass flow data. Select Set Pit Details and then select a pit on a bypass flow string. The bypass data is found on the Pit Main and Pit->Bypass tabs.

1. Move to inlet marked I-16 above and select SAK2D for the pit type (you may be asked to confirm the changes from the drainage.4d file).
2. Note the Inlet config has been changed to Sag pit and it cannot be changed. This has been set in the drainage.4d file.

1. Select MH1050 for the Wipit type (you may be asked to confirm the changes from the drainage.4d file).
2. Note the Inlet config has been changed to Manhole, the Diameter/length to 1.05 and the Width has been cleared. These changes are set in the drainage.4d file.
The downstream pit will now show in the **Bypass pit** field. If the bypass string does not go to another inlet (the network outlet is never an inlet) then the **Bypass pit** will be marked as **LOST**.

**Always confirm bypass pits set to LOST are correct. An incorrect bypass to LOST would mean water is leaving your system when it should be included in the calculations.**

If a setout string was found (see **Pit->Setout** tab), the **Road grade** will appear in grey. You may override this value by selecting the **Manual** tick box beside the value and entering your own value. If a road centre string was selected, the **Road xfall** field will also have a value.

If **Sag pit** was selected and a catchment string was selected, the **Max pond depth** will be displayed. The catchment strings from all 3 sets are draped onto the finish surface tin and the low point located. The **Max pond depth** is calculated as

Max pond depth = catchment string low point - Grate RL.
Negative Pond Depths

Negative pond depths are usually caused by one of two errors in input. The first may be that the grate level is too high. Often this happens when the Grate RL mode on the Pit->Main tab has not be set correctly or if Sz + setout string option is used the Sz value on the Pit->Setout tab has been entered correctly.

The second common error is that the catchment string has not been drawn around the crest of the catchment. The lowest section of the catchment string must be drawn carefully because it is the lowest point on the string that determines the overflow elevation. If in doubt, profile the catchment string with the design tin shown in the section view. Double check were the low point is.

4.7 Checking locations for measuring road grade, crossfall and max ponding depth

Strings indicating the location of inlet capacity parameters are generating in the construction drainage data model when Set Pit Details is selected.

The location of the low point, from all 3 catchment set polygons, is shown as a green vertex (plus sign).

Trouble finding the small green +? Select Models->String info table and select the sag marker line in the table. A large cross hair will show you the location in plan views.

Verification strings in the same model confirm the locations where the road grade and crossfall have been measured. To check these strings add the construction drainage data model to the plan view. The following image shows a close up of the verification strings at a pit.
The default location of the road grade measurement is one pit diameter upstream of the setout point, along the setout string. The road crossfall is measure one pit diameter away from the setout point towards the road centreline. These are 3d super strings and therefore you may profile them in the section view. With the grades toggled on (check under **Toggle**) you can verify the slopes.

The location of the road grade and crossfall measurements can be changed in the **road design file**. The distance upstream to measure the road grade is controlled by the **Grade offset** column one the rows where the setout strings are defined. The road crossfall is controlled by the **Xfall offset** column on the rows where the road centre lines are defined. The distance the measurements are taken is controlled by the **Slope measurement distance**.

The green line indicates where road grade was measured and the magenta line indicates where the road cross fall was measured.
Important Notes

1. If no bypass flow string is supplied for a pit, the inlet capacity is set to 100%.
2. If you have a problem with the inlet capacity calculations, check the Storm Analysis hydrology report for details.

4.8 Viewing Inlet Capacity Curves

The inlet capacity information is stored in the drainage.4d file. We will now plot the inlet capacity curves in 12d. This will confirm what is in the drainage.4d but changing these plots will not change the inlet capacity calculations.

Put a z before CAP CURVES in the panel below. This will generally put these files at the end of your model list so they are not in the way when you are working.

From the main menu select

Design->Drainage-Sewer->More->Write inlet curves to model

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prefix for curves models</td>
<td>model box</td>
<td>CAP CURVES</td>
<td></td>
</tr>
<tr>
<td>Flow scale factor</td>
<td>input</td>
<td>1000</td>
<td></td>
</tr>
<tr>
<td>Depth scale factor</td>
<td>input</td>
<td>1000</td>
<td></td>
</tr>
</tbody>
</table>
Inlet and bypass flow values will be multiplied by this value before creating the strings.

**Depth scale factor** input 1000

Depth values for sag curves will be multiplied by this value before creating the strings.

**Only consider coord data** tick box off

Inlet capacity curves may be expressed as formulas, curve coordinate or both. Selecting this box stops curves with only formulas from being plotted as strings.

**Clean models before hand** tick box on

The curve models are cleaned before the new strings are created.

**Run** button

Models and strings are created from the drainage.4d file

**Finish** button

remove the panel from the screen
5.0 12d Storm Analysis Bypass and Flooded Width Calculations

Once the bypass pits are selected and the Drainage.4d setup file/database has been setup for bypass flow the storm analysis engine must have this feature enabled. Select Consider bypass flow.

**Excess Flow**

The $Q_x$ value controls how excess flow is handled in the bypass flow calculations. If the hgl at the pit reaches the grate level then no more water can enter the pit even if there is inlet capacity. The flow that will not enter the pit is considered excess flow. When a value greater than zero is entered here, the inlet will initially have its inlet capacity restricted by this value. Upstream inlets are done first as this may reduce the hgl in the downstream system. The system is automatically rerun adjusting the flows by this amount each time.

If the inlet capacity is reduced to zero and the hgl is still above the pit then water is removed from the pit and considered as $Q_s$ (surcharge flow). In the hydraulic reports this value is found as a negative Inlet Flow $Q_i$.

**Overland Flow Calculations**

The storm analysis engine will calculated flooded widths from normal depths along the flow path and ponding extents at SAG inlets. A bypass flow model (Global-Utility Models tab) is required for these calculations.

The Utility String Editor should be used where bypass flow strings combine at a pit. Without using this editor it is assumed that 100% of the catchment flow flows down each bypass flow string thereby overestimating the flooded widths.

The Utility String Editor could be used to change the Manning’s along the string (approach channels to culvert for example) or the maximum flooded width warning limit (before a pedestrian crossing or a highway off-ramp).

The models and the default input data for these calculations are entered on the Flood Extents tab.
Select **Calculate overland flooded extents** to activate the fields on the panel.

**Model for sag ponds** is used to hold strings that indicate the extent of flooding at the pits marked as SAG inlets. The total approach flow is used with the cap_curve_sag in the Drainage.4d setup file/database to determine the depth of flooding above the grate level. A closed contour at this flood elevation is then selected near the centre of the inlet. A super string is then created at this level with the colour and **fill blend** transparency selected (1.0 is solid).

**Model for flooded width** holds the strings indicating the normal depth - flooded width calculation results. These strings are created with a fixed elevation of the flood level. The strings will have string attributes with all of the calculations details.

**Calculations**

1. Cross sections are cut perpendicular to the overland flow string at the interval **X-section separation**
ration with a length of X-section length. No calculations are done for sect of the bypass flow string with in Model of exclusion zones polygon.

2. The x-section string is then trimmed using the Trim settings. The section above had a x-section length of 20 and was trimmed at the levee. The levees setting has the routine search for levee (high points) on either side of the low point near the bypass flow string. The levee points are found if sections drops more than the Levee tolerance value after the high point is found.

3. The flow for the section is calculated using the bypass flow string chainage to interpolate between the upstream bypass flow and the downstream approach flow. The percentage of catchment flow used in the calculation of the approach flow for this bypass string may be changed using the Utility String Editor.

4. The slope of the surface near the bypass flow line is measured for each section. If the slope is less than Min longitudinal grade (%) then this cross section is skipped in the calculations.

5. Manning n value is the default roughness used in the calculations. This value may be changed at any vertex along the bypass flow string using the Utility String Editor.

6. The flow’s calculated at the indicated level are multiplied by the Manning’s Q correction factor. A factor of 0.8 would cause the flooded widths to increase and the road capacity to decrease.

7. The maximum depth calculated will be at the point where water overflows the edges of the section (Road capacity) unless Contain overflow within levees is selected. This will cause frictionless vertical walls to be placed at the ends of the section so that higher water level may be calculated when the flow is greater that the road capacity.

Warning Models

Model for W warnings will contain copies of the flooded width strings with the colour selected if the flooded width is greater than the default Max W value.

Model for D*V warnings will contain copies of the flooded width strings with the colour selected if the depth * velocity is greater than the Max D*V value.

Model for Q warnings will contain copies of the flooded width strings with the colour selected if the flow is greater than the capacity of the section. The capacity is the flow where the water over tops one of the sides of the section.
6.0 Utility String Editor

Position of option on menu: Design => Drainage-Sewer => Utility String Editor

This editor is used to edit properties of the strings used by the DNE. Properties always change at an existing vertex.

**Cross Section Strings (Manning’s n)** - set the left and right bank n values. The centre n value is assigned by the DNE.

**Flooded Width Values on Bypass Flow Strings** - the default setting of the bypass flow strings when used to calculate flooded widths in the Drainage Analysis. Changes are in effect until the end of the string or it has been re specified at vertex at a higher chainage.

Vertex labels are created whenever properties are set (Textstyle is required).

**Usage**

First the string is selected at the vertex where the values are to be assigned. Next select the purpose of the string (cross section or bypass) to unlock the appropriate fields. A textstyle favourite is required as the vertex is labelled with the assigned values. Enter the values into the fields and then select Set to set the values as vertex attributes and create the label as a vertex annotation.

On selecting the Utility String Editor option, the Drainage Utility String Editor panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Vertex index</strong></td>
<td>vertex</td>
<td>selected vertex</td>
<td></td>
</tr>
</tbody>
</table>

*Once the string is selected use this to move between vertices*
Style for Vertex Labels

A label is created on the vertex using this textstyle favourite

**Left bank** Input

mannings n value, to delete clear and select set

**Right bank** Input

mannings n value, to delete clear and select set

**Max Flooded within** Input

This changes the threshold were warning bars are created during flooded width calculations. It remains in effect till the next change or the end of the bypass flow string.

Qdc percentage Input

This changes the percentage of the Qdirect+Qcatchment that is used to interpolate the discharges during flooded width calculations. It is generally set on the first vertex past upstream pit and remains in effect till the next change or the end of the bypass flow string. The flow changes from the bypass flow at the upstream pit to this value/100*(Qdirect+Qcatchment).

**Manning’s n** Input

This changes the Manning’s n value used for during flooded width calculations. It remains in effect till the next change or the end of the bypass flow string.

**Pick** button

Use this button to select the string. Select near the vertex you want assign the values to.

**Set** button

Creates the attributes and the label on the vertex.

**Finish** button

Removes the panel from the screen.

**Help** button

Launches the 12d help
In the example above, The Qdc is set to 80% at the eastern end of the catchment. The Qdc is set to 2% for the water overtopping the road. The 18% of the area is not considered large enough to do the flooded width calculation for. If desired, another bypass flow string approaching from the east could be drawn but the final bypass string to the west (direction during bypass should remain).
7.0 Drainage.4d setup file/database

The drainage.4d file controls many of the settings for the pit and pipes types inside 12d. This section details the format and features of the drainage.4d file. Changes to this file take effect only after 12dmodel has been restarted.

7.1 Editing the drainage.4d file

When 12d Model starts up, it checks to see if an environment variable called DRAINAGE_4D exists and if it does, then the file it points to is used to provide the available types of manholes (maintenance holes) and pits. If the environment variable is not set, then 12d Model searches for a file called drainage.4d in the standard 12d Model search sequence for set up files.

12d model ships a drainage.4d file in the "program files\12d\12dmodel\10.00\set_ups" folder. Do NOT change this file. Copy it into your user folder "\12d\10.00\User" and edit it there. Files in the user folder are used by preference and they are never over written by a 12d update.

**File Format**

1. spaces in text - any text string that includes spaces or only numbers, must be enclosed in double quotes ".
2. comments - anything after // until the end of the line is ignored.
3. blank lines - blank lines are ignored

Duplicate definitions are not allowed. ie. you cannot have 2 manhole types with the same name.

From the main menu select

- Design->Drainage-Sewer->More->Edit drainage.4d

1. Select the Find button to search the 12d path for the current drainage.4d file.
2. If the file is found in the setups folder, select Copy to working folder and then Find again.
3. Now that the file is found in the working folder, select the More info button (the folder) and then Open to edit the file.

**You must restart 12d for these changes to become active. Select Project->Restart!**

At startup, refer to the output window for any error messages. 12d will print the line number where it gave up. When looking in the long list of files, the drainage.4d file is loaded after the shp files. Sometimes one error will result in many other errors to follow so fix the first one, save your changes and restart again.
7.2 Creating and Modifying Manhole Types

We will now create a new manhole type for an enlarged grated inlet. For training purposes we will do it in steps restarting 12d model between each step.

1. Create a new manhole type
2. Add manhole commands to set the size and manhole thickness
3. Add manhole commands to create pit connection points where 2 pipes may be connected on the long side.
4. Add manhole commands to set the manhole level modes
5. Add a manhole command to create a user defined attribute.

7.2.1 Create a new manhole type

The order the manhole commands appear in the file is the order they appear in the type drop down list in the DNE.

1. Go to the bottom of the file and type the following.
   Manhole "AK2D enlarged" {
   }
2. Save the file
3. In 12d model close the Edit drainage.4d panel.
4. From the 12d model main menu select Project=>Restart
5. Check the output window for errors (just below the shp files.. there are easy to find as there are so many of them. Your should see the message
   File found <C:\12d\10.00\Courses\drainage\drainage.4d>
6. With the DNE, change inlet I-5 to the new manhole type AK2D enlarged. Note that you are free to change the diameter/length, width and many of the other DNE Pit field.s

   Manhole must be capitalised.
   Use “ (double quotes) not the single ‘ OR 2 single side by side ‘.
   Use {} NOT () or []

7.2.2 Add manhole commands to set the size and manhole thickness

The mhsize command sets the DNE length and width fields (rectangular manhole) and locks them from being changed.

mhdiam is used to set the diameter (circular manhole) and clear the width,

The mhthickness command block sets the manhole wall thickness. The diam_thickness command has the manhole depth followed by the wall thickness. The line diam_thickness may be repeated if you want the pit wall thickness to change if the depth becomes greater than the specified value. Depth is measured from the cover level to the sump level.

The indenting is not required but makes the commands easier to read.
1. add a few blank lines between the braces in your new manhole definition and type the new commands shown in bold.

   Manhole "AK2D enlarged" {
       mhsiz 1.86 0.835
       mhthick {
           diam_thick 0.000 0.150
       }
   }

2. Save the file
3. From the 12d model main menu select Project=>Restart
4. Check the output window for errors.

7.2.3 Add manhole commands to create extra connection points

With connection points enabled on the DNE->Global tab, a connection point is created at the mid points of the internal sides of the manhole. Additional connection points may be added with their offsets from the manhole centre.

1. add a few blank lines before the last brace in your new manhole definition and type the new commands shown in bold.

   Manhole "AK2D enlarged" {
       mhsiz 1.86 0.835
       mhthick {
           diam_thick 0.000 0.150
       }

       con_points "AL2D" {
           con_point 0.930 0.000
           con_point -.045 0.4175
           con_point .045 0.4175
           con_point -.093 0.000
           con_point -.045 -.04175
           con_point .045 -.04175
       }
   }

2. Save the file
3. From the 12d model main menu select Project=>Restart
4. Check the output window for errors.
5. Use Strings->Points Edit->Move to move the end of the pipe that connects to I-5. You will see that it will snap to 2 points on the long side and 1 point on the short sides.
7.2.4 Add manhole commands to set the manhole level modes

We will now set the construction setout point and grate level to be obtained from the road setout string, the cover level to be 0.150 higher than the grate and a sump depth of 200mm.

1. add a few blank lines before the last brace in your new manhole definition and type the new commands shown in bold.

Manhole "AK2D enlarged" {
    mhsize 1.86 0.835
    mhthickness {
        diam_thickness 0.000 0.150
    }
    con_points "AL2D" {
        con_point 0.930 0.000
        con_point -.465 0.4175
        con_point .465 0.4175
        con_point -0.930 0.000
        con_point -.465 -0.4175
        con_point .465 -0.4175
    }
    attribute_integer "cover rl mode"          8
    attribute_real    "setout adjustment z"    0.150
    attribute_integer "grate rl mode"          1
    attribute_real    "sump offset"            -0.200
    attribute_integer "setout xy mode"         1
    attribute_integer "setout z mode"          1
}

2. Save the file
3. From the 12d model main menu select Project=>Restart
4. Check the output window for errors.
5. Use the DNE to select the i-5 inlet. You will be prompted to verify that you want the design parameters to change for each attribute you have added.
7.2.5 Add manhole commands to create a user defined attribute

We will now create a manhole text attribute called “reference dwg” that we can add our drainage plan plot.

1. add a few blank lines before the last brace in your new manhole definition and type the new commands shown in bold.

   Manhole "AK2D enlarged" {
     mhsize 1.86 0.835
     mhthickness {
       diam_thickness 0.000 0.150
     }
     con_points "AL2D" {
       con_point 0.930 0.000
       con_point -.465 0.4175
       con_point .465 0.4175
       con_point -0.930 0.000
       con_point -.465 -.04175
       con_point .465 -.4175
     }
     attribute_integer "cover rl mode" 8
     attribute_real "setout adjustment z" 0.150
     attribute_integer "grate rl mode" 1
     attribute_real "sump offset" -0.200
     attribute_integer "setout xy mode" 1
     attribute_integer "setout z mode" 1
     attribute_text "reference dwg" "Dwg 47.1 Rev A"
   }

2. Save the file
3. From the 12d model main menu select Project=>Restart
4. Check the output window for errors.
5. Use the DNE to select the pit. This will set the attribute for this manhole. The Set Pit details would do this for all manholes in the model.
6. Select Apply or more to another pit.
7. Use Strings->Properties->Attributes to select the manhole and on the pit table you will find the new attributes “reference dwg”.

7.3 Pit Inlet Capacities

The pit inlet capacity tables contained within the Drainage.4d setup file/database are used by the 12d drainage modules and exported to other design packages in different ways but with a common philosophy.

These tables may be plotted in 12d Model using Viewing Inlet Capacity Curves.

7.3.1 On grade pits

The grade and crossfall values for the tables are threshold values, i.e. the next set of capacity factors/curves will not be used until the measured crossfall and grade are equal to or exceed the
threshold values for the curves. Curves with the same crossfall threshold are grouped together and the correct group is selected first. The road grade is then used to select the curve within the crossfall group.

Each inlet selects one road grade curve from the drainage.4d file. 12d Model does not interpolate between the curves.

Some simple sample pit definitions follow to demonstrate how the pit inlet capacities are calculated. The drainage.4d file supplied in the library has extensive curve data from model testing.

Manhole "SEP 25" {
  mhsize  1.200 0.900
  mhdesc  "SEP with 25 l/s"
  mhnotes ""
  mhgroup "SA"
  cap_multi   1.0
  cap_fixed   0.025
}

Manhole "SEP 50 percent" {
  mhsize  1.200 0.900
  mhdesc  "SEP with 50%"
  mhnotes ""
  mhgroup "SA"
  cap_multi   1.0
  cap_percent 50.
}

Manhole "SEP Grade x 10" {
  mhsize  1.200 0.900
  mhdesc  "SEP with 25 l/s"
  mhnotes ""
  mhgroup "SA"
  cap_curve_grade "curve 1" {
    road_grade 0.0
    cap_multi 1.0
    cap_fixed 0.010
  }
  cap_curve_grade "curve 2" {
    road_grade 2.0
    cap_multi 1.0
    cap_fixed 0.020
}
7.3.2 Exporting Inlet Capacity to External Programs

Drains Version 1 and ILSAX

The cap1, cap2, cap3 and cap4 values are used to describe the inlet capacity of the pit as described in their user manuals.

Drains Version +

The 12d inlet curve names are exported to Drains as the pit family.

xpswmm, xpstorm and RAT-HGL

If cap2, cap3 and cap4 are all equal to zero then a fixed inlet capacity equal to cap1 will be exported to RAT-HGL. If the sum of these three values is greater than zero then a pit type will be created in the format of pit_type-crossfall-roadgrade. For example SA2-3-2 for a SA2 pit with a road crossfall of 3% and a road grade of 2%. A rating curve with this name will have to exist inside RAT-HGL. 12d has no way of transferring the rating curve itself into RAT-HGL.

PC Drain

Similar to RAT-HGL, PC Drain has its own rating curves defined internally. The road grade is sent as a separate piece of data to PC Drain so that the pit inlet capacity may be determined.

PC Drain places a suffix code in the pit type to specify that the pit is a SAG pit. For example an 9S.03 indicates that pit type 9 is a sag pit and the maximum depth before bypassing is 30mm. 12d model does this automatically when exporting.

7.3.3 Add manhole commands for inlet capacity

Manhole inlet configuration and bypass pit entries determine if these inlet capacity commands are used. Both may be set in the Drainage Network Editor.

cap_config

The inlet configuration may be set via the following command

```
cap_config x
    Mode x
    Manhole m
    Ongrade g
    Sag s
```
Inlet Capacity Equation

The inlet capacity equation is built up with 3 optional components (single polynomial + curve polynomial + curve coordinates). Generally, only one of the 3 components is used for each manhole type but they may all be used if desired.

\[
\text{inlet capacity} = \text{inlet efficiency} \times \text{inlet multiplier} \times \left[ \text{single polynomial} + \text{curve multiplier} \left( \text{curve polynomial} + \text{curve coordinates} \right) \right]
\]

An inlet efficiency (choke factor) is specified in the Drainage Network Editor. An inlet efficiency (choke factor) of 0 would stop all water from entering the inlet.

Curve Coordinates (On grade and SAG)

For on-grade and sag inlets, the inlet capacity may be determined by entering coordinates along the inlet capacity curve. These coordinates are usually obtained from hydraulic model studies or analytical methods such as HEC-22.

For on grade inlets, the coordinates are Qapproach and Qin, and the curves may change with road grade and cross fall threshold values. The inlet capacity curves are never extrapolated.

Example

Manhole "Ongrade Inlet A" {
    cap_config G
    cap_curve_grade "0.5G" {
        road_grade 0
        coord 0.000 0.000
        coord 0.060 0.060
        coord 0.140 0.112
        coord 0.260 0.174
        coord 0.430 0.244
        coord 0.500 0.270
    }
    cap_curve_grade "1G" {
        road_grade 0.75
        coord 0.000 0.000
        coord 0.060 0.060
        coord 0.140 0.108
        coord 0.260 0.164
        coord 0.430 0.227
        coord 0.500 0.248
    }
}

For sag inlets, the coordinates are Depth (base units) and Qin, and there is only one curve. Each curve has a curve multiplier specified with a cap_multi parameter (discussed below).
Example

Manhole "SAG Inlet A" {
    cap_config S
    cap_curve_sag "SAG" {
        coord 0.000 0.040
        coord 0.045 0.101
        coord 0.070 0.151
        coord 0.095 0.245
        coord 0.120 0.302
        coord 0.170 0.347
        coord 0.220 0.371
        coord 0.270 0.391
    }
}

Inlet Curve Block Commands

Inlet curve blocks may be specified for both on-grade or sag inlets. Inside the curve block you may include the Polynomial Inlet Capacity Commands and Coordinate Inlet Capacity Commands.

    cap_curve_grade "unique name for the pit type" {
        road_grade x.xx
        road_xfall x.xx
    }

    cap_curve_sag "unique name for the pit type" {
}

Inside the cap_curve_grade block the road grade and road crossfall threshold values (percent) may be set. The road grade and crossfall are calculated by the Drainage Network Editor. When the 12d analysis engine selects the inlet curve, all curves with the same road_xfall are grouped together and then within the crossfall group the road_grade curves is selected. The inlet curve with the maximum grade threshold that is less than or equal to the road grade is selected.

Rules for 'cap_curve_grade' entries:
- Only applicable to on-grade pits.
- All cap_curve_grade names must be unique within a Manhole block.
- If both 'road_grade' and 'road_xfall' entries are omitted, only one cap_curve_grade entry is allowed within a pit.
- The cap_curve_grade 'coord' entries (if used) must be in order of increasing Qa.

    cap_curve_sag "unique name for the pit type" {
}

Rules for 'cap_curve_sag' entries:
- Only applicable to sag pits.
- Only one cap_curve_sag entry is allowed within a pit, and it must have a valid name.

Coordinate Inlet Capacity Commands

The coord command must be used inside the cap_curve_grade or cap_curve_sag grouping.

    coord x.xx y.yy

x.xx must be in increasing order.

For cap_curve_grade group, the coord command has the parameters Qapproach and Qin.

For cap_curve_sag group, the coord command has the parameters Depth and Qin.

Please continue to the next section Drainage Definitions - Pipe Types.
7.4 Drainage Definitions - Pipe Types

Pipe types may be used to set the following pipe properties via the DNE.

- Pipe nominal/actual diameters and thickness
- Roughness method and value
- Rational method design mode and design percent depth
- Minimum pipe height for the rational design engine
- User defined pipe attributes

Each definition (pipe block) in the file begins with the key word `Pipe`, followed by the pipe type and then curly braces `{ }`. The order that the definitions appear in the file determines the order they appear in the drop down lists inside 12d Model.

The minimum requirement for a pipe type definition is

Pipe “name” {
}

}
7.4.1 Pipe Thickness

pipethickness {
  diam_thickness x.xxx y.yyy a.aaa b.bbb c.ccc d.ddd
}

- x.xxx: nominal diameter choices will appear in the DNE->Pipe->Diameter drop down
- y.yyy: internal diameter (base units) will be entered into the DNE->Pipe->Diameter field
- a.aaa: optional top thickness (base units) 0.000 if omitted
- b.bbb: optional bottom thickness (base units) top thickness if omitted
- c.ccc: optional left thickness in direction of chainage (base units) top thickness if omitted
- d.ddd: optional right thickness in direction of chainage (base units) top thickness if omitted

An example pipe definition follows.

Pipe "2" {
  // HUMES class 2 rubber ring joint pipe thicknesses
  pipethickness {
    // nominal_diam internal_diam top [bottom] [left] [right] (looking in the direction of chainage)
    diam_thickness 0.225 0.229 0.025
    diam_thickness 0.300 0.300 0.031
    diam_thickness 0.375 0.375 0.035
    diam_thickness 0.450 0.450 0.042
    diam_thickness 0.525 0.534 0.041
    diam_thickness 0.600 0.610 0.044
    diam_thickness 0.675 0.685 0.048
    diam_thickness 0.750 0.760 0.052
    diam_thickness 0.825 0.838 0.054
    diam_thickness 0.900 0.910 0.066
    diam_thickness 1.050 1.070 0.075
    diam_thickness 1.200 1.220 0.076
    diam_thickness 1.350 1.370 0.077
    diam_thickness 1.500 1.524 0.095
    diam_thickness 1.650 1.676 0.095
    diam_thickness 1.800 1.828 0.102
  }
}

7.4.2 Pipe Attributes

attribute_integer "attribute name1" x  x is an integer value (no decimal, stored exactly by computers)
attribute_real "attribute name2" x.xxx x is a real value (used to store numbers with decimals or
  very large or very small numbers
attribute_text "attribute name3" "text" text is a series of words or numbers not intended for calculations

The following special attribute commands create/modify an attribute as described above but these attributes also control calculations performed by the set pit details button on the Drainage Network Editor. The DNE fields will be locked when these attributes are defined for the selected pipe type. If these attribute are not defined for the selected pipe type the DNE field will not be locked and remain unchanged.

roughness_n x.xx> DNE field ->Pipe=>Main=>Roughness
DNE field ->Pipe=>Main=>Roughness type (set to Manning)
roughness_k x.xx DNE field ->Pipe=>Main=>Roughness
Colebrook k roughness value in millimetres
DNE field ->Pipe=>Main=>Roughness type (set to Colebrook)

attribute_real x.xx DNE field ->Pipe=>Design=>Min pipe height
min height in base units

attribute_integer "design size mode" x DNE field ->Pipe=>Design=>Design mode

Mode
Pressurised Pipe: Freeboard design 0
Part-full Pipe: Freeboard design 1
Part-full Pipe: Flow depth design 2
Open Channel: Freeboard design 3

attribute_real "design percent depth" x.xx DNE field
Pipe=>Design=>Flow-depth at pipe entrance

An example of these setting follows:

Pipe "CHNL GRASS EXISTING 1" {  //Open Channel 1
  roughness_k 0.040
  attribute_integer "design size mode" 3  // open channel mode
}
8.0 Open Channel Flow

12d can model flow in open channels a trapezoidal sections. Suggestions for drainage network editor settings are listed below.

Generally, simple channels leading into a pipe network are often not modelled as open channels. The flooded width calculations can perform flooded width calcs (normal depth however) along the channel and the depth at the headwall is calculated using the headwall ku method.

If gradually varied depth/backwater calculations are desired then the channel will need to be modelled as a drainage string. Also if the pipes discharge into a channel then this channel will also need to be modelled as a drainage string.

Key points

The pit grate level must always be at or above the top of the open channel conduit.

Changes in vertical grade and horizontal alignment require a pit in the drainage string. The pit diameter is usually set to zero.

Channels may exist in the tin or you may be proposing a channel to be cut into the tin. The grading and grate level modes will be different for each case. These channel type will be referred to as “Existing” or “Proposed”

Pit-Main Tab

1. Selecting the CHNL auto pit type changes many setting in the DNE.
   - **Cover RL mode** is changed to Max obvert.
   - **Grate RL mode** is changed to Max obvert.
   - **Pit diameter** of diameter of zero. This will result in a single line on the drainage long sections instead of a pit.
   - **Ku method** is set to Direct and a Ku of 0 for the channel change of grade points (pits).
   - **Inlet config** - On-grade pit - it has a 200% inlet capacity. The 200% inlet capacity is in case a
choke factor is accidentally applied.

2. Select the Pit Setout tab

**Pit-Setout Tab**

- **Setout xy mode** is set to Pit centre
- **Setout z mode** is set to Sump Invert which is the lowest of the channel inverts if Sump offset = 0(Main tab).

3. The **Chainage mode** may be be changed to No Road if the channel centre line is not to be used for setout. If the default was Centre string this will stop the Problem message saying the centreline string is not found.
4. Change to the **Pipe->Main** tab

5. Change the **Pipe type** to **CHNL GRASS PROPOSED**. This changes the following:
   - the **Roughness type** to **Manning**
   - the **roughness** for the open channel to 0.040

6. Set the **Height**, **Top width** and **Bottom width** of the channel.

**Note:** The pipe type can now be changed back to channel if you needed to alter any of the locked settings. Selecting the **CHNL GRASS PROPOSED** first set most of the setting correctly as a good starting point.
Pipe-Design Tab

7. Change to the **Pipe->Design** tab
8. Set the **Align mode** to “IL-IL drop”
9. Set the **Align drop** value to 0 (unless you are designing drop structures for your channel.
10. **Min Grade %** for open channels is usually much less than pipes.

Note: The **Design mode** has been changed to “**Open Channel: Freeboard Design**”. This will allow supercritical flow to continue through the channel junctions. Often the Freeboard limit will be different for a channel than the pipe system.
9.0 Major Flood Events

To keep the results file from the minor event copy the drainage models using

**Save your project.** The following routine copies the models that are saved on disk!

**Models->Utilities->Copy Project Models**

1. Select your current project
2. **Type** the name of your drainage model followed by the wildcard*
3. **Type** the new name for your minor results followed by the wildcard*
4. Tick the models that you want to copy
5. Select **Copy**
6. Select **Finish**
Now that the minor results are safely stored away, edit the drainage model using the DNE. For major flood events the user may desire to use an alternative set of values for

- Catchment tc,
- Catchment C,
- Pit direct inflow (Qdi),
- Pipe direct inflow (Qpi),
- Pit choke factor for ongrade inlets,
- Pit choke factor for SAG inlets,
- Outlet tailwater levels.

These controls are found on the Storm Analysis Panel, Main tab.

1. Ensure you have selected the **drainage** model and then go to **Storm analysis**.
2. Type the new return period.
3. Select the **major** storm setting.
4. Turn off the **Modify pipe inverts** and **Modify pipe sizes**.
5. Change the name of your report files by adding **100** after drainage.

You are now ready to analyse the major event and check the surface flooding conditions.
10.0 Excavation Quantities

Sample templates are included in the 12d library (pipe template.tpl). The templates from this template library may be added to your project using

```
Design=>Templates=>Utilities=>Input.
```

**Usage**

Access this report from the menu selection

```
Design => Drainage => Reports => Excavation Quantities
```

This routine uses 12d templates to calculate the excavation volume for all of the drainage strings in a model. An option to create section for a tin on top of the pipe is also available so that the drainage long sections can include hatching between the obvert of the pipe and the design tin under roads.

Templates with names set to the pipe diameters (times 1000) are used for the calculations, thus trench shapes can be customised and over excavation for bedding materials can be included. Net area calculations to exclude pipe area are not supported.

**Key points**

1. One template for each pipe size (mm)
2. If obvert templates are used, add the prefix “obvert “ to the pipe size
3. Carefully consider the tin selected.

A template must exist for each pipe size in the model (pipe size x 1000). For example a 0.3m pipe will require a template to exist named 300. A 0.5ft pipe would require a template named 500. A sample template library is included in the 12d library in the file `pipe_template.tpl`.

The templates are run along the strings and the total volumes are reported. Volumes for each strings are given in the report file.

If a tin is created from these strings then volumes by depth can be determined using `Design=>Volumes=>Exact=>Tin to tin`

On selecting the Excavation quantities option, the Drainage Excavation Quantities panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>

*Model to contain all of the pit and pipe network to be worked on.*

*Strings generated from the templates will be stored in this model*

*Sections generated from the templates will be stored in this model*

*Cut and fill volumes will be sent to this report*

*tins from which the volumes will be calculated*

*Distance between the sections*

*Sections generated from the templates will be assigned this colour (strings colours are defined in the templates)*

*Delete the strings in these models before processing.*
Template are run from pit centre to centre if this is not selected. The templates stop at the edge of the pit if selected. This is often selected with the following option Use obvert templates.

Use obvert templates tick box

Templates must be named with the prefix “obvert”. i.e. obvert 300. The template is still run along the invert of the pipe but the user now has a section “set” of templates that can be used to create a tin on top of the pipe as well as below.

An example report file follows.

```
----------------------------- BEGIN APPLY TEMPLATE REPORT ------------------------------
apply template to string report -
  string  E
  tin     design
  separation  10.000
left template  375
right template 375

```
11.0 Network Quantities Report

This panel is accessed from the menu selection

**Design => Drainage Sewer => Reports=> Network Quantities**

**Key points**
1. Items are counted/totalled by depth and optionally type.
2. The routine will not "double count" items even if the ranges overlap.
3. Types are case sensitive, types with spaces in the name must be enclosed in quotes and the wild card * may be used.
4. Use vertically offset tins and "banded" depth ranges to get quantities under roads, foot paths etc. This is discussed later in detail.
5. Erase count file fields if the items are not to be counted.

On selecting the **Network quantities** option, the **Drainage quantities** panel is displayed.

![Drainage Quantities Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

The second item in a count line is used to filter by diameter (in meters/ft) or the pipe size attribute. The
**diameter** can only be used when no box culverts or trapezoidal channels are used. The *pipe size attribute* is the label generally used in the plan plots. This is the pipe size in mm/inches (375), for box culverts width x height (750x375) and for trapezoidal channels TopwidthBottomwidthxHeight (T5000B1000x500).

Tin

*This tin will be used for the pipe and pit depths.*

MH config file

*This file specifies the types and depth ranges for the pits. Details of this file are contained below.*

Pipe config file

*This file specifies the types and depth ranges for the pipes. Details of this file are contained below.*

HC config file

*This file specifies the types and depth ranges for the house connections. Details of this file are contained below.*

HC pit config file

*This file specifies the types and depth ranges for the HC pits. Details of this file are contained below.*

HC jump ups file

*This file specifies the types and depth ranges for the house connections jump ups. Details of this file are contained below.*

Report file

*a sample report file is given below.*

Report unused ranges

*the depth ranges for the pit/pipe/house connections are defined in the *.4d files. Selecting this option will cause the depth ranges in the file to be printed even if there are no pit/pipe/house connections in these depth ranges (zero quantity values will be shown).*

Report types

*Selecting this option will cause the pit/pipe/house connection types used in the model types to be listed (even if quantities are not requested in the *.4d files). Since this is a complete of the type used in the model, the list informs the user what types have not been included in the quantity calculation.*

Count

*executes the option.*

Finish

*removes the dialogue from the screen*

The *.4d files listed above are contained in the 12d library directory. Each line is the file performs a count (count lines). No items are counted twice. Therefore, if an item is counted its type and then a count line is found the wild card is used for the type, the type already counted will not be included in the count.

The format for a count line is three or four values (space delimited) per line. Size is optional.
<type (from drainage.4d)> <size> <starting depth> <ending depth>

Notes:

All types with spaces in the name must be enclosed in quotes. The wild card * may be used.

The size is optional and if omitted the all sizes will be counted in this group (do not use the * for a wild card).

The starting depth and ending depth are required for all count lines.

Quantities Under Roads and Footpaths

By creating super tins with vertically offset sections, quantities under roads, footpaths etc. can be determined, for example.

Offset your road design tin up by 1000m (Tins->Utility->Translate/Copy) and then use the depth range 1000-1999 for pipes under roads.

Create a tin from the footpaths only, null by angle length with a small length to remove the road and then offset it vertically by 2000m. The depth range 2000-2999 is not the quantities under the footpath.

Sample count lines

// sum concrete cover manholes is various ranges

"CONC COVER" 0.0 1.6
"CONC COVER" 1.5 3.0
"CONC COVER" 3.0 999.9 // this is expected to be zero
"CONC COVER" -999.0 0.0 // trap errors

// any that are not Concrete cover will be counted here

* 0.0 1.6
* 1.6 3.0
* 3.0 999.9

Diameters Used
----------

1.100

Sample count lines for pipes follow.

```
// sum class 2 pipes by diameter and for various ranges
// count 375
2 0.375 0.0 2.0
2 0.375 2.0 5.0
2 0.375 5.0 999.

// count 450
2 0.450 0.0 2.0
2 0.450 2.0 5.0
2 0.450 5.0 999.

// count 525
2 0.525 0.0 2.0
2 0.525 2.0 5.0
2 0.525 5.0 999.

// count pipe sizes that were missed
2 * 0.0 2.0
2 * 2.0 5.0
2 * 5.0 999.

// count all other missed pipes
* 0.0 999.
```

Since the **Report unused ranges** tick box was selected, these lines were printed even though there were no pits in the data ranges.

This data results from selecting the **Report types** tick box.
12.0 Exporting to Drainage Design Software Packages

12d contains most of the data required for your drainage design packages. However, each packages has specific design variables that 12d does not have access too. The design process is intended to export your data from 12d to the design package, design the drainage system and then read the results back into 12d for your long sections.

If pits/pipes are to be added/deleted from your network during the design process you are safest to add/delete the pit/pipe to 12d and to your design package separately.

Not recommended and as a poor alternative, you have the option of reading the results back into 12d, adding/deleting the pits/pipes and then exporting the data to a new drainage project in your drainage design software. As 12d does not have access to all of the data in the design packages this method is not recommended!

Some of the drainage design programs offer a third option that allows you to import data “on top of” an existing project thereby merging and over writing the existing data. Be sure to contact the drainage software supplier to obtain exact details of how the merging process is performed.

The interface is run by selecting Import/Export from the Drainage Network Editor

Design->Drainage-Sewer->Network Editor
The **Drainage model** is the model currently being edited.

The **I/O format** selects which external program the 12d is interfacing with. Some programs use the windows clipboard and others use files. If the clipboard is used the data will also be written to a file by 12d in case you need to take the data to another computer.

**Export** enables the export fields below and exports when **Run** is selected.

The **Export options** have slightly different effects depending on the **I/O format** (program) selected above. Therefore they will be discussed later with the various formats.

**Export pipe diameters and inverts** is generally select for existing systems only. If your design program will set invert levels and pipe sizes then turn this tick box off for new systems. Some design programs will require initial inverts and pipe sizes. In this case this box should be selected on the first export.

**Export default catchment/pit parameters** is generally selected for the first export. For subsequent exports turn this selection off and then only the catchment areas (if the model is supplied above) will be exported.
13.0 Drainage Data Input and Output to Spreadsheets

Spreadsheets are an effective method to manage the numerous variables urban drainage designers create in the modelling process. Spreadsheet data can be transferred to and from 12d in tab delimited files and stored within 12d as “user definable attributes”. These attributes are linked to the pit and pipes within a network. Drainage long section plots can display the pipe attributes in the “arrows” data area and pit attributes in the bubbles area. Drainage plan drawing can also show these pit and pipe attributes.

Drainage strings will be created if they do not exist in the model but pits cannot be added to existing strings.

Spreadsheet options

13.1 12d to spreadsheet transfers

This interface is accessed the **Import/Export** button on the Drainage **Network Editor**.

1. Select Spreadsheet clipboard
2. Leave as **clipboard.txt** to send the data to the windows clipboard as well as this file.
3. Mapping files are the most current 12d technology. Leave this selected.
4. Usually leave this off! Select to export the junction pit at the end of all drainage lines (very rarely needed).
5. You may also select to limit the output if desired. If you like using spreadsheets for data entry, the PCdrain data and ILSAX data formats are useful for adding data for the first time for either program.
6. Select Run to place the data on the clipboard.
13.1.1 Options

The **Spreadsheet Options** section allows the user to define the amount of data exported.

**All Data:** All of the 12d drainage string data and the user defined attributes will be exported to the clipboard in a tab delimited format. The 12d data names and the user defined attribute names will appear at the top of the spreadsheets columns.

**ILSAX:** For the ILSAX program, the spreadsheet column headings will change depending on the pipe and catchment indicators (P2 card) and the inlet type (P3 card). Therefore, use the ILSAX pipe editor macro to set up one pit/catchment for the type of data you wish to enter. Now when you export the pipe network data the column headings will include the names of the relevant parameters.

**User defined below:** The **Customised list file name** is used to define the drainage values, their order and format you desire.

The **customised list file** is a text file where each line contains a drainage variable or a spreadsheet IO command (blank lines are ignored unless preceded by the header command). The spreadsheet IO commands are all lower case and listed below:

- **header** to define a line of text to be exported
- **blank** to leave a blank column in the output
- **pit data** the following attributes are for the pit.
- **downstream pit data** the following attributes are for the downstream pit.
- **upstream pit data** the following attributes are for the upstream pit(s).
- **pipe data** the following attributes are for the pit’s outlet pipe
- **downstream pipe data** the following attributes are for the downstream pipe(s)
- **upstream pipe data** the following attributes are for the upstream pipe(s)
- **variable name** a 12d drainage variable names
- **factor** the following variable is multiplied by this factor
- **decimals** the following variable will export with these decimal places

The simplest way to create your own customised tab delimited file is to set the **Preset Output**
field to All data and leave the customised list file name field blank. Selecting Set, Finish and then Copy from the main dialogue. The data will be placed on the clipboard and a customised list file, named output_list.txt will be created containing the names of all of the drainage variables in the 12d model. Use a text editor to add/or delete the variable names, change their order and/or add spreadsheet IO commands. Save the file with a new name! The output_list.txt file is overwritten on every export.

A listing of a customised list file follows. Note the words in the header file have a “tab” between them so that they will be spaces across the spreadsheet columns.

<table>
<thead>
<tr>
<th>header</th>
<th>Pipe Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>Name Length U/S IL D/S IL Slope(%) Class Dia I.D. Rough Pipe Is No. Pipes</td>
</tr>
<tr>
<td>pit data</td>
<td>*pit name</td>
</tr>
<tr>
<td>pipe data</td>
<td>*length low ch invert high ch invert</td>
</tr>
<tr>
<td>factor</td>
<td>100 *grade</td>
</tr>
<tr>
<td>pipe type</td>
<td>factor 1000 diameter</td>
</tr>
</tbody>
</table>

After creating your customised list file, select Options again and change the Preset Output field to User Defined below and enter the new customised list file name that you saved above. Select Set then Finish and finally Copy to put the formatted data onto the clipboard.

The data can be pasted into a spreadsheet program for checking or additional formatting.

CUSTOM FORMATED DATA MIGHT NOT BE PASTED BACK INTO 12d!

The data must be in the “12d drainage spreadsheet” format to be read into 12d.

Caution with pit names in the form 1-1 or 1/1. Some spreadsheets will interpret these values as dates. If you use these formats for your pit names you will have to paste command them in once, format the columns that contain the pits names as text data and then paste the information in again.

One final word on using the copy/paste commands in the Microsoft Excel program. The Paste Special command using the “Skip Blanks” option will allow you to copy a large block of 12d data (with blanks in it) on top your data so that your data is preserved where it coincides with the blanks. To use this option paste the data into a blank spreadsheet and then select copy again. The Paste special option with “Skip Blanks” will now be available.

13.1.2 Spreadsheet to 12d transfers

This item is accessed from the Import/Export button on the Drainage Network Editor.
The following panel will appear.

![Diagram of the Drainage Network Editor: Import/Export panel]

The following panel will appear.

Tab delimited, “12d drainage spreadsheet” format or “from to” format data must be on the clipboard in order to update a 12d drainage model or create a new model. These format are described below.

### 13.1.3 Updating an Existing Model

The data usually is generated by 12d using the **Export** option, pasted into a spreadsheet and then copied back to the clipboard so that 12d can be updated.

When 12d exports the drainage model to a spreadsheet it includes a column for the unique string identifier and a unique pit identifier (unique to the drainage model not the 12d project). The names of the strings and pits may be changed via the spreadsheet if these columns are present at import time.

If the pit id column is not present, 12d will search the drainage model for a matching pit name. When the pit is a junction between drainage lines, only the trunk line will be the data updated.
13.1.4 Creating a New Model

It is possible to create a new string or an entire drainage network using this format. However, pits cannot be added to an existing string. The entire drainage string must be created at once. Two formats are available, the “from-to pit” format and the “12d drainage spreadsheet” format.

At present the network editor must select a drainage string to become active. Therefore, if you are not adding strings to a network, you will have to create a drainage network with one “dummy” pit. Select this one “dummy” pit to activate the editor. After importing the data and the new drainage lines are created the “dummy” pit may be deleted.

12d drainage spreadsheet Format

The top left cell in the clipboard data must be the text “12d” to specify this format. The minimum amount of data required to create a new string is the string name, pit name, x and y coordinates. You can add as much additional data as you have available. This would include pipe diameters inverts etc. The pits must be listed from upstream to downstream order. If the string is to join a trunk line, the junction pit must be included for both the tributary and the trunk line.

An example file exists called new_network.txt is supplied in the library. Open this file in a spreadsheet or a text editor and copy it to the clipboard. Set the I/O Action to Import and select Run. The new drainage lines will exist in the model currently being edited.

From-to Pit Format

The top left cell in the clipboard data must be the text “from to” to specify this format. The minimum amount of data required to create a new string is the upstream pit name "*pit name), the downstream pit name (*ds pit name) and the x(x location) and y(y location) coordinates of the upstream pit. If the string is to join a trunk line, the junction pit must be included for both the tributary and the trunk line.

An optional column for the pit cover elev (cover elev) may be specified. Once the network has been created additional pipe and pit data may be added using the “12d drainage spreadsheet” format described above.

An example file exists called new_from_to_network.txt is supplied in the library. It is shown below. Open this file in a spreadsheet or a text editor and copy it to the clipboard. Enter a new model name in the Drainage model field and select paste. The new drainage model will now exist.
13.2 “12d drainage spreadsheet” Format

Each column of data is used for a 12d drainage variable or a user defined attribute. Each row represents a pit and the downstream pipe (controlled by the direction of flow variable) within the drainage network. A sample is shown below.

<table>

Duplicate Definitions

Strings Variables such as “direction” are may be defined for numerous pits on the same string. Searching in a top down direction through the file, the last definition found for the string will be set.

Invert levels may be set via pipe data or pit data or combined. It is recommended that the user only use one method and not combine them. Both are exported so delete the ones you are not going to use. The variables are processed from left to right, so if duplicate definitions of an invert level or found the right most data will be set.

The format definition

1. Row1, column 1 must contain either “12d”, or “from to”. Therefore, the first column must be a 12d drainage variable (cannot be a user defined attribute).
2. Row 1. The text <pit> at the top of the column indicates the column contains a user defined pit attribute and similarly <pipe> indicates a user defined pipe attribute.
3. Row 2. This row contains the names of the 12d drainage variable names and the pit/pipe attributes. All names are case sensitive so be careful where you use capital letters. A list of 12d drainage variables is found below.

Names beginning with an asterix (*) will not be processed (except pit/string names when unique identifiers are present in the data). 12d drainage variables names beginning with an asterix indicate that this data was calculated at export time and cannot be read back into 12d (for example, pipe length, pipe grade and deflection angle).

Prefixing an user defined attribute name with “DELETE ” (no quotes, note the space after the DELETE) will cause the attribute to be deleted from all pits/pipes within the model.
4. Row 3. The text in this row define the type of attribute to be stored within 12d. The only valid choices are;

   integer
   real
   text

   If you want to change an attribute type you must delete the attribute and create it again. If you simply change the attribute type in the third row then that attribute will not be updated.

5. Blank lines may be inserted as desired.
6. You are not required to fill in all of the cells in the spreadsheets. Blank cells are ignored (you must use a space to remove all data from text attributes (the space will not be stored).
7. Pipe names are included in the data so that they can be changed but they are not used to identify the pipe. Pipe data will always be assigned to the pipe following the pit in the direction of ascending chainage. If flow directions is ascending then the pipe data will be for the downstream pipe. If the flow direction is descending then the pipe data will apply to the upstream pipe.

14.0 Detailed Drainage Plan Drawing - Creating MH Symbols

There are many methods to create the drainage symbols and one is presented here. The pit symbol is drawn so that the symbol “sits on” the road string that it aligns with (the road string is the y reference). For drawing lintels and grates, assume the road is downhill to the right. See diagram below.

Two symbols are required, one for the left side of the road and one for the right side (referred to as the mirror symbol in the plan ppf). 12d checks the downhill direction of the road strings when using these symbols to determine which is the left and right side of the road.

Either draw your own symbol or import the symbols using File IO>Data Input->4ds/12da data and selecting the file inlet symbols.12da

To create the symbol in 12d draw the left pit symbol in a model by itself. The pit should “sit on” the zero “y” grid line. A 900 wide by 600 long inlet with a 1.2m lintel is shown above.

From the main menu, select Project->Tree

Expand Project then expand Symbols and finally select Create Symbol.
Write will add the new symbols to the symbols.4d file so that they will be available to other projects.

Leaving this panel open as we will need it after we create the mirror image of the pit.

To create the mirror image of the symbol about the x axis use the CAD mirror about X axis command. 12d will require you do this one string at a time. Version 7 does not mirror into a new model so you will want to duplicate the pit symbol model first using Utilities->A-G->Duplicate.

Now repeat the process of creating the right side mirrored symbol. Note that the location of the pit centre is now negative and add the suffix mirrored to the symbol name.

Do not forget to select Write again to save the symbols to the symbols.4d file.
These symbols can now be used in the **Maintenance hole** tab of the Drainage Plan Plot ppf editor. If your version of 12d supports, **native-size symbol**, in the ppf editor then use this mode. If not, select scalable symbol and enter the size equal to the full width of the symbol (height if it is greater).
15.0 User Defined Attributes

These drainage attributes are automatically created by 12d when required but you are free to change them or add more as desired. The attributes may be exported to a spreadsheet and edited and then imported back into 12d. To edit/add the user defined attributes within 12d select either

\textbf{Strings=>Properties=>Attributes} or \textbf{Strings=>User=>Attribute Editor}. This second editor is described below.

First Select \textbf{Pick} to select the string that contains the user attributes (the drainage string). The strings will be highlighted in white when they are selected.

All catchment data is store with the pits in drainage strings. To access the pit attributes, select the drop down icon and then select \textbf{pit}. A circle will be drawn around the pit selected. \textbf{Next} and \textbf{Prev} will now move you from pit to pit.

Select the drop down icon and then select the \textbf{Attribute Name} from the list of existing user defined attributes. These attributes include all of the attributes in the model that the string exists in.

They may not be defined for the pit you are editing. \textbf{Not found} will be displayed in the \textbf{Data} field if the pit does not have that attribute defined.

To change the value for the attribute enter the new value in the \textbf{data} field. If the attribute does not exist, deleting the \textbf{not found} text and adding data will create it. The message on the right will be displayed whenever you are creating a new attribute.
15.1 Drainage Pit attributes 2010

Pit attributes are created and/or updated when the user selects **Set Pit Details.**

- **Pit length** real 0 mhsise (first value) from drainage.4d file
- **Pit width** real 0 mhsise (second value) from drainage.4d file
- **Pit group** text mhsigroup from drainage.4d file
- **Cover RL** real 446.685248

15.3
16.0 Detailed Drainage Plan Drawing

12d drainage has the capability to create detailed drainage plan drawings with the following features:

- Create symbols at the inlets and the type of symbol is controlled by the inlet type (given when you create the inlet).
- Create text labels for inlet types and user defined pit attributes
- Draw lines with line styles and colours to represent pipe sizes
- Create text labels for pipe diameters, inverts and user defined pipe attributes
- Create text labels for house connection types, invert levels and chainages
- Indicate direction of flow on pipes.

An example is shown below

Usage

This option is accessed from the menu selection

Design => Drainage-Sewer => Plots => Plan Annotations
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plot parameter file</strong></td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Optional - no dpf is required.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default settings will create a schematic drainage drawing. A custom dpf may be selected if desired.</td>
<td></td>
</tr>
<tr>
<td><strong>Load design details from</strong></td>
<td>model box</td>
<td></td>
<td></td>

<td></td>
<td></td>
</tr>
</tbody>
</table>
smart clean will update text that has been moved and clean the rest. Full clean will all text from the plan annotations model.

Set colour as string name tick box
when selected the string colour will be used for the string name (to be used for DWG/DXF export using map files)

Plot button
Creates the labels in the model specified

Find button
used to locate plot parameter input boxes using Version 5 plot parameter names

IMPORTANT! to turn off any data change the text height to zero.

Select Maintenance holes from the tree to set the symbols to be used for the various pit types.
Select the MH type as desired and use **scalable symbol** and **setout point**. For the symbols enter the names that you used when you created the symbols.
Plotting a symbol at the pit setout point is a good confirmation of the data printed in the setout reports. The settings to create this symbol are shown on the left.
17.0 Drainage Long Section Plotting - Hatching Under Roads

The drainage long section plotting has been discussed in the Intro Drainage Course. Here we will discuss the technique for hatching under roads and/or footpaths.

The following steps are required.

1. Run the Excavation volumes routine using the obvert templates to create sections and strings for a tin on top of the pipe (obvert tin). Select **Stop section at end of manhole** to prevent the pits from being hatched.

2. Create the obvert tin from the strings and sections then and null by angle length with a small length value so that the tin is nulled near the pits.

3. Create a design tin that extends to the limit of the roads.

4. Use the hatching section of the drainage long section plot to select the hatching style.

17.1 Creating the Obvert strings.

Run the Drainage Plan Plot by selecting Plot from the Drainage Network Editor.

Select the drainage_design.ppf file from the library.
Select the folder icon then **Open** the pfp.
Confirm that the **Pipe string level mode** is set to **pipe obverts** and that all symbols with elevations are not used. This include:

- MH setout points,
- Flow arrows,
- Pit symbols

Now plot the drawing and we will use the pipe strings at the obvert level to create a tin.
17.2 Create and Null the Obvert tin

To create the obvert tin select.

**Tins->Create->Triangulate Data**

Enter a **New tin name** as desired.

![Triangulate a Data Source](image)

Select the **Data** tab.
Select the plot model created above.

The tin will now only exist on top of the pipe and it is ready to use for hatching.
17.3 Create a Roads Only Tin

The design tin is already nulled to remove the long triangles. If the footpaths were to be excluded from the tin then they should be removed from the road design strings. You could run a template that did not include the footpath and has a **Final Maximum slope width** of zero or just copy the desired road strings to one model and remove unwanted strings. We will use the later techniques.

Add all of the road string and kerb return models onto one view and then select

Utilities->A-G->Change

**View** select the view that contains all of the road strings

**Copy to model** type the name of a model for all of the road strings.

Select **Change** copy the strings.
Now to create the tin select Tins->Create->Triangulate data

Select the Filter icon at the end of the selection strip. Now select the Model tab and select the Name of the model that holds all of your road and kerb strings road strings only (tab not shown here).

Select the String Info tab and enter the name of the strings that you want to remove from the road only model. In this case it is path.

Select Filter Select to select these strings.

Select the second Target button Move to model and select the model trash and then select Change.

Repeat this for string names int.

We are now ready to triangulate the road only tin.
Enter a function name (optional) and **New tin name** and then select the **Data** tab.

**Model** - Select the model containing the road only strings.

**Length** - Select a length just greater than the width of half the road so that the tin will not be nulled from the end of the roads.

Select **Triangulate**.
Chapter

Page 5573

17.4 Use the Hatching Feature in Drainage Longsections

We are now ready to create the drainage longsection plots. Set up a section view with the a string in the drainage model profiled, the vertical exaggeration set, the desired tins displayed and the service models added. From the main menu select,

**Design->Drainage-Sewer->Plots->Longsections**

![Drainage Plot PPF Editor](image)

From the **Plot parameter file** field select a drainage longsection ppf from the library and then select **Read**.

In the **View to load details from** field select the section view you have setup for the drainage long section.

Now select **Hatching cut/fill**
Define set is set to 1.

Original tin is set to the obvert tin.

New tin is set to the road only tin.

Now select the + beside the Hatching cut/fill and then select fill.

Use set # is entered as 1. Fill separation, hatch angle, colour and linestyle selected as desired.

Draw sides of tin, Draw original tin and Draw new tin are not required unless you want these
extra line in the drawing.
Select **Plot** and add the plot model **drainage LS plot1** onto a PLAN view to preview the drawing.

The hatching is shown to the left at a 2mm spacing with the tins and sides not drawn.
18.0 Flooded Width Analysis and HEC RAS

There are 2 flooded width methods in the drainage module. The first can be used with any of the external drainage packages and the second is part of the 12d storm analysis. The first is found on the main menu

Design->Drainage-Sewer->Calc flooded widths

The name of the overland flow string becomes the name of the HECRAS project.
1.0
1.0 Dynamic Stormwater Design

This manual, the **Dynamic Stormwater Design**, describes how to use 12d model to calculate catchment hydrographs and perform unsteady flow hydraulic computations on drainage networks. The rainfall runoff and loss methods supported include the time area unit hydrograph (ILSAX) with Horton infiltration (from runoff), and the New Zealand SCS hydrology method.

The starting point for this manual is a 12d drainage network already constructed with catchment areas assigned, inlet and manhole properties set and vertical grading applied. These tasks are described in detail in the [Stormwater Part 1 Design Course](#). The network will have open channels, bypass flow routes and pits with inlet capacity settings as described in [Stormwater Part 2 Design Course](#).

This manual, **Dynamic Stormwater Design Course** contains:

- review and modifying the 12d hydro file with respect to IFD data, rainfall temporal patterns, infiltration loss methods (horton and SCS curve numbers),
- selecting the hydrological runoff method (Ilsax2 or NZ SCS) and the infiltration loss method,
- using cross section shapes cut from the tin for bypass flow paths and open channels
- running the analysis and reviewing the graphical output, plan and long section plots and the custom spreadsheet reports.
- create parallel pipes with different sizes and invert levels,
- adding and initial sizing of storage basin with fixed discharge,
- discuss graphical basin links,
- create outlet structures including, culverts, weir spillways, orifice controls, bubble up pits,
- underground storage tanks,
- bypass over road crown

2.0 Starting with a Basic Drainage Network

In this document, the generic terms **pit** or **manhole** refer to inlets, catch basins and manholes. The exception to this is when referring to inlet types in the Drainage Network Editor (DNE). The term **manhole** specifically refers to an inlet with zero inlet capacity. Pit types, dimensions and inlet capacities are set in the drainage.4d file.

These course notes assume that you have completed the Stormwater Design Course and that you have experience creating 12d model drainage networks with catchments areas. This course will begin with a completed drainage design found in the directory

```
\12d\9.00\Courses\drainage\basins
```

The project name is **basins**.
3.0 Hydro-Rainfall File with Infiltration

Access the rainfall editor from the main menu

**Design->Drainage-Sewer->Rainfall Editor**

### Key Points

1. Several rainfall files are shipped in the 12d library as examples.
2. One of the 3 Intensity method MUST be entered. Do not leave blank rows in the IFD Table.
3. All dynamic drainage runs require temporal patterns.
4. Dynamic drainage (ILSAX 2) requires Horton losses
5. Dynamic drainage (NZ SCS) requires SCS losses
6. Rainfall data is in mm/hr NOT mm (important for NZ)
7. Tailwater series are time versus elevation data for outlets.
8. Initial and continuing losses are not supported in release V9c1e

#### 3.1 Intensity Frequency Duration (IFD) Data

The **IFD table** method is the most common (refer to figure above). The rainfall intensity is entered in mm/hr for metric data and in/hr for US units. The top row is the return period in years and the first column is the rainfall duration in minutes. The top left corner cell is always zero.

When using the TP 108 method for the Auckland region, the 24hr rainfall depth is extracted from the Appendix A and then converted to mm/hr before entering it into the IFD table. Thus only 2 lines may exist in the 12d grid.

Note that areal reduction factors must be accounted for by the user as they are not included in the 12d rational hydrology engine.
3.2 Rainfall Temporal Patterns

Temporal patterns are referred to as storms in dynamic drainage. Several example hydro files are included in the 12d library. These examples have the temporal patterns for the minor and major storms in the 8 zones of Australia.

Temporal patterns are not required for the SCS NZ method as the standard 24 hour temporal pattern from TP108 is built into the 12d analysis engine.

The **Run storm**, **Zone filter**, **From ARI** and **To ARI** columns are used determine which storms are analysed (run). The **Run storm** column must be checked for that temporal pattern to be analysed. Many storms may be selected.

The **Zone filter** is optional. Entering a value here will allow the selected storms to be further filtered. A **Zone filter** field (accepts wild card characters) is found on the DNE Global tab that is used to determine which of the selected storms (paragraph above) are analysed.

The **ARI** field on the Run panel is used with the **From ARI** and **To ARI** columns. The value on the run panel must be within the From-To range for the storm to be analysed.

The **Duration** column determines the total length of the storm. This value divided by the **Interval** must be a whole number and this number determines the number of % values to be entered to the right of the **Interval column**. The total of the percentage must equal 100.

3.3 Horton Losses

The pervious portion of the catchments used in the **ILSAX 2** analysis will have a loss type defined describing the soil type. The loss type is defined in the DNE Default->catchment and catchment tabs.
These soil types use the classifications of Terstriep and Stall (1974), based on the system developed by the U.S. Department of Agriculture. The default values entered from the library represent the soil types of

1. Type A - low runoff potential, high infiltration rates (consists of sand and gravel
2. Type B - moderate infiltration rates and moderately well-drained
3. Type C - slow infiltration rates (may have layers that impede downward movement of water)
4. Type D - high runoff potential, very slow infiltration rates (consists of clays with a permanent high water table and a high swelling potential)

Numbers are assigned to each soil type to allow interpolation between the defined soil types. When interpolated values are used they must be included in the list (2.5 and 3.5 for example). Interpolated values do not need loss data entered. If loss data is entered for the interpolated names then this data will be used rather than an interpolation occurring. If any loss data is entered then all of the values must be entered.

Four preset AMC points are defined in the rainfall file to mark AMC conditions ranging from dry (AMC1) to saturated (AMC4). The required data for each line is the Initial loss rate, Final loss rate, decay rate and 4 antecedent moisture conditions (AMCs). The AMC values are entered in depth of rainfall (mm) they represent the total rainfall prior to the start of the temporal pattern.

The AMC point numbers are set once for all catchments on the DNE Global tab. Value between 1 and 4 (decimal value are permitted) are entered for the minor and major events.

3.4 SCS NZ Losses (Initial Abstraction and Curve Numbers)

The SCS NZ method uses Initial abstraction (Ia) and the curve number (CN) to determine the losses for the catchments. Names are given to the SCS curve numbers in the rainfall file. These names and Ia (entered as storage values) and selected in the DNE catchment data.

A curve number of 0 results in zero runoff while a CN=100 results in 100% runoff. TP 108 recommends the selection of the curve number by identifying 1) the soil type and 2) the land use. A CN=98 an Ia=0 are recommended for impervious areas.
4.0 Rational to Dynamic ILSAX2 in the DNE

The user does not have to start with the rational hydrology method but since this method has a pipe sizing algorithm it is often run first. The following steps will prepare a drainage network for dynamic hydrology.

Changing to ILSAX 2 is done on the DNE Global->Main tab.

4.1 Infiltration Losses

If this is the first time in this project you have switched to ILSAX2 you will be prompted for the default infiltration loss. These loss types are retrieved from the rainfall location file (Horton losses) specified above. Select one of these and then select **Update All**. These losses are only applied to the previous percentage of the catchment.
4.2 Storage Losses
Both the impervious and pervious portions of the catchments have storage losses. This amount of rainfall depth (in mm) is removed from the start of the rainfall pattern. The default values are entered on the **Defaults Catchments** Tab.
5.0 Rainfall Runoff Calculations

12d currently supports 2 rainfall runoff methods.

See ILSAX 2
See SCS NZ

5.1 ILSAX 2

The ILSAX mode 2 uses a triangular shaped unit hydrograph with the time to peak equal to the recession time. The time to peak equals the tc value throughout the 12d DNE.

5.2 SCS NZ

The SCS NZ uses a unit hydrograph as described in TP 108 Table 4.1 (hydrograph number of 3/4). 12d calculates the time to peak value (tp) = 2/3 the time of concentration (tc).

The %impervious value is used to create a composte CN and a composite initial abstraction Ia

One of the optional tc methods uses the equation derived from a regression analysis of Auckland catchments (BCHF, 1999c). On the Defaults->Catchments->Set 1 tab set the Impervious and Pervious Tc methods to NZ Auckland TP108. The default length and slope values will be used unless they are specified for each catchment.
6.0 Dynamic Hydraulics

As with the rational method hgl calculations it is essential that the pit grate levels are entered correctly. With no bypass specified, water is lost from the analysis when the hgl exceeds the grate level. When bypass is specified the water will not be lost until the level exceeds the highest bank of the bypass section shape (see below).

12d uses the St Venant unsteady flow and continuity equations to solve for the flows in the pipe network. With these equations it is the water level in the pits that determines how much flow travels through the conduits. The hgl is not calculated from the flows. Viewing the results from this perspective will help immensely.
6.1 Flows in and out of the Pits

The diagram below shows the possible flows through a pit. When bypass is used, there are 2 hgl levels; one level for all of the conduits with inverts at or above the grate level and another for conduits with inverts below the grate level.

The pit inlet capacity and choke factors determine the amount of approach flow that is captured. If the HGL of the subsurface reaches the grate level, the captured flow becomes zero and only the surface hgl is used to determine the flows in all conduits. When the hgl drops below the grate again, 2 hgl levels will again be used.

The continuity balance is monitored during analysis and the results of this check are stored as a model attribute “dynamic/xx/calculated hydraulic continuity error percent” where xx is the duration of the storm. A detailed output file is also created for each storm analysed. The file name begins with the name of the drainage model and ends with the storm duration (plus the extension rpt).

6.2 Default Bypass Section Shapes and Slopes

In the rational method, bypass flows (water that could not enter the inlet because of either inlet constrictions or hgl levels) were bypassed to the Bypass pit. With the dynamic analysis, a channel
shape is required so that the hgl levels and the storage effects can be modelled. If all of the bypass routes have the same shape then you need only cut one default shape and it will be used for all routes. However you can enter a shape string for every bypass route if desired.

The bypass distance is determined from the length of the bypass flow string and the channel has a constant grade. If a changing grade or channel shape is required then the bypass should be to a drainage line modelled as a natural channel (see section further in the notes).

The invert elevations of the bypass channel are set by the grate elevation of the upstream and downstream pits. However, when the bypass is to the pit LOST then there is no downstream grate level so the slope of the bypass channel will be defined. The Lost grade value is specified here as 1%. 12d needs this to determine the water forces try to hold the water into the bypass channel.

The Manning’s n value is the default for the entire section. If left and right bank n values are desired they are entered on the Bypass Shape tab.

6.3 Create and Editing Channel Shapes

The channel shape may be entered manually or created by drawing a string perpendicular to the flow path and 12d will cut section from the finished surface tin. It is recommended that you keep you section shape strings in one model for data management purposes. The strings are drawn from left to right looking in the direction the bypass string (the direction of flow). To create this string enter the new model name in the CAD Control Bar. Entering a name for the string is optional. If only 2 points are to be used for the shape string then use the Create Line button from the CAD tool bar.

![Image of Drainage Network Editor interface with highlighted Bypass Shape tab and fields filled with data such as Distance, Manings n, and Lost grade.](image-url)
After drawing the string it needs to be selected via the Bypass section location pick button (see below). Once picked and accepted, select Set Pit Details to have the bypass shape cut from the finished surface tin specified on the Global tab. This shape may be seen on the Bypass Shape tab and the chainage elevation data displayed.

The elevations on this graph are not used. The data is relative to the lowest elevation on the section. This becomes level 0.0 for the shape and the channel inverts added to determine the final elevation.

Left and right bank n values may also be entered if desired. They Left n is used to the left of the Left bank chainage and the Right n is used to the right of the Right bank chainage. The centre chainage is entered on the Default->Pits->Main tab.
If you manually change any of the chainages and elevations they will be lost the next time you select **Set Pit Details**. To prevent this RB select the **Bypass section location** and select **Clear**. Now there is no string so the data cannot be recalculated.

### 6.4 Explicit Bypass Section Shapes and Slopes

We will now explicitly define a bypass flow shape for bypass link. Water flow across the crown of the road should not use a kerb and gutter shape. Instead we need the shape and invert elevation for the road crown that the water will overtop.

To create a shape string for the bypass across road 2, draw the string from east to west (left to right looking in the direction of flow).
Now select the bypass shape for crossing the crown of the road. Select the **Set Pit Details** button to have 12d calculate the bypass shape from the finished surface tin. Change to the Bypass Shape tab to see the shape. Note the **bypass pit** and **Distance** fields will already be completed from the bypass flow string calculations. Entering a manning’s $n$ value is optional.

You will also note that there are 2 other bypass flow routes that can be used. To use these the bypass pit and distances will need to me manually set. The hgl above the grate determines the head that will drive the water down the various channels.
The enlarge the plot RB select inside the graph area and select **Maximise** from the menu. Note the lowest level on the section shape is approximately 25.5. This is the grate level of the pit. Press **Esc** or select the title area to close the graph. Left and right channel n values with their chainages may be entered in the fields below the graph. If these values are left blank the n value from the centre of the channel will be used, NOT the n values from the default bypass channel shape.

If this bypass shapes was to be used in the model now, the bypass channel would go from one grate level to the other without any reference to the crown of the road level. To model the flow path from the crown of the road to the pit 3.5S we will raise the upstream invert level to the road crest level (25.790).
Select the **Apply** button to store the changes and note that the lowest point of the bypass shape graph is now raise the 25.79.

See [Create and Editing Channel Shapes](#) for details about manually entering data or changing the shape.
7.0 Running Dynamic Drainage

The dynamic engine analyses the network but does not design the components. Multiple storm patterns may be run simultaneously and the results from individual storms as well as the worst case from all currently analysed storms is saved. The results may be viewed graphically or in user defined reports. If your computer has a multiple core processor each storm will be processed by different processors and 12d will accumulate the results as the storms finish analysing.

7.1 Storm Analysis

Select the Storm Analysis button. To generate plan labels for the worst case dynamic results select the drainage_dynamic_design ppf file from the library. Also change the name of the Model for plan results so that you can keep the results from previous rational hydrology runs. Select the Run button.

A process window will be launched for each storm analysed and the status will be printed in the output window. Always watch this window for messages. Below are message from a sample run,

===> Checking Storm: 1
===> Storm: 1  OK
===> Updating Catchment Attributes
===> Updating Node Attributes
===> Updating Link Attributes
===› Updating Model Attributes
Elapsed Time: 6.67 secs
Run finished normally.

A run with errors would have a message like the following:

Dynamic Drainage Analysis (Build 5.1.026)
Dynamic Runoff Method: ILSAX 2
ari0.0
zone: 0
1 TP_Durations: 25.00
===› Solving Storm: 1
ERROR: Bypass section not defined for conduit: 7/A-SEP_to_6/A-SEP(S)
Model failed to solve.

7.2 Reviewing Results - Plan Labels
As with the rational method, the plan plots indicate the peak values. If multiple storms are run then this pfp file will print the max from all storms run.

So that the dynamic results are not mixed with the rational results, the worst case results are stored with the prefix **dynamic**. Results from individual storms have the prefix **dynamic/xx** where xx is the max time of the rainfall event.

For example the pipe attribute for the maximum pipe flow

| calculated pipe max flow | rational hydrology result |
| dynamic/calculated pipe max flow | worst case dynamic result |
| dynamic/calculated pipe max flow critical storm | storm where above results occurred |
| dynamic/25/calculated pipe max flow | 25 min storm dynamic result |
| dynamic/calculated pipe max flow | worst case dynamic result |
7.3 Reviewing Results - Graphs

Graphs indicating the results are created on the **Graphs** tab of the DNE. These graphs are a sampling of the time step results and usually does not include all time steps. Therefore, if the peak indicated in the attributes occurs between 2 plot points the peak may not be on the graph.

Select the **Storm event** to view. Nothing is displayed yet. When **All** is selected, the results from all the storms analysed in the last run are displayed. Graphs types that display more than one line will not be displayed when all is selected. There will be far too many lines on the plot to properly identify them.

Now select the data to view using the drop down boxes or by selecting the below and pressing enter. For example the **Rainfall/Runoff**.
The panel cannot be resized but it can be maximised via the right mouse menu. ESC returns to smaller view. The peak from the plot data (not the attribute) is indicated at the top of the graph.

You can zoom into the graph areas by dragging a rectangle inside the graph area. You must right mouse select and choose **Undo Zoom** to return to the full plot.

The available graphs are:

**Catchment graph types** (used in conjunction with **Sub catchment** selection)

**Rainfall/runoff**

The **Total rainfall** is the rainfall intensity calculated from the IFD data, the return period and the temporal patterns.

**Excess rainfall** (ILSAX 2) is the water that is left over after the rainfall losses infiltrate into the soil.

*For the impervious area, excess rainfall = total rainfall - storage*

*For the pervious area, excess rainfall = total rainfall - storage - infiltration*

**Runoff** starts when the excess rainfall depth exceeds the storage depth and the intensity is greater than the infiltration. Most frequently runoff starts from the impervious area first, (no infiltration, small storage and short tc) and then from the pervious area.

- **Runoff**   The runoff component of the **Rainfall/runoff** graph (good for all storms).
- **Rainfall**   The rainfall component of the **Rainfall/runoff** graph (good for all storms).
- **Losses**    These are the horton infiltration losses that are subtracted from the pervious component of the catchment (good for all storms).
Pit graph types

12d analysis has 2 systems for conveying flow. The **surface system** created with bypass flow strings (open channels with their inverts at the pit grate levels) and the **link system** created with the 12d drainage strings.

**Grate & Invert Depths:**
- The top is the **Grate depth** showing the depth of flow in the surface channel measured from the grate level. The bottom is the **Invert depth** showing the depth in the link system above the pit invert.

**Grate & Invert Elevations:**
- Shows both the bypass and link system water elevations. Good to see when the link elevation reaches the grate level to stop the inflow of water through the grate.

**All Inflows & Outflows:** (Inflows are + and outflows are - (S means surface)
- Flows for each link and bypass are listed separately.
  - **Local** is the total **Catchment** flow from all 3 catchment sets plus direct flow,
  - **In**: Links and surfaces flows entering the pit.
  - **Out**: Links and surfaces flows leaving the pit.

**Total Inflows and Outflows:**
- **Local**: the total **Catchment** flow from all 3 catchment sets plus direct flow,
  - **Inflow to Invert**: the sum of **In**: (links) + **Captured flow** This is the total inflow into the pit for the link system.
  - **Outflow from Invert**: the sum of **Out**: (links) This is the total outflow from the pit for the link system.
  - **Approach Flow**: the sum of the **Local** + **In**: (surface)
  - **Captured Flow**: determined from the **Approach Flow** (on grade pits) or **Grate Depth** (sag pits)
  - **Bypass Flow**: Approach flow - Captured Flow

**Depth above Invert** see invert depth above

**Depth above Grate** see grate depth above

**Elevation** - see Invert elevation above

**Elevation Bypass Flow** - see Grate elevation above

**Basin volume** - only available on pits with basin curve data.

**Catchment Flow** - Total of **Runoff** for Sets 1, 2 and 3.

**Link Inflow and Captured Inflow**: surface and link pit elevations, **Link Inflow** (see **Inflow to invert** above) and **Captured Inflow** (see **Captured Flow** above)

**Link Outflow**: see **Outflow from Invert** above

**Approach Flow**: see above

**Bypass flow**: see above

**Inflow**: see **Link Inflow** above

**Overflow** - the flow that is lost from the drainage system when the hgl exceeds the maximum level at the pit.
- The maximum level at the pit is largest of
  1) the cover level,
2) the grate level + depth of bypass channel
3) the maximum storage level in the basin storage data.

**Ku** - the link flow, upstream velocity, Ku and head loss of the primary outgoing link.

**Pipe graph types** (link system)

**Dynamic Section:** a section view of the entire string showing the hgl in the links and surface channels. The lower dashed line connect the grate levels and the upper shows the top of the surface channels. If the hgl goes above the top of the surface channel water will be lost from the system.

**All Link Results**  3 charts: The colour of the right axis label is the same as the graph line it represents.
- **HGL US, HGL DS** (left axis)
- **Depth** (right axis) - depth at the mid point of the link
- **Capacity** (left axis) - the ratio of the current pipe flow / (pipe full, HGL at grade capacity)
- **Froude Number** (right axis) - Froude number at the mid point of the link
- **Flow** (left axis) flow in the link
- **Velocity** (right axis) - velocity at the mid point of the link

**Bypass graph types** (bypass system)

same results graphs as for the **pipe graph types** above
8.0 Adding Storage Basins

Storage basins are created by adding an elevation versus area curve at a pit. Without the area curve the default area of a pit is defined by the diameter or the length, width settings in the drainage.4d file.

The elevation area curve may be entered manually for initial estimates or measured from the finished surface tin (inside a string defining the extent of the basin).

The outlet structure is the link exiting the basin pit. This is often a weir, orifice or discharge limiting pipe.

An optional basin link may be used to separate the outflow structure from the basin pit. This allows the user to place the outlet structures in their correct position. The basin link is only a graphical link and often has its diameter set to zero to help indicate that it is not a hydraulic component of the system.

8.1 Selecting the Basin Location

The node modelling the basin is the outlet of the pipe or channel discharging into the basin. The pit becomes a basin when the user enters elevation versus area curve for the basin or selects a polygon around the top of the basin. With the polygon method, 12d will create the elevation versus area curve from the finished surface tin. We will use an existing string from the survey data but you may easily create your own polygon around the top of the basin.

For an initial sizing you only need to enter the basin invert elevation and area into the grid.

If the outlet pipe has an upstream invert level below the lowest basin curve entry, this lower section of the pit will use the default pit area.
8.2 The Outlet Structure and the Basin Link
The basin outlet generally includes more than one structure. Typical arrangements include a low flow pipe that restricts the outflow from the basin and a high flow spillway used in larger events. Every outlet structure is linked to the basin pit with a basin link. Often the outlet structure is a fair distance from the basin pit and we want the outlet structures drawn in their correct location. IF the diameter of the basin link is set to zero it joins the basin pit to the outlet structure but preforms no hydraulic function in the model.

The minimum elevation in the elevation data becomes bottom of the basin and the outlet invert cannot be below this level. If there is a drop pit for the outlet then ensure that the base of the drop pit is first elevation in the basin data. The area will be the area of the pit. The second entry will be the top of pit level with the same pit area.

8.3 Creating the Basin link
The pipe downstream of a basin pit is a basin link. When the diameter is set to zero, the data set on this link is for graphical presentation and has no hydraulic function.
For clarity in the section view we will set the levels to the bottom elevation of the basin and set a zero pipe diameter to make the link as unobtrusive as possible.

Locking the link inverts will ensure the invert elevations are not changed with a regrade pipe selection. Remember this is a graphical link and the values do not affect the hydraulic calculations.
8.4 Data for the Outlet Control Pipe

For initial sizing of the basin you can set the diameter of the pipe to 0.001m so that no flow goes through it. Now enter a negative pipe direct flow and this will become the constant outflow from the basin (usually set to your pre-development peak discharge). Once you size the basin, return here, remove the negative flow and select a pipe size to yield similar results.

The upstream invert is being set to the bottom of the basin and then we will lock this invert. We will leave the engine to set the DS invert level.

The length will depend of your drawing.
8.5 Adding a Second Outlet Structure (Spillway Weir)

A second drainage string will be needed for the spillway. Again it will start with a basin link and then have a weir section. From the main menu select

**Design->Drainage-Sewer->Create**

Select the Same as button and pick a drainage string in the model. This will fill in all of fields. Name must be unique so change this data. Finally select Create.

Then select Add/Append MH from the menu.

The plan view below shows the basin link and the spillway weir location. Draw the string in the direction of flow and ensure you start with a point snap on end of the channel.

Once the string has been created the pit data at the upstream side of the weir need to be set.
On the Pit->Main tab we are going to set the cover level at the highest expected water level in the basin. The grate level will have the same level as the cover level. The Pit type does not affect the calculations for the weir.

We have also assigned a name to this pit.
On the pipe-main tab we will see the US invert level to weir crest level (20.0). The DS Invert is set the same but will have no affect on the calculations. The Diam/Height determines when the weir will start acting as an orifice. Generally used in underground storage tanks. In this case we will set it to a value higher than the expect flow depth (1.0 m). The Width is the dimension of the weir perpendicular to the flow. The Disch Coef is optional as the default will be used if it is blank.

The tailwater levels are now set to the expected levels for the minor and major events.

Enter a name for the outlet.
9.0 Natural Section Shapes

The channel shape may be cut from the design tin by drawing a string at the desired location. It is a standard convention to draw it from left to right looking in the direction of flow.

In this example we are going to connect the end of the culvert to a channel down to the spillway and then eastward to the end of the project. Set the Defaults, **Pit Type** to *chnl auto* and **Pipe Type** to *CHNL GRASS EXISTING 1* with a **height** of 4.0. This height will not affect the calculations but will show the approximate channel top in the section view. This will mean you no not have to change them later.

Use the **Points Edit->Append** to add the extra links as shown below. Ensure that the centre of the drainage string is in the lowest part of the channel. Finally, extent the spillway to the channel.

Enter the model name **dr natural shapes** into the CAD toolbar model field before drawing this string.

Once you have drawn the string you can select it from the **Pipe->Channels** tab. Selecting **Set Pit Details** will have the shape cut from the design tin and displayed in the grid and graph area. If you do not want the shape cut from the tin you can just enter the shape in the grid area. Once again the shape obtains its elevation by setting the lowest point onto the invert elevations.
Left and right bank chainages and n values may be entered if desired. If blank the link’s n value will be used. There is no default left and right bank n values.
10.0 Orifice Control on a Pipe

Use the Strings->Points Edit->Insert command to add a pit upstream of the outlet pipe. This new pipe will be set to an orifice to control the flow entering the pipe.

Lock the invert levels so that the orifice will not move in elevation,
11.0 Storage Tanks as Basin or Pipe

A storage tank may be modelled as a box culvert or as a basin but do not do both as this will double count the storage. To model the tank using basin areas Set conduit type to a Basin link and set the pipe diameter to a value that is meaningful for the long section appearance. Once it is marker as a basin link it will not affect the calculations.
11.0.1 Drainage Utility Program

Position of option on menu: Design => Drainage-Sewer => More => Misc. utilities

The Drainage utility program contains functions to significantly reduce the time required to perform drainage tasks. These tasks include:

Assign Pit names

To use the export routines, every pit in 12d must have a pit name. This selection automatically creates the pit names for the entire model or selected strings. Examples of pit names are 1,2,3..., A1,A2,A3..., Pit 3-A, Pit 3-B.

Reset pit cover levels

This selection sets the cover levels for the manholes to the design tin or design strings. The user will be prompted for each manhole to select a tin level, a string level (if a design string model is supplied) or keep a manually set level. The tin/string/manual selection will be stored and the levels reset now and whenever the pit/pipe interfaces exports the data (unless this last option has been manually turned off).

Regrade pipe levels

The selection applies the default grading rules (cover level) to reset the pipe invert levels for the entire network. Manhole cover levels are not changed during this function.

Label Catchments and Label drainage network

This selection quickly creates labels for a drainage and catchment plan. The pits are labelled with their name, the pipes with their diameters and the catchments with their area and the pit they drain to. These labels must be updated using this selection whenever the catchment or network is changed. To turn off the automatically drawn pit names in the current view select Menu=>Settings=>Text=>Toggle and select the drainage model.

Analyse Flooded Width

This is the only hydraulic calculation that takes place in 12d. The normal depth along the bypass flow paths is calculated using discharges imported from hydrology/hydraulic packages including spreadsheets. This flooded width is drawn to scale at intervals along the bypass flow path and colour coded (blue if less than a specified limit and red if greater than the limit).

Usage

This panel is accessed from the menu selection

Design => Drainage-Sewer => More => Misc. utilities
The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>drainage model</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>catchment area model</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Assign pit names</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>design tin</td>
<td>tin box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>design model</td>
<td>model box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **drainage model**
  
  *Model to contain all of the pit and pipe network to be worked on.*

- **catchment area model**
  
  *Model to contain the catchments strings for the Drainage Model above*

- **Assign pit names**
  
  *This button launches a dialogue for setting the names for the pit and pipes in the network model.*

- **design tin**
  
  *This optional field allows the user to specify a new tin for the surface levels of the pits. If you are using road grade and cross fall for pit inlet capacity it is preferable leave this blank and to link the pits to a string using the design model field below. If some or all of the pits are linked to strings in the design model below, they will still use the strings selected.*

- **design model**
  
  *This model contains the strings for the pit cover levels (the string directions are also used for road grade and cross fall). If this model is changed you will be prompted to select new strings to link the pits to.*
Reset pit cover levels button

This button will reset the pit levels to the design strings in design model or to the tin specified in design tin above. The first time this is selected you will be prompted to choose whether to set the pit cover level to the design tin or a string in the design model. more about design strings

Regrade pipe levels button

The selection applies the default grading rules (cover level) to reset the pipe invert levels.

network labels model model box drainage labels network

Model to contain the network labels for the Drainage Model above. This model is cleaned out each time Label drainage network is selected.

catchment labels model model box drainage labels catchment

Model to contain the catchment labels for the Catchment Area Model above. This model is cleaned out each time Label catchments is selected.

catchment units choice box ha, acres

Conversion factors of 10,000 will be used for ha and 43560 for acres.Not that not all design packages support both units.

text parameters input box

Select the + to access the text parameters (colour, size, alignment etc.) for the text created with Label Catchment or Label drainage network

label catchments button

This selection creates labels indicating the catchment name and area in the units specified above.

CAUTION: If you change you catchment strings or rename you pits you must run this routine to update the labels.

label drainage network button

This selection creates labels indicating the pipe size and pit name for the network model.

CAUTION: If you change you change the pipe sizes or rename you pits you must run this routine to update the labels.

analyse flooded width button

This selection launches the dialogue for analysing the flood along bypass flow paths. The bypass flows must be imported from your design package/spreadsheet before running this selection.

11.0.1.1 Set Pit Names

The Set pit name selection names the pits and pipes for the drainage model (both pits and pipes can be named). Three numbering schemes are available:

- drainage strings names are used as the prefix followed by the pit number (ex A-1)
- drainage strings names are used as the suffix followed by the pit number (ex 1/A)
- the pits are sequentially numbered. (ex 1,2,3,...)
The names can have pre-text added to the beginning of the pit name and a separator between the string name and the pit number (/- etc.) if desired.

**Design Program Notes:**

**PCdrain users:** Since catchments contain only 3 characters do not use separators. Using the letters A-Z for strings and numbers 1-99 will give you 26 strings and up to 99 pits on each string. Using the numbered stem works very well in PC Drain.

**Micro Drainage users:** Pits and pipes are numbered separately in Micro drainage. The pipes must use the numbered sequence with the most upstream pipes numbered with the smallest numbers. Number of digits must be set to 3.

**ILSAX users:** You must use alphabetic characters for your string names and no more than 3 characters

**See Also**

Labelling a drainage network  
Displaying the Auto Pit Names  
Drainage overview  

**Usage**

The selection is found on the drainage network editor and is accessed through the main menu by selecting

Design=>Drainage-Sewer=>Drainage Network=>Drainage=>Network editor

Select the Set Pit Names button and the following panel will appear.

![Drainage Network Editor: Set Pit Names](attachment:image.png)

The fields and buttons used in this panel have the following functions:
<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>Model box</td>
<td>drainage model from main dialogue</td>
<td></td>
</tr>
</tbody>
</table>

**Naming Method**

- **Pit num - String name** for string A pit 1 the name is 1A
- **String name - Pit num** for string A pit 1 the name is A1
- **Sequential numbering** the strings names are sorted alpha-numerically and the pits are numbered starting at **First pit number**

**Pre text**

input box
this text will precede the pit name (ex Pit A01)

**String/pit separator**

input box
the character that separates the string name from the pit number. For example if pit names A/01, A/02 etc. where desired a "/" would be entered. You may omit the separator if none is desired.

**First Pit Number**

integer box
the starting pit number on the drainage lines. For drainage strings with the flow direction set as descending chainage the first pit is the junction pit.

**Min digits in pit numbers**

integer box
a non zero value will pad the pit numbers with leading zeros. (ex if 2 is entered, pit 1 is not A/1 but rather A/01)

**Reverse numbering order**

tick box
Unselected, pit **First pit number** is at the low chainage end of the line. Selected, pit **First pit number** is the second pit from the high chainage end of the line.

**Number pits**

tick box
the pits are assigned names. This allows the pit and pipes to be names differently.

**Number pipes**

tick box
the pipes are assigned names. This allows the pit and pipes to be names differently.

**Run**

button
name the pits/pipes. The pit at the high chainage of the string is not labelled. The only time you will need to name this pit is when it is the outlet from the system.

**Back to Editor**

button
return to the network editor.

**Help**

button
display this page.

Usage

This panel is accessed from the menu selection Design => Drainage => More=>Version 6=>Pit/pipe design interface

The fields and buttons used in this panel have the following functions.

Field Description      Type      Defaults      Pop-Up
import/export format <c> input box      XP SWMM      Spreadsheet clipboard,
select the drainage design program to export/import to.

**drainage model**   
**Required** Model to contain all of the pit and pipe network to be exported/imported. Also see Drawing the Drainage Network

**file name**   
**Required** file to be read or written to. If a clipboard format is chosen for import/export format above then the data will also be written to this file on a Copy selection

**catchment area model**   
**Optional** model to contain the catchments strings for the Drainage Model above. Also see Designating Catchment Areas

**catchment units <c>**   
ha, acres

Conversion factors of 10,000 will be used for ha and 43560 for acres. Not that not all design packages support both units.

**catchment characteristics model**   
**Optional** strings in this model will be used to define the catchment slope and width (XP SWMM only)

**bypass flow model**   
**Optional** model to contain the bypass flow strings for the Drainage Model above. Also see Creating Bypass Flow Strings

**road design string model**   
**Required if bypass flow model** is specified above. Also see Pit Inlet Capacity, road grade/crossfall and Bypass routes

**services model**   
**Optional** if the strings in this model cross the drainage network the crossing data (drainage chainage, invert elevation and thickness) will be sent to the design package

**additional services model list (file)**   
**Optional** if your services lie in more than one model then enter a text file name here and then select edit from the fields file icons. Type the names of all of the service models and then save the file.

**project description**   
**Optional** this description will be sent to the design program

**export pipe diameters and inverts**   
**tick box**
Select this tick box to export the pipe diameters and inverts. see also Quick Check Lists for Drainage Design Software

**Export default catchment/pit parameters**

- **Tick box**
  - **Tick** selected all default catchment parameters are exported
  - **Not selected** only catchment area is exported if **catchment area model** is specified above. see also Quick Check Lists for Drainage Design Software

**Options**

button

several calculations are preformed before all exports. Advanced users may turn some off for large models (100’s of pits). The option to re-link your pits to new design strings is also included here. More options

**Write/Copy**

button

This will create/over write the file specified above in **file name**. If **Copy** button is present the data will also be placed on the windows clipboard as Tab delimited text.

**Read/Paste**

button

**Read** will read the file specified above in **file name**. **Paste** read the data from the windows clipboard. Both selections will update the drainage strings in the model specified above in **drainage model**. If the **Spreadsheet clipboard** import is selected and the strings are not present in the model they will be created.

**11.0.2.1 Options**
Selecting the Options button brings up the dialogue to the left. Additional choices may be present at the bottom of the dialogue depending on the Import/Export Format that you selected on the main dialogue:

**Catchment areas** when selected the catchment areas are linked to the drainage pits and the areas recalculated. See also Designating Catchment Areas.

**Re-link pits to road strings-tin** when selected a dialogue for each pit will be presented asking which design string or tin to link the pit to. See also Selecting design string or tin.

**Calculate bypass flow routes** when selected will calculate the downstream bypass pit, road grade and crossfall and inlet capacities. See also Pit Inlet Capacity, road grade/crossfall and Bypass routes.

**Calculate now** will calculate the selected option immediately and return the user to the main dialogue.

**Set** will set the options but no calculations will be performed until a Write or Copy is selected from the main dialogue.

**Finish** removes the panel from the screen.
21 Rivers

Position of menu: Design=>Rivers

The Rivers option is used to prepare data for analysis packages and examine the results from the analysis.

21.1 River Interface Models

The River interface strings are split into different models depending on the strings function. Also the string names are used to define names of entities such as cross sections and reservoirs when they are exported. Following is a list of the river interface string types:

River strings
Source strings
Reservoir Strings
Spill Strings
21.1.1 River Strings

The river centre line and bank are defined by the strings in the River strings model. The centre line string is used to:

- measure the centre line distance between the sections,
- mark to zero chainage (or starting chainage) on the cross section, and
- if automatic source strings are created they will be perpendicular to this string
- define culvert locations and sizes (XP SWMM only)

The left and right bank strings are used to:

- measure the bank distances between the sections and
- mark the cross section chainage where the conveyance (usually roughness) changes

The names of the strings must be left bank, right bank and centre line river name, reach name (centre may be spelled center).

The left bank is on the left side of the river looking downstream and the right bank is on the right (looking down stream). These strings need not touch each other and may extend from one river reach to another.

HEC RAS and UNET

The centre line string must begin at the downstream end of the river. The modelling convention for these programs is to have the low chainage at the downstream end. You may use super, 2D, 3D or alignment strings in this model. If you put other strings in this model you will receive warning messages saying that these strings will not be used.

Each reach of the river MUST have its own centre line string and they must "touch" each other to create a river confluence.

A sample of a river strings model for HEC RAS with one confluence is shown below. The line style for the centre line is not required. It is used only to show the direction of the centre line string.

Notes:

left bank strings are shown in red, right bank in blue and centre line strings in yellow and green. The line style for the centre line strings is Drainage_4D->Flow line. This is not required but shows the direction of the string. The string labels were created with Strings->Label->User-
>Label strings with names.

**Centre line string direction is very important!**

- HEC RAS, UNET, XP SWMM start at the **DOWN**stream end of the river
- ISIS and Mike 11 start at the **UP**stream end of the river

**ISIS and MIKE11**

The centre line strings are drawn starting **upstream** for the ISIS and Mike 11 programs.
21.1.2 Source Strings

Cross sections are created at the location of the **source strings**. These source strings are initially created at a user defined spacing and section length using any one of the river interfaces writers. The user may alter these sections as desired. These may be shortened if they intersect at sharp bends in the river; they may be extended at extremely wide river sections or extra points may be added so that the section is no longer a straight line.

Source strings can be deleted and additional sections can be added by creating new source strings. The **Create source strings** tick box on the interface panel must **NOT** be selected to use the customised strings.

A quick way to manually create 2 point string is via the CAD tool bar.

A sample of source strings (shown in magenta) is presented below. The source strings may run in any direction except for Mike11. In Mike11, the cross sections will be created in the same direction as the source strings. For all other interfaces the low chainage will be used for the left bank (section viewed looking downstream).
21.1.3 Reservoir Strings

The reservoir strings may define inline reservoirs or offline storage. The elevation of the first point on the string sets the maximum level to be used in the stage storage curve. 12d will determine the minimum level inside the reservoir string and then calculate the volumes at a 1m (2 foot for imperial units) increment. The default increment may be changed by creating a string attribute "stage increment" (see stage increment).

Inline reservoirs are "touched" by centre line strings both upstream and downstream. Offline storage areas are linked to the cross sections via Spill strings.

Other features of the reservoir strings are

- Auto height
- XP SWMM catchment parameters

A sample drawing showing an inline reservoir in cyan (1-277) follows. Note that the river centre line touches the reservoir string both upstream and downstream. The left and right bank strings may continue straight through the reservoir.

A sample drawing of an offline reservoir follows (the reservoir string is shown in green). Note that the spill string (black) starts at the source string (point 1), then follows the section line to be cut and exported (points 2 to 5) and ends by touching the off line reservoir string at point 6. The river strings do not touch the offline storage strings.
Chapter 21  Rivers

River Interface Models
21.1.4 Spill strings

Spill strings are strings that link offline storage areas to a cross section (see drawing above). The string must begin by "touching" the source string and then proceed to the first point on the spill section. During the export the first point will NOT be exported as part of the spill section. After defining the end of the spill section the last point on the string must "touch" the reservoir string. Again this last point will NOT be exported as part of the spill section.

The default roughness for the spill section is the "left n" from the main export panel, the default slope is 0.5% and the default length is 100. See the manual setting table for manual override settings.

**XPSWMM Only.** 2 point culvert strings (6 max) may be draw across the spill string to create a multi conduit. The culvert strings should be drawn in the same direction as the spill string so that the upstream and downstream inverts follow in the same direction.
21.1.5 Define Culvert Locations

12d allows culverts to be included as a segment of a super string. The XP SWMM rivers interface allows culverts in 2 models. In the spill string model, multiple two point superstring may cross a spill string to indicate a culvert through the embankment. In the river string model a segment of the river centre line may marked as a culvert. For parallel culverts, segment attributes must be used. If a source string crosses the same segment than a multi-link with both the culvert and the natural section will be exported.

Important note: Version 10.0 of xpswmm (at the time of writing) will only use inlet control curves on culverts with positive slopes.

Adding a Culvert to a super string

1. **Super strings only!**
   - Convert string to a super string (if required)
     - Strings->Convert

2. **Mark the ends of the culvert.**
   - Add a vertex at the upstream and downstream end of the culvert (Toggle vertices on if desired)
     - String->Points Edit->Insert

3. **Mark the segment as a culvert or pipe**
   - Use the super string segment editor to set the culvert data.
     - Strings->Properties->Segments (all) and change Segment properties to use **culvert each segment** (box) or **pipe each segment** (round). Note that if there is one box culvert on the centre line then all must be box culverts. If you need pipes and box culverts combined, set the width to zero for pipes.
   - Also set the Justify mode to indicate the type culvert levels you wish to specify.

If there are two (max is 7) culverts at this location that have different inverts or sizes add the following user defined attributes to the segment. The comment attributes are printed by the Culvert Table routine and are used to label the culvert as well. If there are a number of identical culverts, the attributes "number of pipes" (integer) can be set to a value greater than 0. Additional attributes to customise the culvert are listed at the end of this section. Default mannings n are 0.024 for pipes (corrugated metal) and 0.012 for box (concrete).
4. Conduit Factors are automatically set. Circular pipes are set to "Headwall (circular corrugated metal)" and box culverts are set to "45 deg Wingwall Flares (Rect, Conc)". Expansion and contraction energy loss coefficients have default values of 1.0 and 0.5 respectively but these may be changed using the attributes indicated below.

![Super Segment Properties](image1)

5. **Set the upstream and downstream levels**
Select a vertex at the end of segment, ensure the **height mode** is **each vertex** and set the height. Use the **Next** or **Prev button** to move to the other end of the culvert and set its height as well.

![Super Vertex Properties](image2)
### Additional Culvert Segment Attributes (Spill and River strings)

<table>

21.3 HEC-RAS Interface

Position of menu:  Design=>Rivers=>HEC-RAS interface

The HEC-RAS interface creates the HEC-RAS project files ready to open and run. This includes the project, plan, flow and geometry files. Water levels are read back into 12d where they may be viewed in a 3D perspective view to easily identify extents of flooding.

The HEC-RAS walk right menu is,

- Read HEC-RAS results
- Presenting Water Level Results
- Import cross sections (GIS file)
- Read HECRAS Interp sections
- Read HEC2 Data
- How to for Rivers
- Frequently Asked Questions (Rivers)

Exporting to HEC-RAS

The HEC-RAS project is created from a surface tin (representing the river bed and overbanks) and a model containing strings identified by their names “left bank”, “right bank and the name prefix, “centre line”. Any additional strings in the specified model will be ignored (warning messages will be given when you run the macro that any additional strings are being ignored). The low chainage (often zero) of the centre line strings must be at the downstream end of the reaches.

Cross sections are created at the location of the source strings. These source strings are initially created using the HEC-RAS option at a user defined spacing and section length. The user may alter these sections as desired. These may be shortened if they intersect at sharp bends in the river; they may be extended at extremely wide river sections or extra points may be added so that the section is no longer a straight line.

Source strings can be deleted and additional sections can be added by creating new source strings. The Create source strings tick box on the interface panel must NOT be selected to use the customised strings.

Presenting HEC-RAS Results in 12d

After the HEC-RAS analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the HEC-RAS results. These strings are then triangulated to create a water surface tin from which the water level boundaries are determined. These results can then be shown in plan, long section, cross section and in 3D perspectives.

More details
21.3.1 HEC-RAS Write Panel

Position of option on menu:  Design=> Rivers=>HEC-RAS interface=>Create HEC-RAS project

The HEC-RAS interface creates the HEC-RAS project files ready to open and run. This includes the project, plan, flow and geometry files. Water levels are read back into 12d where they may be viewed in a three dimension perspective view to easily identify extents of flooding.

Usage

The HEC-RAS panel for creating the HEC-RAS project follows.

![HEC-RAS Interface Writer](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>INPUT MODELS</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
River strings model  
Model containing the centre line, left bank and right bank strings. The centre line strings must begin downstream and proceed upstream. The name of the river may follow the words “Centre line” (note the ending space). For example the centre line string may be named “Centre line Parramatta River, downstream reach”. The comma separates the river name from the reach name. If no comma is included then the river name is repeated for the reach name.

Confluences are modelled by using a separate string for all reaches. Thus a system with a branch is modelled with three strings. The branch will be one string and the main reach will have a downstream string and an upstream string. The reaches must touch at the confluence.

The distance from the start of the upstream strings to the first cross section is used to model the confluence length.

The left and right bank strings need not be separate strings (see figure below).

Source string model  
New source strings will be created in this model or existing source strings are contained in the model. See Create source strings tick box below.

Rename Source Strings  
If selected the source strings will be a name using the chainage along the river centre line. The number of decimals and the Centre line chainage factor (ft to miles or m to km) are specified below.

Centre Line Chainage Factor  
The cross section names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

Number of decimals  
When Rename source strings is selected, the source strings name will have the specified number of decimals.

CREATE SOURCE STRNGS OPTIONS

Create Source Strings  
When selected existing source strings are deleted and new ones created perpendicular to the centre line at the specified spacing and length. Once you have created the sources strings they can be easily modified. On the Strings->Points Edit menu you will find the selections Move (to move the end points), Insert (to insert additional points).

Distance between sections  
The distance between the cross sections. At present no check is made for overlapping cross sections around river bends.

Section Length  
The length of the cross section with zero chainage at the mid point.

CROSS SECTION DATA

Cross section model  
The cross sections created and exported are stored in this model.

Surface Tin (not the model)
Tin or super tin to create the cross sections from (remember a tin is like a string. It is placed in a model.).

**Levee Tolerance**  
Real box  
If the surface level drops more than this amount while moving away from the channel centre line then the crest is marked as a levee. A value of zero means that no levees are marked.

**Delta Y tolerance**  
Real box  
This value filters out points on the cross section. Imagine a tube of this diameter passing over the cross section. The tube is elongated until one point lies outside the tube. The tube is shortened to the previous point and then all points inside the tube are deleted from the cross section. The tube then moves on to the next point. The filtered (smoothed) and original sections are kept for comparison. The final water tin is created from the ground tin and therefore the boundary string is located using the unfiltered section.

**STARTUP DATA**

**Manning’s n**  
Real box  
Manning’s n values for the left, right and centre channel sections.

**Discharge**  
Real box  
This discharge is used at the upstream end of all reaches. If you have multiple river branches, you can set the flow for each branch inside HEC-RAS or inside 12d. This can be changed at each section. See manual settings.

**Units**  
Choice box  
This selection will set the default units for the project being created.

**Project file name**  
Input box  
The HEC-RAS project name. Remember HEC-RAS (2.0 or earlier) is limited to 8 characters only. If the total path name is too long HEC-RAS will not analyse the project.
21.3.2 HEC-RAS Read Panel

Position of option on menu: Design=>Rivers=>HEC-RAS interface=>Read HEC-RAS reports

After the HEC-RAS analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the HEC-RAS results. These strings are then triangulated to create a water surface tin.

How to for Rivers
Frequently Asked Questions (Rivers)

Usage

The HEC-RAS read panel follows.

EXISTNG DATA

River strings model  Model box
The river strings model specified in the write panel.

Cross Section model  Model box
The cross section model specified in the write panel. This must be specified but is only used when reading the *.rep file types (see File format below). The interface will search the string names in this model for the cross sections specified in the HEC-RAS report. A match is successful if the HEC-RAS
cross section chainage and the string name are within the tolerance specified below in Chainage tolerance.

Shape string model  Model box

For meandering rivers, the cross sections (shown in green above) may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings (shown in red above) can be created to create a water surface (shown in blue above) to follow the river. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach.

Ground surface tin  Tin box

If a boundary string model is specified below, the intersection of this ground surface and the water surface will be determined. The strings will be stored in the model from the boundary string model field.

File format  Choice box

The GIS format should be used in most cases. The rep format is used for reading the HECRAS report files with the “Standard Table 1” selected in HECRAS.

HEC-RAS report file name  File box

The HEC-RAS report file (GIS format) is created using the HEC-RAS menu selection

File=>Export GIS data

The HEC-RAS report file (REP format) created using the HEC-RAS menu selection
File=>Generate Report

The report must include the Standard Table 1.

RESULTS DATA

Water surface tin model  Model box
The model to contain the new water surface tin.

Water surface tin  Tin box
The name of the water surface tin to be created.

Water level results model  Model box
The model where the water surface strings will be created at each cross section and shape string.

Boundary string model  Model box
The model to contain the intersection strings between the water and ground surfaces specified above. If left blank no intersection strings will be calculated.

PARAMETERS

Chord Length  Model box
This value set the spacing for the points on the water level strings (both cross section and shape strings). It is recommended that you use a length of no more than half of your average cross section and shape string lengths. A large value in this field may result in unexpected water level profiles for meandering rivers.

Centre line chainage factor  Model box
This data is only required if the Shape string model is used. The shape string names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

Chainage Tolerance  Real box
This is the tolerance used when the cross section chainage from the HEC-RAS report is compared with the cross section string names. A value of 0.00001 is excellent if you have not altered the cross section names in 12d or HEC-RAS.

However, if you have altered chainage names then you may have to increase the value of the tolerance. Suppose the tolerance is set to 0.001 and the water level for section 0.056 is read from the HEC-RAS report file. The interface will search for the first string with a name between 0.055 and 0.057. If you chose to great of a tolerance then more than one water level result will match a 12d cross section and a warning message will be given.

If you have one specific cross section that you would like to have a different tolerance set for (maybe only one section is giving you troubles), use the Attribute Editor (Strings->User->Attribute Editor), select the cross section string and create a real type attribute named tolerance set to the tolerance desired.
21.3.3 Import cross sections (GIS file)

Position of option on menu: Design=>Rivers=>HEC-RAS interface=>Import cross sections (gis file)

This option is used to import HEC RAS cross sections, interpolated cross sections, source strings (Cut lines), river centre lines and storage area boundaries into 12d. Note that the imported data will be given the X,Y coordinates used in the HECRAS project.

- **River strings model**: The imported centre line strings will be stored in this model (REACH: CENTERLINE: data). If blank these string will not be imported.
- **Source string model**: The imported source strings will be stored in this model (CROSS-SECTION: CUT LINE: data). If blank these string will not be imported.
- **Cross section model**: The imported cross section strings will be stored in this model (CROSS-SECTION: SURFACE LINE: data). If blank these string will not be imported.
- **Storage area model**: Storage area boundaries will be stored in this model (strings not supported in 12d V7 interface). If blank these string will not be imported.
- **HEC RAS GIS File**: The GIS file generated from HEC RAS (*.RASexport.sdf)
- **Section colour**: Colour box
Cross sections will be created using this colour unless the section name contained illegal characters.

**Clean model** tick box

If selected all strings in the Cross section model will be deleted before the cross sections are imported.

**Process** button

Executes the option and the number of string imported will be reported in the message area.

**Finish** button

Removes the dialogue from the screen.

**Notes:**

The RASexport.sdf file is created from HEC RAS using File->Export GIS Data. From this panel the desired data to be exported may be selected. In this example all three Geometry tick boxes have been selected.
21.3.4 Read HEC-RAS interp sections

Position of option on menu: Design=>Rivers=>HEC-RAS interface=>Read HEC-RAS interp section

This option is used to import HEC RAS interpolated cross sections (names begin with *) based on their distance along the left and right bank strings.

The low chainage must be at the downstream end for both the "left bank" and "right bank" strings.

21.4 XP-SWMM Interface

Position of menu:    Design=>Rivers=>XP SWMM interface

The XP-SWMM interface launches your XP-SWMM program and loads either a default xp file from the set_ups path (master_rivers.xp) or your existing project. The 12d data is automatically imported in the XP-SWMM project (via a *.xpx file) to either create a new river reach or update an existing reach. Water levels are read back into 12d where they may be viewed in a 3D perspective view to easily identify extents of flooding.

The XP-SWMM walk right menu is,

How to for Rivers
Frequently Asked Questions (Rivers)

Exporting to XP-SWMM

The XP-SWMM project is created from a surface tin (representing the river bed and overbanks) and a model containing strings identified by their names “left bank”, “right bank and the name prefix, “centre line”. Any additional strings in the specified model will be ignored (warning messages will be given when you run the macro that any additional strings are being ignored). The low chainage (often zero) of the centre line strings must be at the downstream end of the reaches.

Cross sections are created at the location of the source strings. Source strings can be deleted and additional sections can be added by creating new source strings. The Create source strings tick box on the interface panel must NOT be selected to use the customised strings.

Presenting XP-SWMM Results in 12d

After the XP-SWMM analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the XP-SWMM results (xpx file). These strings are then triangulated to create a water surface tin from which the water level boundaries are determined. These results can then be shown in plan, long section, cross section and in 3D perspectives.

More details
21.4.1 XP-SWMM Write Panel

Position of option on menu: Design=>Rivers=>XP SWMM interface=>Create xpx file and run XP SWMM

The XP-SWMM interface creates the XP-SWMM project files ready to open and run. This includes the project, plan, flow and geometry files. Water levels are read back into 12d where they may be viewed in a three dimension perspective view to easily identify extents of flooding.

River and Source Strings
Hydrology Data
XP-SWMM Interface overview
Read XP-SWMM results
Presenting Water Level Results
How to for Rivers
Frequently Asked Questions (Rivers)

The source strings define the location where cross sections are cut from the ground surface TIN. A node is created in XP-SWMM at this location and the cross section shape is used to the next downstream node (no cross section is created at the most downstream source string).

The centre line and overbank channel lengths are measured in the downstream direction. XP SWMM link and node input panels are displayed below with the relationship to the 12d Model described.
XP SWMM Link Data

cross section chainage at intersection of left and right bank strings
max elev - min elev at upstream cross section

n values from 12d panel
channel lengths measured along river strings

Minimum cross section elev from upstream node.
Minimum cross section elev from downstream node.
XP SWMM Node Data

The slope of the conduit/link is calculated by assuming that its invert matches vertically with the invert of the downstream link. The overflow levels at the nodes are calculated by determining the lowest of the bank levels for the upstream and downstream links. The least of the overflow depths at the nodes is then used as the link diameter.
Usage

The XP-SWMM panel for creating the XP-SWMM project follows.
The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>River strings model</strong></td>
<td>Model box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Model containing the centre line, left bank and right bank strings. **The centre line strings must begin downstream and proceed upstream.** The name of the river may follow the words “Centre line” (note the ending space). For example the centre line string may be named “Centre line Parramatta River, downstream reach”. The comma separates the river name from the reach name. If no comma is included then the river name is repeated for the reach name. 

The left and right bank strings need not be separate strings (see figure below). |

| **Source string model**   | Model box     |          |        |
| New source strings will be created in this model or existing source strings are contained in the model. See **Create source strings** tick box below. |

| **Create Source Strings** | Tick box     | not selected |        |
| When selected existing source strings are deleted and new ones created perpendicular to the centre line at the specified spacing and length. Once you have created the sources strings they can be easily modified. On the **Strings->Points Edit** menu you will find the selections **Move** (to move the end points), **Insert** (to insert additional points). |

| **Distance between sections** | Real box |        |        |
| The distance between the cross sections. At present no check is made for overlapping cross sections |
around river bends.

**Section Length**

Real box

The length of the cross section with zero chainage at the mid point.

**Cross section model**

Model box

The cross sections created and exported are stored in this model.

**Centre Line Chainage Factor**

Real box

The cross section names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

**Number of decimals**

Integer box

The cross section names are created with this many decimals. CAUTION XP SWMM only allows 10 characters for the names and each link name begins with "Lx-" That leaves 7 characters for the chainages.

**Surface Tin (not the model)**

Tin box

Tin or super tin to create the cross sections from (remember a tin is like a string. It is placed in a model.).

**Levee Tolerance**

Real box

Not implemented in XP-SWMM.

**Manning's n**

Real box

Manning’s n values for the left, right and centre channel sections.

**Delta Y tolerance**

Real box

This value filters out points on the cross section. Imagine a tube of this diameter passing over the cross section. The tube is elongated until one point lies outside the tube. The tube is shortened to the previous point and then all points inside the tube are deleted from the cross section. The tube then moves on to the next point. The filtered (smoothed) and original sections are kept for comparison. The final water tin is created from the ground tin and therefore the boundary string is located using the unfiltered section.

**Discharge**

Real box

This discharge is used at the upstream end of all reaches. If you have multiple river branches, you can set the flow for each branch inside XP-SWMM or inside 12d. This can be changed at each section. See manual settings

**Units**

Choice box

This selection will set the default units for the project being created.

**Project file name**

Input box

The XP-SWMM *.xp name to be created or updated. An xpx file will also be created using this name to transfer the data.

After selecting the Process button the cross section strings will be created and exported to a xpx file (using the project file name as the stem. Never included ".xpx" in the project file name) The xpx file will be over written without any warning. This is only used as a temporary transfer file.
12d needs to know where XP SWMM program and the XP SWMM working directory are. The system file that contains these locations is called XPSWMM.4d. (See System file path for its location). The file contents are as follows:

- Line 1 the XP SWMM working directory
- Line 2 the full path to the XP SWMM program
- Line 3 the destination of the hydro.ini file when it is created

IMPORTANT: include the final "\" on lines 1 and 3.

The XPSWMM.4d file as supplied follows;

```
c:\xps\xp-swmm\work\n
c:\xps\xp-swmm\xpswmp32.exe

c:\xps\xp-swmm\n```

Next 12d will check for an XP project in your XP SWMM work directory (project file name + ".xp"). If it does not exist the file Master_rivers.xp will be copied from the System file path to your XP SWMM working directory. If a wp file already exists in your working directory you will see the following options dialogue.

![XP SWMM interface]

Create xpx file and run XP SWMM
Read XP SWMM xpx results file
Culvert Table

The default is to update the wp file. Nodes and links in the file with the same names as in the export will be updated. If they do not exist they will be added. The import will NOT delete any nodes or links inside XP SWMM. This option is often used to merge rivers data with urban drainage data.

The overwrite option will copy the Master_river.xp file into the working directory and overwrite the existing file.

In either of the two cases the xpx file will be imported after XP SWMM has started. When you exit your XP SWMM session regardless of whether or not you save the XP file the XPX file will be exported over writing the original export file from 12d.

Your third option if not to run XP-SWMM at all and work with the XPX file as you see fit.
21.4.1.1 Export Details

The following diagram displays how the values from 12d are exported to XP-SWMM.

At every source string location a node is created in XP-SWMM. The cross section geometry is then used for the downstream reach and is exported looking in the downstream direction.

The node name is set manually or calculated inside 12d by obtaining the centre line chainage at the intersection with section string. This value is divided by the Centre line chainage factor and rounded to the Number of decimals specified in the 12d export dialogue box. This value is then prefixed with the reach index followed by a dash. The downstream link name is set to the node name prefixed with "L". If you are planning to merge the river file with an XP SWMM drainage network then you will want to manually set the node names to the drainage pit names for the most upstream and most downstream source strings.

When selecting the Number of decimals in the 12d export dialogue, ensure that the total link name generated does not exceed the XP limit of 10 characters.

The section number variable is not exported to XP-SWMM.

Where the centre line cross the section in 12d is marked as zero chainage in XP-SWMM. The left overbank (-17.373) and the right overbank (9.898) are determined by the intersection of the left and right bank strings with the section. The n values are the values that are entered in the 12d export dialogue box. The maximum depth is calculated by subtracting the lowest elevation from the greatest elevation for both this cross section and the downstream cross section. The minimum of the two values is used.

The channel length is determined by subtracting the downstream section’s centre line chainage from the current section centre line chainage. The Centre line chainage factor is NOT used in this calculation.

Upstream elevation is obtained by calculating the minimum elevation at the current section and the downstream elevation is the same value for the downstream cross section. The channel slope is calculated using these elevations and the channel length above.

The horizontal distortion factor and section vertical shift are set to zero. A section coordinate point is generated every time the source string crosses a 12d triangle edge, at the centre line and the left/right bank locations.
The spill crest level at the node is set to the maximum level on the cross section. Constant inflow is zero unless the node is the most upstream section on the reach are the flow value for the source string has been set manually see manual settings.

21.4.1.2 Hydrology Data

Hydrology data may be exported to the runoff layer of XP SWMM for both the reservoir strings and the source strings. There are 2 requirements to enable the hydrology.

21.4.1.2.1 Key Points

1. If you plan to use storage areas, you need to draw reservoir strings (all in one model) and each should have a name (to become the XP SWMM node name).

2. You must create a file named "hydrology.txt" and store it in the project working folder. This file will contain the default xpx variable names. These defaults may be over ridden using the same xpx variable name as a string attribute on the source/reservoir string (see format below).

3. The reservoir or source string must have an integer string attribute named "xpx r rfcmnt" with a value greater than 0 (max of 5). Use the Strings->Properties->Attributes or Strings->User->Attribute Editor to create/change this attribute.

4. Total area for the reservoir strings is calculated at each export time.

21.4.1.2.2 Hydology.txt file format

The file is tab delimited and each line consists of three pieces of data: the XPSWMM variable name, the default value, and the type of data (integer, real or text).

You enter the xpx variable name

Any of these default values may be specified using a string attribute on the reservoir or source string. The attribute name must be of the same type as defined in the hydrology.txt file. If data for a second XP SWMM catchment is desired add a " 2" to the end of the attribute name. Up to 5 catchments are allowed in XP SWMM.

A sample hydrology.txt file follows:
// SCS hydrology screen
R_CN    85    real
R_TC    60    real
R_SHF   256   integer
R_SHAPE 0    integer
R_IADEPTH0.04  real
R_IAFRAC0 0.2 real
R_IA 1    integer
CNTLS 5    integer
R_FSCS 1    integer

// sub catchment screen
R_RAINSEL:"SCS Type II FL Mod." text
R_INFILSEL '"text
R_GWTAG 0    integer

// runoff node screen
R_WAREA 1. real
R_WIMP 1. real
R_WIDTH 1. real
R_WSLOPE 1. real

21.4.1.2.3 Attribute name format for string attributes.
The attribute name is the XP variable name prefixed by "xpx " with the underscore character in the xpx variable replaced by a space. For example the xpx variable "R_RAINSEL" would be set using the attribute name "xpx R RAINSEL".

21.4.1.3 Exporting River Junctions
River junctions are defined by the intersection of the centre line strings in 12d. The cross section immediately downstream of the intersection becomes the junction node. It is used as the downstream cross section for all upstream branches. The channel length for the last link on the tributary is set to the distance the centre line string extends beyond the cross section. The distance downstream along the main branch is NOT INCLUDED!
21.4.2 XP-SWMM Read Panel

Position of option on menu: Design=>Rivers=>XP SWMM interface=>Read XP SWMM xpx results file

After the XP-SWMM analysis is complete and the XP-SWMM program is closed the water level data is written to an xpx file that 12d will read. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the XP-SWMM results. These strings are then triangulated to create a water surface tin.

Frequently Asked Questions (Rivers)

Usage

The XP-SWMM read panel follows.

![XP-SWMM Interface Reader](image)

**River strings model**

*Model box*

*The river strings model specified in the write panel.*

**Cross Section model**

*Model box*

*The cross section model specified in the write panel. The interface will search the string names in this model for the cross sections specified in the XP-SWMM report. A match is successful if the XP-SWMM cross section chainage and the string name are within the tolerance specified below in Chainage tolerance.*
**Shape string model**  
For meandering rivers, the cross sections (shown in green above) may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings (shown in red above) can be created to create a water surface (shown in blue above) to follow the river. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach.

**Centre line chainage factor**  
This data is only required if the Shape string model is used. The shape string names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

**Ground surface tin**  
If a boundary string model is specified below, the intersection of this ground surface and the water surface will be determined. The strings will be stored in the model from the boundary string model field.

**XP-SWMM report file name**  
The XP-SWMM xpx file created automatically created when closing XP-SWMM or via the XP-SWMM menu selection

File=>Export Data
**Water surface tin model**  Model box

*The model to contain the new water surface tin.*

**Water surface tin**  Tin box

*The name of the water surface tin to be created.*

**Water level results model**  Model box

*The model where the water surface strings will be created at each cross section and shape string.*

**Boundary string model**  Model box

*The model to contain the intersection strings between the water and ground surfaces specified above. If left blank no intersection strings will be calculated.*

**Chord Length**  Model box

*This value set the spacing for the points on the water level strings (both cross section and shape strings). It is recommended that you use a length of no more than half of your average cross section and shape string lengths. A large value in this field may result in unexpected water level profiles for meandering rivers.*

**Chainage Tolerance**  Real box

*This is the tolerance used when the cross section chainage from the XP-SWMM report is compared with the cross section string names. A value of 0.00001 is excellent if you have not altered the cross section names in 12d or XP-SWMM.*

However, if you have altered chainage names then you may have to increase the value of the tolerance. Suppose the tolerance is set to 0.001 and the water level for section 0.056 is read from the XP-SWMM report file. The interface will search for the first string with a name between 0.055 and 0.057. If you chose to great of a tolerance then more than one water level result will match a 12d cross section and a warning message will be given.

If you have one specific cross section that you would like to have a different tolerance set for (maybe only one section is giving you troubles), use the Attribute Editor (Strings->User->Attribute Editor), select the cross section string and create a real type attribute named tolerance set to the tolerance desired.
21.5 MIKE11 Interface

Position of menu:  Design=>Rivers=>Mike11 interface

The MIKE 11 interface creates the MIKE 11 project files including *.bnd11, *.hd11, *.nwk11, sim11 and the cross section data text file (to be imported into *.xns11). Water levels are read back into 12d where they may be viewed in a 3D perspective view, on cross sections and on river profiles. Plan drawings easily identify extents of flooding and all data can be plotted onto engineering drawings.

The Mike11 walk right panel is,

Presenting Water Level Results
How to for Rivers
Frequently Asked Questions (Rivers)

Exporting to MIKE 11

The MIKE 11 project is created from a surface tin (representing the river bed and overbanks) and a model containing river centre line strings (identified by the name prefix, “centre line”). The low chainage (often zero) of the centre line strings must be at the upstream end of the reaches.

Cross sections are created at the location of the source strings. These source strings are initially created using the MIKE 11 option at a user defined spacing and section length, imported from drawing packages or manually created in 12d. The user may alter these sections as desired. They may be shortened if they intersect at sharp bends in the river; they may be extended at extremely wide river sections or extra points may be added so that the section is no longer a straight line.

Source strings can be deleted and additional sections can be added by creating new source strings. The Create source strings tick box on the interface panel must NOT be selected to use the customised strings.

Presenting MIKE 11 Results in 12D

After the MIKE 11 analysis is complete the maximum water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the MIKE 11 results. These strings are then triangulated to create a water surface tin.

How the water level boundaries are determined
21.5.1 MIKE 11 Write Panel

Position of option on menu: Design=>Rivers=>Mike11 interface=>Create Mike11 files

The MIKE 11 interface creates the MIKE 11 project files including *.bnd11, *.hd11, *.nwk11, *.sim11 and the cross section data text file (to be imported into *.xns11). Water levels are read back into 12d where they may be viewed in a 3D perspective view to easily identify extents of flooding.

- Frequently Asked Questions (Rivers)

Usage

12d creates most of the files necessary to run MIKE11. The exception to these are the time series files (both water level and discharge data). The simulation file created assumes that these files will have the same name as the centre line strings used in 12d. For example, if you name your centre line string centre line Major River then your time series files will be named Major River-H.DFS0 for the tail water conditions and Major River-q.dfs0 for your discharges.

The *.bnd11, *.hd11, *.nwk11 and *.sim11 files are created by appending 12d data to default data found in the following files.

cross_sections.4d
hd11-end.4d
hd11-header.4d
nwk11-header.4d
nwk11-options.4d
sim11-header.4d
sim11-period.4d

The user need not modify these files unless they would like to change the default values used when first creating the MIKE11 project. If you plan to modify these files, they are found in the 12d setups directory. Before modifying they should be copied to the 12d user directory (global defaults) or into the current project directory if they are project specific.

The MIKE 11 panel for creating the MIKE 11 project follows.
The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>River strings model</strong></td>
<td>Model box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Model containing the river centre line strings. The centre line strings must begin upstream and proceed downstream.* The name of the river must follow the words “centre line” (note the ending space). The name of the river may follow the words “Centre line” (note the ending space). For example the centre line string may be named “Centre line Parramatta River, downstream reach”. The comma separates the river name from the reach name. If no comma is included then the river name is repeated for the reach name.

Confluences are modelled by using a separate string for all reaches. Thus a system with a branch is modelled with three strings. The branch will be one string and the main reach will have a downstream string and an upstream string. The reaches must touch at the confluence.

| **Source string model** | Model box   |          |        |

New source strings will be created in this model or existing source strings are contained in the model. See Create source strings tick box below.

<table>
<thead>
<tr>
<th><strong>Create Source Strings</strong></th>
<th>Tick box</th>
<th>not selected</th>
</tr>
</thead>
</table>

When selected existing source strings are deleted and new ones created perpendicular to the centre line at the specified spacing and length. Once you have created the sources strings they can be easily modified. On the Strings->Points Edit menu you will find the selections Move (to move the end points), Insert (to insert additional points).
Distance between sections Real box
The distance between the cross sections. At present no check is made for overlapping cross sections around river bends.

Section Length Real box
The length of the cross section with zero chainage at the mid point.

Cross section model Model box
The cross sections created and exported are stored in this model.

Centre Line Chainage Factor Real box
The cross section names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

Surface Tin (not the model) Tin box
Tin or super tin to create the cross sections from (remember a tin is like a string. It is placed in a model.).

Bank Marker Tolerance Real box
If the surface level drops more than this amount while moving away from the channel centre line then the crest is used as a Bank Marker. A value of zero means that no bank marks are created.

Delta Y tolerance Real box
This value filters out points on the cross section. Imagine a tube of this diameter passing over the cross section. The tube is elongated until one point lies outside the tube. The tube is shortened to the previous point and then all points inside the tube are deleted from the cross section. The tube then moves on to the next point. The final water tin is created from the ground tin and therefore the boundary string is located using the unfiltered section.

Manning’s n Real box
Manning’s n values for the channel sections.

Initial depth Real box
This depth is added to the minimum elevation on the cross section and is used as the starting water level for the cross section.

Units Choice box
This selection will set the default units for the project being created.

Project file name Input box
The MIKE11 project name. All of the MIKE11 files will begin with this name and the appropriate extensions added.
21.5.2 Running MIKE11

Three steps are required to run MIKE11 with the files 12d creates.

1. Create your time series files.
2. Inside MIKE11, create a new cross sections file and import the cross sections.
3. Open the simulation file, and load the network file to have the grid points calculated.
21.5.3 Creating Time Series Files

Your time series files must be named with the prefix of the river string name. For example if your centre line string in 12d was named centre line Major River your time series files need to named Major River-H.DFS0 for the tail water conditions and Major River-q.dfs0 for your discharges.

The standard time series dates are from 12:00 to 12:30 on 01 January 2000 with a one minute time step. If other periods are desired, you can either change the file sim11-period.4d in the 12d library before running the interface or change the dates inside MIKE11 after you read in the data. DO NOT USE THE ORIGINAL FILES! Copy the file you are changing into the 12d user directory and modify it there. 12d will look for the file here first.
21.5.4 Importing Cross Sections

From the MIKE11 main menu select **File->new** and then under Mike11 select **cross sections** from the dialogue box.

From the main menu select **File->Import->Import Raw data & Recompute**. Select the *.txt file with the **Project file stem** you specified in the 12d-Mike11 Write Panel. Now save this file with the same **Project file stem** (MIKE11 adds the .xns11 extension).
21.5.5 Calculating Grid Points

From the main menu select File->Open and select the *.sim11 file with the Project file stem you have specified in 12d. On the Input tab property sheet select Edit beside the Network file. Press Ctrl+T to take you into the table editing mode and then select the Grid Points tab property sheet. On the sheet select Generate Grid Points and then save the file.

You should now get the “Green lights” on the Start property sheet of the simulation file editor.
21.5.6 MIKE 11 Read Panel

Position of option on menu:  Design=>Rivers=>Mike11 interface=>Read Mike11 results (max)

After the MIKE 11 analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the MIKE 11 results (maximum water level).

Water levels are interpolated to create water level strings at the shape string locations. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach. These strings are then triangulated to create a water surface tin.

The MIKE11 executable file, `res11read.exe` must be found in the directory `c:/mikezero/bin` so that 12d can read the Mike11 binary data files.

River strings model  Model box

The river strings model specified in the write panel.

Cross Section model  Model box

The cross section model specified in the write panel. The interface will search the string names in this model for the cross sections specified in the MIKE 11 report. A match is successful if the MIKE 11 cross section chainage and the string name are within the tolerance specified below in Chainage tolerance.

Shape string model  Model box

For meandering rivers, the cross sections (shown in green above) may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings (shown in red above) can be created to create a water surface (shown in blue above) to follow the river. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach.

Centre line chainage factor  Model box

This data is only required if the Shape string model is used. The shape string names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

Ground surface tin  Tin box

If a boundary string model is specified below, the intersection of this ground surface and the water surface will be determined. The strings will be stored in the model from the boundary string model.
field. Super tins cannot be used for this function. A composite tin is required for the tin-tin intersect.

**MIKE 11 report file name**  Input box

*This is the binary data file that will be converted to an ASCII text file and read by 12d. The maximum water levels at each cross section will be extracted from the file.*

**Water surface tin**  Tin box

The name of the water surface tin to be created.

**Water surface tin model**  Model box

*The model to contain the new water surface tin.*

**Water level results model**  Model box

*The model where the water surface strings will be created at each cross section and shape string.*

**Boundary string model**  Model box

*The model to contain the intersection strings between the water and ground surfaces specified above. If left blank no intersection strings will be calculated.*

**Chord Length**  Model box

*This value sets the spacing for the points on the water level strings (both cross section and shape strings). It is recommended that you use a length of no more than half of your average cross section and shape string lengths. A large value in this field may result in unexpected water level profiles for meandering rivers.*

**Centre Line Chainage Factor**  Real box

*The cross section names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.*

**Chainage Tolerance**  Real box

*This is the tolerance used when the cross section chainage from the MIKE 11 results file is compared with the cross section string names. If a Centre line chainage factor of 1 is used a value of 0.1 is appropriate. If a Centre line chainage factor of 1000 or 5280 is used a Chainage tolerance of 0.00001 is more appropriate.*

However, if you have altered chainage names then you may have to increase the value of the tolerance. Suppose the tolerance is set to 0.001 and the water level for section 0.056 is read from the MIKE 11 report file. The interface will search for the first string with a name between 0.055 and 0.057. If you chose to great of a tolerance then more than one water level result will match a 12d cross section and a warning message will be given.

If you have one specific cross section that you would like to have a different tolerance set for (maybe only one section is giving you troubles), use the Attribute Editor (Strings->User->Attribute Editor), select the cross section string and create a real type attribute named tolerance set to the tolerance desired.

- Frequently Asked Questions (Rivers)
21.6.1 How the water level boundaries are determined

For meandering rivers, the cross sections (shown in green above) may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings (shown in red above). Note that water levels are extended when the shape strings are in a junction area or past the end.
of a reach, can be created to create a water surface (shown in blue above) to follow the river.

The water surface is draped over the ground surface and the boundary strings (strings defining the edges of the water surface – shown in yellow above) are created. They may be used to trim the water surface or shade your ground surface tin for flood inundation mapping. Boundary strings also include islands! Shading the river bed blue, in a 3D perspective view, is an effective way to show the water level extents and still view the shape of the river bottom (it has the effect of very clean water that you can see through!).
21.6.2 Sample Presentations and Drawings

The water surface may be

- contoured (elevation),
- depth contours created,
- water surface coloured by depth (shown above),
- cross sections plotted
- and longitudinal profiles drawn (shown below).
- All of these results can be plotted complete with your customised drawing sheets.
- Finally, you may walk down the water course in the perspective view (and record this to an Windows AVI file).

![Plan 1](image)

Close up view of cross section labels with water levels
Chapter 21  Rivers

Presenting River Water Level Results
Close up of text (user chooses wording, size, colour, text style etc.)

The tin created can be viewed in a perspective view and sections taken where desired. A sample perspective view follows.
Example of cross sections long sections and depth colouring see the HEC-RAS Interface topic.
21.6.3 Defining the Water Surface Boundaries

The water surface and its boundary is created by 12d. The first step is to trim the water surface back to the boundary strings. Since the water boundary does not generally form a closed polygon (the left and right river boundaries will need to be joined at one end of the river) use the Strings=>Strings Edit=>Join to connected strings.

If the water surface reached the edges of you cross sections then there will be numerous breaks in the boundary string. The best solution is to extend the cross sections and/or add additional shape strings. If it is not a major error in modelling then the break in the boundary can be joined using the Strings=>Strings Edit=>Join.

If boundary strings are created outside that water level boundaries they should not be used in this area. Boundary strings should only be used inside the area defined by your water level results.
21.6.4 Trimming the Water Surface Tin and Islands

Use the Triangle=>Null=>by polygons selection to null triangles inside the polygon you have created above.

Select your water surface tin and change the Poly mode to Outside. Now select the Poly button and pick the boundary string. The triangles outside the polygon will now be nulled.

If you have some islands in the model then change the Poly mode to Inside and select the islands.

If you have numerous islands, say more than 10 it may be easier to copy all of the islands into one model using the fence command (Utilities->Fence->Fence).

The Model to fence is the boundary strings model and the Model for fence inside is the new model to contain the islands. The Exclude model containing fence should not be ticked. Select Poly and then pick the boundary string. All of the islands inside the boundary string will not be copied to the islands model.
21.6.5 Colouring the Ground Surface with Flood Zones

The boundary strings can also be used to colour the ground surface. Colouring the river bed blue is an effective way to show the water level extents and still view the shape of the river bottom (the effect of very clean water that you can see through!).

First, define the water surface boundaries (see above). Next re-triangulate the ground tin so that it includes the boundary string model (Triangles=>Edit=>Tin). Next select Triangles=>Colour=>Colour within polygon. The following panel will appear.

Select your ground tin and the desired colour. Next select the Poly button and pick the boundary string to be coloured inside. If islands exist change, change the colour (to a ground colour) and then select the island string.
21.6.6 Colour by Depth

The water surface can be coloured by depth. This function calculates the depth between the water surface and the ground surface and creates "faces" of different colours. The colours to be used are specified in a depth range file. This option requires the purchase of the Volumes Option.

From the main menu select Options->Volumes->Exact->Tin to tin.

Original tin this is your ground survey tin
New tin this is your water surface tin
Range file two range files are supplied. One with a range from 0 to 5 and another from 0 to 50. The library contains a spreadsheet the can quickly create other range files or you may edit the using the built in range editor.

To use the built in range file editor select + beside you range file then edit.
You may change the range value and the colours as desired. Be sure to select **Write** to save the changes before selecting **Finish**.

See also Range File Creation

**Plan View to paint** you can paint a current view without saving the face data. This is a good option if you wish to take a quick look at the depth colours in one area.

**Model for faces** the faces can be stored in a model. Note that faces consume a great deal of hard disk space. Therefore you may consider colouring one area at a time using the **Poly** option.

**Poly** If your water surface tin is very large than you may want to only colour a portion of the tin. You must create a polygon (Strings->Create->2d) and then pick this polygon. When your select **Volume** only the area inside the polygon will be coloured.

**Volume** select this button to colour the surface.
21.6.7 Depth Contours

Once you have the tin coloured by depth you might want to add depth contours. From the main menu select Options->Tin->Analysis->Depth Contours. This option requires the purchase of the tin Analysis module.

![Image of depth contours]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>

<tr>
<td>Start level</td>
<td>enter a zero for this value</td>
</tr>
</tbody>
</table>
Presenting River Water Level Results

End level: enter a level greater than the greatest depth.

Interval: enter the contour interval as desired.

2d/3d strings: 2d strings.

Calculate: this will create your contour strings.

Adding Values to the Contours

Since there are numerous ways to label the contours, it is performed as a separate step. From the main menu select Strings->Label->Contours.

Contour method: the example above uses Line removal and Centred line read from below. This copies the contour lines themselves and inserts a break in the line.

Start distance: this is usually left as zero. It changes the start point for the first label on each contour.

Separation: this determines the spacing of the contour labels.
21.6.8 Colour the ground surface by elevation

With the water surface coloured by depth, you may want to colour the ground surface by elevation.

This colouring may be done from either From the main menu select Options->Volumes->Exact->Tin to height or Triangles->Colour->Tin height colour.

Options->Volumes->Exact->Tin to height

Options->Volumes->Exact->Tin to height requires the purchase of the Volumes module. First select Triangles->Tin info from the main menu and then select you ground surface tin. You will want to copy the minimum z level from this pane.

Now from the main menu select Options->Volumes->Exact->Tin to height
Select your ground surface to colour and enter the minimum elevation (from above) into the Height field. The Range file "$LIB/ground_colouring_green.drf" is found in the library.

**Plan View to paint**  you can paint a current view without saving the face data. This is rarely used in this case.

**Model for faces**  the faces can be stored in a model. Note that faces consume a great deal of hard disk space. Therefore you may consider colouring one area at a time using the Poly option.

**Poly**  If your ground surface tin is very large than you may want to only colour a portion of the tin. You must create a polygon (Strings->Create->2d) and then pick this polygon. When your select Volume only the area inside the polygon will be coloured.

**Volume**  select this button to colour the surface.
21.7 UNET Interface

**Position of menu:** Design=>Rivers=>UNET interface

The UNET interface creates the *.cs file. Water levels are read back into 12d where they may be viewed in a 3D perspective view to easily identify extents of flooding.

The UNET walk right menu is,

Frequently Asked Questions (Rivers)

Exporting to ISIS

The ISIS project is created from a surface tin (representing the river bed and overbanks) and a model containing river strings identified by their names “left bank”, “right bank and the name prefix, “centre line”. Any additional strings in the specified model will be ignored (warning messages will be given when you run the macro that any additional strings are being ignored). The low chainage (often zero) of the centre line strings must be at the upstream end of the reaches.

Cross sections are created at the location of the source strings. These source strings are initially created using the ISIS option at a user defined spacing and section length. The user may alter these sections as desired. These may be shortened if they intersect at sharp bends in the river; they may be extended at extremely wide river sections or extra points may be added so that the section is no longer a straight line.

Source strings can be deleted and additional sections can be added by creating new source strings. The Create source strings tick box on the interface panel must NOT be selected to use the customised strings.

Reservoir Strings are 2d strings that define the extents of the reservoir. The volume is calculated in increments of 1 or the value set in the attribute stage increment for this string. The volumes start from a level with zero volume to the level set for the 2d reservoir string.

The reservoir strings may define inline reservoirs or offside storage. Inline reservoirs are "touched" by centre line strings both upstream and downstream. Offline storage areas are linked to the cross sections via spill strings.

Spill strings are 2d strings that link offline storage areas to a cross section. The string must begin by "touching" the source string and then proceed to the first point on the spill section. During the export the first point will NOT be exported as part of the spill section. After defining the end of the spill section the last point on the string must "touch" the reservoir string. Again this last point will NOT be exported as part of the spill section.

Presenting ISIS Results in 12d
After the ISIS analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the ISIS *.zzr file. These strings are then triangulated to create a water surface tin from which the water level boundaries are determined. These results can then be shown in plan, long section, cross section and in 3D perspectives.

More details
21.8.1 ISIS Write Panel

Position of option on menu: Design=>Rivers=>ISIS interface=>Create ISIS file

The ISIS interface creates the ISIS project files ready to open and run. This includes the project, plan, flow and geometry files. Water levels are read back into 12d where they may be viewed in a three dimension perspective view to easily identify extents of flooding.

Presenting Water Level Results
How to for Rivers
Frequently Asked Questions (Rivers)

Usage

The ISIS panel for creating the ISIS project follows.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>

ISIS Interface

Page 5691
River strings model  
Model containing the centre line, left bank and right bank strings. The centre line strings must begin downstream and proceed upstream. The name of the river may follow the words “Centre line “ (note the ending space). For example the centre line string may be named “Centre line Parramatta River, downstream reach”. The comma separates the river name from the reach name. If no comma is included then the river name is repeated for the reach name.

Confluences are modelled by a using a separate string for all reaches. Thus a system with a branch is modelled with three strings. The branch will be one string and the main reach will have a downstream string and an upstream string. The reaches must touch at the confluence.

The distance from the start of the upstream strings to the first cross section is used to model the confluence length.

The left and right bank strings need not be separate strings (see figure below).

Source string model  
New source strings will be created in this model or existing source strings are contained in the model. See Create source strings tick box below.

Create Source Strings  
When selected existing source strings are deleted and new ones created perpendicular to the centre line at the specified spacing and length. Once you have created the sources strings they can be easily modified. On the Strings->Points Edit menu you will find the selections Move (to move the end points), Insert (to insert additional points).

Distance between sections  
The distance between the cross sections. At present no check is made for overlapping cross sections around river bends.

Section Length  
The length of the cross section with zero chainage at the mid point.

Storage strings  
These 2d strings define the extents of the storage area. For more details see Reservoir strings.

Spill strings  
These 2d strings define the location to cut the spill section and start end points define the cross section and reservoir, respectively. For more details see Spill strings.

Cross section model  
The cross sections created and exported are stored in this model.

Centre Line Chainage Factor  
The cross section names are created by dividing the chainage on the centre line by this factor. Typically 1000 is used to convert metres to kilometres and 5280 to convert feet to miles.

Number of decimals  
The cross section names are created with this many decimals. CAUTION XP SWMM only allows 10 characters for the names and each link name begins with "Lx-" That leaves 7 characters for the chainages.
Surface Tin (not the model)

Tin or super tin to create the cross sections from (remember a tin is like a string. It is placed in a model.).

Bank Marker

Not currently implemented in ISIS

Delta Y tolerance

This value filters out points on the cross section. Imagine a tube of this diameter passing over the cross section. The tube is elongated until one point lies outside the tube. The tube is shortened to the previous point and then all points inside the tube are deleted from the cross section. The tube then moves on to the next point. The filtered (smoothed) and original sections are kept for comparison. The final water tin is created from the ground tin and therefore the boundary string is located using the unfiltered section.

Manning’s n

Manning’s n values for the left, right and centre channel sections.

Initial depth

Not currently implemented in ISIS.

Discharge

This discharge is used at the upstream end of all reaches. If you have multiple river branches, you can set the flow for each branch inside ISIS or inside 12d. This can be changed at each section See manual settings

Units

This selection will set the default units for the project being created.

Project file name

The ISIS project name. The extension "dat" will automatically be added for you.
21.8.2 ISIS Read Panel

Position of option on menu:  Design=>Rivers=>ISIS interface=>Read ISIS results

After the ISIS analysis is complete the water level results are read back into 12d. Water level strings are created with the plan shape of the cross sections at the elevation retrieved from the ISIS results. These strings are then triangulated to create a water surface tin.

ISIS Interface overview
Create ISIS files
Presenting Water Level Results
How to for Rivers
Frequently Asked Questions (Rivers)

Usage

The ISIS read panel follows.

River strings model  Model box

The same river strings model specified in the write panel. The river strings are used to sort the cross section and the shape strings. The left and right bank strings are used to check the direction of the strings.

Cross Section model  Model box

The same cross section model specified in the write panel. The interface will match the ISIS label and
the string name (without the "SECT "). If the ISIS labels were created by 12d then an exact match should result.

However, if the ISIS file was not created by 12d, the file can still be mapped by manually creating cross section strings (2d or 3d strings). See Mapping non 12d and historical water level data.

Shape string model Model box
For meandering rivers, the cross sections (shown in green above) may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings (shown in red above) can be created to create a water surface (shown in blue above) to follow the river. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach.

Reservoir Model box
Reservoir strings are assigned elevations from the ISIS zzr file. This model is the same as the storage area strings specified in the write panel.

Centre line chainage factor Model box
This data is only required if the Cross sections have been manually created and have no names yet. See Mapping non 12d and historical water level data.

ISIS results file name File box
The ISIS zzr file is automatically generated by ISIS.
Ground surface tin  Tin box
If a boundary string model is specified below, the intersection of this ground surface and the water surface will be determined. The strings will be stored in the model from the boundary string model field.

Water surface tin model  Model box
The model to contain the new water surface tin.

Water surface tin  Tin box
The name of the water surface tin to be created.

Water level results model  Model box
The model where the water surface strings will be created at each cross section and shape string.

Boundary string model  Model box
The model to contain the intersection strings between the water and ground surfaces specified above. If left blank no intersection strings will be calculated.

Chord Length  Model box
This value set the spacing for the points on the water level strings (both cross section and shape strings). It is recommended that you use a length of no more than half of your average cross section and shape string lengths. A large value in this field may result in unexpected water level profiles for meandering rivers.

Chainage Tolerance  Real box
This tolerance is not used for the standard 12d cross section names. However, if the cross section names have been created manually and they can be converted to a real number then this is the tolerance used to match the cross section label from the ISIS report to the cross section string names. A value of 1.0 to 10. is common. See Mapping non 12d and historical water level data for more details.

A sample of the *.zzr file that is read by 12d follows.
A sample of the zzr file that is read follows.

21.9 How to for Rivers

This section lists specific tasks for the rivers interface. Worked examples are contained in the courses directory of 12jobs and training manuals are found in the documentation directory on the 12d Model distribution CD.

- Change manual override settings for river strings via attributes
- Manually set a cross section name
- Specify a local inflow at a cross section
- Change the stage increment for reservoir strings
- Boundary Strings are broken. How do I stop this?
- Plot river xsections with the river sections names?
21.9.1 Manual Override settings

Many of the automatic settings can be overridden using string attributes via the String Attribute Editor. To use the editor

1. Select the river or source string to add/edit the attribute for
2. In the Attribute Name column use the selection list to find the attribute to change. If it is not listed then type the attribute name into one of the boxes.
3. Change the attribute Type to Integer/Real/Text as required
4. Type the attribute value into the Data field (erase the not found if required).
5. Select Process, Next, Previous or Pick string. Selecting Finish will NOT save the attribute.

You will be prompted that you will create a new attribute if you have typed in a new attribute for that string.

21.9.2 Boundary Strings are broken. How do I stop this?

The boundary strings will be broken into sections when the boundary string goes outside the area defined by the cross sections. See below.

In these two cases the water level has not exceeded the extents of the cross sections but the boundary strings (black) has gone outside the limits of the water level strings (magenta). **Shape strings** are used to expand the area of the water levels between the sections. The water level assigned to the shape string is a linear interpolation between the upstream and downstream cross section water levels. The interpolation is prorated using the distance along the centre line of the river.

Important! water levels are extended when the shape strings are in a junction area or past the end of a reach.

Shape strings are 2d strings. The direction is not important except for Mike11 models. For Mike11 they must be in the same direction as the cross section strings (usually left bank to right bank). The following drawing shows the boundary string when 2 shape strings have been added (green).
21.10 Mapping non 12d and historical water level data

12d can map water levels from river engineering models that were not created by 12d. If the water level results are in the standard HECRAS GIS, HECRAS report, ISIS zzr, UNET, XP SWMM xpx or Mike11 binary file then the standard 12d readers can be used. If the data is historical or not in any of the standard format the River Mapper feature can be used.
21.10.1 River Mapper

Position of option on menu:  \textbf{Design=>Rivers=>River Mapper}

River cross section water level data in an text file may be mapped and displayed using the 12d River Mapper interface. 2d strings are created by the user with the plan shape of the cross sections. 12d assigns water levels from a text file to these strings. These strings are then triangulated to create a water surface tin.

See also

\textbf{Presenting Water Level Results}
\textbf{How to for Rivers}
\textbf{Frequently Asked Questions (Rivers)}

Usage

The steps are as follows:

1. Create the \textbf{river strings} (centre line, left bank and right bank).
2. Create 2d \textbf{source strings}. Use your name for the cross section as the string name. 12d will match the water levels in the file to this string using the name as the key. If you do not assign a name the interface will assign names to strings according to the chainage along the centre-line and the value of \textbf{Centre line chainage factor}.
3. From the \textbf{Design->Rivers} menu select \textbf{River Mapper}.
4. Fill in the fields in the dialogue for the rivers strings (step 1 above) and the cross sections (step 2 above).

\begin{center}
\includegraphics[width=0.5\textwidth]{river_mapper.png}
\end{center}

\textbf{River strings model}  \hspace{2cm} \textbf{Model box}
The river strings model specified in the write panel.

**Cross Section model**  
Model box

The cross section model specified in the write panel. The interface will search the string names in this model for the cross sections specified in the HEC-RAS report. A match is successful if the HEC-RAS cross section chainage and the string name are within the tolerance specified below in **Chainage tolerance**.

**Shape string model**  
Model box

For meandering rivers, the cross sections may not be at a close enough spacing to create a water surface that follows the river. 2D shape strings can be created (automatically or manually) to create a water surface to follow the river. Note that water levels are extended when the shape strings are in a junction area or past the end of a reach.

**Centre line chainage factor**  
Model box

If you assigned the source/cross section string a name in Step 2 this field is not used. Otherwise, the centre line chainage and the Centre line chainage factor are used to name your source string/cross sections in 12d. The cross sections will be named in the same units as the 12d data if a Centre line chainage factor of 1 is specified. If your existing data uses cross section names in your data file are in kilometres and your 12d data in meters, you will want to use a Centre line chainage factor of 1000. If your existing data cross section names are in miles and your 12d data is in feet then a Centre line chainage factor of 5280 would be used.

**Mapper results file name**  
File box

The report is a tab (or space) delimited text file (usually created by a text editor or spreadsheet). The format is

```
cross section name <tab> water level elevation
```

each section name with its water level must be on a separate line. For example.

```
Section A     2.31
Section B     2.32
```

If the names contain letters (abc..) then the section name must match the 12d string names exactly (case sensitive). If the names are real numbers than a tolerance for the matching (global and string specific) can be set (see parameters).
1.0 Rivers Rename and Move Cross Sections

Position of option on menu: Design => Rivers => Xsections rename and move

River cross section names begin with the river reach number followed by the cross section chainage. To plot these x sections they need to be renamed to the 12d chainage standard. This routine gets the cross section model name moves the cross section to a model with the name as a prefix followed by the reach number. The reach number is removed from all of the cross section name.

On selecting the Xsections rename and move option, the panel is displayed.

These defaults are used when creating a manhole in a drainage string. The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

Cross section model

This model holds the cross sections created by one of the river interface routines. The name of this model will be used as the prefix for the new models to hold the renamed cross sections.

Clean existing models

When selected the models that the cross sections are to be moved to will be cleaned before the supplied cross sections are moved into them.

Process

Moves and renames the cross sections

Finish

Remove the panel
1.1 12d System Path

When looking for system files 12d first checks your local project directory (the directory that hold the *.project folder), and then the system folders. Unless you have changed these folders in your env.4d file the path is first "program files\12d\12dmodel\5.00\user" and then "program files\12d\12dmodel\5.00\set_ups". In summary:

1. local project directory (the directory that hold the *.project folder
2. program files\12d\12dmodel\5.00\user
3. program files\12d\12dmodel\5.00\set_ups

Never modify the files in set_ups. Copy them to the user directory and make your changes there. Here they are safe from being changed during future 12d updates. The only time you will want files in the local project directory is when you have some project specific data. Master_drainage.xp and Master_rivers.xp are good examples of such cases.

More on System files
Attribute Editor
1.1.1 FAQ Rivers

XP SWMM does not start or gives errors when starting from 12d
22 Pipeline

Position of menu:  Design =>Pipeline

The Pipeline option is used to place large diameter pipelines.

The pipeline is very similar to an alignment string in that it is defined by separate horizontal and vertical geometries.

The major differences between a pipeline and an alignment is that a pipeline has a diameter and normally uses circular curves in the vertical geometry rather than the parabolic curves used for alignments.

The pipeline is entered by placing the invert (bottom) of the pipe. Hence in a plan view, the horizontal geometry places the centre of the pipeline. The vertical geometry of the pipeline is for the invert (bottom) of the pipeline.

Note

A pipeline string is not the same as a pipe string. A pipe string is only a 3d string with a diameter.

The Pipeline walk-right menu is

For the option Create, go to 22.1 Create
   Editor  22.2 Editor
   Defaults  22.4 Defaults
   Plots  22.5 Plots
   Reports  22.6 Reports
22.1 Create

Position of option on menu: Design => Pipeline => Create

The Create option is used to produce new pipelines. If a pipeline string already exists, the Edit option is used to modify it.

On selecting the Create option, the Create Pipeline String panel is displayed.

To create a new pipeline string, the pipeline's name, model, colour, style, spiral type and pipe diameter, plus the standard length of pipes used to make up the pipeline are entered into the appropriate fields and the Create button selected.

As for a 3d string, to create a new pipeline string with some of the same name, colour, model, style etc. as an existing string (not necessarily a pipeline), the same as button is chosen and the appropriate string selected.

The Create Pipeline String panel is then removed and the Pipeline Edit menu and Pipeline Edit Info panel fired up.

The Pipeline Edit menu contains all the options for creating/editing a pipeline string. The Pipeline Edit Info panel contains information areas.

The Pipeline Edit menu and Pipeline Edit Info panel are
As for an alignment string, to create a new pipeline string the user selects the Append=>HIP’s option from the Pipeline Edit menu and start placing points in a plan view.

Since the Pipeline Edit menu and Pipeline Edit Info panel are the same as those used when editing a pipeline string, the options will be discussed in the following sections under the pipeline Edit option.

For information on pipeline editing, please continue to the section 22.3 Pipeline Editor.
22.2 Editor

Position of option on menu:  Design =>Pipeline =>Editor

This is the same option as Editor from the Strings walk-right menu on the 12d Model menu.

The string editor is used to modify any 12d Model strings. After selecting the Editor option, the Edit String panel is placed on the screen to record any error messages.

![Edit String panel](image)

The option is already in the Pick mode (the Pick & Edit button only needs to be selected if the pick was cancelled) and the user simply picks and accepts the string to be edited.

From the picked string's type, the editor is able to determine the edits that apply to the string and list them in the string's Edit menu.

If a pipeline string is selected, the Pipeline Edit menu and Pipeline Edit Info panel (as shown in the previous section) are placed on the screen.

The individual edit operations for a pipeline string will now be discussed in detail.

Please continue to the next section 22.3 Pipeline Editor.
22.3 Pipeline Editor

Position of option on menu:  
Design => Pipeline => Editor

A pipeline string is defined by specifying both the horizontal and vertical geometry of the invert (bottom of the pipeline) as separate operations.

The horizontal geometry consists of a series of \((x,y)\) points (called horizontal intersection points) and circular curves applied to the intersection points.

Vertical geometry also consists of a series of points but they are defined with respect to the plan length of the string (chainage) and height. Hence, the vertical geometry is defined by a series of (chainage,height) points (called vertical intersection points) and circular curves applied to the vertical intersection points.

The horizontal geometry is usually defined in a plan view and the vertical geometry in a section view. Hence the pipeline string editor can edit information for the string on both plan and section views.

**Note:** the string can only be edited on a section view if the string is also profiled on the section view.

On selecting a pipeline string the Pipeline Edit menu and Pipeline Edit Info panel are placed on the screen.

The Pipeline Edit menu is

<table>
<thead>

and the Pipeline edit info panel is
To edit the selected pipeline string, simply select the required edit option from the list of all possible edits in the pipeline edit menu.

The edit is cancelled by selecting the cancel option. The edited string is restored to its pre-edit state and the option terminated.

The edit is finished and the new string placed in the given model when the finish option is chosen. The edit option then terminates.

When either quit or finish is selected, a yes-no-cancel panel is displayed and the user must confirm the selection.

The pipeline edit info panel is used to display information and messages during editing of the pipeline string.

The main message area indicates the purpose of the mouse buttons at each step.

Message area 1 displays the current pipeline edit option and message area 5 indicate the next step in the edit option.

Message areas 2 and 3 are used to display information about the string as the cursor is moved near the string and the string points. For example, for the closest IP, the (x,y,z) position and radius of the IP is displayed in area 2, and in area 3 the bearing-in, bearing-out and deflection angle for the adjacent IPs.

Message area 4 displays the cover above the pipeline and the vertical, horizontal and combined joint deflection.

Most of the options are identical to the edit options for an alignment string and will not be discussed in detail again. The options that are only applicable to a pipeline string will be fully described.

22.3.1 Append

22.3.1.1 HIPs

In a plan view, the append=>HIPs option is used to create the first horizontal point in a new pipeline string, to append a new horizontal intersect point to the end of the string or to prepend a new horizontal intersection point to the beginning of the string. The horizontal geometry is for the centre of the pipe in plan.

22.3.1.2 VIPs

In a section view, the append=>VIPs option can be used to create and edit the vertical geometry of the picked string if the string is a primary string on any section view. This can be achieved by using either the VG edit or the profile option from the section view View ops menu. The vertical geometry is for the invert (bottom) of the pipe.
The **append** option is the same as **append** for an alignment string and will not be described further.

### 22.3.2 Move

The **move** option can be used for moving individual horizontal and vertical intersection and tangent points.

The option acts on the horizontal geometry if the point to move is selected in a plan view, or the vertical geometry if the point to move is selected in a section view.

The **move** option is the same as **move** for an alignment string and will not be described again.

### 22.3.3 Insert

The **insert** option is designed to place a new intersection point in a string between two adjacent horizontal or vertical intersection points (note that the inserted point does not have to be on the line joining the two intersection points).

The **insert** option is the same as **insert** for an alignment string and will not be described again.

### 22.3.4 Between

The **between** option is similar to the **insert** option except the inserted point **does** have to be on the line joining the two intersection points. To accomplish this, the cursor position is automatically projected onto the IP-IP line to give the new IP point position.

The **between** option is the same as **between** for an alignment string and will not be described again.

### 22.3.5 Delete

The **delete** option is used to delete horizontal or vertical intersection points from the string.

The **delete** option is the same as **delete** for an alignment string and will not be described again.

### 22.3.6 Extend

The extend option is used to move an intersection point along the line joining the intersection point to its neighbouring intersection point.

The **extend** option is the same as **extend** for an alignment string and will not be described again.

### 22.3.7 Height

The height option is used to modify the height of a vertical intersection point in the string.

The **height** option is the same as **height** for an alignment string and will not be described again.

### 22.3.8 Curves

The **curves** option allows the user to add circular curves of a given radius to a either horizontal or vertical intersection points.
The \textit{curve} option is the same as \textit{curve} for an alignment string and will not be described again.

22.3.9 Parabolas

The \textit{parabolas} option is for adding parabolic curves to the \textit{vertical geometry}. For pipelines, circular curves are normally used on vertical curves.

The \textit{parabolas} option is the same as \textit{parabolas} for an alignment string and will not be described again.

22.3.10 Utilities

The Alignment Utilities walk-right menu contains a number of useful miscellaneous options for the pipeline string. The menu is

Each of these options is the same as for an alignment string and will not be discussed again.

22.3.11 Utilities 2

The \textit{utilities 2} walk-right menu contains options to modify the diameter of the pipeline and to set the standard length of the pipes used to construct the pipeline.

The \textit{utilities 2} walk-right brings up the Pipeline Utilities menu:
22.3.12 Diameter

The Diameter option is used to change the diameter of the pipeline string.
After selecting the option, an enter value typed-input box is displayed on the screen containing the pipeline’s current diameter.
The new diameter is entered into the typed-input box, terminated with <return>.
The typed-input box then disappears and the option terminates.

22.3.13 Length

The Length option is used to change the length of the standard pipe used to construct the pipeline string.
The length of the pipes used in constructing the pipeline string is used for calculating joint deflections along the pipeline.
After selecting the option, an enter value typed-input box is displayed the pipeline's current standard pipe length.
The new length is entered into the typed-input box, terminated with <return>.
The typed-input box then disappears and the option terminates.

22.3.14 Info

The pipeline edit info panel is toggled on/off by the info option in the pipeline edit menu.

22.3.15 Quit and Finish

Even after points are created for the new string, the create process can be aborted by selecting the quit option from the pipeline edit menu. The option then terminates and no string is created.
The create process is completed and the new string created and placed in the given model when the finish option is chosen from the pipeline edit menu.
When either the finish or quit option is selected, a yes-no-cancel panel is displayed and the user must confirm the selection.
22.4 Defaults

Position of menu:   Design =>Pipeline =>Defaults

The defaults menu sets default depth to tin and joint deflection angle.

The default walk-right menu is

For the option Depth to tin, go to
Joints

22.4.1 Depth to Tin

Position of option on menu:   Design =>Pipeline =>Defaults =>Depth to tin

On selecting the tin option, the pipeline tin defaults panel is displayed.

This panel is for setting the default terrain tin which is used to calculated the cover above the pipeline.

22.4.2 Joints

Position of option on menu:   Design =>Pipeline =>Defaults =>Joints

On selecting the joints option, the pipeline joint defaults panel is displayed.

This panel is for setting the maximum joint deflection for the individual pipes that make up the pipeline.
22.5 Plots

Position of menu: Design => Pipeline => Plots

Currently the plots menu contains only one option and it is used for producing longsection plots of major pipelines.

The plots walk-right brings up the pipeline plots menu:

[Pipeline Plots]
[Longsections]

This option will now be described in more detail.

Please continue to the next section 22.5.1 Longsections.

22.5.1 Longsections

Position of option on menu: Design => Pipeline => Plots

Position of option on menu: Plot => Pipeline Plot PPF Editor

For more information please go to the section 26.7 Pipeline Plot PPF Editor

Continue to the next section 22.6 Reports.
22.6 Reports

Position of menu: Design => Pipeline => Reports

The Reports walk-right menu contains reports for joint deflections along the pipeline and crest and sag points.

For the option Deflection, go to 22.6.1 Deflection
Crest/sag points 22.6.2 Crest/Sag Points

22.6.1 Deflection

Position of option on menu: Design => Pipeline => Reports => Deflection

The deflection report gives the horizontal, vertical and combined joint deflections along the pipeline.

After selecting the Deflection option, the Pipeline Joint Deflection Report panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report file</td>
<td>name of the file for the report</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Mode</td>
<td></td>
<td>input</td>
<td>interval, critical, summary</td>
<td></td>
</tr>
</tbody>
</table>

If interval - reports the joint deflection at the interval given plus any horizontal or vertical intersection points without curves on them

If critical - only reports points where the deflection is greater than the value given in the pipeline joint defaults panel.

If summary - gives the maximum joint deflections

Interval input 10
the chainage distance between points along the pipeline where joint deflections are to be reported

Pick & Report button
pick the pipeline string to report on.

22.6.2 Crest/Sag Points

Position of option on menu: Design => Pipeline => Reports => Crest/Sag Points

After selecting the Crest/sag points option, the String Crest/Sag Points Report panel is displayed.

This is the same option as the Reports => Strings => Crest/sag points.

For more information please go to 22.6.2 Crest/Sag Points.

For each selected string, the string's crest/sag points are written to the report file given in the report file field of the panel.
Position of menu: Design => Volumes

For tins, 12d Model provides two distinct methodologies for calculating volumes: End Area and Exact. See 23.1 Definition of Cut and Fill and 23.2 End Area and Exact Volumes.

For both the end area and exact cases, the volumes are broken up into cut and fill volumes. By using an approximation method, volumes can be calculated between two tins for a given height range.

Exact volumes can also be calculated for closed trimeshes.

The Volumes walk-right menu is

For the options see:
- End area: 23.3 End Area
- Exact: 23.4 Exact
- Trimesh: 23.5 Trimesh
- Grid cell: 23.6 Grid Cell
- Stockpile: 23.7 Stockpile
- Tin to tin ht range: 23.8 Tin to Tin by Height Range
- Cut/fill text in poly: 23.9 Create Cut/Fill Text Within Polygon
23.1 Definition of Cut and Fill

**Cut** is defined to be where ever the new surface or given height is **below** the original surface. That is, you have to **cut** to get from the original surface to the new surface. The sign of cut quantities is set via the **Cut volume sign** field from the **Default settings** tab of the Defaults panel (Utilities=>Defaults) and the default for cut volume sign is positive.

**Fill** is defined to be where ever the new surface or given height is **above** the original surface. That is, you have to **fill** to get from the original surface to the new surface. The sign of fill quantities is the opposite to the value for cut and cut is set via the **Cut volumes sign** field from the **Default settings** tab of the Defaults panel (Utilities=>Defaults). The default for fill is **negative**.

Go to the next section [23.2 End Area and Exact Volumes](#) or return to [23 Volumes](#).
23.2 End Area and Exact Volumes

In the **End Area** methods using tins, the sections are *automatically* created through the tins. From the sections, cut and fill areas for the sections and the cut and fill volumes between the sections are calculated. End Area is an approximation method. For more information on the end area volume calculations, go to the section 23.2.1 *Theory of End Area Volumes*.

For **Exact** volumes, the volume between a tin and a plane or between two tin is determined by working out the exact geometrical shapes between the tins and summing their volumes. Unlike the end area methods which are approximations, the Exact method calculates the exact volume. For more information on the exact volume calculations, go to the section 23.2.2 *Theory of Exact Volumes*.

The only method that is not an approximation is **Exact** Volumes.

But even these volumes should always be double checked by using an End Area with parallel sections. And a couple of different angles of the sections should be used to make doubly sure that the End Area method is good.

The next best after **Exact** are the **End Area** method with **parallel sections**.

The worst approximations are **End Area** methods where the **sections are NOT parallel**. For example when calculating volumes using the sections along an alignment with curves.

With the End Area approximation methods, how good the approximation also depends on what the data is like. If the calculation is along an alignment then how good the approximation is will also vary depending on how tight the curves on the alignment are, the distribution of cut and fill with respect to the alignment, whether the alignment is in the middle of the sections etc.

However with all the End Area section methods, you should always look at the generated sections through the tins to make sure they have all worked correctly.

Exact volumes are more accurate than End Area volumes. However, for most End Area calculations with parallel sections and a small distance between sections, the results are the same to any reasonable degree of accuracy.

The reason for having both methods available in 12d Model is

(a) to provide an independent check on the volumes produced
(b) each method produces a different breakup of the volumes.

In the **End Area** method, cut and fill volumes are produced on a section by section basis. This is needed for applications such as mass-haul calculations.

For the **Exact** method, cut and fill volumes are easily calculated between different **depth** values. This is useful for applications such as depth (isopach) analysis.

For both the end area and the exact method, 12d Model provides options to calculate the volume

(a) between a surface (tin) and a fixed height (z-value)

and

(b) the volume between two surfaces (tins) - an original surface (tin) and a new surface (tin).

**NOTE**: For the **end area volumes**, sections are automatically generated and used for the calculations. You **do not** need to generate the sections separately.

For checking purposes, each of the End Area volumes options can keep the generated sections so that they can be checked.
For more information on the End Area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.

For information on the End Area options, please go to the section 23.3 End Area.

For more information on the Exact volume calculations, go to the section 23.2.2 Theory of Exact Volumes.

For information on the Exact volume options, please go to the section 23.4 Exact.
### 23.2.1 Theory of End Area Volumes

In the **end area** method of calculating volumes, sections are automatically generated through the tins. For each section, cut and fill areas are calculated and then cut and fill volumes are calculated from the cut and fill areas. For the definition of cut and fill, please go to the section [23.1 Definition of Cut and Fill](#).

For the end area method, 12d Model provides options to calculate the volume between a surface (tin) and a fixed height (z-value) and the volume between two surfaces (tins).

In the **end area** methods of calculating volumes, sections can be generated through a tin or tins at either a **given angle** or at right angles to a **selected** string.

When using the **sections along a string** options, it is possible for a generated section to be broken into more than one part and a parameter exists to only use those sections that contain the selected string.

For each generated section, the **cut** and **fill** areas are calculated and then the volumes between the two sections using either the **average end** (see [23.2.1.1 Average End Area Formula](#)) or the **two section prismoidal** methods (see [23.2.1.2 Two Section Prismatic Formula](#)).
NOTE: For the end area volumes, sections are automatically generated and used for the calculations. You do not need to generate the sections separately.

See
- 23.2.1.1 Average End Area Formula
- 23.2.1.2 Two Section Prismoidal Formula
23.2.1.1 Average End Area Formula

Using the Average End Area method the volume between two consecutive sections is calculated by the formula

\[ \text{Volume of cut between the two sections} = \frac{D 	imes (C_1 + C_2)}{2} \]

where

- \( D \) = distance between the two sections
- \( C_1 \) = area of cut for the first section
- \( C_2 \) = area of cut for the second section

The **Total cut volume** is the sum of the cut volumes between each pair of sections.

Similarly

\[ \text{Volume of fill between the two sections} = \frac{D 	imes (F_1 + F_2)}{2} \]

where

- \( D \) = distance between the two sections
- \( F_1 \) = area of fill for the first section
- \( F_2 \) = area of fill for the second section

The **Total fill volume** is the sum of the fill volumes between each pair of sections.

Go to the next section 23.2.1.2 Two Section Prismoidal Formula or return to 23.2.1 Theory of End Area Volumes.

23.2.1.2 Two Section Prismoidal Formula

The two section prismoidal method, as its name suggests, is a modification of the standard prismoidal method but it uses only two sections rather than the three sections required by the standard prismoidal method.

Using the Two Section Prismoidal method the volume between two consecutive sections is calculated by the formula

\[ \text{Volume of cut between the two sections} = \frac{D 	imes (C_1 + C_2 + \sqrt{C_1 \times C_2})}{3} \]

where

- \( D \) = distance between the two sections
- \( C_1 \) = area of cut for the first section
- \( C_2 \) = area of cut for the second section

The **Total cut volume** is the sum of the cut volumes between each pair of sections.

Similarly

\[ \text{Volume of fill between the two sections} = \frac{D 	imes (F_1 + F_2 + \sqrt{F_1 \times F_2})}{3} \]

where

- \( D \) = distance between the two sections
- \( F_1 \) = area of fill for the first section
- \( F_2 \) = area of fill for the second section

The **Total fill volume** is the sum of the fill volumes between each pair of sections.

For the definition of cut and fill, please go to the section 23.1 Definition of Cut and Fill.

For information on the end area options, please go to the section 23.3 End Area.

For information on the theory for exact volumes, please continue to the section 23.2.2 Theory of Exact Volumes.
23.2.2 Theory of Exact Volumes

This method calculates the exact volume between two triangulated surfaces (tins), or between one triangulated surface and a plane of constant height.

The volumes are calculated by mathematically subdividing the triangles from both tins into areas that contain only one triangle from each tin.

In three dimensions, these areas represent well defined polygons with the plane of the triangle from one tin as its top and the plane of the triangle from the other tin as its bottom.

For each small area, the cut and fill volume between the two tins can be calculated exactly. The total cut and fill volume between the two tin is simply the sum of the cut and fill volumes for each small area.

For the definition of cut and fill, please go to the section 23.1 Definition of Cut and Fill. For information on the exact volume options, please go to the section 23.4 Exact.

The calculated volumes by the exact method can be produced and reported on over user supplied depth ranges. Similarly, a view can be coloured on a depth basis using the same range file.

IMPORTANT NOTE - the volume totals are only calculated for the depths in the range file. If the depth ranges does not cover the entire depth difference between the tins then the totals...
which are the sum of the different depth ranges will **not** be the same as the volumes between the two tins.

For information on the theory for end area volumes, please go to the section 23.2.1 Theory of End Area Volumes.
23.3 End Area

Position of menu: Design => Volumes => End area

These volumes are calculated using the end area method. For more information on the end area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.

The options tin to height and tin to tin use parallel sections defined at a user supplied angle and separation distance, to calculate the end areas.

The options string tin to height and string tin to tin use sections defined at right angles to a user selected string, for their end area volume calculations. The distance between sections is supplied by the user.

The options sections to height and sections to sections use sections already created to calculate volumes using end areas.

In all the volume options, the sections are restricted to a user defined polygon.

12d Model reports on the cut, fill and balance for each of the sections used in the calculations and also the total cut, fill and balance.

In the report, the sign for cut (negative or positive) is given by the cut volume sign from the Defaults panel (fill will have the opposite sign).

The End area walk-right menu is

![End Area Volumes menu]

- end area volumes between surface and height
- between surfaces
- along string between surface and height
- along string between surfaces
- between a model of sections and height
- between two models of sections
- between a model of sections and a tin
- for one or more material layer(s)

Each option in this menu will now be described.

For the options see

- 23.3.1 End Area - Tin to Height
- 23.3.2 End Area - Tin to Tin
- 23.3.3 End Area - String Tin to Height
- 23.3.4 End Area - String Tin to Tin
- 23.3.5 End Area - Sections to Height
- 23.3.6 End Area - Sections to Sections
- 23.3.7 End Area - Tin to Sections
- 23.3.8 End Area - Material Section to Section

For more information on the end area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.
23.3.1 End Area - Tin to Height

Position of option on menu:  Design => Volumes => End Area => Tin to height

The Tin to height option is used to find volumes between an existing surface and a user supplied height. The volumes can only be calculated within a user supplied polygon.

For more information on the end area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.

On selecting the Tin to height option, the End Area Volume From Tin to a Height panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
### Angle for sections

**input** 90.0 0,45,90

*angle* (in degrees) of the lines to section along.

### Dist between sections

**input** 10.0 1,10,100

*distance* between the lines to section along.

### Model for sections

**input** available models

If non-blank, the sections though the tin used for the end area calculations are retained and placed in the model given in this field. The sections are given the same colour as the tin.

If blank, the sections are not kept.

### Difference model

**input** available models

If non-blank, the sections which are the difference between the tin sections and the height are retained and placed in the model given in this field.

If blank, the sections are not kept.

### Difference colour

**input** available colours

*colour* for the difference sections strings

### Clean sections models beforehand

**tick box**

If tick, the model of sections and difference sections are cleaned out before the option runs.

### Poly

**poly string-select**

If selected, the string, rectangle or lasso used as the bounding polygon for the volume calculations.

### Report file

**input** *.rpt*

Name of the file to contain the volume report. If the file already exists, the report will be appended to the file. If no name is given, no report is produced.

### Report mode

**input** summary summary, full

If *full*, the cut and fill details for every section are included.

If *summary*, just the cut and fill totals are given.

### Volume mode

**choice box** Average end area average end area, prismaticald - 2 sections

The two methods in 12d for calculating volumes using areas of sections. For more information on each method, go to [23.2.1.1 Average End Area Formula](#).

### Volume

**button**

*The* volume between the tin and the height (z-value) within the selected bounding polygon is calculated by the end area method. The sections through the polygon will be calculated along straight lines at the angle given by the *angle* field and at a separation given by the *dist* field. The sections are made against the tin given in tin field.

### How to Use the Panel and Panel Messages

(a) Select the bounding string by choosing Poly and picking the required string.

(b) Volume processing begins on selecting the Volume button.

Progress messages - sent to the panel message area calculating volumes

Completion message - sent to the panel message area c cut volume f fill volume bal total (balance) volume

<Esc> can be used to terminate the option during volume calculations.

Continue to the next section [23.3.1 End Area - Tin to Height](#) or return to [23.3 End Area](#).
23.3.2 End Area - Tin to Tin

Position of option on menu: Design => Volumes => End Area => Tin to tin

The Tin to tin option is used to find volumes between an existing and a new surface. The volumes can only be calculated within a user supplied polygon.

The Tin to tin option is used to find volumes between an existing and a new surface. The volumes can only be calculated within a user supplied polygon.

For more information on the end area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.

On selecting the Tin to tin option, the End Area Volume Between Tins panel is displayed.

The fields and buttons used in this panel have the following functions.

</tbody>
</table>

The fields and buttons used in this panel have the following functions.
Original tin

name of the original tin for determining volumes.

New tin

name of the new tin for determining volumes.

Angle for sections

angle (in degrees) of the lines to section along.

Dist between sections

distance between the lines to section along

Original tin sections

if not blank, the sections though the original tin used for the end area calculations are retained and placed in the model given in this field. The sections are given the same colour at the original tin. If blank, the sections are not kept.

New tin sections

if not blank, the sections though the new tin used for the end area calculations are retained and placed in the model given in this field. The sections are given the same colour as the new tin. If blank, the sections are not kept.

Difference model

if not blank, sections which are the depth from the original tin to the new tin are created and placed in the model given in this field. That is, the value on the difference section is:

\[ z_{\text{diff}} = z_{\text{value of original section}} - z_{\text{value of new tin}}. \]

Hence triangulating the difference sections and contouring them will give you the depths isopachs between the two tins. If blank, the sections are not kept.

Difference colour

colour for the difference sections strings

Use extrapolated areas

tick box not tick

If not tick, areas (and hence volumes) are only calculated where both sections exist. Hence the sections are limited to where both occur. If tick, when the sections are not the same length, the end points of the above and below sections are connected thereby extrapolating the smaller section. This method is not recommended since data does not exist.

Original extrapolated sections model

if non-blank, the extrapolated sections created from the Original sections are placed in this model. If blank, the extrapolated sections for the original sections are not kept.

New extrapolated sections model

if non-blank, the extrapolated sections created from the New sections are placed in this model. If blank, the extrapolated sections for the new sections are not kept.

Extrapolated colour

colour box available colours

colour for the extrapolated sections

Clean sections models beforehand

tick box

If tick, the model of sections and difference sections are cleaned out before the option runs.
Poly  
poly string-select
  if selected, the string, rectangle or lasso used as the bounding polygon for the volume calculations.

Report file  
input  *.rpt
  name of the file to contain the volume report. If the file already exists, the report will be appended to the file. If no name is given, no report is produced.

Report mode  
input  summary  summary, full
  if full, the cut and fill details for every section are included. If summary, just the cut and fill totals are given.

Volume mode  
choice box  Average end area  average end area, prismoidal - 2 sections
  the two methods in 12d for calculating volumes using areas of sections. For more information on each method, go to 23.2.1.1 Average End Area Formula

Volume  
button
  The volume between the new and the original tins within the selected polygon string is calculated by the end area method. The sections through the polygon selected by poly will be calculated along straight lines at the angle given by the angle field and at a separation given by the dist field. The sections are made against the tins given by the original and the new tin fields.

How to Use the Panel and Panel Messages
(a)  Select the bounding polygon string by choosing Poly and picking the required string.
(b)  Volume processing begins on selecting the volume button.
  Progress messages - sent to the panel message area calculating volumes
  Completion message - sent to the panel message area
  c cut volume  f fill volume  bal total (balance) volume

<Esc> can be used to terminate the option during volume calculations.

Continue to the next section 23.3.3 End Area - String Tin to Height or return to 23.3 End Area.
23.3.3 End Area - String Tin to Height

**Position of option on menu:** Design => Volumes => End Area => String tin to height

The volume options already described calculate the volumes by forming parallel sections through the tin and then using the end area method between adjacent sections.

In many situations, the sections to be used are defined to be at right angles to a user selected string. This method is commonly used in road calculations.

The options **String tin to height** and **String tin to tin** both use sections defined at right angles to a user selected string for the end area volume calculations. For both options, the volumes can only be calculated within a user supplied polygon.

It optionally uses the whole section within the polygon or only the part of the section that contains the string.

For more information on the end area volume calculations, go to the section 23.2.1 Theory of End Area Volumes.

On selecting the **String tin to height** option, the **Volume Along a String to a Height** panel is displayed.
The fields and buttons in this panel are used as follows.

Continue to the next section 23.3.8 End Area - Material Section to Section or return to 23.3 End Area.
23.3.8 End Area - Material Section to Section

**Position of option on menu:**  Design => Volumes => End Area => Material section to section

The Material section to section option calculates the volumes for one or more material layers where a material layer is given by two models of sections representing the top (First model) and the bottom (Second model) of the material layer.

The cut and fill volumes for each material layer is written to a table on the panel, and optionally to a report.

This option uses models of sections already created by other options such as Apply MTF or Tins => Sections => X sections

The cut and fill volumes are calculated using the **End Area** method (see 23.2.1 Theory of End Area Volumes).

Selecting Material section to section brings up the Material Volume Report (Section to Section) panel
Volumes are End Area and a comparison is made by using the distance between ALL the sections specified.

The chainage limits for the volume calculations are defined by the smallest chainages on the sections in the First and Second Models, or by the Optional Section Start Chainage and Optional Section End Chainage ranges given in the panel.

The First and Second Models used over these limits, must have matching sections, and no large gaps in either model.

If the chainage limit in the smaller model falls within the limits of the chainages in the larger model and no optional chainages are used, then the chainage limit of the smaller model is used.

In this case no interpolation is done up to the start or after the end of the smaller model chainage limits, in relation to the larger model.

However, if there is a large chainage gap in the smaller model then some interpolation will be done between the first and last section in this area, in relation to the larger model.

The latter is not desirable and the optional chainage ranges should be used to take into account the chainage gap in the smaller model.

The fields and buttons used in this panel have the following functions.

the end area volumes is run for each of the Optional Chainage ranges or for the extents of the smaller model, if no optional chainages are specified

The volumes are calculated for each material using a chain from the Library. This can be verified in the output window.

Starting chain: Vol Sect to Sect.chain

Return to 23.3 End Area.
### 23.4 Exact

**Position of menu:**  Design => Volumes => Exact

These volumes are calculated by dividing the tins up into small prisms whose volumes can be calculated exactly. For more information on the exact volume calculations, go to the section

[23.2.2 Theory of Exact Volumes](#)

In the exact volume options, the volumes calculations can be restricted to a user defined polygon or if no polygon is provided, the volumes will be only be calculated for the regions where both the triangulations exist.

With the exact method, volumes can easily be calculated for depth bands from

(a) the given height to the tin for "tin to height" volumes

or

(b) the new tin to the original tin for "tin to tin" volumes.

Hence for the calculations, a range file can be supplied giving depth pairs and 12d Model will report the cut, fill and balance for each of the depth pairs and also the total of the cut, fill and balance for all the pairs.

In the report, the sign for cut (negative or positive) is given by the cut volume sign from the default settings panel (fill will have the opposite sign).

The range file consists of a list of depth ranges and colours, one set per line, in the format

```
lower_depth  upper_depth  depth_colour
```

This line represents all depths satisfying

```
lower_depth <= depth < upper_depth.
```

For each range in the file, the total cut and fill volumes for the depth range will be reported on, and the depth_colour can be used to colour all areas on a plan view satisfying the range.

**IMPORTANT NOTE - when are depth file is used,** the volume totals are only calculated for the depths in the range file. If the depth ranges does not cover the entire depth difference between the tins then the totals which are the sum of the different depth ranges will not be the same as the volumes between the two tins or the volumes from a tin to a height.

**Example of a Depth Range File**

```
// depth range file
// format: lower_depth  upper_depth  colour_for_depth_range
// depth is measured positive down and negative up.

-20 -10 red       // colour red where the depth is greater or equal to -20 and less than -10
-10 0 magenta    // colour magenta where the depth is greater or equal to -10 and less than 0
0 10 green       // colour green where the depth is greater or equal to 0 and less than 10
10 20 "dark green" // colour dark green where depth is >=10 and less than 20
```

The Exact walk-right menu is
The options in this menu will now be described.

The name of the tin for which the volume between two heights will be calculated.

If fill, the fill volume between the two heights is calculated.

If cut, the cut volume between the two heights is calculated.

Volume is calculated between the height min and the height max values.

Increment
the volumes between the height min and height max are reported on and is broken up into intervals
given by the increment value.

Plan view to paint
input available views
if non-blank, the region used for calculations will be painted in the given plan view. The colour will be
green if type is fill, or red if type is cut.

Report file
input *.rpt
name of the file to contain the volume report. If the file already exists, the report will be appended to
the file. If no name is given, no report is produced.

Poly
poly string-select
if selected, this string is used as the bounding polygon for the volume calculations.

Volume
button
The volume between the height min and height max for the tin within the selected bounding polygon is
calculated by the exact method.

<Esc> can be used to terminate the option during volume calculations.

Continue to the next section 23.4.2 Exact - Removal Calcs or return to 23.4 Exact.
23.4.2 Exact - Removal Calcs

**Position of option on menu:**  Design => Volumes => Exact => Removal calcs

For a user specified range of heights, this option will calculate the cut volume from each height to a given tin, plus the plan and slope areas for the region of the tin exposed by cutting to the height.

The calculations can be restricted to within a polygon, or if no polygon is selected, the entire tin is used.

For more information on the exact volume calculations, go to the section 23.2.2 Theory of Exact Volumes

On selecting the **Removal calcs** option, the **Removal Calculations** panel is displayed.

Continue to the next section 23.4.4 Exact - Tin to Height or return to 23.4 Exact.
23.4.4 Exact - Tin to Height

Position of option on menu: Design => Volumes => Exact => Tin to height

This panel is used to calculate the volume between a tin and a given height.

The calculations can be restricted to within a polygon, or if no polygon is selected, the entire tin is used.

The calculated volumes can be produced and reported over user supplied depth ranges. Similarly, a view can be coloured on a depth basis using the same range file.

IMPORTANT NOTE - the volume totals are only calculated for the depths in the range file. If the depth ranges does not cover the entire depth difference between the tin and the height then the totals which are the sum of the different depth ranges will not be the same as the volume between the tin and the height.

For more information on the exact volume calculations, go to the section 23.2.2 Theory of Exact Volumes.

On selecting the Tin to height option, the Exact Volume From Tin to a Height panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>

</tbody>
</table>

The fields and buttons used in this panel have the following functions.
the string for defining the sections to be used in the volume calculations. The sections are taken at right angles to this string.

Data source type

Model

Data to search for trimeshes - for a full description go to 4.19.3 Data Source.

Data source

input

source of trimeshes to calculate the volumes along a string for.

Start chainage

input

if not blank, the chainage of the first section to use for volume calculations.

If blank, start at the beginning of the selected string.

End chainage

input

if not blank, the chainage of the last section to use for volume calculations.

If blank, end at the end of the selected string.

Chainage interval

real box 10

the chainage distance between the lines to section along.

Cut limit

real box 50

the plan distance that the section goes out from the selected string.

Report type

choice box original xml, <Customize>

output format for the report.

For information on setting up custom reports from the generated XML file using xslts, see 4.30 Setting Up XML Reports.

Report file

file box

an XML file will be created and a report of this name, and of the type given by Report type will be generated from the XML file. If the file already exists, a panel with Replace and Cancel buttons will be displayed.

Report

button

the volume of each trimesh is calculated between each pair of sections and written to the XML file.

Continue to the next section 23.6 Grid Cell or return to 23.5 Trimesh.
23.6 Grid Cell

Position of option on menu:  Design => Volumes => Grid cell

This panel is used to calculate the cut and fill volume between two tins using the exact method and then creating text for each rectangular cells of user defined sides covering the tins.

The rectangular cells (grid) can be drawn and the text of the cut and fill values for each grid cell and z-values at the cell corners. The total cut and fill can also be created at the bottom of the grid.

Cut is defined to be where ever the design tin is below the natural surface tin. Fill is defined to be where ever the design tin is above the natural surface tin.

For more information on the exact volume calculations, go to the section 23.2.2 Theory of Exact Volumes

On selecting the Grid cell option, the Grid Volumes panel is displayed.

![Grid Volumes Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Natural surface/Design surface</strong></td>
<td>tin box</td>
<td>available tins</td>

</tr>
<tr>
<td>name of the original/new tin for determining volumes.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Calculate tins min, max</strong></td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
when selected, the minimum and maximum x and y values to define the grid cells are calculated and written to the grid x and y minimum and maximum panel fields.

**Grid xmin xmax** input

the minimum and maximum x values to define the grid cells. The two values are separated by one or more spaces.

**Grid ymin ymax** input

the minimum and maximum y values to define the grid cells. The two values are separated by one or more spaces.

**X/Y grid size** input

the X/Y size of the grid cell.

**Label tin z’s** tick box ticked

if ticked, create text values for the z-values from the tins for each of the grid cell corners. The natural surface z value is followed by a N and is placed above and to the right of the corner point. The design surface z value is followed by a D and is placed below and to the right of the corner point.

**Draw grid** tick box ticked

if ticked, the grid is drawn.

**Label total cut/fill** tick box ticked

if ticked, label the total cut, fill and balance at the left hand bottom corner of the grid.

**Cut/Fill/Grid/Z text colours** colour box

colours to use for the cut, fill and z-values and the grid lines.

**Num decimals for z’s** input 3

number of decimal places in the z values.

**Z text size (w)** input

size in world units for the text of the z values.

**Num decimals for volumes** input 0

number of decimal places in the cut and fill volumes.

**Volume text size (w)** input

size in world units for the text of the volumes.

**Model for grid and text** model box available models

model to place all the text and grid lines in.
Report file input *.rpt
name of the file to contain the volume report. If the file already exists, the report will be appended to
the file. If no name is given, no report is produced.

Process button
calculate the grid volumes and grid lines.

Undo button
undo the last set of text and grid lines created whilst the panel was up.

Continue to the next section 23.7 Stockpile or return to 23 Volumes.
23.7 Stockpile

**Position of option on menu:** Design => Volumes => Stockpile

On selecting the Stockpile option, the Stockpile Calculations panel is displayed.

![Stockpile Calculations panel](image)

The fields and buttons used in this panel have the following functions.

**Decimal places**  number box
  number of decimal places for the volumes in the report.

**Stockpile number**  number box
  number of stockpile to use in the report.

**Process**  button
  calculate the volume and/or surface area of the stockpile.

Continue to the next section 23.8 Tin to Tin by Height Range or return to 23 Volumes.
23.8 Tin to Tin by Height Range

**Position of option on menu:** Design => Volumes => Tin to tin ht range

This option is used to calculate the cut and fill volume between two tins breaking the cut and fill volumes up by height ranges.

An approximate method is used which uses the z-value of the tin at a point as the representative of the height for a cell of user specified size "delta x" by "delta y" centred on the point. By making delta x and delta y small, the volumes become more accurate but the computation time increases.

Please note that the volume totals are only for the heights in the range file. If the height ranges don’t cover the entire height difference, then the totals will not be the volumes between the two tins.

Cut is defined to be where ever the new tin is below the original tin. Fill is defined to be where ever the new tin is above the original tin.

In the volumes report, the sign for cut (negative or positive) is given by the cut volume sign from the default settings panel (fill will have the opposite sign).

The height range file consists of a list of height ranges and colours, one set per line, in the format

```
lower_height       upper_height       height_colour
```

This line represents all heights satisfying

```
lower_height <= height < upper_height.
```

For each range in the file, the total cut and fill volumes for the height range will be reported on. The colour is ignored in this option.

**Example of a Height Range File**

```
// height range file
// format: lower_height upper_height colour_for_height_range

110 120 green     // colour green where the height is greater or equal to 110 and less than 120
120
120 220 "dark green" // colour dark green where height is >= 120 and less than 220
```

On selecting the tin to tin ht range option, the tin to tin by height range panel is displayed.
The fields and buttons used in this panel have the following functions.

Return to 23 Volumes.
24 Drafting

The Drafting menu contains options to create data for plots.

The Drafting menu is on Main menu and on 12d Model menu and floating Drafting menu.

For Bearing/distance labelling go to

- 24.1 Bearing/Distance Labelling
- 12.13.35.5 Line Marking
- 25.7.1 Create/Edit Title Block File
- 24.4 Create Crosses at String Points
- 24.5 Create Cut/Fill Symbols
- 24.6 Create World Grid
- 24.7 Create/Edit Dimensions
- 24.8 Chainage/Offset Label Inquire
- 24.9 Display Colours, Textstyles and Linestyles
- 24.10 Draw Symbols for Alignment String
- 24.11 Polygon Hatching
- 24.16 Text and Tables
- 24.13 North Point Insertion
- 17.18.3 Setout Lip Line
- 24.15 Scalebar
- 24.16 Text and Tables
24.1 Bearing/Distance Labelling

Position of option on menu: Drafting => Bearing/distance labelling

This option is used to label a selected line or arc segment with bearing, distance information and arc length information. If the line or arc length is below a given value, the label information is added to a short segment table.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>bd annotation file</td>
<td>file box</td>
<td>*.bdf files</td>
<td>file containing values for the text parameters.</td>
</tr>
<tr>
<td>Read</td>
<td>button</td>
<td></td>
<td>read the file given in the “bd annotation file” field.</td>
</tr>
<tr>
<td>Save</td>
<td>button</td>
<td></td>
<td>save the current text parameter settings to the file given in the “bd annotation file” field.</td>
</tr>
<tr>
<td>Save as</td>
<td>button</td>
<td></td>
<td>save the current text parameter settings in a file.</td>
</tr>
<tr>
<td>Bearing parameters</td>
<td>input box</td>
<td>none/complete bearing parameters incomplete</td>
<td>if none, don’t label bearings.</td>
</tr>
</tbody>
</table>
If complete, all the bearing parameters have been set.
If incomplete, not all the bearing parameters have been set so the labels can’t be created.

Create bearing text

tick box

if tick, bearings are labelled.

Distance parameters

input box

none/complete bearing parameters incomplete

if none, don’t label distances.
If complete, all the distance parameters have been set.
If incomplete, not all the distance parameters have been set so the labels can’t be created.

Create distance text

tick box

if tick, distances are labelled.

Label all segments

tick box

if tick, all segments of the selected element are labelled.
If not-tic, only the selected segment is labelled.

label style

input box b/d, d/b, /bd b/d /db, bd, db

defines how to label the bearing and distances. For example, d/b means distance above the line and bearing below the line. Bearing or distance is only labelled if the appropriate flags are set.

Add text models to view

tick box

if tick, all models containing text are added to the view containing the selected segment.

Minimum length

input box 0

if non-zero, then if the length of the segment is less than this value, then it is given a short segment number and added to the short segment table.

Next short segment no.

input box 1

the next number to use for short segments.

Pick

button

select the segment to be labelled.

Undo

button

undo the last set of created labels.
24.2 Line Marking

Position of option on menu: Drafting => Create line marking
This option creates a title block file from a model of data. It has already been documented as
View => Visualisation => Line marking
in the section 12.13.35.5 Line Marking.

24.3 Create Titleblock

Position of option on menu: Drafting => Create title block
This option creates a title block file from a model of data. It has already been documented as
Plot => Create title block file
in the section 25.7.1 Create/Edit Title Block File.
24.4 Create Crosses at String Points

Position of option on menu: Drafting => Create crosses for strings

This panel is used to create crosses at the points of strings. The cross is made up of two 2d strings with the intersection of the two strings being the (x,y) position of the point in the string. The option is mainly used to create crosses to send to packages that don’t support a cross at a point.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data source</strong></td>
<td>data source</td>
<td>Model</td>

<tr>
<td><strong>Model for crosses</strong></td>
<td>model box</td>
<td>available models</td>
<td></td>
</tr>
<tr>
<td><strong>Colour for crosses</strong></td>
<td>colour box</td>
<td>available colours</td>
<td></td>
</tr>
<tr>
<td><strong>Cross size (w)</strong></td>
<td>input box</td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>

Run button
run the option

Undo button
undo the last set of crosses created whilst the panel has been up.
24.5 Create Cut/Fill Symbols

Position of option on menu:  Drafting => Create cut/fill symbols

This option is used to create cut and fill symbols (tadpoles) between strings or the names of the points across x-sections. The choice of symbols and the points they go between is controlled by a parameter file.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference string</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use X-section model</td>
<td>tick box</td>
<td>not ticked</td>
<td></td>
</tr>
<tr>
<td>X-section model</td>
<td>model box</td>
<td>available models</td>
<td></td>
</tr>
<tr>
<td>Model for symbols</td>
<td>input</td>
<td>available models</td>
<td></td>
</tr>
<tr>
<td>Clean model for symbols first</td>
<td>tick box</td>
<td>not ticked</td>
<td></td>
</tr>
<tr>
<td>Colour for symbols</td>
<td>input</td>
<td>available colours</td>
<td></td>
</tr>
<tr>
<td>Parameter file</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use max symbol width</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Max symbol width</td>
<td>input</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

string used to define chainage and perpendicular

if ticked, the points on the cross-sections in the model are used as the names to create symbols between.

model of cross sections used if “Use X-section model” is ticked.

model for the created cut-fill symbols

if ticked, the Model for symbols will be cleaned before the new symbols are created and added.

colour for the created cut-fill symbols

file specifying what symbols are drawn between what strings (or points on x-sections).

if tick, the symbols are only stretched to the maximum size given in the “Max symbol width” field.
maximum distance in world units to stretch the symbol.

**Process** button

Run the option.

**Undo** button

undo the last set of cut-fill symbols created by running the panel. The “Undo” function is lost once the option is finished.

**Notes:**

// Sample file for plotting symbols to denote cut/fill slopes
// All lines starting with // are comments. Blank lines are ignored
//
// The file layout is:

// ch_start ch_end ch_inc side str1 str2 symbol1 %1 symbol2 %2
//
// eg 110 150 10 L "trial1->c1" "trial->c2" tadpole 100 tadpole 50
//
// ch_start defines the start chainage
// ch_end defines the end chainage
// ch_inc defines the chainage increment
// side is one of L, R or LR (left, right, both)
// str1 is the name of the string (or point on x-section) to start tadpole
// str2 is the name of the string (or point on x-section) to end tadpole

// If strings are used, the string model name must be contained in the
// string definition i.e. in the format “model->string_name”
//
// The symbols drawn between the strings (or points) alternate between
// symbol1 and symbol2 and the symbols are drawn as the
// given percentages %1 and %2 respective of the distance
// between the strings (points).

// The symbol can be one of "
// tadpole     - predefined tadpole shape
// line       - predefined batter tick
// "model=xxxxx" - where model "xxxxx" contains 3d strings
// defining the symbol shape. This is as per
// user-defined batter symbols in 4D.
// NB. only 3d strings are supported in the macro

// Example

    0 700 10 LR "road str->c2" "road str->c3" tadpole 100 tadpole 50
    0 700 10 LR "road str->c4" "road str->c5" line 90 line 50
    0 700 10 LR "road str->f2" "road str->f3" "model=symbol" 100 tadpole 50
    0 700 10 LR "road str->f4" "road str->f5" line 90 line 50
24.6 Create World Grid

Position of option on menu:   Drafting => Create world grid

This option is used to create a grid, identical to the one drawn on a plan view, but in world units. This can then be output to CAD systems that do not allow grids to be easily created.

Selecting the Create world grid option, brings up the Create World Grid panel:

![Create World Grid Panel](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clip mode</td>
<td>choice box</td>
<td>rectangle, view</td>
<td></td>
</tr>
</tbody>
</table>

If rectangle, icons appear for drawing a rectangle, a rotated rectangle or selecting a plot frame.

Selecting the rectangle and rotated rectangle icons require the user to draw the rectangle to define the area to produce the grid for.

Selecting the plot frame icon requires the user to select a plot frame and the view area from the plot frame defines the area to produce the grid for.
If view, a View Box appears and a view is selected to define the area to produce the grid for.

**Draw mode**

- choice box
- full lines
- full lines, crosses, marks
  
  the type of the grid being drawn - full lines, crosses or marks.

If full lines, then solid lines are drawn at the grid x and y spacing.
If crosses, then crosses of size cross/mark size are drawn at the intersection of the grid x and y spacing.
If marks, then solid lines size cross/mark size are drawn at the beginning/end of the grid at the x and y spacing.

**Cross/mark size**

- input
  
  size in world units of the grid crosses/marks.

**Grid East (x)**

- Interval input
  
  the distance between the East (x) grid lines. If this value is zero, the x grid lines will not be drawn.

- Text mode input
  
  the x (East) grid lines can be labelled with their x value. If the grid lines are labelled, the labels can be drawn on the top, the bottom or both ends of the x-grid lines.

  if off, no text is created for the x-grid lines.

  If bottom, text is created only at the bottom of the x-grid lines.

  If top, text is created only at the top of the x-grid lines.

  If top & bottom, text is created at the top and bottom of the x-grid lines.

- Pre*postfix input
  
  if non blank, pre*post text to use for the labels on the x-grid lines.

  prefix/postfix (pre*post) to be applied to the value of x (East). If pretext only, just give the text. If post text is required, precede it by a *. For example E*m will place E before the x value and m after the number.

**Grid North (y)**

- Interval input
  
  the distance between the North (y) grid lines. If this value is zero, the y grid lines will not be drawn.

- Text mode input
  
  the y (North) grid lines can be labelled with their y value. If the grid lines are labelled, the labels can be drawn on the top, the bottom or both ends of the y-grid lines.

  if off, no text is created for the y-grid lines.

  If left, text is created only at the left of the y-grid lines.

  If right, text is created only at the right of the y-grid lines.

  If left & right, text is created at the left and right of the y-grid lines.

- Pre*postfix input
  
  if non blank, pre*post text to use for the labels on the y-grid lines.

  prefix/postfix (pre*post) to be applied to the value of y (North). If pretext only, just give the text. If post text is required, precede it by a *.

**Output settings**
| Grid colour | colour box available colours | colour for the grid lines. |
| Textstyle data | textstyle box | textstyle data (height, angle etc) for the text for the grid labels. |
| Grid model | model box available models | model for the grid lines and text. |
| Create border | tick box tick | if tick, a rectangle around the area to create the grid for, is created. |
| Create | button | create the grid according to the values given in the panel. |
24.7 Create/Edit Dimensions

Position of option on menu: Drafting => Create/edit dimensions

This option is used to create and edit dimensions.

This option is currently under development.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>read in an existing range file.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Write button

write out the data in the pages to the given range file.
24.8 Chainage/Offset Label Inquire

Position of option on menu:  Drafting => Chainage/offset label inquire

This option is used to calculate and label the perpendicular distance from a selected point to a selected centreline, and the chainage of the point dropped perpendicularly onto the centreline.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Line colour</td>
<td></td>

<tr>
<td>Prefix offset</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Textstyle data</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Centreline</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Model for labels**  
model box  
Label chg off  
available models  
if non-blank, create text for the calculated offset and chainage values and place it in this model.

**Line colour**  
yellow  
available colours  
colour of the line drawn.

**Linestyle**  
linestyle box  
hidden2  
available linestyles  
text style for the text.

**Symbol colour**  
cyan  
available colours  
colour of the symbol drawn at the point.

**Symbol size**  
0.5  
size (in world units) of the symbol drawn at the point.

**Label method**  
choice box  
Chng/Offset  
Chng/Offset, Offset/Chng  
method of labelling the line from a selected point to the dropped point.

**Prefix chainage**  
Ch  
prefix for the chainage value.

**Prefix offset**  
Off  
prefix for the offset value.

**Textstyle data**  
textstyle data box  
available text data  
textstyle, size, colour etc. for the text.

**Centreline**  
string select  
select the string to use for the calculation of chainage and offset.

**Pick**  
button  
pick a position and the offset from the position to the position dropped perpendicularly onto the selected Centreline is calculated, plus the chainage on the Centreline of the dropped point. The values are reported in the panel’s message area and if Model for labels is non-blank, text of the values is created and place in the model.
24.9 Display Colours, Textstyles and Linestyles

**Position of option on menu:** Drafting => Display colours, text and line styles

This option creates a model to display either all the colours, linestyles or textstyles defined for a project.

![Display Colours, Textstyles and Linestyles](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>

<tr>
<td>Solid hatch</td>
<td>tick box</td>
<td></td>
<td>if ticked, a solid fill of the given hatch colour is used.</td>
</tr>
<tr>
<td>Hatch polygon</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
select the string to hatch.

**Preview** button

draw the hatching to see if it is correct - the hatching function has not been defined.

**Set** button

define the hatching function with the values given in the panel fields.
24.12 Translate Strings

**Position of option on menu:** Drafting => Multi string translate

This panel is used to translate strings selected by name group of a window. Selecting Multi string translate brings up the Translate Strings panel.

![Translate Strings panel](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single</td>
<td>button select a single string to translate.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>button select a string and all strings with the same name on the view will be translated.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Group</td>
<td>button select a string and all strings with the same group on the view will be translated.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Window</td>
<td>button click and release to define the first point of the window and then move the cursor and click and release to define the second point of the window. A position is then selected and as the cursor is moved, all strings in the view that are totally inside the window are translated and placed at the next selected position.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Undo</td>
<td>button undo the last set of strings translated whilst the panel has been up.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
24.13 North Point Insertion

Position of option on menu: Drafting => North arrow

This option creates a point with a textstyle of the north point arrow. Selecting North arrow brings up the North Point Insertion panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linestyle</td>
<td>input box</td>
<td>4dnorth</td>
<td></td>
</tr>
<tr>
<td>Linestyle for the north point arrow - leave as 4dnorth.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Size factor</td>
<td>input box</td>
<td>15</td>
<td></td>
</tr>
<tr>
<td>Factor the north arrow by this value.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

24.14 Quarter Points
Position of option on menu:  Drafting => Quarter points bubbles and table

This option is used to create bubbles and/or a report for the critical horizontal and vertical points and quarter points (by chord or by chainage) for any arcs in an alignment string.

This option has already been documented as

Survey => Setout => Setout lip line

in the section 17.18.3 Setout Lip Line.
24.15 Scalebar

**Position of option on menu:**  Drafting => Scale bar

This option is used to create a scale bar. Selecting Scale bar brings up the Create Scalebar panel.

![Create Scalebar Panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Model for scalebar</strong></td>
<td>model box</td>
<td>available models</td>

</tbody>
</table>
24.16 Text and Tables

Position of menu:  Drafting => Text and Tables

The Text and Tables menu contains options to create text data and tables for plots.

The Text and Tables menu is

![Text and Tables Menu]

For the option **Defaults**, go to 24.16.1 Defaults - Text
- Create quick text 24.16.2 Quick Text Input
- Create/edit paragraph text 24.16.3 Text Creation/Edit
- Table create/edit 24.16.4 Table Create/Edit
- Information Leader 24.16.5 Leader Create (Information)
- Leader create 24.16.6 Leader Text Creation
- Leader edit 24.16.7 Leader Edit
- Replace text 24.16.8 Replace Text
- Reverse bearing 24.16.10 Reverse Bearing
- Short segment table 24.16.11 Short Segments Table
- Short segment report 24.16.12 Short Segment Report
- Short segment table utilities 24.16.13 Short Segments Table Utilities
- Alignment/super alignment table 24.16.14 Alignment & Super Alignment

**Table**
- Tabulate alignment - IP’s, TC’s 24.16.15 Tabulate Alignment - IP’s and CT’s
- Tabulate alignment - elements 24.16.16 Tabulate Alignment - Elements
- Tabulate kerb return 24.16.17 Tabulate Kerb Return
- Tabulate range file 24.16.18 Tabulate Range File
- Tabulate symbols/linestyle legend 24.16.19 Symbol / Linestyle Legend -

**Tabulation**
- Text file input same option as 24.16.3 Text Creation/Edit
24.16.1 Defaults - Text

**Position of option on menu:** Drafting => Text and Tables => Defaults

This option is used to project text defaults that are used with the "Fonts" button on many of the text options.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Text model</strong></td>
<td>model box</td>
<td>Text</td>
<td>available models</td>

<td></td>
<td></td>
</tr>
</tbody>
</table>
24.16.2 Quick Text Input

**Position of option on menu:**  Drafting => Text and Tables => Create quick text

The quick text option creates lines of text using the text defaults. The text can be edited and modified using the create/edit paragraph text.

![Text Input](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Text box</strong> button</td>
<td>button</td>
<td></td>

<tr>
<td><em>type the text to be created into the text box.</em></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Place text</strong> button</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td><em>pick a position to become the justification point for the first line of text.</em></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
24.16.3 Text Creation/Edit

**Position of option on menu:** Drafting => Text and Tables => Create/edit paragraph text

The option creates and edits a paragraph of text created with this option or the quick text option.

![Image of Text Creation/Edit panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text Input Type</td>
<td>method of creating text - type in a paragraph or read from a file</td>
<td>choice box</td>
<td>paragraph, file</td>
<td></td>
</tr>
</tbody>
</table>

- **Paragraph**
  - *Create* button: select create to bring up the text box to type text into.
  - *Edit* button: select edit to pick and edit existing text.

- **Text file**
  - *Name of the file to read in.*

- **Text parameters**
  - **Box/Shadow/None**
    - *Radio button* box
      - *If box is ticked,* draw a box around the text.
      - *If shadow is ticked,* draw shadowed box around the text.
      - *If none is ticked,* don’t draw a box around the text.
  - **Box colour**
    - *Colour box* orange
Colour of the box around the text

**Shadow colour**

- Colour box: orange

Colour of the shadow around the box around the text

**Location x y z**

- X, y, z box: pick ops menu

*Pick the position for the text.*

**Font**

- Button: bring up the values for the text - e.g. model, colour, size etc.

**Inquire**

- Button

**Process**

- Button: create the text and place it at the given location.
24.16.4 Table Create/Edit

Position of option on menu: Drafting => Text and Tables => Table Create/edit

*This option is currently under development*

This option reads in a csv file and loads the data into a grid on the panel. The data can be edited in the grid and then a table produced in a model.

An existing table in a model can also be selected and the data read into the grid on the panel. The data can then be edited and the table updated.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>file to read in and display in the grid on the panel.</td>
<td>file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Read</td>
<td>read the specified file in and display it in the grid on the panel.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Write</td>
<td></td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
write the data in the grid on the panel to the specified file.

**Table settings**

create the text and place it at the given location.
24.16.5 Leader Create (Information)

Position of option on menu: Drafting => Text and Tables => Information leader

This option creates a leader that can extract and list certain information about the string selected. Information such as AREA, STRING LENGTH, SEGMENT LENGTH and GRADE can be displayed.

A choice list is available and can be partially user defined.

General notes can also be placed that do not extract information from any string selected.

Leaders can be moved along the string they relate to, and subsequent information values updated.

Selecting the Information leader option brings up the Leader Create (Information) panel:

![Leader Create (Information) panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
Leader Type

Information Leader tick box ticked
If ticked, information or general notes can be created.

Label Map / Ver Text Leader tick box not ticked
If ticked, any vertex text or text created via the Label Map File can be converted into a leader, allowing the text to be moved but still have the leader at the original location.

Linestyle linestyle box LEADER ARROW 500 available linestyles
If non-blank, entry used as leader arrow scale.

Leader Colour colour box white available colours
If non-blank, entry used as leader colour.

Leader Model model box 12D LEADER INFO available models
If non-blank, entry used as leader model.

Textstyle data input "ISO" white 2.5 available Textdata
If non-blank, entry used as text properties.

Information Type (# subs) choice box GENERAL available choices
If non-blank, entry used as type of information leader. The list is generated from a defaults file in the library.

Global Text Angle real GENERAL
If non-blank, entry used as angle for text during placement of leader.

Add Leader Cog tick box ticked
If ticked, leader cog will be added.

Leader Text
From the choice above, default text is placed in the Leader Text box on the panel.
Any calculated information value, such as AREA, LENGTH will be substituted for the # that may appear in the Leader Text.

Place Leader button
Select a position along a string that suits the type of information selected from the choice box (segment for SEGMENT LENGTH, a vertex for XYZ COORDS, etc.).

General notes (i.e. notes without the # in the Leader Text) may be placed using the cursor position as well.

Placement of the leader is controlled by the Leader Start Options.

Flip Text button
Select an information leader already placed. Upon accepting the string, the text will be flipped to the opposite side of the leader.

+- Cog button
Select an information leader already placed. Upon accepting the string, the cog will be added or removed.

Edit Leader button
Select an information leader already placed to edit the text. The text will be displayed in the edit box.

Update Text button
If selected, the text will be updated on the selected leader.

**Leader Start Options**

**Pick Point**  
*Click box*  
*If ticked, the start of the leader will be at the selection point.*

**Mid Point**  
*Click box*  
*If ticked, the start of the leader will be at the mid point of the string selected or segment selected, depending on the Information Type.*

**Centroid**  
*Click box*  
*If ticked, the start of the leader will be at the centroid of the string selected.*

**Suppress any Original Vertex Text (Set Ht to 0)**  
*Click box*  
*Available only for the leader option Label Map / Ver Text Leader, where the vertex text on the original string selected can be invisible by setting its height to zero.*

**Auto Update Leader Model**  
*Button*  
*If selected and the string the leader is linked to has changed, and/or the leader is moved to another position on the string, information in the leader relating to the string will be updated.*

**Undo Last**  
*Button*  
*If selected, will undo the last leader placed.*

**Save Style**  
*Button*  
*Writes out a default file to the .project folder using the current Information type displayed (e.g. STRING_LENGTH) as part of the file name.*

**STRING_LENGTH_LEADER_TEXTSTYLE.def**

Example data written to file:

- **Text_Style**: "ISO"
- **Text_Colour**: 7
- **Text_Whiteout_Colour**: 0
- **Text_Border_Colour**: 0
- **Text_Size**: 2.500
- **Text_Units**: paper
- **Text_Angle**: 0.0000

This file can be copied to a user_lib area for use in other projects.

**Rot / Move**  
*Button*  
*This option is two-fold depending on where you select the leader.*

*If the leader is selected at the arrow or first vertex, then the Move command is activated.*

*If moving the leader from, say, one radius segment to another radius segment, then the leader only needs to be placed close to the segment, as the Auto Update Leader Model will lock it onto the segment and in this case update the radius value.*

*If the leader is selected anywhere else, then the Rotate command is activated.*

*The leader rotates about the arrow insertion point.*

Area syntax special:

**AREA**

"Area #"  "2"

Drop down Display Text which can be set as "Area *ha" to define hectares Decimal places

**TIN_DEPTH**

"Depth #"  "2"

Drop down Display Text which can be set as "Depth *mm" to define millimetres Decimal places

Attributes syntax special:

**USER_STRING_ATTRIBUTE** "#"

**USER_VERTEX_ATTRIBUTE** "#"

**USER_SEGMENT_ATTRIBUTE** "#"

Drop down Display Text of "#" that will be substituted with attr value

Note: An attribute with the name "Leader" can be set on any string, for any of the above attributes.

It will appear automatically in the choice box along with any others set here
24.16.6 Leader Text Creation

Position of option on menu:  Drafting => Text and Tables => Leader create

This option is used to create leader lines and text.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leader arrow size</td>
<td>input box</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>length (in world units) of the head of the arrow of the leader line.</td>
<td></td>
</tr>
<tr>
<td>Leader colour</td>
<td>colour box</td>
<td>cyan</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>colour of the leader line or arrow</td>
<td></td>
</tr>
<tr>
<td>Text side</td>
<td>choice box</td>
<td>Right</td>
<td>Right, Left</td>

<td>Leader</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>create the leader by first picking the point for the arrow end and then the point for the opposite end where the text goes. Once the second point is place, the &quot;Leader Text Input&quot; panel is displayed for entering five lines of text.</td>
<td></td>
</tr>
</tbody>
</table>
24.16.7 Leader Edit

**Position of option on menu:**  Drafting => Text and Tables => Leader edit

This option is used to edit leader lines and text.

![Leader Text Edit](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Line 1-5</strong></td>
<td>input box</td>
<td>lines of text from the selected leader.</td>
<td></td>

<td>tick box</td>
<td>tick</td>
<td>if tick, the leader arrow remains fixed when the leader is moved.</td>
</tr>
<tr>
<td><strong>Pick</strong></td>
<td>button</td>
<td>select the leader to be modified.</td>
<td></td>
</tr>
<tr>
<td><strong>Font</strong></td>
<td>button</td>
<td>brings up panel for defining information about the text (size, model colour etc.).</td>
<td></td>
</tr>
</tbody>
</table>
**Move** button

move the select leader and its associated text. If "rotate leader" is ticked, then the leader arrow head is left fixed.

**Set** button

redefine the leader line and text with the current values in the panel fields.
24.16.8 Replace Text

**Position of option on menu:** Drafting => Text and Tables => Replace text

**Position of option on menu:** Utilities => H-Z => Find/replace text

This option is used to find and replace text in text strings, 4d string, super strings for vertex and segment text.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>text to replace the searched text with</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Match whole words</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| **if not tick, text is selected if the "find text" is only part of the text.**
|                       |           |          |        |
| Match case              | tick box   |          |        |
| **If tick, only find the text when the text is exactly the same as the "find text", not just a part of the text.**
|                       |           |          |        |

If not tick, case is ignored when trying to find a match.
If tick then case is not ignored when trying to find a match.

**Regular expressions** tick box

If tick then the **Find what** text can contain regular expressions.

If not tick, the **Find what** text is not considered to contain regular expressions.

**New** button

after selecting new the parameters for the find and replace can be changed.

**Find** button

find the search text. The text is highlighted and centred in the view.

**Find Next** button

find the next occurrence of the search text.

**Replace** button

replace the text.

**Replace all** button

replace all occurrences of the text.
24.16.9 Find and Replace Text

Position of option on menu: Drafting => Text and Tables => Replace text

This option is used to find and replace text.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>data source type</td>
<td>input box</td>
<td>string, model, view</td>
<td></td>
</tr>
<tr>
<td>Model name</td>
<td></td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Search for</td>
<td>text to search for</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Replace with</td>
<td>if non-blank, text to replace the searched text with</td>
<td>input box</td>

<td></td>
</tr>
<tr>
<td>Replace</td>
<td>replace the text.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Replace all</td>
<td>replace all occurrences of the text.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
24.16.10 Reverse Bearing

Position of option on menu: Drafting => Text and Tables => Reverse bearing

This section of documentation is a work in progress and will be updated in subsequent releases.
24.16.11 Short Segments Table

Position of option on menu:  Drafting =>Text and Tables =>Short segment table

This panel is used to create a short segment table.

This option is still under development.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td></td>
<td>input box</td>
<td>model</td>
<td>model, string, view</td>
</tr>
<tr>
<td>Model of numbers</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Table for</td>
<td></td>
<td>choice box</td>
<td>lines</td>
<td>lines, arcs, lines and arcs</td>
</tr>
<tr>
<td>Model for table</td>
<td></td>
<td>model box</td>
<td>Table</td>
<td></td>
</tr>
<tr>
<td>Text size</td>
<td></td>
<td>input box</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Text colour</td>
<td></td>
<td>colour box</td>
<td>red</td>
<td></td>
</tr>
<tr>
<td>Text units</td>
<td></td>
<td>choice box</td>
<td>world</td>
<td>world, pixels</td>
</tr>
<tr>
<td>Text style</td>
<td></td>
<td>input box</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
textstyle for the created text.

**Table position**

Input box for the location for the top left hand corner of the table. Either type in an x y position or click on "+" and use "Pick xyz" to locate the table.

**Add table to view**

Check box to add the model containing the table to the view.

**View to add**

Input box for the view to add the table to.

**Process**

Button to create and place the short segment table.

**Undo**

Button to undo the last short segment table created whilst the panel has been up.
24.16.12 Short Segment Report

Position of option on menu: Drafting => Text and Tables => Short segment report

This panel is used create a report on the short segments.

This option is still under development

![Report Short Segments](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>input box</td>
<td>model</td>
<td>model, string, view</td>
<td></td>
</tr>
<tr>
<td>Model of numbers</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Report type</td>
<td>formatted</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Report file</td>
<td>report box</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Data source**

*data to process and report on the short segments.*

**Model/string/View of numbers**

*name of the report file.*

**Process**

*create the short segment report*
24.16.13 Short Segments Table Utilities

Position of option on menu:  Drafting => Text and Tables => Short segment table utilities

This panel is used to modify an existing short segments table.

This option is still under development.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pick a table</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Text size</td>
<td>input box</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Text colour</td>
<td>colour box</td>
<td>red</td>
<td></td>
</tr>
<tr>
<td>Text units</td>
<td>choice box</td>
<td>world</td>
<td>world, pixels</td>
</tr>
<tr>
<td>Text style</td>
<td>input box</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Table position</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following notes apply:

- **Text units**: units for the text size - default is world units.
- **Move**: move the selected table to the new location.
- **Delete**: delete the selected table.
24.16.14 Alignment & Super Alignment Table

Position of option on menu:  Drafting => Text and Tables => Alignment/Super alignment table

This option is used to create a report and/or a table in a model for an alignment and super alignment string in an IP or element format.

This option is under development.
24.16.15 Tabulate Alignment - IP’s and CT’s

Position of option on menu:  Drafting => Text and Tables => Tabulate alignment - IP’s TC’s

This option is used to create a report and/or a table in a model of an alignment string in an IP and tangent point format.

The table is created by a function so that if the alignment string changes, the table can be easily recalced.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function name</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>name of the function</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reference string</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>select the string to create the table and/or report for.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Chainage interval</td>
<td>input box</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>if zero, only information on the tangent and intersection points is given. If non-zero, the chainage interval to use to report the information about the reference string. The horizontal tangent and intersection points are included.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Start/End chainage</td>
<td>input box</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>start/end chainage to use. If 0, the start/end chainage is used.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Location x y z</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>location for the top left hand corner of the table. Either type in an x y position or click on '+' and use 'Pick xyz' to locate the table.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Report file</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if non blank, name of the report file. If blank, don’t create the report.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Font button

brings up panel for defining information about the text (size, model colour etc.).

Process button

process the reference string and create the report. The table is not yet created.

Place text button

create the table and place it at the given location.
24.16.16 Tabulate Alignment - Elements

Position of option on menu: Drafting => Text and Tables => Tabulate alignment - elements

This option is used to create a report and/or a table in a model of an alignment string in an horizontal element format.

The table is created by a function so that if the alignment string changes, the table can be easily recalced.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function name</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reference string</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CTP IP tolerance +/-</td>
<td>input box</td>
<td>0.002</td>
<td></td>
</tr>
<tr>
<td>Location x y z</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Report file</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Additional heading</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Font</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The function name is the name of the function to be used in the reference string. The reference string is the string to create the table and/or report for. The CTP IP tolerance is the tolerance for the curve. The location is the location for the top left hand corner of the table. The report file is the name of the report file. The additional heading is additional information for the heading above the table. The font button brings up a panel for defining information about the text (size, model colour etc.). The process button processes the reference string and creates the report. The table is not yet created.
Place text button

create the table and place it at the given location.
24.16.17 Tabulate Kerb Return

Position of option on menu: Drafting => Text and Tables => Tabulate kerb return

This option creates a table for a kerb return.

![Kerb Alignment Tabulation](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function name</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reference</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Chg interval type</td>
<td>choice box</td>
<td>by number (Arc)</td>
<td>by number (Arc)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>by distance (Arc)</td>
<td>by special chg file</td>
</tr>
<tr>
<td></td>
<td></td>
<td>by number (Chord)</td>
<td></td>
</tr>
<tr>
<td>Interval number</td>
<td>input box</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CTP IP tolerance +/-</td>
<td>input box</td>
<td>0.002</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>xxxx</td>
<td></td>
</tr>
<tr>
<td>Interval number</td>
<td>input box</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>xxxx</td>
<td></td>
</tr>
<tr>
<td>Location x y z</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>location for the top left hand corner of the table. Either type in an x y position or click on &quot;+&quot; and use &quot;Pick xyz&quot; to locate the table.</td>
<td></td>
</tr>
<tr>
<td>Report file</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>if non blank, name of the report file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If blank, don't create the report.</td>
<td></td>
</tr>
<tr>
<td>Heading</td>
<td>input box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
heading above the table.

Font button

brings up panel for defining information about the text (size, model colour etc.).

Process button

process the reference string and create the report. The table is not yet created.

Place text button

create the table and place it at the given location.
24.16.18 Tabulate Range File

**Position of option on menu:** Drafting => Text and Tables => Tabulate range file

This option creates a table for a range file.

![Range File Tabulation](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range type</td>
<td>choice box</td>
<td>slope percent xfall</td>
<td>slope percent xfall</td>
</tr>
<tr>
<td></td>
<td></td>
<td>slope 1 v in, slope degrees</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>depth, aspect, height</td>
<td></td>
</tr>
<tr>
<td>Range file</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Range units</td>
<td>input box</td>
<td>text to place beside each line of upper and lower values.</td>
<td></td>
</tr>
<tr>
<td>Heading</td>
<td>input box</td>
<td>heading to place at the top of the table.</td>
<td></td>
</tr>
<tr>
<td>Location x y z</td>
<td>input box</td>
<td>location for the top left hand corner of the table. Either type in an x y position or click on &quot;+&quot; and use &quot;Pick xyz&quot; to locate the table.</td>
<td></td>
</tr>
<tr>
<td>Font</td>
<td>button</td>
<td>brings up panel for defining information about the text (size, model colour etc.).</td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>button</td>
<td>create and place the range table.</td>
<td></td>
</tr>
</tbody>
</table>
24.16.19 Symbol / Linestyle Legend - Tabulation

**Position of option on menu:**  
Drafting => Text and Tables => Tabulate symbol/linestyle legend

This option can create a legend showing features and their associated linestyle, colour, symbol etc.

There are 3 distinct parts to the macro. Once a data selection is chosen, the data can be analysed by either using a map file or the data features themselves.

**Map File Extraction:**
If specified, the 12d Map File is read and data sorted by string name (Name column).
If the Extract Data button is clicked, the Map File Extraction grid is populated.
The Description column is used in the legend and is controlled by the Mode selected, either Model Name or Comment.

**Data only Extraction:**
If no map file is specified, then the data is sorted in relation to Name, Linestyle, Colour and Weight.
If the Extract Data button is clicked, the Data Only Extraction grid is populated.
The Description column is used in the legend and is controlled by the Mode selected: Model Name, String Name, Linestyle, Symbol, Ver attr + Name, Name +Ver Attr.

Once a mode is selected, clicking the Update button will update the Description field.

**Symbol Tabulation:**
This tabulation is for symbols, e.g. survey station points.
The table is in the format of Name, Easting, Northing & Level.
The title of the Name column can be changed.
The data to be tabulated is given by the Tabulation by choice box. It can be either tabulating the Point ID or the Vertex Text.

The fields and buttons used in this panel have the following functions:
### Legend / Tabulation Parameters

**Data Source Legend**  
*selection*  
*model, view, string*  
*selection data to extract legend information*

**Map File**  
*input*  
*if non-blank, then the map file is used with the data selection to sort and populate the <Map File Extraction> grid*

**Model**  
*input*  
*model name for legend tabulation*

**Textstyle**  
*input*  
*text parameters for all text*

**Location x y z**  
*xyz box*  
*insertion point for top left corner of legend*

**Heading**  
*input*  
*if non-blank, heading placed at top of legend*

**Line spacing**  
*real 2*  
*spacing for adjustment of lines of text*

**Feature Column Width**  
*real 12.5*  
*width for display of sample line and symbol in legend*

**Line Colour**  
*input red available colours*  
*the colour of separation lines in the tabulation*

**Symbol Size Default**  
*real 5*  
*default size for symbols in table*

**Rows per table**  
*integer*  
*if blank, the legend table will be created vertically*  
*if non-blank, more than one legend may be created, arrayed in either horizontal or vertical*  
*the format is: +ve number for Horizontal array -ve number for Vertical array*

**Extract Data**  
*button*  
*Sorts the source data and populates either the Map File Extraction grid or Data only Extraction grid*

**Create Legend**  
*button*  
*Creates the tabulation using all parameters set in the general tab*

**Undo Last**  
*button T*  
*his undo is only available while the panel is still open and only works on the last table created.*  
*Once the panel is finished all tables can be accessed via the normal 12d undo.*

**Move Table**  
*button*  
*Any Legend Tabulation can be moved for clarity (Esc or rmb to cancel)*

---

### Symbol Tabulation

**Data Source Tabulation**  
*selection*
selection data to extract tabulation information

**Model**
- model box
  - model name for symbol tabulation

**Textstyle**
- textstyle box
  - text parameters for all text

**Location x y z**
- XYZ box
  - insertion point for top left corner of tabulation

**Heading**
- input
  - if non-blank, heading placed at top of tabulation

**Line colour**
- colour box
  - red
  - available colours
  - the colour of separation lines in the tabulation

**Line spacing**
- real
  - 2
  - spacing for adjustment of lines and text

**Station name**
- input
  - STN
  - maximum 8 characters

**Tabulation by**
- choice box
  - Point ID
  - Point ID / Vertex Text
  - value used to define symbol e.g. Survey Station may use point ID < 901 >

**Process**
- button
  - processes the data

**Create Tab**
- button
  - creates the symbol tabulation using the above parameters.
24.16.20 Text File Input

**Position of option on menu:** Drafting => Text and Tables => Text file input

This option has already been documented as 24.16.3 Text Creation/Edit

Drafting => Text and Tables => Create/edit paragraph text
25 Plots

Position of menu: It is on the main menu as Plot.
The Plots walk-right menu is:

- plot an existing ppf
- edit an existing ppf
- Plot sheet set up and plot
- create/edit/plot plot frames
- Long section plot manager
- plotting set ups
- old plotting options
- Plots User menu

The options 25.2 Plot Binary PPFs and 25.3 Edit Binary PPFs are both walk-right menus which list all the binary PPFs in the project and the when the PPF is double-clicked, it is Plotted/Edited.

For the options see:
- 25.1 Plot and PPF Editors
- 25.2 Plot Binary PPFs
- 25.3 Edit Binary PPFs
- 25.4 Plot Sheet
- 25.5 Plot Frames
- 25.6 Long Plot Manager
- 25.7 Plotting Setups
- 25.8 Old Plotting
25.1 Plot and PPF Editors

Position of menu:  Plot => Plot and PPF editors
The Plot and PPF editors walk-right menu is

- Cross sections
- Long sections
- Plot frames
- Drainage
- Drainage plan
- Melbourne Water
- Pipelines
- Convert ascii to binary
- Copy title data

For the options see:

- 26.3 Section X Plot PPF Editor
- 26.4 Long Plot PPF Editor
- 26.9 Plot Frame and PPF Editor
- 26.5 Drainage Long Plot PPF Editor
- 26.8 Drainage Plan Plot PPF Editor
- 26.6 Melbourne Water Plot PPF Editor
- 26.7 Pipeline Plot PPF Editor
- 26.10 Convert Ascii PPF to Binary
- 26.11 Copy Title Data
25.2 Plot Binary PPFs

The binary PPFs can have enough information in them to totally generate the plot from the ppf.
The options in this section will run the selected (binary) ppfs and generate the plot as defined by all the plot parameters in the ppf file.
The plot the ppf, just walk right on the appropriate plot type and a walk-right menu will appear with the existing binary ppfs included in the project, and a [Lib] and [User Lib] to display the ppfs in these two library areas.
When a file is selected from the list, it is then used to generate a plot.

Go to the next section 25.3 Edit Binary PPFs or return to 25 Plots.

25.3 Edit Binary PPFs

The options in this section will bring up the selected (binary) ppfs into the appropriate PPF Editor.
The edit the ppf, just walk right on the appropriate plot type and a walk-right menu will appear with the existing binary ppfs included in the project, and a [Lib] and [User Lib] to display the ppfs in these two library areas.
When a file is selected from the list, it is then opened in the appropriate PPF Editor.

Go to the next section 25.4 Plot Sheet or return to 25 Plots.
25.4 Plot Sheet

Position of menu:   Plot => Plot sheet

The *Plot sheet* option is for defining the layout of plotting areas on a sheet of paper and to produce a pdf file of what is on the sheet of paper.

That is *Plot Sheet* is for setting up plot compositions. For V11 it is only for setting up areas from plan views.

The *Plot Sheet* menu is:

![Plot Sheet Menu]

See

25.4.1 Plot Sheet Create
25.4.2 Plot Sheet Edit
25.4.3 Plot Sheet Plot
25.4.4 Plot Sheet Delete
25.4.1 Plot Sheet Create

**Position on menu:**   Plot \(\Rightarrow\) Plot sheet \(\Rightarrow\) Create

*Plot sheet create* is for creating a new plot sheet file.

Selecting *Create* brings up the *Create Plot Sheet File* panel.

![Create Plot Sheet File Panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot sheet file</td>
<td>file box</td>
<td>*.*12dpsf files</td>
<td>*.*12dpsf files</td>
</tr>
</tbody>
</table>

*name for the file to create.*

*This file name must not already exist in the working folder.*

<table>
<thead>
<tr>
<th>Create</th>
<th>button</th>
</tr>
</thead>
</table>

*when pressed, a new plot sheet file is created with the name given in the *Plot sheet file* field and then the *Plot Sheet Create/Editor* panel is started with that file as the Plot Sheet File being edited. See 25.4.2.1 Plot Sheet Create/Edit.*

Go to the next section 25.4.2 Plot Sheet Edit or return to 25.4 Plot Sheet.
25.4.2 Plot Sheet Edit

Position on menu:  Plot => Plot sheet => Edit

The Edit option works in two ways - you can click on Edit itself or walk right on Edit and see a list of all the plot sheet files in the working folder.

The Edit walk right lists all the plot sheet files is the working folder.

Selecting a plot sheet file from the list, or from another area, brings up the Plot Sheet Create/Editor panel already loaded with the selected plot sheet file. See 25.4.2.1 Plot Sheet Create/Edit.

By clicking on Edit itself, the Edit Plot Sheet File panel is brought up.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot sheet file</td>
<td>name for the plot sheet file to edit. This file name must exist in the working folder.</td>
<td>file box</td>
<td>*.12dpsf files</td>
<td></td>
</tr>
<tr>
<td>Edit</td>
<td>when pressed, the existing plot sheet file with the name given in the Plot sheet file field is edited and the Plot Sheet Create/Editor panel is started with that file as the Plot Sheet File being edited. See 25.4.2.1 Plot Sheet Create/Edit.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Go to the next section 25.4.2.1 Plot Sheet Create/Edit or return to 25.4 Plot Sheet.
25.4.2.1 Plot Sheet Create/Edit

The Plot Sheet Create/Edit panel is for creating/editing the layout of plotting areas on a sheet of paper, and then to produce a pdf file of what is on the sheet of paper.

If the Plot Sheet Create option was used, then the Plot Sheet Edit panel is brought up with the new file loaded but there is nothing defined for the Plot Sheet.

If the Plot Sheet Edit option was used, then the Plot Sheet Edit panel is brought up with the existing file loaded so there will already be some information defined on the Plot Sheet.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot sheet file</td>
<td>file box</td>
<td></td>
<td>*.12dpsf files</td>
</tr>
</tbody>
</table>

name for the file to save/read in the information for a plot sheet layout.

Read button
read in the plot sheet file given in the Plot sheet file field and load the information into the panel.
For any Frames in the file, a Plot Frame is created, and a model and the Plot Frame added to the
model. If a view has been recorded for that model when the plot sheet file was written, and that view currently exists, then the model is added to that view.

**Write** button
write out the current information defined in the panel to a plot sheet file with the name given in the **Plot sheet file** field.

**Plot Sheet Area**
the black area represents the sheet of paper being plotted (the **Plot Sheet**) with (0,0) in the bottom left hand corner of the plot sheet.

The areas where plotting will occur on the Plot Sheet are defined by **Frames** and each created Frame is displayed in the black area. A Frame contains all the information for producing the plot inside the area of the Frame.

For example, a Frame may be a **Plan Frame** and defines an area of a Plan View to plot. The Frame then needs a Scale to give the Frame a world size, a rotation and a World Coordinate to fully define a region to plot. Using these values, a Plot Frame is then created and linked to the Frame. The Plot Frame is added to a Plan View to define which data is to be plotted inside the Frame.

**Title block** button
brings up the Title Block section of a Plot Frame.

After the title block information has been filled in, the **Set** button must be pressed and then **Finish** to remove the panel.

If the title block file (tbf file) includes the Sheet size, then that size is automatically used to set the sheet size for the **Sheet Size** button.

If a user title block has been selected, the text and line work in the title block will be drawn in the Plot Sheet Area so that you see where to add Frames to the Plot Sheet without overwriting the title block. No
substitution is made for the $ text variables in the title block file.

Sheet size button

brings up a Sheet size box for entering the size of the size of the Plot Sheet. Once a size has been typed in, or selected from the pop up, the Plot Sheet Area is drawn with an aspect ratio to match the selected paper size.

If there is a Sheet size in the selected user title block file, the Sheet size is automatically set to that size and the Sheet Size button does not need to be used.

Create frame button

this button is used to define a Frame in the plot sheet area. After clicking the button, two points are selected in the plot sheet area to define the area on the plot sheet that the Frame will plot to.
Currently all created Frames are Plan Frames so after the Frame is created, the **Create Frame for Plan Plot** panel is displayed. See [25.4.2.1.1 Create Frame for Plan Plot](#).

**Edit frame** button

- this button is used to edit an existing Frame in the plot sheet area.
- After clicking the button, a Frame is selected by clicking LB **anywhere inside** the Frame in the Plot Sheet Area.
- When the Frame has been tentatively picked with the LB but not yet accepted, **Resize** grips are displayed on the four corners and on the four sides of the Frame. These grips are used to resize the Frame, and hence the associated plotting area.
- Plus when the cursor is over the edge of a Frame, a **Translate** grip is displayed. The **Translate** grip is used to move the Frame around in the Plot Sheet Area.
How the *Resize* grips extend the plotting area depends on **Make centre of frame the origin**.

*If Make centre of frame the origin is ticked* then no matter which resize grip is used, the resulting plotting area is still *centred* on the **World Coordinate**.

*If Make centre of frame the origin is not ticked* then the plotting area is extended in the direction indicated by the Resize grip and the **World Coordinate** may be changed.

If you haven’t accepted the Frame after the Resizing and Translating, then you can pick another Frame to resize or translate by simply clicking LB inside the new Frame.

When a Frame is accepted after a tentatively pick, then the **Create Frame for Plan Plot** panel is displayed so that the Frame properties can be modified. See 25.4.2.1.1 Create Frame for Plan Plot.

After the **Create Frame for Plan Plot** panel has been finished, the **Edit** is still active and another Frame can be selected to edit.

**Translate Plot Frame** button

This button is used to change the value of the **World Coordinate** of a Frame by dynamically translating the **Plot Frame** that corresponds to the Frame.

After clicking the button, a Frame is selected by clicking LB anywhere inside the Frame in the Plot Sheet Area and then accepting the pick.

When the Frame is accepted, a **Translate a Frame** panel is displayed showing the value of the **World coordinate** for the Frame. Then when you move the cursor onto a Plan View which has the **Plot Frame** associated with the selected Frame on it, the **World Coordinate** of the Plot Frame and Frame are changed to the current cursor position. This continues until a new **World Coordinate** is selected on the Plan View.
Once the Frame is translated then you can pick another Frame to translate.

**Rotate Plot Frame button**

This button is used to change the value of the Rotation of a Frame by dynamically rotating the Plot Frame that corresponds to the Frame.

After clicking the button, a Frame is selected by clicking LB anywhere inside the Frame in the Plot Sheet Area and then accepting the pick.

When the Frame is accepted, a Rotate a Frame panel is displayed showing the value of the Rotation for the Frame. Then when you move the cursor onto a Plan View which has the Plot Frame associated with the selected Frame on it, the Rotation of the Plot Frame and Frame are changed to the rotation defined by the current cursor position. This continues until a cursor position is accepted and that defines the new Rotation for the Plot Frame and Frame.
Once the Frame is rotated then you can pick another Frame to rotate.

**Delete Frame** button

This button is used to delete a Frame in the **Plot Sheet**. The associated Plot Frame and model containing the Plot Frame are also deleted.

After clicking the button, a Frame is selected by clicking LB anywhere inside the Frame in the Plot Sheet Area and then accepting the pick.

When the Frame is accepted, the Frame is deleted, and its associated Plot Frame and the model containing the Plot Frame are also deleted.

Once a Frame is deleted, another Frame can then be selected to delete.

**Utilities** button

This button brings up the **Plot Sheet Utilities** panel to change the settings for the Plot Sheet.
Background colour  
the colour for the background of the Plot Sheet drawing area. "Grey 105" is a good colour to use because both blank and white strings are visible when drawn on "Grey 105".

Highlight colour  
the colour to highlight the Frames in the Plot Sheet Drawing Area when they are selected.

Frame default colour  
the colour to draw the Frames borders in the Plot Sheet drawing area.

Frame assist on  
if ticked, when a new Frame is being created or an existing Frame moved in the Plot Sheet Area, when the cursor it is near the side of another Frame then guide lines are drawn in the Plot Sheet Area to help in placing the new Frame to be on the same horizontal or vertical line as the sides of existing frames.

Auto bring view to top?  
if ticked, when the buttons Edit Frame or Delete Frame, or Plot Frame Move or Plot Frame Rotate, are selected and a Frame then selected, the View that the corresponding Plot Frame is on is brought to the top so that the View is not obscured by other Views.

Display drawing area  
if ticked and the title block file has a drawing area defined, the n it is shown in the Plot Sheet Area.

The drawing area of the title block when the buttons Edit Frame or Delete Frame, or Plot Frame
Fields and Buttons Under the Plot Sheet Area

PDF file file box *.pdf files

name of the file to write the pdf plot out to.

Plot button

generate a pdf plot with the name given in the PDF file field.

Finish button

when the Finish button is selected, all the Plot Frames and the models containing the plot frames, that have been created by Plot Sheet are deleted.

Go to the next section 25.4.2.1.1 Create Frame for Plan Plot or return to 25.4 Plot Sheet.
25.4.2.1.1 Create Frame for Plan Plot

The **Frame Create** panel defines the information required to create a plan plot in the Frame.

The size of the Frame in **millimetres** is known from the Plot Sheet and so with a **Scale**, the Frame then defines a rectangle in world units (metres).

A **World Coordinate** for one point in the Frame and a **Rotation** then fully defines a world rectangle.

A **Plot Frame** of a given name can then be created and added to a view to represent the information to be plotted in the Frame.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frame name</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>the name for the frame. It must be unique amongst all the Frames for the Plot Sheet.</strong> A name is automatically generated but it can be changed as long as it is still unique for the Plot Sheet. <strong>A Plot Frame</strong> will be created with the name of the plot sheet file (without the .12dpsf) followed by a space and the <strong>Frame name</strong>. A <strong>model</strong> will also be created with the name &quot;<strong>PF</strong>&quot; followed by the Plot Frame Name. The Plot Frame will be added to this model.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frame colour</td>
<td>colour box</td>
<td>available colours</td>
<td></td>

</tr>
<tr>
<td>Rotation</td>
<td>measure box</td>
<td>0 degrees</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>available measures</strong> angle of rotation for the plot frame. The angle is in degrees and is measured in a counter clockwise direction from the positive x axis. <strong>Make centre of frame the origin?</strong> if <strong>ticked</strong>, the <strong>World coordinate</strong> is taken to be the world coordinate for the <strong>centre</strong> of the Frame.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

![Frame Create Panel](image-url)
If not ticked, the World coordinate is taken to be the world coordinate for the bottom left hand corner of the Frame.

World coordinate

input

xyz ops menu

x_origin  y_origin  z_origin

this is a point in world units to be used as either the centre, or the bottom left hand corner, of the Frame. The values can either be typed in as three values separated by spaces, or selected by clicking LB on the xyz ops icon and then picking a point in a plan view.

When the World coordinate is selected from a plan view, then after the Set button is clicked, the plot frame is created, added to the created model, and the model added to the view that the world coordinate was selected from.

Draw viewport

tick box ticked

if ticked, when a plot is generated, a box is drawn around the Frame.

Set

button

when Set is pressed, a Plot Frame of the name plot sheet file (without the .12dpsf) followed by a space and the Frame name is created. A model, with the name "PF " followed by the Plot Frame name, is then created and the Plot Frame is added to this model.

The model containing the Plot Frame is then added to the plan view that the World coordinate was selected from.

Go to the next section 25.4.3 Plot Sheet Plot or return to 25.4 Plot Sheet.
25.4.3 Plot Sheet Plot

**Current position on menu**: Plot ➝ Plot sheet ➝ Plot

*Plot sheet plot* is for plotting a plot sheet file that is on disk without having to bring up the plot sheet file in the *Plot Sheet Editor*.

The *Plot* walk right operates in three ways.

1. The *Plot* walk-right displays a list of all the plot sheet files (*.12dpsf files) and by double clicking on a plot sheet file in the list, the plot sheet file will be run and the associated plots produced.

2. If the walk right *Plot ➝ Plot sheet ➝ Plot* is being displayed from the *Main Menu* on the top of *12d Model*, then clicking on the name *Plot* on the *top of the walk right* will bring up the *Plot Plot Sheet File* panel.

![Plot Sheet File Panel](image1)

Selecting the name of the plot sheet file in the field *Plot sheet file* and then pressing *Plot* will generate the plot.

3. If the walk right is being displayed from a pinned menu, then clicking on *Plot* on the *Plot Sheet menu without walking right* will also bring up the *Plot Plot Sheet File* panel.

![Plot Sheet File Panel](image2)

Again as in the previous case, selecting the name of the plot sheet file in the field *Plot sheet file* and then pressing *Plot* will generate the plot.

Go to the next section 25.4.3 Plot Sheet Plot or return to 25.4 Plot Sheet.
25.4.4 Plot Sheet Delete

Position on menu: Plot -> Plot sheet -> Delete

Plot sheet Delete is for deleting a plot sheet file from disk.

Selecting Delete brings up the Delete Plot Sheet File panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot sheet file</td>
<td>file box</td>
<td>*.12dpsf files</td>
<td></td>
</tr>
</tbody>
</table>

name for the file to be deleted.

Delete button

delete the file given in the Plot sheet file field.

Return to 25.4 Plot Sheet.
25.5 Plot Frames

Position of menu:  Plot ➔ Plot frames

Although plan view plots can be generated in 12d Model by plotting the contents of the plan view with the Plot option, the plot will only have a simple title block.

To create plan plots of an arbitrary size, rotation and scale and with complex title blocks, 12d Model uses plot frames.

Basically a plot frame consists of a sheet size (in mm), margins within the sheet and a scale for the plot. This will define a plotting area in world coordinates (the plot frame).

The plot frame can be arbitrarily positioned and rotated on a plan view.

The Plot frames walk-right menu is

- create a plot frame
- edit an existing plot frame
- change name, model and colour of a plot frame
- copy a frame
- plot one or many plot frames
- rotate a plot frame
- translate a plot frame
- delete a plot frame
- more plot frame options

For the option Create, go to

- 25.5.1 Plot Frame Create
- 25.5.2 Plot Frame Editor
- 25.5.3 Plot Frame Change
- 25.5.3 Plot Frame Change
- 26.9 Plot Frame and PPF Editor
- 25.5.6 Plot Frame Rotate
- 25.5.7 Plot Frame Translate
- 25.5.8 Plot Frame Delete
- 25.5.9 More Plot Frames
25.5.1 Plot Frame Create

Position of option on menu:  Plot => Plot frames => Create

On selecting the Create option, the New Plot Frame Create panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title file</td>
<td>title file box</td>
<td>all title files</td>

</tr>
</tbody>
</table>

name for the title file to use when plotting the plot frame. The title block file can contain default information for the rest of the panel fields. See 26.2.6.5 Values Used for Defaults when Creating Plot Frames

name for the plot frame.

the model for the plot frame.

the colour for the plot frame.

scale for the plot.

the width and height values (separated by spaces) or the name of a user defined sheet size.

angle of rotation for the plot frame.
origin (in world units) for the corner of the plot frame - given as three values separated by spaces. The values can either be typed in, or selected by clicking LB in the origin panel view and getting up the xyz ops menu and selecting the pick xyz option.

**Draw viewport border**
- tick box: ticked
  - if ticked, plot the box around the plotting area (viewport).

**Draw Frame border**
- tick box: not ticked
  - if ticked, plot the box around the frame.

**Create**
- button
  - create the plot frame and then put up the plot frame edit panel for the created plot frame.

**Same as**
- button
  - after picking the Same as button, an existing plot frame is selected and its information is used to fill in the above panel fields.

**Margin tab**

**Left/right margin (mm)**
- 10.0
  - the left/right hand side margin between the sheet and the plotting area inside the sheet.

**Bottom/top margin (mm)**
- 10.0
  - the bottom/top margin between the sheet and the plotting area inside the sheet.

**How To Use the Option**

The plot frame contains all the information required to define the physical area in real world units to be plotted, the position on the sheet of the area being plotted, the plotter type and the plot file name.

Once the frame is created, the New Plot Frame Edit panel for the created plot frame is automatically placed on the screen so that the frame’s position can be adjusted using the Translate and Rotate buttons.

Go to the next section 25.5.2 Plot Frame Editor or return to 25.5 Plot Frames.
25.5.2 Plot Frame Editor

Position of option on menu: Plot => Plot frames => Editor

The plot frame editor is used to edit existing plot frames. It is automatically placed on the screen when a plot frame is created so that the frame’s position can be adjusted using the Translate and Rotate buttons.

On selecting the Editor option, the New Plot Frame Edit panel is displayed.

Most of the fields and buttons used in this panel are the same as the New Plot Frame Create panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

name for the title file to use when plotting the plot frame. The title block file can contain default information for the rest of the panel fields. See 26.2.6.5 Values Used for Defaults when Creating Plot Frames.

name for the plot frame.

the model for the plot frame.

the colour for the plot frame.

scale for the plot.
**Sheet size wd ht (mm)** choice box available sheet sizes
the width and height values (separated by spaces) or the name of a user defined sheet size.

**Rotation angle** measure box 0 degrees available measures
angle of rotation for the plot frame.

**Origin** input

\[ x_{\text{origin}} \quad y_{\text{origin}} \quad z_{\text{origin}} \]

origin (in world units) for the corner of the plot frame - given as three values separated by spaces. The values can either be typed in, or selected by clicking LB in the origin panel view and getting up the xyz ops menu and selecting the pick xyz option.

**Draw viewport border** tick box ticked
if ticked, plot the box around the plotting area (viewport).

**Draw Frame border** tick box not ticked
if ticked, plot the box around the frame.

**Pick** button
select the plot frame to be edited.

**Set** button
update the plot frame with the information in the above panel fields.

**Translate** button
after picking the Translate button, the plot frame will move with the cursor until a point is selected to give the final position of the plot frame.

**Rotate** button
after picking the Rotate button, the plot frame is further rotated around the left hand corner of the sheet, by the angle made between the rotation point and the current cursor position. The plot frame will continue to rotate until a point is selected to fix the rotation angle.

**Margin tab**

- **Left/right margin (mm)** 10.0
the left/right hand side margin between the sheet and the plotting area inside the sheet.

- **Bottom/top margin (mm)** 10.0
the bottom/top margin between the sheet and the plotting area inside the sheet.

Go to the next section 25.5.3 Plot Frame Change or return to 25.5 Plot Frames.
25.5.3 Plot Frame Change

Position of option on menu: Plot -> Plot frames -> Change

The change option is used to modify a plot frame's name, model or colour.

On selecting the change option, the Plot Frame Change panel is displayed.

![Plot Frame Change Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>New name</td>
<td>name box</td>
<td>available names</td>
<td>if non-blank, then the name of the selected plot frame will be changed to the name given in the new name field.</td>
<td></td>
</tr>
<tr>
<td>New model</td>
<td>model box</td>
<td>available models</td>
<td>if non-blank, then the selected plot frame will be moved to the model given in the new model field.</td>
<td></td>
</tr>
<tr>
<td>New colour</td>
<td>colour box</td>
<td>available colours</td>
<td>if non-blank, then the colour of the selected plot frame will be changed to the colour given in the new colour field.</td>
<td></td>
</tr>
</tbody>
</table>

Pick button
select the plot frame to be changed.

Change button
update the plot frame with the information in the above panel fields.

Go to the next section 25.5.4 Plot Frame Copy or return to 25.5 Plot Frames.
25.5.4 Plot Frame Copy

Position of option on menu: Plot => Plot frames => Copy

The copy option is used to make a copy of a plot frame. On selecting the Copy option, the Plot Frame Copy panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model for frame</td>
<td>model box</td>
<td>available models</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dx dy</td>
<td>input</td>
<td>xyz ops menu</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Model for frame**: If blank, then the model of the copied plot frame will be the same as that of the picked frame. If non-blank, then the copied plot frame will be placed in the model given in the model for frame field.
- **dx dy**: Translation in world units to apply to the copied plot frame - given as two values separated by spaces.
- **Pick**: Select the plot frame to be copied - the copy will be made as soon as the selected plot frame is accepted.

Go to the next section 25.5.5 Plot Frame Plot or return to 25.5 Plot Frames.
25.5.5 Plot Frame Plot

**Position of option on menu:**  Plot => Plot frames => Plot

The Plot option is an alternative way of bringing up the Plot Frame PPF Editor panel. See [26.9 Plot Frame and PPF Editor](#).

Go to the next section [25.5.6 Plot Frame Rotate](#) or return to [25.5 Plot Frames](#).
25.5.6 Plot Frame Rotate

Position of option on menu: Plot => Plot frames => Rotate

The Rotate option is used to rotate a plot frame about a selected point.

On selecting the Rotate option, the Plot Frame Rotate panel is displayed.

![Plot Frame Rotate Panel]

The buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rotate button</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

after picking the Rotate button, the user is first asked to select a plot frame to rotate, and then to selected a point to rotate about. Once the rotation point has been selected, the plot frame is further rotated by the angle made between the rotation point and the current cursor position. The plot frame will continue to rotate until a point is selected to fix the rotation angle.

The option then repeats.

Go to the next section 25.5.7 Plot Frame Translate or return to 25.5 Plot Frames.
25.5.7 Plot Frame Translate

Position of option on menu: Plot -> Plot frames -> Translate

The Translate option is used to translate a plot frame.

On selecting the Translate option, the Plot Frame Translate panel is displayed.

The button used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Move</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

After picking the Move button, the user is first asked to select a plot frame to translate. Once the plot frame has been selected, the plot frame will move with the cursor until a point is selected to give the final position of the plot frame.

The option then repeats.

Go to the next section 25.5.8 Plot Frame Delete or return to 25.5 Plot Frames.
25.5.8 Plot Frame Delete

**Position of option on menu:**  Plot => Plot frames => Delete

The `Delete` option just gets up the standard **String Delete** panel which can be used to delete plot frames as well as strings. See [14.19 Delete](#).

Go to the next section [25.5.9 More Plot Frames](#) or return to [25.5 Plot Frames](#).
25.5.9 More Plot Frames

Position of menu: Plot => Plot frames => More

This menu contains options to create plot frame seeds, insert plot frame seeds into a view and create plot frames along a string.

The More Plot Frames walk-right menu is

```
<table>
<thead>
<tr>
<th>More Plot Frames</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot frames along string</td>
</tr>
<tr>
<td>Plot frame insert</td>
</tr>
<tr>
<td>Plot frame seed create</td>
</tr>
</tbody>
</table>
```

Each option in this menu will now be described.

For the option *Plot frames along string*, go to

- 25.5.9.1 Create Plot Frames along String
- 25.5.9.2 Insert Plot Frame
- 25.5.9.3 Create Plot Frame Seed
25.5.9.1 Create Plot Frames along String

Position of option on menu:  Plot => Plot frames => More => Plot frames along string

On selecting the plot frames along string option, the create plot frames along string panel is displayed.

![Create Plot Frames along String Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alignment string</strong></td>
<td>string select</td>
<td></td>

<td>if non-blank, add to plot frame to this view.</td>
</tr>
<tr>
<td>Process</td>
<td>button</td>
<td>insert the selected seed plot frame at the given location at the given scale.</td>
<td></td>
</tr>
</tbody>
</table>

How To Use the Option

The selected plot frame is inserted at the given location with the given scale.

Go to the next section 25.5.9.3 Create Plot Frame Seed or return to 25.5.9 More Plot Frames or 25.5 Plot Frames.
25.5.9.3 Create Plot Frame Seed

Position of option on menu: Plot => Plot frames => More => Plot frame seed create

On selecting the Plot frame seed create option, the Plot Frame Seed Create panel is displayed.

![Plot Frame Seed Create Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pick</td>
<td>string select</td>
<td>pick the plot frame to add to the plot frame seed library.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Set</td>
<td>button</td>
<td>add the selected plot frame to the plot frame seed library.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

How To Use the Option

The plot frame contains all the information required to define the physical area in real world units to be plotted, the position on the sheet of the area being plotted, the plotter type and the plot file name.

The Plot Frame Seed Create panel adds selected plot frames to a library of plot frame seeds. The seeds from the library can be inserted in a plan view using the Insert plot frame seed option.

Return to 25.5.9 More Plot Frames or 25.5 Plot Frames.
25.6 Long Plot Manager

Position on menu:  Plot ➞ Long plot manager

This section of documentation is a work in progress and will be updated in subsequent releases.

Selecting Long plot manager brings up the Longsection PPF Manager panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>

Go to the next section 25.7 Plotting Setups or return to 25 Plots.
25.7 Plotting Setups

Position of menu: Plot ➞ Plotting setups

The Plotting setups walk-right menu is:

- Create/edit title block file
- Read title block file
- Pen mapping – colours.4d
- Plotter mapping editor
- Pixels to mm
- Hardware arcs
- Default DPI
- Interface colours
- ACAD plot map file
- DWT plot template file
- DGN plot seed file

For the options, go to:

- 25.7.1 Create/Edit Title Block File
- 25.7.2 Read Title Block
- 25.7.3 Pen Mapping
- 25.7.4 Plotter Mapping File Editor
- 25.7.5 Pixels to mm
- 25.7.6 Hardware Arcs
- 25.7.11 DGN Plot Seed File
- 25.7.8 Default DPI
- 25.7.9 ACAD Plot Map File
- 25.7.10 DWT Plot Template File
- 25.7.11 DGN Plot Seed File
25.7.1 Create/Edit Title Block File

Position of option on menu: Plot => Plotting setups => Create/edit title block file
Position of option on menu: Drafting => Create title block file

This option is used to create a title block file from string data in a model or a view. If it is a model, the model attributes can also contain information that is used for creating plot frames. For example, Sheet size, left/right margins, etc.).

The data in the model/view should be set up with (0,0) representing the left hand bottom of the plotting sheet and the units in model/view represent millimetres on the paper. So text should be defined with World units and a metre in world units is taken to be a millimetre in the title block itself. That is, a text size 5 world units will plot as 5 mm.

For more information and the format of the title block file, go to the section 26.2.6 Title Block.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Model/View</td>
<td>model/view box</td>
<td>available models/views</td>
<td></td>
</tr>
</tbody>
</table>

the data in this model/view is written to the title block file to be used as the linework and text in a title block.

The Set button is used to create model attributes for the information in the Plot frame parameters.
section, so if the Set button is to be used, then only a Data Model can be used here.

Plot frame parameters
these parameters are written to an info block in the title block file and are only used when defining a plot frame using the option Plot =>Plot frames =>Create. The parameters can also be written as attributes in the Data Model using the Set button.

Name
if not blank, the name to use for the plot frame.

Model
model box available models
if not blank, model for the plot frame.

Colour
colour box available colours
if not blank, colour for the plot frame.

Scale 1:
input
if not blank, scale for the plot frame

Sheet size
input available sheet sizes
if not blank, sheet size for the plot frame

Angle
angle box
if not blank, angle of the plot frame - measured anticlockwise from the positive x-axis

Left margin, Right margin, Top margin, Bottom margin
margins for the plot frame

Draw viewport border
 tick box tick
if ticked, a border is drawn around the view port in the colour of the plot frame.

Title block file
file box *.tbf files
name of the file to contain the title block information.

Set
button
save the plot frame parameters as attributes in the Data model.

Write
button
run the option – create the title block file.

Go to the next section 25.7.2 Read Title Block or return to 25.7 Plotting Setups or 25 Plots.
25.7.2 Read Title Block

Position of option on menu: Plot => Plotting setups => Read title block file

The Read title block file option is for reading in a title block file and placing the lines, arcs and text defined in the title block file into a given model.

On selecting the Read title block file option, the Read Title Block File panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

Go to the next section 25.7.3 Pen Mapping or return to 25.7 Plotting Setups or 25 Plots.
25.7.3 Pen Mapping

This option brings up the Edit Colours panel which has a column Pen No. that is used as the default pen number that a colour is mapped to.

The individual colour-to-pen numbers may be overridden by a pen mapping file.

For more information on this option, go to the section 4.22 Colours.

Go to the next section 25.7.4 Plotter Mapping File Editor or return to 25.7 Plotting Setups or 25 Plots.
25.7.4 Plotter Mapping File Editor

Position of option on menu: Plot => Plotting Setups => Plotter mapping file editor

The Plotter Mapping Editor is used to create a plotter mapping file (pmf file) which is used when making a plot from 12d Model. The plotter mapping file defines:

(a) the mapping from 12d Model colours to the plotter pens
(b) the rgb (colours) and weights for the plotter pens

When defining Plotters Different plotter mapping files are used for different plotter configurations. For example, different plotter mapping files would be used when plotting the same plot in 12d Model to a mono-colour plotter or to a colour plotter.

For plotting to a mono-colour plotter, 12d Model colours would be mapped to the one black pen but with possible different weights for different colours. So only one pen colour would be needed and its colour would be set to black (Red 0, Green 0 and Blue 0).

For plotting to a colour plotter, 12d Model colours could be mapped to different colours and weights on the plotter.

The text definition of the plotter mapping file is given in the next section 25.7.5 Pixels to mm.

On selecting the Plotter mapping editor option, the Create Plotter Mapping File panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map file</td>
<td>file box</td>
<td>* .pmf file</td>

12d Colour colour box  
the 12d colour to define the pen mapping for.

Use Pen Number integer box  
the number of the pen on the plotter for the 12d colour to be mapped to.

Weight real number box  
the weight to use for the plotter pen for the given 12d colour.

Define Pen Colours tab

Pen Number integer box  
the number of the plotter pen to define the colour for.

Red/Green/Blue input  
the value between 0 and 255 of red/green/blue to be used for the colour of the plotter pen.

Go to the next section 25.7.5 Pixels to mm or return to 25.7 Plotting Setups or 25 Plots.
25.7.5 Pixels to mm

**Position of option on menu:** Plot => Plotting setups => Pixels to mm

To plot an object, it must be possible to calculate the size in millimetres that the object will have in the plot.

However, in 12d Model it is possible for text and linestyles to be defined in the screen unit pixels, and since the size of a pixel varies between screens, there is no direct millimetre equivalent for a pixel.

To allow text and linestyles with only a pixel size to be plotted, a factor to convert pixels to millimetres is used.

When plotting, all text and linestyles defined only in pixel units are multiplied by the pixels-to-millimetre factor to determine its size in the plot.

On selecting the Pixel to mm option, the Pixels to Millimetres Plot Factor panel is displayed.

![Pixels to Millimetres Plot Factor panel](image)

To define a new factor, simply type the value into the Factor field and select Set.

The pixel-to-millimetres value is stored for the project.

For a new project, the initial value is loaded from the Defaults file and is defined in the file by

```
PIXELS TO MM PLOT FACTOR value
```

For information on the Defaults file, see 39.2.7.3 Defaults File (defaults.4d).

Go to the next section 25.7.6 Hardware Arcs or return to 25.7 Plotting Setups or 25 Plots.
25.7.6 Hardware Arcs

Position of option on menu: Plot => Plotting setups => Hardware arcs

When plotting arcs, the arc can either be broken into a series of straight lines within 12d Model, or plotted using the arc command (if it exists) for the relevant plotter.

The initial default for hardware arcs is set by the environment variable HARDWARE_ARCS_4D, but this can be overridden by the option Plots => Plotter setups => Hardware arcs.

This option allows the user to choose whether

(a) the plotter arc command is used (hardware arcs)

or

(b) before plotting, the arc is broken into a series of lines.

On selecting the hardware arcs option, the Draw Hardware Arcs panel is displayed.

To use hardware arcs in plots, simply change the Draw arcs in hardware tick box to tick and select Set.

Go to the next section 25.7.7 Interface Colours or return to 25.7 Plotting Setups or 25 Plots.
25.7.7 Interface Colours

**Position of option on menu:** Plot => Plotting setups => Interface colours

When drawing interface strings in 12d Model, cut areas are denoted in red, fill areas in green and sections on the surface in yellow (and yellow if the section became undefined).

However, when plotting it is convenient to map the interface colours to other colours.

This panel is used to define new colours for the interface colours, and the new colours are then mapped to pens using the pen mapping table or plotter mapping file.

On selecting the interface colours option, the plotting colours for interface string panel is displayed.

![Plotting Colours for Interface Strings](image)

To define new colours, simply type the values into the appropriate panel fields and select Set.

**Note** - the new interface colours are not used for displaying interface strings in 12d Model, only for plotting.

Go to the next section 25.7.8 Default DPI or return to 25.7 Plotting Setups or 25 Plots.
25.7.8 Default DPI

**Position of option on menu:**  Plot =>Plotting setups => Default DPI

The *DPI* value give the default dots per inch that is used for plotting rasters.

On selecting Default DPI, the Default Raster DPI panel is displayed.

![Default Raster DPI Panel](image)

To define a new Default DPI, simply type the value into the DPI panel fields and select Set.

Go to the next section 25.7.9 ACAD Plot Map File or return to 25.7 Plotting Setups or 25 Plots.
25.7.9 ACAD Plot Map File

Position of option on menu: Plot -> Plotting setups -> ACAD plot map file

When plotting to AutoCAD, an AutoCAD map file can be used which uses the 12d Model colour of an entity in the plot as a key to mapping the entity into AutoCAD.

On selecting the ACAD plot map file option, the AutoCAD Map File Create/Edit panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map file</td>
<td>file box</td>
<td></td>
<td>* .amf files</td>
</tr>
<tr>
<td>Read</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Write</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Grid</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>12d Colour</td>
<td>colour box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Acad Layer</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The definition of the amf file is given in 43.2.1.2 Definition and Example of a .tbl File

the 12d colour to match against. This can include wild cards * and wild characters ?.

the name for the file to save/read in an AutoCAD mapping file.

read in the amf file given in the Map file field and load the information into the panel.

write out the current information defined in the panel to an amf file with the name given in the Map file field.
Acad Colour text box
the AutoCAD colour. This can only be a number between 0 and 256 or BYLAYER.
This can be BYLAYER which will be for AutoCAD BYLAYER.
Use * for the 12d Model colour.

Acad linestyle text box
the AutoCAD line type.
This can be BYLAYER which will be for AutoCAD BYLAYER.
Use * for the 12d Model linestyle.

Acad Textstyle text box
Not currently used. The AutoCAD text style.
Use * for the 12d Model text style.

Comment text box
comment about this line of data.

Go to the next section 25.7.10 DWT Plot Template File or return to 25.7 Plotting Setups or 25. Plots.
25.7.10 DWT Plot Template File

Position of option on menu: Plot =>Plotting Setups =>DWG plot template file

When creating plot files in AutoCAD format, an AutoCAD template file can be used.

On selecting the DWT plot template file option, the AutoCAD Plotter Drawing Template File panel is displayed.

To define an AutoCAD plot seed file to use for AutoCAD plotting, simply select either DWG or DXF for the File format, type the file name into the plot seed file panel field and select set.

25.7.11 DGN Plot Seed File

Position of option on menu: Plot =>Plotting Setups =>DGN plot seed file

When creating plot files in Microstation DGN format, a Microstation DGN seed file can be used.

A DGN seed file can be pointed to by the environment variable DGN_PLOT_SEED_FILE_4D and a folder containing the seed files can be pointed to with the environment variable MS_SEEDFILES_4D.

The Microstation seed file can also be set by this option.

On selecting the DGN plot seed file option, the DGN Plot Seed File panel is displayed.

To define a Microstation IGDS plot seed file to use for Microstation plotting, simply type the file name into the Plot seed file panel field and select Set.

Return to 25.7 Plotting Setups or 25 Plots.
25.8 Old Plotting

**Position of menu:** Plot ➝ Old plotting

The Old plotting walk-right menu is

```
Old Plotting
Edit a ppf ➝
Plot a ppf ➝
X plot
Long plot
Long Section Plot Many
Drainage/Sewer
Melbourne Water
Pipeline
Edit title block alias data
Create plot frame
Edit plot frame
Plot plot frame
```

For the option *Edit a ppf*, go to

- 25.8.1 *Edit a ppf*
- 25.8.2 *Plot a ppf*
- 25.8.3 *X Plot*
- 25.8.4 *Long Plot*
- 25.8.5 *Plot Many Long Sections*
- 22.9.2 *Drainage Longsections*
- 22.9.3 *Melbourne Water*
- 22.5 *Plots*

*Edit title block alias data* 25.8.9 *Edit Title Block Alias Data*

*Create plot frame* 25.8.10 *Create Old Plot Frame*

*Edit plot frame* 25.8.11 *Editor Old Pot Frame*

*Plot plot frames* 25.8.12 *Plotting Old Plot Frames*
25.8.1 Edit a ppf

**Position of option on menu:** Plot => Old plotting => Edit a ppf

The *Edit a ppf* option is used to edit V5 text plot parameter files (*.ppf) with the editor pointed to by the `EDITOR_4D` environment variable.

The *Edit a ppf* walk-right menu provides a list all the plot parameter files (files ending in .ppf) in the current folder.

When a file is selected from the list, it is loaded into the editor pointer to by the environment variable `EDITOR_4D`. 

![Edit a ppf menu](image)
25.8.2 Plot a ppf

Position of option on menu: Plot => Old plotting => Plot a ppf

The V5 text PPFs for long section, cross section and plot frames can have enough information in them to totally generate the plot from the pff. The plot a pff option is used to plot such a plot parameter file (*.ppf).

The Plot a pff walk-right menu provides a list all the plot parameter files (files ending in .ppf) in the current folder.

When a file is selected from the list, it is then used to generate a plot.

Note - the plot parameter file is defined in 44 Text Plot Parameters.
25.8.3 X Plot

Position of option on menu: 
Plot => Old plotting => X plot

The X plot option is used to make the traditional pages of cross-section plots, that is, stacked x-sections, with offsets and elevations labelled for each cross section string, and elevations displayed for each of the tins on the section view.

For 12d Model V5, each string to be plotted is assumed to be on a straight line in plan. Hence the cross section is taken as a straight line from the first point of the string to the last point of the string. The chainage of the first point of the string is used as the offset.

For 12d Model V6 and above, sections do not have to be a straight line in plan. The chainage of the first point of the string is used as the offset.

The format of the x-section plot is partially controlled by fields in the Section X Plot panel but more extensive control is possible using a plot parameter file (*.ppf). The plot parameter file is fully documented in the 44.2 Cross Section Plot Parameter File section of the Appendix, 44 Text Plot Parameters.

The cross section plot is tailored by using the plot parameter file (.ppf file) given in the plot parameters field. A default .ppf file is set by pointing to it with the environment variable

```
X_SECTION_PPF_4D pathname of default .ppf file
```

In the pathname to the default .ppf file, $LIB is used to stand for the library folder set by LIB_4D. For example, “$LIB/cross.ppf” is the file cross.ppf in the library area.

Which x-sections are to be plotted is specified by giving the model containing the appropriate cross sections. Sections are also drawn through any triangulations and service items on the section view. Vertical exaggeration, services and corridor settings are taken from a plot parameter file or from the settings for the section view.

X-sections can be labelled with either the offset from the centreline and heights for each of the x-section points, or simply the position of the centre-line.

The required page size is given, plus the scale (the vertical exaggeration is taken from the view settings) and the sections are then plotted in columns on the plotter page. Once a page is full, a new plot page is automatically begun.

The stacked x-section plots in each column can be lined up by their centre-lines.

After selecting the X plot option, the Cross Section Plot panel is displayed.

The Title button on the bottom of this panel controls the use of a title block file and the plotting of a border and two lines of title. If the title button is selected, the Cross Section Plot Title panel is displayed.
The fields and buttons used in the first panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plot parameters</strong></td>
<td>file box</td>
<td>X_SECTION_PPF.4D</td>
<td>available *.ppf files</td>
</tr>
</tbody>
</table>

File of plot parameters used for extra control of the x section plot. The default .ppf file is pointed to by the environment variable X_SECTION_PPF_4D.

For more information on the x section plot parameters, please go to the section 44.2 Cross Section Plot Parameter File in the Appendix 44 Text Plot Parameters.

| Plot parameters write                  | file box    | available *.ppf files  |                          |

File to write a copy of the plot parameters necessary to regenerate the plot.

| Section view                          | input/output | current view           | available views          |

Section view to use for plot definitions such as the tins to profile, the models of services, corridor width and vertical exaggeration.

| Model of X-sections                   | model box    | available models       |                          |

The model containing all the x-sections to be plotted. The x-sections are plotted in the same order as they are in the model.

Each string to be plotted is assumed to be on a straight line in plan. Hence the cross section is taken as a straight line from the first point of the string to the last point of the string. The chainage of the first point of the string is used as the offset.
Plotter type
------------------------
**input**  
**hp**  
**hp, dxf, postscript etc.**

*file format for the plot output.*

Plot file stem
------------------------
**input**  
since more that one plot page may be produced, the plot file stem plus a plot page sequence number followed by the ending for the plotter type is used as the plot file names.

Start/end chainage
------------------------
**input**  
the plots cover the chainage range for the cross sections given by the start and end chainage fields. If the start/end chainage is blank, the star/end chainage of the x-section strings are used.

Sheet size wd ht (mm)
------------------------
**choice box**

Chapter 25  Plots

The fields and buttons in Title tab are:

- **Use title file** tick box not ticked
  
  *if ticked, a user defined title block file is used.*

- **Standard Title** tick box ticked
  
  *if ticked, the standard 4D Solutions border and two lines of title are placed on the bottom of the plot*

- **Title file** file box available *.tf files
  
  *if non-blank and use title file is set to tick, then the file given in this field is used to generate a user defined title block for the plot.*

- **Title line 1/2** input
  
  *first/second line of title information*

- **Title height (mm)** input 5
  
  *height (in millimetres) to draw the characters in the two lines of title information.*

- **Title colour** input cyan available colours
  
  *colour used for the border and the title information.*
25.8.4 Long Plot

**Position of option on menu:** Plot => Old plotting => Long plot

The Long plot option is used to make traditional long section plots with string chainages and elevations labelled for the primary string and elevations and depths displayed for each of the tins on the section view.

The format of the long section plot is partially controlled by fields in the section long plot panel but more extensive control is possible using a plot parameter file (*.ppf). The plot parameter file is fully documented in the 44.3 Long Section Plot Parameter File section.

After selecting the Long plot, the Long Section Plot panel is displayed.

The long section plot is tailored by using the plot parameter file (.ppf file) given in the plot parameters field. A default .ppf file is set by pointing to it with the environment variable

```
LONG_SECTION_PPF_4D pathname of default .ppf file
```

In the pathname to the default .ppf file, $LIB is used to stand for the library folder set by LIB_4D. For example, "$LIB/long.ppf" is the file long.ppf in the library area.

The title button on the bottom of this panel controls the use of a title block file and the plotting of a border and two lines of title. If the title button is selected, the section long plot title panel is displayed.

The pagination button on the bottom of this panel controls whether the long section plot is broken into pages, by a chainage length or millimetres of plot.

If the pagination button is selected, the Section long plot pagination panel is displayed.

</table>
name of the file to write out the long section plot to.

Start/end chainage  
input

the plot covers the chainage range given by the start and end chainage fields. If the start/end chainage is blank, the start/end chainage of the primary string is used.

Chainage increment  
input 100

chainage increment to label the long plot with chainage and height values.

Sheet size wd ht (mm)  
input available sheet sizes

The width and height values (separated by space) or the name of a user defined sheet size.

Scale 1:  
input

horizontal scale for the plot. The vertical scale is taken from the ppf or the section view.

Plot primary string  
tick box ticked

if ticked, the primary string is plotted along with any horizontal geometry displayed in the section view.

Use HG VG for min, max  
tick box ticked

if ticked, the chainage range available for plotting is from the minimum of the horizontal geometry (HG) and the vertical geometry (VG) to the maximum of the HG and VG. Useful for kerb returns.

If not ticked, the chainage range available for plotting is from the minimum of the horizontal geometry (HG) to the maximum of the HG.

Label depths  
tick box ticked

if ticked, label in boxes at the bottom of the plot, the distance between the primary string and the tins.

Text style  
input 1

text style to be used in the long section plot boxes.

Box text ht (mm)  
input 3

height (in millimetres) to plot the chainage and elevations in the boxes in the long section plot.

Box colour  
colour box cyan available colours

colour used for the chainage text and the boxes.

Datum value  
input

if non-blank, the value to be used as a datum. If blank, then a suitable datum value will be calculated.

Offset model  
input available models

if non-blank, then all the strings in the offset model will be projected onto the primary string and drawn and labelled on the long section plot.

Title tab  
brings up the section long plot title panel.

Use title file  
tick box not ticked

if ticked, a use supplied title block file is used.

Standard Title  
tick box ticked

if ticked, the standard 4D Solutions border and two lines of title are placed on the bottom of the plot.

Title file  
file box available *.tf files

if non-blank and use title file is set to tick, then the file given in this field is used to generate a user defined title block for the plot.

Title line 1/2  
input

first/second line of title information
Title height (mm) input 5

Height (in millimetres) to draw the characters in the two lines of title information.

Title colour colour box cyan available colours

Colour used for the border and the title information.

Pagination tab

Brings up the section long plot pagination panel.

Pagination tick box ticked

If ticked, the long section plot is broken into separate plots of length given in the length field, from the start chainage to the end chainage. If the overlap field is non-zero, then each page of the long section plot also includes the overlap value of the end of the previous page of plot.

The units for length and overlap can be either chainage distance or millimetres on the plot page.

Hence apart from the first page and possibly the last page, the plot will have a total length given by the sum of the length and the overlap panel fields.

Pagination mode input chainage chainage, millimetres

The units for length and overlap can be either chainage distance or millimetres on the plot page.

If pagination mode is set to chainage, the units are chainage distance.

If pagination mode is set to millimetres, the units are millimetres on the plot.

Length measure box 600

If pagination is set to ticked, the length of new plot to be included in the current plot.

Overlap measure box 25

If pagination is set to ticked, the length of the previous plot page to be included in the current plot.

Plot button

Write out the plot for the long section plot between the chainages given in the start and end chainage fields. The format of the file is given by the plotter type.
25.8.5 Plot Many Long Sections

**Position of option on menu:** Plot => Old plotting => Long Section Plot Many

The Long Section Plot Many option is used to plot individual long section plots for each string selected by the Data source.

On selecting the Long Section Plot Many option, the Section Long Plot Many panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data to plot</td>
<td>- Data source type</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data source</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Plot parameters</td>
<td>file box</td>
<td>* .ppf files</td>
<td></td>
</tr>
<tr>
<td>Section view</td>
<td>view box</td>
<td>available views</td>
<td></td>
</tr>
<tr>
<td>Plotter type</td>
<td>input</td>
<td>hp</td>
<td>available plotters</td>
</tr>
<tr>
<td>Plot file</td>
<td>input</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When the Plot button is selected, individual long section plots will be created for all the strings selected in the data source field.
25.8.6 Drainage/Sewer Plot

**Position of option on menu:** Plot => Old plotting => Drainage/Sewer

The Drainage/Sewer option is for creating drainage and/or sewer long-section plots.

The option has already been described under Design => Drainage-sewer => Plots.

See [22.9.2 Drainage Longsections](#).

25.8.7 Melbourne Water Sewer Plot

**Position of option on menu:** Plot => Old plotting => Melbourne Water

The Melbourne Water option is for creating sewer long-section plots to Melbourne Water specifications.

The option has already been described under Design => Drainage-sewer => Plots.

See [22.9.3 Melbourne Water](#).
25.8.8 Pipeline Plot

**Position of option on menu:**  Plot => Old plotting => Pipeline

The Pipeline option is for creating pipeline long-section plots.

Given the plot sheet size and the horizontal and vertical scales, the longsections for the pipelines are plotted starting at the top of the sheet and moving across the sheet. Once one row is full, if there is room the plot moves down the page and begins a new row. When a plot sheet is full, a new plot sheet is automatically begun.

The pipeline plots include

- the horizontal and vertical joint deflection at any vertical intersection points which have no curves on them
- the natural surface height and chainage at any pegs or positions from the specials model, plus the invert level and depth to pipe at the position
- for any services which cuts the pipeline, the name, diameter, invert level, the distance along the pipeline of the cut point plus the invert level and depth of the invert for the pipeline and the cut point.

After selecting the Pipeline option, the Plot Pipeline Network panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plot parameters</strong></td>

</tr>
<tr>
<td>the section view to be used to define the vertical exaggeration, corridor widths, tins to section through, services models to section etc.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Plot file stem</strong></td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>since more that one plot page may be produced, the plot file stem plus a plot page sequence number followed by .plt is used as the plot file names.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Specials model</strong></td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>model of text strings which are used as extra labels for the plots.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Peg interval</strong></td>
<td>input</td>
<td>50</td>
<td></td>
</tr>
</tbody>
</table>
| if the specials model is blank, the pipelines are labelled with the text **peg** at the peg interval along the
pipeline.

Scale 1:  
horizontal scale for plotting the pipeline long sections. The vertical exaggeration is taken from the section view given in the section view field.

Sheet size wd ht (mm)  
input  
available sheet sizes

if non-blank, the width and height values in millimetres (separated by space) or the name of a user defined sheet size.
If blank, the sheets size is calculated to fit the long section plot.

Pipeline line ht (mm)  
input  
the maximum allowable height for a longsection plot for a pipeline line. Datum breaks are applied to any part of the longsection that will not fit into the pipeline line ht.

Start plot chainage  
input  
If blank, the start chainage of the pipelines is used; if non blank, the plots start at this chainage for each pipeline.

End plot chainage  
input  
If blank, the end chainage of the pipelines is used; if non blank, the plots finishes at this chainage for each pipeline.

Plot  
button  
write out the pipeline longsection plots for the pipelines in the model given in the network model field.
The fields and buttons for margin tab:

**Left/right margin (mm)** 10.0

the left/right hand side margin between the sheet and the plotting area inside the sheet.

**Bottom/top margin (mm)** 10.0

the bottom/top margin between the sheet and the plotting area inside the sheet.

The fields and buttons for the title tab:

**Use title file** tick box

*if ticked, a user defined title block file is used.*

**Use Standard title** tick box tick

*if ticked, the standard border and two lines of title are placed on the bottom of the plot*

**Title file** input *.tf

*if non-blank and use title file is set to tick, then the file given in this field is used to generate a user defined title block for the plot.*

**Title line 1/2** input

*first/second line of title information*

**Title height (mm)** input 5

*height (in millimetres) to draw the characters in the two lines of title information.*

**Title colour** input cyan available colours

*colour used for the border and the title information.*
25.8.9 Edit Title Block Alias Data

**Position of option on menu:** Plot => Old Plotting => Edit title block data

NO LONGER USED IN V7

This panel is used to easily change to data in your drawing title blocks (set values for the user_text_n field in a title file).

The **Title block ppf** is the ppf that is created by the panel. You may want to create a title block ppf for every drawing you create. This way you can easily re-plot a drawing with the same title block data. This is the ppf name that you will use in the future plot panels when you are ready to plot using the title block.

The **Base ppf** field is an existing ppf that includes all of your default plot parameters for creating your drawing. It must reference a title file.

12d marks the location of your title block data using the variables user_text_1, user_text_2 etc. Since it is difficult to remember what user_text_1 represents in the title block, 12d allows you to use a meaningful name reference (Main title for example) instead of user_text_1. The Alias button allows you to set these alias names for the title file referenced in your base ppf.

The Advanced button is only used if the same text data is to be used in another Title Block ppf (share the data between drawing).

The Set button creates/updates the title block ppf and the title file values that you entered.

![Title Block Data Editor](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title block ppf</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Old Plotting* 
*Page 5921*
this is the ppf that is created by the panel. This is the ppf name that you will use in the future plot panels when you are ready to plot using the title block. The Title Block ppf is usually stored locally (in the current folder).

**Base ppf**

this ppf must exist (often in library or your user library). It will contain all of your default plot parameters for creating your drawing. It must reference a title file (see notes below). When you press enter, the ppf file is read to find the name of the title file you reference. Once the title file is found, the alias names are read from the title alias file if available.

To convert an existing ppf file into a Base ppf file use a text editor to delete all references to user_text_n variables in the file.

**Current page**

choice box available pages

if more than one page of data (10 fields) are required additional pages will be listed here.

**Value**

input box

the data to be shown into your drawing title block is entered here. The description to the left is either user_text_n (Note that there may be a gap in the numbering sequence) or an alias that has been set up using the alias button below.

**Alias**

button

if the fields have the names user_text_1, user_text_2 etc. use the button to change the names to a more meaningful description. These new names will be stored in the same folder as the with the title file specified in your base ppf file (the extension als will be added). The following panel will be displayed.

![Set Aliases](image)

Note that there may be gaps in the user_text_n sequence. Only the variable used in the title file will be listed.

**Advanced**

button
this feature allows you to share text data between different title block ppf files. The actual text data is stored in a title file txt (*.tft) file. Selecting the button will bring up the following panel and allow you to change the *.tft file to be used. Generally you will select a *.tft file previously set up for another title block file.

Select the Set button to set your select. The text data will be read and the main panel updated when you select the Finish button.

Set button creates/updates the Title block ppf file and *.tft file.

Notes:

Short-cuts:

*.als and *.tft files can be copies, renamed and then edited using the Title Block Edit Panel or your own text editor.

Alias files (*.als) are kept in the same folder as the your title files. Once you have one alias file set up copy the alias file and rename the copy the same name as the title file but add the additional extension .als. For example:

title file 4d_drainage_long_section_a1.tf

alias file 4d_drainage_long_section_a1.tf.als

CAUTION: The user_text_n variables should represent the same data in both title files. For example user_text_1 should be the main title in both files.

Title file text files (*.tft see advanced) files are kept in the same folder as the your Title block ppf. If you choose not to share a tft between Title block ppf files you can simply copy and rename them. Once you have saved one *.tft file, copy the file and rename the copy the same name as the title block file but add the additional extension .tft

Title Block ppf

The title block ppf file does not contain any data itself. Rather it references a *.tft file containing the text data and your base ppf file (file containing all of your default plot parameters). An example ppf file follows:

The Title Block ppf file is a ppf file with the Base ppf and user text values (in the tft file) referenced by #include statements.

#define ALIAS 1
section_long_plot "plot 2" {
// TITLE BLOCK PPF FILE
#include "Base_ljg.ppf"
#include "Title_block.ppf.tft"
}
**Base ppf**

The Base ppf can be anywhere including local, Library and User Library. It must contain a reference to a title file in the `use_title_file` parameter. The `user_title_file` parameter must be in the file and can't be in an #include file.

The following is an example title file reference.

```plaintext
use_title_file yes
title_file "your title file.tf"
```

Note: If you already have `user_text` variables defined in your Base ppf these values will not be used and a warning message will be issued at plot time. It is best to remove all `user_text` variables from your existing ppfs before attempting to use them with this new 4d facility.

The panel scans the title file reference and records all of the `user_text_n` entries that are used. **Only those used are displayed in the panel.** Next a file with the `.als` is located. If found the alias values are used in the panel instead of `$user_text_1, $user_text_2` etc.

If an alias file (same name as the title file PLUS the extension `.als`) has been previously created using the Alias button, the aliases for the `user_text's` are used on the left hand side of the panel. If an alias file has not been found, they can be created by simply selecting the Alias button.

The Base ppf is also checked to see if a

```plaintext
#ifndef ALIAS
    section_long_plot "plot 2" {
    #endif
```

exist around the opening "xxxxxxx {" and closing "}" braces. If not, a Base PPF file update panel is displayed.

Select **Automatically update ppf now** and select the Process button. The extra lines then are added to the Base ppf.

For example, the beginning and end of the updated file will look like:

```plaintext
BEGINNING
#ifndef ALIAS
section_long_plot "plot 2" {
    #endif

END
#ifndef ALIAS
} #endif
```
Clicking on the Alias button brings up the Set Aliases panel. Simply fill in the names to use instead of the words $user_texts_n in the Title Block - User Text Data Editor panel. Selecting Set writes out an aliases file which has the same names as the title file but with the appended ending .als.

**Set**

After selecting Set, the values for the user_texts are written to a file specified under **Advanced** (if used) or of the same name as the Title block ppf but with .tft appended.
25.8.10 Create Old Plot Frame

**Position of option on menu:** Plot => Old plotting => Create plot frame

On selecting the Create old option, the **plot frame create** panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

</tbody>
</table>
Title tab

**Left/right margin (mm)** 10.0
- the left/right hand side margin between the sheet and the plotting area inside the sheet.

**Bottom/top margin (mm)** 10.0
- the bottom/top margin between the sheet and the plotting area inside the sheet.

**How To Use the Option**

The plot frame contains all the information required to define the physical area in real world units to be plotted, the position on the sheet of the area being plotted, the plotter type and the plot file name.

Once the frame is created, the **plot frame edit** panel for the created plot frame is automatically placed on the screen so that the frame’s position can be adjusted using the **Translate** and **Rotate** buttons.
25.8.11 Editor Old Pot Frame

Position of option on menu:  Plot => Old plotting => Editor plot frame

The plot frame editor is used to edit existing plot frames. It is automatically placed on the screen when a plot frame is created so that the frame’s position can be adjusted using the Translate and Rotate buttons.

On selecting the Editor old option, the plot frame edit panel is displayed.

Most of the fields and buttons used in this panel are the same as the plot frame create panel - see the previous section 25.8.10 Create Old Plot Frame. The different ones are

Field Description | Type | Defaults | Pop-Up
--- | --- | --- | ---
Pick button | | | select the plot frame to be edited.
Set button | | | update the plot frame with the information in the above panel fields.
Translate button | | | after picking the translate button, the plot frame will move with the cursor until a point is selected to give the final position of the plot frame.
Rotate button | | | after picking the rotate button, the plot frame is further rotated around the left hand corner of the sheet, by the angle made between the rotation point and the current cursor position. The plot frame will continue to rotate until a point is selected to fix the rotation angle.
25.8.12 Plotting Old Plot Frames

Position of option on menu: Plot => Old plotting => Plot plot frame

The plot old option is used to make a plot of the data on a given plan view for all the selected plot frames (selected by the data source). Note that the plots are of a given plan view and the plot frames do not have to be on the plan view.

On selecting the plot old option, the plot frames plot panel is displayed.

![Plot Frames Plot Panel](image)

25.8.13 Plotter Mapping Table

Position of option on menu: Plot => Plotting setups => Plotter Mapping

The **Plotter mapping file** can be used with pen plotters but is more specifically designed for electrostatic and inject plotters and allows the user to

(a) map the full 10,240 12d Model colours to particular plotter pens and also specify a width (or weight) to be used for PCL5, HPGL2 and postscript plotters.

(b) specify the red, green and blue mix for pens on HPGL2 and colour postscript plotters

There are also two special formats of the plotter mapping file which are used for plotting to Autocad dxf/dwg and Intergraph dgn. The special mapping files use the 12d Model colour as a key to tables which control how the information is passed to DXF/DWG and DGN.

(c) .tbl file used with plotting to Intergraph dgn

(d) .amf used with plotting to Autocad dxf and dwg

The .tbl and .amf files are documented in the 43.3 Mapping 12d Colours to Pens and RGBs and 43.2.1.3 Definition and Example of a .amf File sections in the Appendix 43 Plotters and Plotting.

On selecting the **plotter mapping** option, the **Plotter Mapping Table** panel is displayed.

25.8.13.1 Initialization of the Plotter Mapping File

25.8.13.1.1 When using the Plotter Mapping Table panel:

When used with the Plotter Mapping Table panel, the pen_mapping and pen_colours sections are initialised before the plotter mapping file is used. This is to ensure that any colours and/or pens not mentioned in the file but used in a plot, do have valid definitions.

The initialisation sequence for the plotter mapping file used with the Plotter Mapping Table panel is:

Before the plotter mapping file is used:

(a) a default pen_mapping table is constructed for the colours in colours.4d by:

\[
\text{colour } n \rightarrow \text{pen } n \quad \text{with the default weight from the Plotter Mapping Table panel.}
\]

(b) a default pen_colours table for pens 0 to 10,240 is set up by:

\[
\text{pen } n \quad \text{default_red} \quad \text{default_green} \quad \text{default_blue}
\]

where default_red, default_green, default_blue are the red, green and blue of the default colour from the Plotter Mapping Table panel.

If the merge colours.4d flag is set in the Plotter Mapping Table panel, the rgb columns from the colours.4d file are used to define the pen_colours and the pen mapping number is used to construct the pen_mapping table.

The plotter mapping file is then processed and over writes any of the above initial mapping values.

25.8.13.1.2 When Using a Plotter from Plotters.4d:

A plotter mapping file can be set for a user defined plotter in the file plotters.4d. In this case, the Plotter Mapping Table panel is not used and hence the initialisation sequence is slightly different.

For a user defined plotter, the initialisation sequence for the plotter mapping file is:

Before the plotter mapping file is used

(a) a default pen_mapping table is constructed from the colours in the colours.4d file by:

\[
\text{colour } n \rightarrow \text{pen } n \quad \text{default_weight}
\]

where default_weight is the default_weight if one is given in the specified plotter mapping file or zero if the default_weight does not exist.

(b) a default pen_colours table for pens 0 to 10,240 is set up by:

\[
\text{pen } n \quad \text{default_red} \quad \text{default_green} \quad \text{default_blue}
\]

where default_red, default_green, default_blue are the red, green and blue of the default colour if one is given in the specified plotter mapping file, or rgb 0 0 0 if the default_colour does not exist.

The plotter mapping file is then processed and over writes any of the above initial mapping values.

25.8.13.2 An Example of a Plotter Mapping File

An example of a plotter mapping file (.pmf) is:

```
default_colour 100 0 100
default_weight 0.1
pen_mapping { // pen mapping and weight table
```
### Old Plotting

<table>
<thead>
<tr>
<th>colour</th>
<th>pen</th>
<th>weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>0.15</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>0.25</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0.5</td>
</tr>
</tbody>
</table>

```plaintext
pen_colours {
// pen colours table

//pen red green blue values 0-255
0   0  0  0 // pen 0 is black
1   255 0  0 // pen 1 is red
3   0  255 0 // pen 3 is green
}
```
25.8.14 Pen Mapping Old

Position of option on menu:
NO LONGER USED

Although 12d Model uses up to 10,240 different colours, most plotters have a smaller number of pens. Consequently for any plot, it is necessary to define what pen number corresponds to each 12d Model colour.

For all plotters types except Eagle, the pen mapping option can be used to define the correspondence between 12d Model colours and plotter pens for the first sixteen colours. The other colours are given in the colour_map.def file. For Eagle plots, the eagleplt.pmf file is used to map colours to pens.

The pen mapping option is only used if a plotter mapping is not being used (see next section).

On selecting the pen mapping option, the current pen mapping table is displayed in the colours to pens panel.

When starting a new project or entering an existing project, the default pen mapping table is defined by the colours.4d file.

Once inside the project, any pen number in the table can be modified by changing the appropriate pen field and then selecting the set button. The modified table is stored until 12d Model is quit or the user changes to another project.

The pen mappings for colours above sixteen are given in the colours.4d file but can not be displayed or modified by the colours to pens panel.

Whenever a plot is created using non-eagle plotter types, the colours are mapped to the pen numbers given in the colours to pen table before writing out the plot file.

For Eagle plots, the eagleplt.pmf file is used to map colours to pens.

Note - when 12d Model is started up again or the user changes to a new project, the table reverts to its default settings as given in the colours.4d file.
26 PPF Editors

26.1 General Information on PPF Editors

For the special plot types:

Cross sections, General Long sections, Plot Frames, Drainage Long sections, Drainage plan, Melbourne Water long sections and Pipeline Long sections.

there are plot parameters for controlling what items are drawn on the plots, what colours are use, what the text is and its colour and sizes, what the title block, what information is in the title block including user supplied values that can vary with each plot, etc.

The plots themselves are considered to be drawn onto a sheet of paper with the origin (0,0) in the bottom left hand corner and with drawing units of millimetres.

So when any of the plots is generated from 12d Model, the data is translated and scaled so that it fits onto the positive quadrant with (0,0) in the left hand corner. This means that title blocks and overlay models can be set up knowing exactly where they will sit in relation to a plot.

For each of the special plot types, there is a PPF Editor that allows the user to interactively change any of the plots parameters, specify the type of plotter to use (pdf, model, Windows etc) and actually produce the plot.

All this information can be saved away in a plot parameter file (ppf) for future reuse.

In fact the ppf has all the information required to generate the plot and can even be used to create a plot without any interaction from the user.

An example of a long section plot created in the Getting Started for Design manual is:
This plot, and the other three sheets of the set, are generated straight from 12d Model with no manual drafting at all.

For each of the PPF Editors, the parameters are displayed in a tree structure so they can be grouped together to make it easy to find any parameters to edit and modify.

For example, the Section X Plot PPF Editor looks like:

Clicking on a + will expand the node and on a - will collapse the node.

Clicking on a node will display information on the right hand side of the panel. This is where all the parameter values are entered.
Every plot parameter actually has a name but it is rare that you will ever need to know it. For most parameters you can see what the actual parameter name is by hovering over the parameter itself - a description and the name of the parameter is then displayed:

For the user, the parameter names usually only seen in diagrams explaining what the parameters control but when a plot is generated, the PPF Editor file is actually converted to a readable text file with the parameters and their values in it, and that text file that is used for generating the plot.

This all occurs in the background and it is useful to know because the PPF Editor files are often referred to as **binary PPFs** and the text ones as **Ascii PPFs** and there is even a converter to go from the Ascii PPF to a Binary PPF.

However throughout this manual, PPF will refer to the Binary PPF’s unless stated otherwise.

**Note:** Binary PPFs are normally stored within a project.

Many of the sections of the PPF Editors are common and as much as possible, will be described in one place.

For the items common to all the PPF Editors that are documented in the section 26.2 Nodes, see

- 26.2.1 Plot Parameter File
- 26.2.2 View to Load and Global Variables
- 26.2.3 Sheet Size and Plotter Parameters
- 26.2.4 Notes
- 26.2.5 Plot to models
- 26.2.6 Title Block
- 26.2.10 PPFs To Include
- 26.2.11 Buttons at the Bottom of the PPF Editors

For the individual PPF Editors, see
The first section of the documentation is **26.2 Nodes Common to the PPF Editors**.
26.2 Nodes Common to the PPF Editors

For the items common to all the PPF Editors, see

26.2.1 Plot Parameter File
26.2.2 View to Load and Global Variables

<tr>
<td>Digits in plot file number</td>
<td>file_num_digits</td>
<td>number box</td>
<td></td>
</tr>
</tbody>
</table>

- Leaving *Digits in plot file number* blank or setting a value of 1 or less, will result in file names like we've always known them.
- Setting *Digits in plot file number* to a value of 2 or more, ensures there will be at least that number of digits in the page numbers built into the plot file names, and if zero-padding is used where necessary to get that number of digits.
- For example, if *Digits in plot file number* is 3 then plot number 7 will have the number 007.

Chapter 26  PPF Editors

26.2.4 Notes

Section: Document your PPF here ...

Region for typing ppf_notes

Type in any notes as documentation for this PPF file.

This information is not plotted.

Continue to the next section 26.2.5 Plot to models or return to 26 PPF Editors.
26.2.5 Plot to models

The **Plot to models** node controls whether models are cleaned before the plot is written to them, and whether the plots go to separate models for each page or all into one model.

The columns for the fields documented in the sections are for:

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean plot models beforehand</td>
<td>plot_model_clean</td>
<td>choice box</td>
<td>do not clean</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>prompt for clean</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>always clean</td>
</tr>
</tbody>
</table>

when plotting to a model, it defines whether to clean (delete the elements in) any resultant plot models that may already exist, before generating the plot(s).

This parameter is only applicable if plotting to a model or models.

Note that if the models are cleaned using this parameter, any non-plot or locked elements found in the models will not be cleaned from the models, and the plot job will be cancelled.

**Section: Translate and merge models**

Whenever a PPF is set to produce multiple sheets of plot models, the **Translate and merge plot models** group of parameters, offer the ability to produce plot models arranged neatly in a row or column of sheets, optionally merged into the single plot model created for the first sheet.

**Note:** The **Origin X** and **Origin Y** parameters are useful when building up larger arrays of plot sheets -- perhaps entire drawing sets -- from multiple PPFs, where each PPF may be specified with a different origin.

**Mode**

The entire group of parameters is activated by setting the Mode to either "row-wise translation" or "column-wise translation". This determines whether the multiple sheets will appear as a row or a column of sheets. If unspecified, "do not translate or merge" is assumed, and the remaining parameters are ignored.

**Spacing (mm)**

determines how far to translate each sheet from the previous sheet. Practically, it should be at least as large as the sheet width or height. For an A1 sheet size, 1000 mm works well as a nice round number.

**Origin X (mm)**

determines the x-coordinate of the bottom-left corner of the first sheet.

If let blank then 0 mm is assumed.

**Origin Y (mm)**

determines the y-coordinate of the bottom-left corner of the first sheet.

If let blank then 0 mm is assumed.

**Merge**

if **ticked**, all sheets produced by the PPF, will be created in a single model and that model is the plot model created for the first sheet.

**Note:** The **Origin X** and **Origin Y** parameters are useful when building up larger arrays of plot sheets -- perhaps entire drawing sets -- from multiple PPFs, where each PPF may be specified with a different origin.

Continue to the next section **26.2.6 Title Block** or return to **26 PPF Editors**.
26.2.6 Title Block

12d Model plots are considered to be drawn onto a sheet of paper with the origin (0,0) in the bottom left hand corner and with drawing units of millimetres. So when any plot is generated from 12d Model, the data is translated and scaled so that it fits onto the positive quadrant with (0,0) in the left hand corner.

This means that linework and text to make up title blocks and other data can be accurately positioned to overlay a 12d Model plot.

For most plots, users can select to have a Standard 12d title block, or use their own Title blocks that have been stored in title block files (tbf).

The format for the title block information is a subset of the 12da format with the special header of title_block and the units inside the tbf are considered to be millimetres.

So inside the tbf file, the set of all title block drawing commands is enclosed within a set of curly brackets { } with the special header

title_block

before the curly brackets.

That is,

title_block

{ 

title block drawing commands in 12da syntax

}

The easiest way to create a tbf file is to create the title block information is to use 12d Model and draw up the title block in a model, or a view of models, and then write the models out to a tbf file using the Create/Edit Title Block File panel (Plot => Plotting setups => Create/edit title block file or Drafting => Create title block file. See 25.7.1 Create/Edit Title Block File).

Because the units for plots are millimetres, the units for the title block drawing commands are taken to be millimetres.

So for the purpose of drawing up a title block in a 12d Model model, the (0,0) for the model corresponds to the origin (0,0) of the plot, and the distances are taken to represent millimetres so you do everything in World units and multiply all the coordinates and distances as the millimetre value multiplied by 1000.

So if text is to be 5 mm high in the title block, then draw text in world units and of size 5. Do not use paper size. If a line is to be 200 mm long, then draw it as 200 World Units.

So for any lines and text drawn up in a model as part of a title block, think of the World units as representing millimetres rather than metres.

Continue to the next section 26.2.6.1 Title Block Section in PPF Editors or return to 26 PPF Editors.

Nodes Common to the PPF Editors
26.2.6.1 Title Block Section in PPF Editors

Each of the PPF Editors has a Title Block section which is the same for each of them.

See:

- 26.2.6.1.1 Title Block Node
- 26.2.6.1.3 Title block - User title info
- 26.2.6.1.4 Title Block - Drawing Register

For general information about a title block, see 26.2.6 Title Block.
26.2.6.1.1 Title Block Node

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>

</tbody>
</table>

**Section: Common title block parameters**

- **Standard title**
  - plot_border
  - if ticked, a standard 12d title block will be used.

- **Use title file**
  - use_title_file
  - if ticked, a user defined title file is used.

**Title line 1**

*If Standard title is ticked, Title line 1 is the first line of title text. If Use title file is ticked, Title line 1 is substituted for the title block variable $title_1.*

**Title line 2**

*If Standard title is ticked, Title line 2 is the second line of title text. If Use title file is ticked, Title line 2 is substituted for the title block variable $title_2.*

**Section: 12d default title block parameters**

- **Text size**
  - title_text_size
  - measure box

- **Text colour**
  - title_colour
  - colour box available colours

**Section: Model to plot in plotter units**

- **Plot data model 1, 2, 3**
  - plot_model
  - model box available models

*The Units for the Plot data model are to be in World Units but each unit is taken to represent a millimetre when plotted. So a height of 5 represents 5mm on the plot. (0,0) in the Plot data model corresponds to (0,0) in the plot. Paper Units should not be used in Plot data models.*

*For more information on plot data models, see 26.2.6.1.2 Plot Data Models.*

Continue to:

- 26.2.6.1.3 Title block - User title info
- 26.2.6.1.4 Title Block - Drawing Register

Or return to 26.2 Title Block or 26 PPF Editors.
26.2.6.1.2 Plot Data Models

A sheet of paper on a plotter has (0,0) in the bottom left hand corner and the units of millimetres. So when any plot (plan, plot frame, long section, cross section, drainage network longsection, Melbourne Water longsection or pipeline longsection) is generated from 12d Model, the data is effectively translated and scaled so that it fits onto a sheet of paper with (0,0) in the left hand corner, and the drawing units are millimetres.

If a title block is drawn, either using either the Standard Title or taking the title drawing information from a User Defined Title File, the title block is also drawn onto the sheet of paper with the drawing units of millimetres.

In each of the Title Block nodes in the plot PPF Editors, models can be given in the Plot data model fields and these models are also drawn onto the plot sheet.

Because of the special nature of the plot sheet, the Origin (0,0) of a Plot data model is matched to the origin of the plot sheet, and the World Units in the Plot data model are taken to be millimetres on the plot sheet. This applies to strings, text, linestyles and symbols in World units. So a height of 5 world units represents 5mm on the plot. (0,0).

For text, linestyles and symbols defined in Paper units (millimetres), one Paper unit in a Plot data model still ends up as one millimetre on the plot.

There is also no clipping done when plotting the Plot data model.

So like the Title Block, the Plot data models are simply an overlay that is plotted on top of the paper plan/long section/x section plot that has just been generated.

Special Notes

1. If the Plot data model is added to a Plan View (for creating, editing etc), then the Plotting scale for the Plan view needs to be 1000 so that any text, linestyles and symbols defined in Paper Units are drawn at the correct size to in relation to the other World Units data in the model, and hence as they would appear on a final plot.

2. When plotting to a model:

   (a) for all the data other than the Plot Data Models, 12d Model multiplies the millimetre size by 1000 and all text, linestyles and symbols are converted to World Units. So that lengths (distances) in the "model of the plot" represent millimetres on the plot page.

      Hence if you plot the "model of the plot", you need to plot with a scale of 1:1000 to get the correct size on the paper plot.

   (b) for the Plot Data Models, a copy of the Plot data model is simply added to the model.
containing the plot

Because the *Plot data model* is simply an overlay with no change of scale and is not clipped, then in the special case of *plotting to a model*, a copy of the *Plot data model* is simply added to the model containing the plot. So World text, linestyles and symbols stay as World text, linestyles and symbols. And text, linestyles and symbols in Paper units stay as text, linestyles and symbols in Paper units.

3. When you *plot to a model* and then display the "model of the plot" on a *Plan View*, the *Plotting scale* for the *Plan View* needs to be 1000 so that text, linestyles and symbols that have come from the *Plot data model* and are defined in *Paper Units* display as they would appear in a final paper plot.

4. If you *plot to a model*, and then add the model of the plot to a Plan View and plot the "model of the plot", *all* the linestyles and symbols will be exploded into lines and arcs.

When creating data in a *Plot data model*, to save confusion it is easiest to create all the data, text, linestyles and symbols in World units, and to think of the World unit as being millimetres.

However many *12d Model* users have many of their linestyles and symbols defined in Paper units and then can be used in the *Plot data model* as long as the *Special Notes* are remembered.

Many people use database tables, such as an Excel spreadsheet, to provide information for the title blocks of the plots. For example, for special drawing numbers and drawing revision. This database is often known as a **Drawing Register**.

For example, in an Excel spreadsheet, the columns of the spreadsheet would have unique names to refer to the information in each column, and each row of the spreadsheet holds the information for a single, specific plot.

The **Drawing Register** node in the **PPF Editor** specifies the type and name of the database to use for the one plot.
be used to retrieve information from, and enough information to determine what row of the
database table is to be used to supply information for the title block of a specific plot.

For example in the spreadsheet above, the *plot file name* will identify a particular plot, and the
information in each of the columns from the rest of the row is the drawing number (*Drg#*), Title
(*Title*) and Revision (*Rev*) for that plot.

Once the **Drawing Register** node has been set up to identify a row of the spreadsheet, the title
block variable to extract the information for column *column_name* from that row of the drawing
register is

\[ $\text{drawing_register}<\text{column_name}> \]

So the **Drawing register** node of a *Long Section Plot PPF* could be

![Section Long Plot PPF Editor](image)

and this could be used in a **User tile info** node as:
Continue to 26.2.6.2 Title Block Variables or return to 26.2.6.1 Title Block Section in PPF Editors or 26 PPF Editors.
26.2.6.2 Title Block Variables

For title blocks, the text drawing command has been extended so that they can use special information such as the project name, project details, current date and time, plotting scales etc. can be automatically inserted into the title block at plot time.

To achieve this, special **title block variables** have been defined and wherever these variables appear in a title block text, they are expanded to their defined value at the time of plotting.

Hence the title block variables are simply place markers which have text values substituted for them when the title block file is used in a plot.

The title block variables all begin with a $ and are followed by either another title block variable or a single space. For example, in the 12da string definition, the line is

```
text  "user text $variable more user text"
```

or

```
text  "user text $variable_1 more user text $variable_2 more user text 
```

For example

```
text  "Project $project"
```

will write out the word "Project " followed by the name of the project.

**Note** - colour, style, xfactor, slant, offset etc. are all assigned as part of the 12da string definition.

List of Title Block Variables

See:

- Project Name
- Project Details
- Folder Details
- Plot Details
- Drawing Register Details
- PPF Details
- Model Details - for the Drainage Long-section Plot only

**Project Name**

$project  // the current project

**Project Details**

*Project details* which are entered by the user for each project (and defined by the option *Project =>Details =>Details*) can be included in the title block and are specified as **title block variables** by beginning with $project_detail and then including the *project detail name* as part of the $project_detail.

$project_detail_project_detail_name

where project_detail_name is the name of the project detail as given in the Projects Detail Editor (and not the Display name which is shown in the Setup Projects Details or Edit Project Details panels)

For example

```
text  "Client: $project_detail_Client"
```

will write out the word "Client: " followed by the text in the project detail with the name "Client."

**Folder Details**
Nodes Common to the PPF Editors

Chapter 26  PPF Editors

The full path name of the working folder

$folder

Plot Details

The following title block variables take values which are passed down from the plot itself:

- $plot_file // the current plot file
- $scale // for plot frames, the current scale
- $horizontal_scale // for section plots, the current horizontal scale
- $vertical_scale // for section plots, the current vertical scale
- $start_chainage // for section plots, the start chainage for the plot
  // sheet
- $end_chainage // for section plots, the end chainage of the plot sheet

Drawing Register Details

$drawing_register<column_name>

When a Drawing Register node has been set up to identify a row of the spreadsheet, the title block variable $drawing_register is used to extract the information for column column_name from that row of the drawing register.

For information on setting up a Drawing Register node, see 26.2.6.1.4 Title Block - Drawing Register.

PPF Details

The following title block variables take values which are passed down from the plot parameter file for the plot

(time parameter files are described in more detail in the rest of this manual):

- $time
  The current date and time. The format for the date and time is given by the plot parameter time_format. See the next section for the description of the format.

- $title_1, $title_2
  $title_1 takes the value from the panel field title line 1 from the section x plot title, section long plot title or plot frame title panels, or from the parameter title_1 in the plot parameter file.
  If title_1 doesn't exist, then $title_1 is blank.
  Similarly for $title_2.

- $user_text_n where n=1,2,... 1000
  $user_text_n takes the value of the parameter user_text_n in the plot parameter file. If user_n doesn't exist, then $user_text_n is blank.
  Aliases can also be defined for the $user_text_n which are used in the PPF editors. See the next section 26.2.6.4 Aliases for $User Text on aliases.

- $page_number
  $page_number has the starting value one, or the value given by the parameter start_page_number from the plot parameter file, and is incremented by one, for each plot produced by the plot option (for example, for each page of a long section plot, for each page of x-section plots or each plot generated from a model of plot frames).

- $drawing_number_prefix, $drawing_number, $drawing_number_postfix
  The values for $drawing_number_prefix and $drawing_number_postfix are passed down from the plot parameter file by the parameters drawing_number_prefix and drawing_number_postfix respectively.
$\text{drawing} \_\text{number}$ has the starting value one, or the value given by the parameter $\text{start} \_\text{drawing} \_\text{number}$ from the plot parameter file, and is incremented by one for each plot produced by the plot option (for example, for each page of a long section plot, for each page of x-section plots or each plot generated from a model of plot frames).

Notes
1. For plot frames, the horizontal scale and vertical scale are given the current scale, and $\text{start} \_\text{chainage}$ and $\text{end} \_\text{chainage}$ are ignored.
2. For section plots, $\text{scale}$ is ignored.

Model Details - for the Drainage Long-section Plot only

The following title block variables take values from the model containing the drainage network.

$\text{model} \_\text{name}$
- The name of the drainage model

$\text{model} \_\text{event} \_\text{type}$
- Type of event of last storm analysed ("Minor" or "Major")

$\text{model} \_\text{return} \_\text{period}$
- ARI of last storm analysed.

Example of Model with Title Block Variables

\begin{center}
\begin{tabular}{|c|c|c|}
\hline
\textbf{Client:} & $\text{project} \_\text{detail} \_\text{Client}$ & \textbf{DESCRIPTION:} \\
\hline
\textbf{SURVEYED:} & \textbf{FIELD BOOK:} & \textbf{DATE:} \\
\textbf{DRAWN:} & \textbf{CHECKED:} & \textbf{$\text{time}$} \\
\hline
\textbf{HORIZONTAL DATUM:} & \textbf{LEVEL DATUM:} & \textbf{SCALE:} \\
\textbf{Di} & & $\text{scale}$ \\
\hline
\end{tabular}
\end{center}

Notes
1. For plot frames, the horizontal_scale and vertical_scale are given the current scale, and $\text{start} \_\text{chainage}$ and $\text{end} \_\text{chainage}$ are ignored.
2. For section plots, $\text{scale}$ is ignored.

Continue to 26.2.6.3 Ad Hoc Queries or return to 26.2.6 Title Block or 26 PPF Editors.
26.2.6.3 Ad Hoc Queries

It is possible to extract information from some external data sources to use in User Title Block variables, or directly in the title block file, to place in the title blocks of plots.

Data can be extracted from
(a) Excel spreadsheets
(b) XML files
(c) Databases supporting ODBC

The external data can be accessed in a completely user definable way, known as an Ad Hoc Queries.

For each different data source, there is a different method to specify how to identify the bit of information needed from the database.

See
- 26.2.6.3.1 EXCEL
- 26.2.6.3.2 XML
- 26.2.6.3.3 ODBC (Open Database Connectivity)

26.2.6.3.1 EXCEL

The Excel spreadsheet to extract information from must have the first row as a header row with the names of each column in it so row (n+1) is only the n'th row of actual information.

The format to retrieve the cell X(n+1) from the Sheet sheet_n is

Excel://Full_Path_To_Excel_File?sheet_n?Xn

It is Xn is because the first row of the spreadsheet is the header row so Xn is referring to the n'th row of actual information but that is the (n+1) row in the spreadsheet.

For example,

Excel://c:\temp\drawing.info.xlsx?Sheet1?A1

will open the Excel file c:\temp\drawing.info.xlsx and get Cell A2 from the sheet Sheet 1.

Return to 26.2.6.3 Ad Hoc Queries
26.2.6.3.2 XML

The format to retrieve the value of the element `sub_elt` inside the element `elt` is

```
XML://Full_Path_To_XML_File?elt/sub_elt
```

For example,

```
XML://c:\temp\drawing_info.xml?PlotData/Title
```

will open the XML file `c:\temp\drawing_info.xml` and extract the value of the Title element below the element PlotData.

```
<User title block parameters
  Title file tbf.tbl
  Name Value
  1 Main Title1 Excel://c:\temp\drawing_info.xsx?Sheet:A1
  2 Main Title2 XML://c:\temp\drawing_info.xml?PlotData/Title
</User>
```

So from the xml file

```
<PlotData>
  <Title>My Title</Title>
  <Client>12d</Client>
  etc
</PlotData>
```

it will get the value "My Title"

Return to 26.2.6.3 Ad Hoc Queries

26.2.6.3.3 ODBC (Open Database Connectivity)

The format to retrieve information from a database is

```
ODBC://ConnectionString?Query
```

Unfortunately the format of the `ConnectionString` and the `Query` to pull data from a database is totally dependent on the database system.

But it would resemble something like

```
ODBC://DSN=MyDBDsn?SELECT Title FROM PlotData WHERE PlotType = 'long'
```

`ODBC` is for advanced users only, and the user must be familiar with the requirements of the end database system.

Return to 26.2.6.3 Ad Hoc Queries
26.2.6.4 Aliases for $User Text

12d Model user defined title blocks can include up to 1,000 markers for placing user defined text ($user_text_n where n can be from 1 to 1000) which is only substituted for actual text at plotting time. Because of the difficulty of knowing exactly what $user_text_n stood for when the title block is being plotted, the concept of aliases has been introduced.

For example, instead of referring to $user_text_4, an alias can be defined to use the "Engineers name:" instead.

The definition of $user_text_n in a title block file has been extended so that it also includes any alias for the $user_text_n.

To define an alias for the $user_text_n in the title block file, simply replace the "_n" by "<n, for the alias>"

For example, if $user_text_1 is to have the alias "Engineers name", the title block file would now contain:

```
text "$user_<1,Engineers name:>
```

The title file and aliases work seamlessly with the interactive PPF editors and Plotters (which are described in their own sections). In the Title block section of the interactive PPF editors and Plotters, the user defined title block file is scanned for any $user_text in it and it is presented as a grid containing all the $user_user_text's in the title block with a column to fill in the values that the user wants to be plotted.

If the format $user_text_n is in the title block file, it is displayed as "User text n in the PPF editor. If an alias exists, then the alias is displayed instead of "User text n".

For example, using the $user_text<1,Engineers name> in a title block file will give:

![Section X Plot PPF Editor](image)

Continue to 26.2.6.5 Values Used for Defaults when Creating Plot Frames or return to 26.2.6 Title Block or 26 PPF Editors.
26.2.6.5 Values Used for Defaults when Creating Plot Frames

There are special parameters that are written in an info block at the top of title block file that are used as defaults for fields in the option Plots=>Plot frames=>Create.

They are

```
info {
    text "plot_frame_name" plot_frame_name
    text "plot_frame_model" plot_frame_model
    text "plot_frame_sheet_size" plot_frame_model
    text "plot_frame_colour" plot_frame_colour
    text "plot_frame_scale" real_number
    text "plot_frame_angle" real_number
    text "plot_frame_left_margin" real_number
    text "plot_frame_right_margin" real_number
    text "plot_frame_top_margin" real_number
    text "plot_frame_bottom_margin" real_number
    text "plot_frame_viewport" 0 or 1
}
```

Continue to 26.2.6.6 Specifying the Format for $time or return to 26.2.6 Title Block or 26 PPF Editors.
26.2.6.6 Specifying the Format for $time

The format for $time is passed down by the plot parameter \texttt{time\_format}.

\begin{verbatim}
    time_format format // format for $time
\end{verbatim}

The format consists of one or more codes and the formatting codes are preceded by a percent sign (%). Characters that do not begin with a % are copied unchanged.

\begin{itemize}
\item \%a \quad abbreviated weekday name
\item \%A \quad full weekday name
\item \%b \quad abbreviated month name
\item \%B \quad full month name
\item \%c \quad date and time representation for locale
\item \%d \quad day of month as decimal number (01 - 31)
\item \%h \quad hour in 24-hour format (00 - 23)
\item \%I \quad hour in 12-hour format (01 - 12)
\item \%j \quad day of year as decimal number (001 - 366)
\item \%m \quad month as decimal number (01 - 12)
\item \%M \quad minute as decimal number (00 - 59)
\item \%p \quad current locale’s A.M./P.M. indicator for 12-hour clock
\item \%S \quad second as decimal number (00 - 59)
\item \%u \quad week of year as decimal number, with Sunday as first day of week (00 - 51)
\item \%w \quad weekday as decimal number (0 - 6; Sunday is 0)
\item \%U \quad week of year as decimal number, with Monday as first day of week (00 - 51)
\item \%x \quad date representation for current locale
\item \%X \quad time representation for current locale
\item \%y \quad year without century, as decimal number (00 - 99)
\item \%Y \quad year with century, as decimal number
\item \%z, \%Z \quad time-zone name or abbreviation; no characters if time zone is unknown
\item \%% \quad percent sign
\end{itemize}

The # flag may prefix any formatting code and the meaning of the format code is changed as follows

\begin{table}
\begin{tabular}{|c|l|}
\hline
\textbf{Format Code} & \textbf{Meaning} \\
\hline
\%#c & long date and time representation, appropriate for current locale. For example, “Tuesday, March 16, 1993, 12:41:29” \\
\%#x & long date, appropriate for current locale. For example, “Tuesday, March 16” \\
\%#d, \%#H, \%#I, \%#, \%m, \%#M, \%#S, \%#U, \%#W, \%#y, \%#Y & Remove leading zeros (if any). \\
\%#a, \%#A, \%#b, \%#B, \%#p, \%#X, \%#z, \%#Z, \%% & # flag is ignored \\
\hline
\end{tabular}
\end{table}

Examples
The format to give the date in the form dd/mm/yy (06/09/97) is "%d/%m/%y"
If you want to remove leading zeros from the day and month (6/9/97) "%#d/%#m/%y"

Nodes Common to the PPF Editors

Return to 26.2.6 Title Block or 26 PPF Editors.
26.2.7 Corridors

A corridor around the primary string is defined by giving a left and right corridor width.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, it is drawn on the long section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.

For a long section plot, the primary string is the string being plotted.

For a x section plot, the primary string is the string currently being plotted in the x section subplot.

Warnings:

When the primary string is not a straight line in plan, then how the strings in the corridor project onto the primary string in the plot is not always well defined. Where every possible the ends of the string are dropped perpendicularly onto the primary string.

However if the primary string have sharp angles in it in plan, then dropping perpendicular may
not be possible and dropping to the closed vertex is all that could be done. This means that many points on a string may drop onto the same point on the primary string.

How should this string be drawn in the profile along the primary string?
All of the string drops onto one vertex

primary string
(plan view)

How should this string be drawn along the profile along the primary string?
The string drops equally onto two segments?

The columns for the fields documented in the sections are for.

Corridors - Model Selection

Section: Corridor - Model selection

Corridor model grid

the grid contains the models of tins and strings (service strings) to be in the corridor and hence draw onto the long section. There can be up to 100 models.

For the parameter corridor_model_n, n is the line number on the grid. That is, n = 1, 2, ..., 100.

Corridor model | corridor_model_n | model box | models containing tins and service strings to be drawn on the section. There can be up to 100 models.

For the parameter corridor_model_n, n is the row number of the cell in the grid.

Continue to the next section 26.2.8 Hatching Cut/Fill or return to 26 PPF Editors.
26.2.8 Hatching Cut/Fill

This option is used to hatch cut and/or fill areas between sets of tins. For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins may be hatched.

The columns for the fields documented in the sections are for:

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>

**Section: Hatching cut/fill - Tin parameters**

Define Set #

integer box

*set number to be used to define different original/new tin sets.*

Original tin

hatch_original_tin_n tin box

tin_name for original surface

New tin

hatch_new_tin_n tin box

tin_name for final surface

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting hatch_cut_separation_n to 0.0.
fill hatching is turned off by setting hatch_fill_separation_n to 0.0.

26.2.9 Cuts

The cuts that the primary string makes though strings in any user-specified model, can be automatically labelled on the x-section/long section plots.

The height, offset/chainage name, attributes, diameter, x and y coordinates, 3d length of CL until cut point of the cut string can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled.

For a x section plot, the offset position for the labelling is the offset on the primary string where it cuts the string.

For a long section plot, the chainage position for the labelling is the chainage on the primary string where it cuts the string.

The height position for the labelling can be specified as the:

(a) top of the boxes
(b) above the maximum height of the strings on the plot,
(c) height value of the cut string,
(d) diameter value of the cut string,
(e) height of the primary string,
(f) height of a tin.

The actual position of the label is defined relative to the above point.

Note: Only case (c) involves the actual height of the cut string. For all other cases, only the
offset/chainage of the cut string is used. Hence, for all cases except (c), the string does need to have a sensible height to be used for cuts through strings. For example, a boundary string may have null heights but only the offset is required and the height of the tin at that offset can be used as the height (case (e)).

The method for specifying which strings are to be checked for cuts is by first specifying the model which contains the strings, and then a name mask which is used to restrict the strings in the model to only those whose names match the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

See

</table>

**Section: Cuts - Model/Name mask parameters**

- **Define Set #**
  - number box
  - set number to be used to define different model/mask sets.

- **Model**
  - cuts_n_model
  - model box
  - model from which cut masks are derived

- **Name mask**
  - cuts_n_mask
  - text box
  - text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.
  - For example: "ke*" or, "?bank*" or, if both masks are required, "ke* ?bank*"
  - If cuts_n_mask is blank, then all strings in the model are used. This is equivalent to name mask being set to "*".

All strings in the model cuts_n_model whose name satisfy the name mask cuts_n_mask are then checked for cuts with the x-sections/longsection, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the nth set.

- **Design x-section**
  - design x-section
  - point where the x-section cuts a string
  - The cut point can be labelled with:
    - offset of the cut point
    - height of the cut point
    - diameter of the cut string at the cut point
    - height of the section or tins at this offset
    - name of the string for the cut point
  - User defined symbols can also be drawn at the cut point

- **Design long section**
  - design long section
  - point where the design cuts a string
  - The cut point can be labelled with:
    - chainage of the cut point
    - height of the cut point
    - diameter of the cut string at the cut point
    - height of the section or tins at this chainage
    - name of the string for the cut point
  - User defined symbols can also be drawn at the cut point

26.3 Section X Plot PPF Editor

Position of option on menu:  Plot => Plot and PPF Editors => Cross sections

The Cross Sections PPF Editor is for creating and/or editing a (binary) X-section PPF and for creating a cross section plot.

Note: Binary PPFs are stored within the project (not in the folder containing the project as the text PPFs were).

On selecting the Cross sections option, the Section X Plot PPF Editor panel is displayed. The plot parameters for controlling the cross section plots are accessed by expanding the appropriate node in the Section X Plot tree (click on the + to expand to node or - to collapse the node) and then clicking on the required node, and the information to fill in is displayed on the right hand side of the panel.

For information on all the different nodes see:

26.3.1 General Information on Cross Section Plots

X-sections are normally generated at chainages along a given centreline and this centreline
chainage is stored as part of the name of each x-section string.

The start chainage of the x-section string is set so that zero chainage is where the Centre line
cuts the x-section in plan. So the chainage along a x-section string is usually referred to as offsets from the centreline position rather than x-section chainages.

The x-sections along the centreline are stored in the one model (the primary model) which is then
used to generate the cross section plot.

Each x-section from the primary model of x-sections generates its own sub-plot for which a x-
section is the primary string. Hence the cross section plot consists of many individual plots drawn
on one or more plot sheets.

The x-sections are plotted in the order they occur in the x-section model or can be sorted by the
centreline chainage that is part of the x-section name.

The x-sections start being plotted at the bottom left hand corner of the cross section plotting
area. The individual x-section plots are then drawn going up the column, and when the column is
full, start from the bottom of the next column.

When a sheet is full, a follow on sheet is created.

If required, all the sub-plots in a column can be automatically positioned up so that the zero
offsets (the centrelines) of each x-section line up.

The x-section sub plots can be drawn and labelled with the two choices of:

(a) centreline case
where the x-section and tins are plotted and an upright at the zero offset, and labels for the offset and height values at the zero offset (normally the centre line position)

(b) **boxes case**

where the x-section is plotted and the heights of the x-section and the tins at all the x-section points are labelled in boxes under the plot of the x-section.

![Diagram showing Centre line Case and Boxes Case](image)

The x-section sub-plot itself consists of the three regions - graph, datum and boxes.

The **graph area** is the area where the actual plots of the strings are drawn. This exists for both the centreline and boxes case.

The **datum area** is the region between graph area and the datum line. This exists for both the centreline and boxes cases.

The **boxes area** is where the offset values and the heights for the strings drawn on the x-section plot are labelled. This only exists for the boxes case.

![Diagram showing Centre line plot, Graph area, Datum line, and Boxes area](image)

For both cases, the x-section sub-plot can be labelled with other information including

(a) grades across the x-section
(b) points across the x-section
(c) cuts the x-section makes through strings
(d) cut and fill areas

All the required parameters for controlling the cross section plot are set up in the **Section X Plot PPF Editor** and will be described in detail in the following sections.

Please continue to the next section [26.3.2 Section X Plot - Front Page](#) or return to [26.3 Section X Plot PPF Editor](#).
26.3.2 Section X Plot - Front Page

Section: Plot parameter file

A plot parameter file can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

This section is documented for all the PPF Editors in 26.2.1 Plot Parameter File.

Section: Section: View to load details from AND Global variables

A section view can be selected to load certain values into fields of the PPDF Editor. For example, Vertical exaggeration and Corridor models. And there are variables to use if some values aren’t given.

These sections are documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

The columns for the fields documented in the sections are for:

**Special chainage file**

*filter_spc_file* file box

*.spc files

*If* non blank, a file of chainages to include sections at even if they are not a regular interval

Please continue to the next section **26.3.7 Extra X Sections To Plot**.
26.3.7 Extra X Sections To Plot

The order and centreline chainages of the x-section subplots for the x-section plot are defined by the sections from the primary model of cross sections.

The sections through any specified triangulations and service models, and offsets for labelling are fully defined by these primary x-sections.

However it is also possible to plot extra x-sections on each of the sub-plots by supplying extra models of x-sections which are at the same plan positions as the primary x-section strings.

Only those x-sections from the extra models that are within a user specified tolerance of a primary x-section are plotted.

The extra models of x-sections and the plan tolerance for checking that the extra cross-sections are the same position as the primary x-sections are

<table>
<thead>
<tr>
<th>Field</th>

</tr>
<tr>
<td>Model name</td>
<td>extra_model_n</td>
<td>input</td>
<td>extra models of x-sections to plot</td>
</tr>
</tbody>
</table>

Please continue to the next section 26.3.8 Plot Sheet Layout.
26.3.8 Plot Sheet Layout

X-sections are normally generated at chainages along a given centreline. This centreline chainage is stored with each x-section string.

The chainages of the actual x-sections are referred to as offsets from the centreline position rather than x-section chainages. The offsets of the x-section are set up so that the zero offset occurs where the x-section crossed the centreline string.

The x-sections along the centreline are stored in the one model (the primary model) which is then used to generate the cross section plot.

The x-sections are plotted in the order they occur in the x-section model and start being plotted at the bottom left hand corner of the sheet (left_margin,bottom_margin).

The individual x-section plots are then drawn going up the column, and when the column is full, start from the bottom of the next column.

When a sheet is full, a follow on sheet is created.

Each x-section from the primary model of x-sections generates its own sub-plot for which the x-section is the primary string. Hence the cross section plot consists of many individual plots drawn on one or more plot sheets.

Each plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Section:</strong> Plot width parameters</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The width of the plot can be a fixed distance left or right of the centre line (zero offset) or for the full section plus an extra left and right distance:

**Absolute extensions**: absolute_extensions tick box

if ticked, the section goes from the left_extension offset on the left to the right_extension offset on the
right. If unticked the section goes for the entire section length plus the left and right extension distances.

Left extension left_extension input

The left_extension value in world units.

Right extension right_extension input

The right_extension value in world units

**Section: Align section parameters**

If required, all the sub-plots in a column can be automatically positioned so that the zero offsets (the centrelines) of each x-section line up.

Line up centrelines line_up_cl tick box

if ticked, each sub plot will be aligned on the plot using the centreline of each x section.

See

26.3.8.1 Plot Sheet Layout - Margins
26.3.8.2 Plot Sheet Layout - Sub Plot Gaps

Or return to 26.3 Section X Plot PPF Editor.
26.3.8.1 Plot Sheet Layout - Margins

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section: Margins for standard 12d title file - Border gaps</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If the default 12d title block is used, then the size of the bottom of title block depends on the size. The following parameters are used in the default title block case and the bottom_border_gap is added to the calculated height of the bottom of the title block.

- **Left (mm)**  \( \text{left\_border\_gap \ input} \)
  
  *left border gap (in millimetres).*

- **Right (mm)**  \( \text{right\_border\_gap \ input} \)
  
  *right border gap (in millimetres).*

- **Top (mm)**  \( \text{top\_border\_gap \ input} \)
  
  *top border gap (in millimetres).*

- **Bottom (mm)**  \( \text{bottom\_border\_gap \ input} \)
  
  *bottom border gap (in millimetres).*

---

**Definition of Plotting Areas for Default 12d Title Block**

- Cross section plot area is inside the dashed lines
- Size depends on text size in the default 12d title block
- \((0,0)\)
- Sheet height
- Sheet width
- \((\text{left\_border\_gap, bottom\_border\_gap + title\_block})\)
Section: Margins for user title file

Left (mm)  
left_margin  
real box  
left margin (in millimetres).

Right (mm)  
right_margin  
real box  
right margin (in millimetres).

Top (mm)  
top_margin  
real box  
top margin (in millimetres).

Bottom (mm)  
bottom_margin  
real box  
bottom margin (in millimetres).

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margin and gap parameters can exist in the one plot parameter file.

The x-sections are plotted in the order they occur in the x-section model and start being plotted at the bottom left hand corner of the cross section plotting area.

The individual x-section plots are then drawn going up the column, and when the column is full, start from the bottom of the next column.

When a sheet is full, a follow on sheet is created.

Continue to the next section 26.3.8.2 Plot Sheet Layout - Sub Plot Gaps or return to 26.3.8 Plot.
Sheet Layout.
26.3.8.2 Plot Sheet Layout - Sub Plot Gaps

The gaps between the sub plots is restricted to those specified below.

Section: Sub plot gaps parameters

The fields and buttons used in this section have the following functions.

<table>

Size depends on text size in the default 12d title block.
Please continue to the next section 26.3.9 Boxes/ Centreline Labels or return to 26.3.8 Plot Sheet Layout.
26.3.9 Boxes/ Centreline Labels

The x-section can be labelled with either

(a) an upright, and the offset and height value at the zero offset (normally the centre line position) - Centre line

(b) the heights of the x-section and the tins at all the x-section points. - Boxes

The choice is given by the parameter *label_type* defined in the section Section: Boxes/Centre line.

A datum line exists for both cases.

For the boxes case, a box area for the offset and heights is created below the datum line. The available parameters for tailoring the box area will be given after describing the datum line parameters.

For the centre line case, the centre line and offset and height of the centre line are shown.

In both cases, the actual cross section plot is drawn above the datum line in the graph area.

The parameters defined below, are common to both boxes and centreline label types.

See

26.3.9.1 Boxes/Centreline Labels - Common Parameters

26.3.9.2 Boxes/Centreline Labels - Boxes

When boxes is selected for label_type, the primary string (usually the design cross section) and each tin in the x-section sub-plot can be labelled with one or two lines of title, and the height at the offset position for each point in the primary string.

The title for the strings, is drawn in the title area of the boxes area. The offsets/heights are drawn in the heights area of the boxes area. Consequently the boxes area is made up of rows of text consisting of:

- string/tin titles followed by the offset/height values across the string/tin.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is:

(a) offset title and values
(b) tin title and heights - natural surface etc. (optional)
(c) primary string title and heights - design x-section (optional)

The title area starts at the relative position (left_sub_plot_gap,bottom_sub_plot_gap).

Or return to 26.3.9 Boxes/ Centreline Labels.
26.3.9.2.1 Boxes/Centreline Labels - Boxes - Datum Lines

For the boxes case, the datum line is positioned the distance \( \text{datum\_below\_gap} \) above the top of the boxes area and the graph area is then positioned the distance \( \text{datum\_above\_gap} \) above the datum line.

Hence the graph area is distance \( (\text{datum\_below\_gap} + \text{datum\_above\_gap}) \) above the top of the boxes area.

The columns for the fields documented in the sections are for.

26.3.9.2.2 Boxes/Centreline Labels - Boxes - Title Area

Many distance definitions in the plot parameter file are given in terms of distance above the top of the boxes area.

The size of the title text is given by the `title_box_text_size` parameter.

The width of the title area is either given by the `space_for_titles` parameter, or if omitted, the required width is automatically calculated.

The columns for the fields documented in the sections are for:

26.3.9.2.3 Boxes/Centreline Labels - Boxes - Heights Area

The **heights area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (*box_text_justification*).

The number of decimal places and the size of the heights text can also be specified.

The height of each individual box area is either given by the *horizontal_line_spacing* parameter, or if omitted, the required height is automatically calculated.

**Section: Boxes - Height area parameters**

The columns for the fields documented in the sections are for.

<tr>
<td>Horizontal line spacing (mm)</td>
<td>horizontal_line_spacing</td>
<td>input</td>
<td>height of each individual box area of title area. Calculated if omitted</td>
</tr>
</tbody>
</table>

The total height of the boxes area is simply given by number of boxes drawn multiplied by the height of one box (they all have the same height).

The **width** of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the labels area plus the width of the heights area.

26.3.9.2.5 Boxes/Centreline Labels - Boxes - Inside Linework

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters `box_line_draw_mode` and `box_line_mode_n`.

The separation lines can be drawn just in the title area, just in the heights area or in both areas.

The parameter `box_line_draw_mode` can be set to control all the separation lines but there are additional parameters, `box_line_mode_n`, which override `box_line_draw_mode` for each of the individual boxes where \( n = 1, \ldots, \text{number of boxes} - 1 \).

The top of the top box is not controlled by `box_line_mode_n` but is controlled by the parameters `draw_box_side_2` and `draw_box_side_6`.

The columns for the fields documented in the sections are for.

<tr>
<td>Multiplier for negative depths</td>
<td>depth_negative_factor</td>
<td>input</td>
<td>if set, this value will be used to multiply negative depth values.</td>
</tr>
</tbody>
</table>
The depth from the primary string to a tin, at a particular offset is defined as
\[
\text{depth} = \text{tin height value} - \text{height of the primary string}
\]
That is, the depth that the primary string is below the tin.

Before plotting, the value of depth is multiplied by either the \textit{depth_positive_factor} or \textit{depth_negative_factor}.

\[
\begin{align*}
\text{if (depth }&\geq 0) \quad \text{plotted_depth_value} = \text{depth} \times \text{depth_positive_factor} \\
\text{if (depth }&< 0) \quad \text{plotted_depth_value} = \text{depth} \times \text{depth_negative_factor}
\end{align*}
\]

Hence the definition of depth can be modified by the parameters:

- \textit{depth_positive_factor} value // multiplier for positive depths
- \textit{depth_negative_factor} value // multiplier for negative depths

For example, if the opposite sign is required for depth, that is,
\[
\text{depth} = \text{height of the primary string} - \text{tin height value}
\]

simply set
\[
\begin{align*}
\text{depth_positive_factor} &= -1 \\
\text{depth_negative_factor} &= 1
\end{align*}
\]

Continue to the next section \textit{26.3.9.2.10 Boxes/CL Labels - Boxes - Upright Offset/Staggering Parameters} or return to \textit{26.3.9 Boxes/ Centreline Labels}. 
26.3.9.2.10 Boxes/CL Labels - Boxes - Upright Offset/Staggering Parameters

For each sub-plot, the offsets of the points across the x-section string (primary string) are used for positioning uprights (leader lines), and the offset and height labels for the uprights.

By default, there is an upright at each point across the primary string.

However, if the primary string is a 4d string, then the text at the points on the 4d string can be used as a key to suppress the labelling and upright at that point. See Section: Exclude uprights at nominated x-sec points.

If the real offset position is used for the horizontal position of the offset/height text, text overwriting can easily occur. To prevent overwriting, the text is automatically staggered.

When staggering occurs, the real offset position is then indicated by the offset markers which are drawn at the top of the text boxes from the staggered text position back to the actual offset position of the upright.

The size and position of the staggers are given by:

26.3.9.2.10.1 Boxes/Centreline Labels - Boxes - Upright off/staggering params - Uprights to exclude

For each sub-plot, the offsets of the points across the x-section string (primary string) are used for positioning uprights (leader lines), and the offset and height labels for the uprights.

By default, there is an upright at each point across the primary string.

However, if the primary string is a 4d string, then the text at the points on the 4d string can be used as a key to suppress the labelling and upright at that point.

The parameters to stop labelling and uprights are:

\[
\text{mask\_name\_n \hspace{1cm} 4d\_string\_point\_text \hspace{1cm} where } n=1,100
\]

After any name masks have been applied, it is often desirable to weed out offset values that are too close together before doing any labelling.

The columns for the fields documented in the sections are for.

Continue to the next section **26.3.9.3.3 Boxes/CL Labels - Centreline - Labelling Offset/Height (Superseded)** or return to **26.3.9 Boxes/ Centreline Labels**.
26.3.9.3.3 Boxes/CL Labels - Centreline - Labelling Offset/Height (Superseded)

In the centre line case, the value of the height of the primary string (usually the design cross section) at the zero offset can be labelled. This is normally where the alignment string cuts the cross section.

The label is made up of the texts:

```
primary_title  offset_title  offset_value  height_text  height_value
```

**Note:** These parameters have now been superseded. The parameters for labelling the height of the primary string at zero offset covers this case. To use the zero offset parameters instead, the primary_height_pre_text would include all text required for the Primary_title, offset_title, offset_value and height_text (offset_value is always 0.0).

The columns for the fields documented in the sections are for.

Continue to the next section 26.3.10 Graph Area or return to 26.3.9 Boxes/ Centreline Labels.
26.3.10 Graph Area

The **graph area** for each section sub-plot is the area where the actual plot of the x-section string is drawn.

The **width** of the graph area is determined by the width of the x-section string being plotted, the left and right extensions and horizontal scale (scale) given by the parameters.

The size of the graph area can be extended to allow for symbols by the following parameters:

The types of strings that are drawn in the graph area of a cross section plot are:

(a) **primary string** the x-section string from the x-section model that is being drawn.

(b) **tins** sections of the primary string through any tins in models in the corridor models.

(c) **services** parts of strings (from models in corridor models) that cut the defined corridor.

The **colour** of the strings in the plot is the actual string colour for cases (a) and (c), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are labelled with heights.

The columns for the fields documented in the sections are for.

Please continue to the next section 26.3.11 Corridors - X Section.
26.3.11 Corridors - X Section

A corridor around the primary string is defined by giving a left and right corridor width. Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, it is drawn on the cross-section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.

This is documented for all the PPF Editors in 26.2.7 Corridors.

Please continue to the next section 26.3.12 Grades.
26.3.12 Grades

The plot of the x-section string is made up of straight lines joining the individual points of the x-section.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section: Grade parameters</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Label grades**

- grade_label

  if ticked, label grades.

Either the individual lines can be used as the segments to be labelled for grade, or adjacent lines of the same grade can be considered to be just one segment and labelled only once.

Hence the segments to be labelled for grade can be the individual lines of the x-section, or the segments defined by changes of grade.

**Label change of grade segments**

- grade_change_only

  if ticked, label change of grade segments. If not, label individual lines.

It is also possible to ignore segments smaller that a given minimum width on the plot.

**Minimum segment 3d length**

- grade_minimum_width

    segments smaller than specified value (in mm) are not labelled

The grade labels are drawn parallel to the segment, centred about the segments end points, and a distance grade_offset above the segment. The size, colour and number of decimal places can all be set.

**Minimum segment plan length**

- grade_minimum_width_2d

**Minimum slope (m/m)**

- grade_minimum_slope

**Maximum slope (m/m)**

- grade_maximum_slope

**Decimal places for grades**

- grade_decimals

    number of decimal places in grade.

    If > 0, trailing zeros are removed after the decimal point.

    If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

**Size for grade text (mm)**

- grade_size

    size of the grade label

**Textstyle for grades**

- grade_textstyle

    textstyle of the grade label

**Colour for grades**

- grade_colour

    number of decimal places in grade

**Grade offset (mm)**

- grade_offset

    distance above the segment for label

**Show grade sign**

- grade_offset

    if ticked, the sign of the grade is labelled.

The grade can be labelled as percent cross-fall, 1 in slope, m/m or VicRoads x:1.

Also a threshold value can be set and any grades whose absolute value are below the threshold
can be labelled in one way, and those above the threshold labelled a different way. Hence, if the absolute value of the grade is less that or equal to the absolute value of \textit{grade\_threshold}, then \textit{grade\_mode} is used, otherwise \textit{grade\_upper\_mode} is used.

*If* > 0, trailing zeros are \textit{removed} after the decimal point. *If* <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Please continue to the next section \textit{26.3.13 X-Section Points}. 

![Diagram of design section with tin (natural surface)](image-url)
26.3.13 X-Section Points

The points across each x-section can be automatically labelled on the x-section plots. The offset, height and name of the point can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled. The offset position for the labelling is the offset of the point.

The height position for the labelling can be specified as the

(a) top of the boxes for the x-section
(b) above the maximum height of the strings on the plot
(c) height of the point on the x-section string (primary string)
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:
Only case (b) involves the actual height of the point on the cross section string. For all other cases, only the offset of the cut string is used.

Other heights, for example, the height of the tin at that offset can be used as the height (case (d)).

The columns for the fields documented in the sections are for.

Please continue to the next section 26.3.14 Hatching Cut/Fill.
26.3.14 Hatching Cut/Fill

This option is used to hatch cut and/or fill areas between sets of tins.

The Hatching Cut/Fill section is common to the PPF Editors and is fully documented in 26.2.8 Hatching Cut/Fill.

Section: Hatching cut/fill - Tin parameters - see 26.2.8 Hatching Cut/Fill
Section: Hatching cut/fill - Cut parameters - see 26.2.8.1 Hatching Cut/Fill - Cut

Section: Hatching cut/fill - Fill parameters- see 26.2.8.2 Hatching Cut/Fill - Fill

Please continue to the next section 26.3.15 Cut/Fill Area Labels.
26.3.15 Cut/Fill Area Labels

If the cross section were produced by the Apply MTF or Apply Function, each section will have as following string attributes with values calculated at the time that the cross sections were created.

- LHS Cut Area
- LHS Fill Area
- LHS Strip Area
- RHS Cut Area
- RHS Fill Area
- RHS Strip Area

From these, the cut left, cut right and cut total, fill left, fill right and fill total, and balance left, balance right and balance total can be labelled on the plot.

The columns for the fields documented in the sections are for.

<table>

Please continue to the next section **26.3.16 Cuts**.
26.3.16 Cuts

The cuts that each x-section string makes though strings in any user-specified model, can be automatically labelled on the x-section plots.

The **Cuts** section is common to the **PPF Editors** and is fully documented in 26.2.9 Cuts.

**Section: Cuts - Model/Name mask parameters** - see 26.2.9 Cuts.

**Section: Cuts - Offset parameters** - see 26.2.9.2 Cuts - Offsets - X Section Only

**Section: Cuts - Height parameters** - see 26.2.9.4 Cuts - Heights

**Section: Cuts - Diameter parameters** - see 26.2.9.5 Cuts - Diameters

**Section: Cuts - Label parameters** - see 26.2.9.6 Cuts - Labels

**Section: Cuts - Symbol parameters** - see 26.2.9.7 Cuts - Symbols

Continue to the next section **26.3.17 Paired Cuts - X Sections.**
26.3.17 Paired Cuts - X Sections

*Paired Cuts* uses pairs of strings and where both strings cut each x-section, the cuts on the x-plot can be labelled with information such as

(a) the name of the first and second cut strings
(b) attributes from the first and second cut string
(c) offset distance between the two cuts of the pair
(d) 3d length between the two cuts of the pair
(e) the offsets on the x-section of the first and second cuts of the pair

Symbols can be drawn at the offsets of the first and second cuts (at a height specified when defining the Cut sets), and a line drawn between the symbols. Using both the line and a symbol of an arrow head makes an arrow between the two cuts.

The method for specifying which strings are to be checked for paired cuts is by first specifying the models (using wild cards and characters) that contains the strings, and then a start name mask to select the all the strings that are to be the first strings in a cut pair, and an end name mask to select all the strings that are the second strings in a cut pair.

For a x-section, all the cuts of the selected start strings are found and the cuts ordered by the offset of the cut on the x-section. Then all the cuts of the selected end strings are found and the
cuts ordered by the offset of the cut on the x-section.

The start cuts are then processed and each start cut is paired with the next end cut with a larger offset than the start cut. It is possible that there are end cuts before the first start cut (orphaned end cuts) and start cut with no following end cut (orphaned start cuts).

Up to twenty five different sets of models and name masks can be used so that different paired cut sets can be labelled in different ways.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Section: Pairing - Model/Name mask parameters</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Define Set #

input

set number to be used to define different model/mask sets.

Model

pairing_n_model

model box

models (the name can include wild cards (*) and wild characters (?)) from which start and end cut masks are derived.

Start name mask

pairing_n_start_mask

input

text string containing the name masks to select the start strings, each separated by one or more spaces, to test the string names against. If the name include spaces then it must be enclosed in the quotes " (eg "bench 2").

Each mask can include wild cards (*) and wild characters (?).

For example: "ke*" or, "?bank**" or; if both masks are required, "ke*  ?bank***"

End name mask

pairing_n_end_mask

input

text string containing the name masks to select the end strings, each separated by one or more spaces, to test the string names against. If the name include spaces then it must be enclosed in the quotes " (eg "bench 2")

Each mask can include wild cards and wild characters.

For example: "ke*" or, "?bank**" or; if both masks are required, "ke*  ?bank***"

Note

If Start name mask is blank and End name mask is not blank, then all strings in the models that are not used as end strings, are used as start string.

If End name mask is blank and Start name mask is not blank, then all strings in the models that are not used as start strings, are used as end string.

This is currently not operational: If Start name mask and End name mask are both blank, then all strings in the models are used. All the strings are cut by the x-section are ordered by offset, and successive pairs of cuts taken to be the cut pairs. There could be one remaining cut point (it has the largest offset) and if so, it is taken to be orphaned start point.
where to get the z-values to use for the two cut positions. This is used in conjunction with the choice in the Adopted height field.

If left blank, at cut string height is used.

Adopted height      pairing_n_height           choice box              lower position, higher position

for the choice selected in the Position field, there will be a z-value at the first cut and another z-value at the end cut. The Adopted height says which of the two z-value to use for placing symbols, lines between cuts, text from Attributes and the Offsets of the first cut and the second cut.

If lower (higher) position, the smaller (greater) of the two z-values will be used.
If start (end), the z-value of the first (second) cut of the cut point pair will be used.
If left blank, lower position is used.

Include orphaned start ?  pairing_n_orphan_start   choice box           yes, no

if Yes and there are start cuts after the last end cut (and so can’t be paired), then the last start cut (i.e. the one with the largest offset) is taken as an orphaned start and it is labelled as though there is a matching end at the end of the x-section.
if No and there are start cuts after the last end cut, then those start cut are ignored.
If left blank, No is used.

Include orphaned ends ?  pairing_n_orphan_end   choice box           yes, no

if Yes and there are end cuts before the first start cut, then the first end cut (the one with the smallest offset) is taken as an orphaned end and it is labelled as though there is a matching start at the beginning of the x-section.
if No and there are end cuts before the first start cut, then those end cut are ignored.
If left blank, No is used.

<tbody>
<tr>
<td>if Mode is attribute of first string or attribute of second string, this is the name of the attribute to use as the label</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Offset  
pairing_label_n_offset  
measure box

the text is raised by this amount above the line between the cut pair

Colour  
pairing_label_n_colour  
colour box

colour of the text

Size (mm)  
pairing_label_n_size  
measure box

size of the text in millimetres. A value of 0 means no text.

Textstyle  
pairing_label_n_textstyle  
textstyle box

the textstyle for the text

Pre-text  
pairing_label_n_pre_text  
text box

text to draw before the label. This can include spaces, including one or more spaces after the last non blank character of Pre-text.

Post-text  
pairing_label_n_post_text  
text box

text to draw after the label. This can include spaces, including one or more spaces before the first non blank character of Post-text.

Decimals  
pairing_label_n_no_decimals  
number box

if the label is a number, then Decimals is the number of decimal places to write the number out to.

If > 0, trailing zeros are removed after the decimal point.
If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Leave gap for text  
pairing_label_n_??  
tick box

if ticked then a gap in the line between the cuts pair is left large enough for the label and the pre-text and post-text.
If not ticked then no gap is left in the line between the cuts pair.

The height used for the label is given by the Position and Adopted height columns in the Set definition.
Rotate text to fit pairing_label_n_roate_text tick box

if ticked, then if the label and the pre-text and post-text will not fit between the start cut and end cut of the cut pair, the text is rotated through ninety degrees.

If not ticked, then the label text is drawn even though it will run over the ends of the cut pair.

Continue to the next section 26.3.17.3 Paired Cuts - Start Offset or return to 26.3.17 Paired Cuts - X Sections.
26.3.17.3 Paired Cuts - Start Offset

The Offset (on the x-section) of the first point of the cut pair can be labelled.

The text for the label consists of pre-text followed by Offset value followed by post-text.

The columns for the fields documented in the sections are for.

Decimals  pairing_start_offset_n_no_decimals  number box

The number of decimal places for the Offset value.
If > 0, trailing zeros are removed after the decimal point.
If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Please continue to the next section 26.3.18 Paired Points.
26.3.18 Paired Points

Most cross sections are created with the vertices having vertex names which correspond to the strings created by template links, or MTF modifiers, or the names of the cut strings when cross sections are created by cutting through strings.

The *Paired Points* option enables a user to link pairs of these vertex names from the cross section being plotted (to create a points pair), and the points from the pair can be labelled with information such as

(a) the name of the first and second point of the pair
(b) vertex attributes of the cross section from the first and second points of the pair
(c) distance between the two points in a pair
(d) 3d length between the two points in a pair
(e) the offsets on the x-section of the first and second points in a pair

Symbols can be drawn at the offsets of the first and second points of a pair (at a height specified when defining the Cut sets), and a line drawn between the symbols. Using both the line and a symbol of an arrow head makes an arrow between the two cuts in a pair.

The method for specifying which named vertices are to be used for paired points is by a **start name mask** (using wild cards and characters) to select all the vertices that are to be the first points in a pair, and an **end name mask** (using wild cards and characters) to select all the vertices that are the second points in a pair.

For a x-section, all the named vertices of the selected **start points** are found and the points ordered by the offset of the point on the x-section. Then all the named vertices of the selected
**end points** are found and the points ordered by the offset of the point on the x-section.

The start points are then processed and each start point is paired with the next end point with a larger offset than the start point. It is possible that there are end points before the first start point (orphaned end points) and start points with no following end point (orphaned start points).

Up to twenty five different sets of name masks can be used so that different paired point sets can be labelled in different ways.

The columns for the fields documented in the sections are for.

<table>

</tr>
</tbody>
</table>

**Section: Pairing - Model/Name mask parameters**

- **Define Set #**: input
  - set number to be used to define different name mask sets.

- **Start name mask**: input
  - text string containing the name masks to select the start points, each separated by one or more spaces, to test the x-section vertex names against. If the name includes spaces then it must be enclosed in the quotes " (eg "bench 2").
  - Each mask can include wild cards (*) and wild characters (?).
  - For example: "ke*" or, "?bank*" or, if both masks are required, "ke* ?bank*"

- **End name mask**: input
  - text string containing the name masks to select the end points, each separated by one or more spaces, to test the x-section vertex names against. If the name include spaces then it must be enclosed in the quotes " (eg "bench 2")
  - Each mask can include wild cards and wild characters.
  - For example: "ke*" or, "?bank*" or, if both masks are required, "ke* ?bank*

**Note**

- **If Start name mask** is blank and **End name mask** is not blank, then all vertices on the x-section that are not used as end points, are used as start points.

- **If End name mask** is blank and **Start name mask** is not blank, then all vertices on the x-section that are not used as start points, are used as end points.

- **If End name mask** and **Start name mask** are both blank, then all vertices on the x-section are used.
  - Successive pairs of vertices taken to be the point pairs. There could be one remaining point (it has the largest offset) and if so, it is taken to be orphaned start point.
Position | choice box
---|---
Adopted height | pairings\_n\_height | choice box | lower position, higher position

where to get the z-values to use for the two paired points. This is used in conjunction with the choice in the Adopted height field.

If left blank, at point height is used.

Include orphaned start? | pairing\_n\_orphan\_start | choice box | yes, no
---|---|---|---
if Yes and there are start points after the last end point (and so can’t be paired), then the last start point (i.e. the one with the largest offset) is taken as an orphaned start and it is labelled as though there is a matching end at the end of the x-section.
if No and there are start points after the last end point, then those start points are ignored.
If left blank, No is used.

Include orphaned ends? | pairing\_n\_orphan\_end | choice box | yes, no
---|---|---|---
if Yes and there are end points before the first start point, then the first end point (the one with the smallest offset) is taken as an orphaned end and it is labelled as though there is a matching start at the beginning of the x-section.
if No and there are end points before the first start point, then those end points are ignored.
If left blank, No is used.

Section: Pairing - End Offset parameters

Use Set #

set number as specified in the Define set #.

The height used for the text is given by the Position and Adopted height columns in the Set definition. This is then adjusted by the field Y (mm).

X (mm) pairing_end_offset_n_x measure box

for placing the text: horizontal adjustment from the Offset of the second point.

Y (mm) pairing_end_offset_n_y measure box

for placing the text: the vertical adjustment to the height given by the Position and Adopted height columns in the Set definition.

Angle (dms) pairing_end_offset_n_angle measure box

angle (measured counterclockwise from the positive x-axis with units of degrees in 4.17.1 HP Notation) to rotate the text.

Colour pairing_end_offset_n_colour colour box

colour of the text.

Size (mm) pairing_end_offset_n_size measure box

size of the text in millimetres. A value of 0 means no text.

Textstyle pairing_end_offset_n_textstyle textstyle box

the textstyle for the text.

Pre-text pairing_end_offset_n_pre_text text box

text before the Offset value. This can include spaces, including one or more spaces after the last non blank character of Pre-text.

Post-text pairing_end_offset_n_post_text text box

text after the Offset value. This can include spaces, including one or more spaces before the first non blank character of Post-text.
Justification          pairing_start_offset_n_justification          justification box

Decimals               pairing_start_offset_n_no_decimals          number box
the number of decimal places for the Offset value
If > 0, trailing zeros are removed after the decimal point.
If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

   Return to 26.3 Section X Plot PPF Editor.
26.4 Long Plot PPF Editor

Position of option on menu: Plot => Plot and PPF Editors => Long sections

The Long section PPF editor is for creating and/or editing a (binary) long-section PPF and for creating a long section plot.

Note: Binary PPFs are stored within the project (not in the folder containing the project as the text ppf's were).

On selecting the Long sections option, the Section Long Plot PPF Editor panel is displayed. The plot parameters for controlling the cross section plots are accessed by expanding to the appropriate node in the Section Long Plot tree (click on the + to expand to node or - to collapse the node) and then clicking on the required node, and the required information to fill in is displayed on the right hand side of the panel.

For information on all the different nodes see:

26.4.27 PPFs To Include - Long Section
26.4.28 Buttons at Bottom of Panel - Long Section
26.4.1 General Information on Long Section Plots

A long section is normally generated along a given centreline and includes sections along the centre line through tins and services.

If the long section plot is too long to fit on one page, it can be broken into a number of pages (sheets) with a user defined overlap between the sheets.

The long plot on each page consists of the three regions - boxes, datum and graph areas.

The **boxes area** is where the titles and the chainage values and the heights/deptths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

Apart from information labelled in the boxes area, the long section plot can label other information such as:

(a) horizontal geometry
(b) vertical geometry
(c) chainage, heights at special points
(d) symbols at special points
(e) bubbles at special chainages
(f) cuts the design string makes through strings
(g) cut and fill areas

A plot of the plan area that the long section traverses can also be automatically included on each page of the long section plot.
All the required parameters for controlling the long section plot are set up in the *Long Plot PPF Editor* and will be described in detail in the following sections.

Please continue to the next section 26.4.2 Section Long Plot - Front Page or return to 26.4 Long Plot PPF Editor.
26.4.2 Section Long Plot - Front Page

The long plot itself consists of the three regions - boxes, datum and graph areas.

The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

Apart from information labelled in the boxes area, the long section plot can label other information including:

(a) horizontal geometry
(b) vertical geometry
(c) chainage, heights at special points
(d) symbols at special points
(e) bubbles at special chainages
(f) cuts the design string makes through strings
(g) cut and fill areas
Section: Plot parameter file

A plot parameter file can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

This section is documented for all the PPF Editors in 26.2.1 Plot Parameter File.

Section: Section: View to load details from AND Global variables

A section view can be selected to load certain values into fields of the PPDF Editor. For example, Vertical exaggeration and Corridor models. And there are variables to use if some values aren’t given.

These sections are documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

The columns for the fields documented in the sections are for:

Panel Field | Parameter name | Type | Pop-Up
---|---|---|---
Name of string to profile | string_to_plot | string select box | 
Model of strings to profile | model_to_plot | model box | 
Horizontal Scale | scale | input | 
Vertical exaggeration | vertical_exaggeration | input | 
Start chainage | start_chainage | input | 
End chainage | end_chainage | input | 

Section: Sheet size setup and Plotter parameters

These sections define the size of the "paper" to plot on, the type of plotter to use and the naming to use for the plot files.

These sections are documented for all the PPF Editors in 26.2.3 Sheet Size and Plotter Parameters.

Section: Chainage range

Use HG VG for min, max determines whether the horizontal geometry (HG) and the vertical geometry (VG) are both used to determine the minimum and maximum chainages for drawing. This allows the vertical geometry to be plotted when it is outside the horizontal geometry (e.g. kerb returns).

Use HG and VG to determine min/max chainage

Use HG and VG for min_max chainage | use_hg_vg_for_min_max | tick box |

if ticked, the min/max chainage will be determined by the Horizontal and Vertical geometry.

Please continue to the next section 26.4.3 Notes - Long Section.
26.4.3 Notes - Long Section
This is documented for all the PPF Editors in 26.2.4 Notes.

Please continue to the next section 26.4.6 Plot Sheet Layout - Long Section.
26.4.6 Plot Sheet Layout - Long Section

**Plot Sheet Layout - Margins**

**Section: Margins for standard 12d title file - Border gaps**

If the default 12d title block is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the bottom_border_gap is added to the calculated height of the bottom of the title block.

- **Left (mm)**
  - `left_border_gap` real box
  - left border gap (in millimetres).

- **Right (mm)**
  - `right_border_gap` real box
  - right border gap (in millimetres).

- **Top (mm)**
  - `top_border_gap` real box
  - top border gap (in millimetres).

- **Bottom (mm)**
  - `bottom_border_gap`
  - bottom border gap (in millimetres).

**Section: Margins for user title file**

- **Left (mm)**
  - `left_margin` input
  - left margin (in millimetres).

- **Right (mm)**
  - `right_margin` input
  - right margin (in millimetres).

---

**Definition of Plotting Areas for Default 12d Title Block**

(long section plot area is inside the dashed lines)

(0,0) size depends on text size in the default 12d title block

---

**Long Plot PPF Editor**
Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margin and gap parameters can exist in the one plot parameter file.

The \((\text{left}_\text{margin}, \text{bottom}_\text{margin})\) defines the left hand corner position of the long plot on the plot sheet.

The \(\text{right}_\text{margin}\) and \(\text{top}_\text{margin}\) need not be set and if missing, will be calculated from the other plot parameters defining the plot layout.

If the sheet sizes are missing, they will also be automatically calculated.

Please continue to the next section 26.4.7 Pagination.
26.4.7 Pagination

If the long section plot is too long to fit on one page, it can be broken into a number of pages (sheets).

The parameter, `pagination_length`, controls the amount of new chainage length on each plot page. Each page of the long section plot can also included a set chainage amount from the end of the previous plot.

Hence apart from the first page and possibly the last page, the plot will have a chainage length given by the sum of the `pagination_length` and `pagination_overlap`.

The columns for the fields documented in the sections are for.

<table>

</thead>
</table>

*length and overlap units.*

<table>
<thead>
<tr>
<th>Chainage length</th>
<th>pagination_length</th>
<th>input</th>
<th></th>
</tr>
</thead>
</table>

*new chainage range on each page.*

<table>
<thead>
<tr>
<th>Chainage overlap</th>
<th>pagination_overlap</th>
<th>input</th>
<th></th>
</tr>
</thead>
</table>

*overlap between pages.*

**Note:**
The `pagination_length` and `pagination_overlap` are given in chainage units or millimetres. The user must choose values which will fit on the selected sheet size or the end of each plot will be truncated by the sheet.

Please continue to the next section 26.4.8 Boxes.
26.4.8 Boxes

Each string in the long section plot can be labelled with one or two lines of title, and the chainages/heights/depths at the user specified chainages for the strings.

The **title** for the strings, is drawn in the **title area** of the **boxes area**.

The **chainages/heights/depths** are drawn in the **heights area** of the **boxes area**.

Consequently the boxes area is made up of rows of text consisting of:

- **string/tin titles** followed by the **chainage/height/depth** values along the string.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is:
(a) optional super-elevation diagram
(b) chainage values
(c) can be primary string heights - user choice
(d) tin heights and depths
(e) offset heights and depths
(f) optional volumes or earth works
(g) can be primary string heights - user choice
(h) zero or more blank boxes
number of boxes to be left blank

The blank boxes are used to place other information in (such as horizontal or vertical geometry) or for other user supplied information.

**Section: Primary string parameters**

The primary string (the design string) is used to define
(a) the design long section
(b) the chainage positions for labelling heights and drawing uprights
(c) the section line used for sectioning through tins
(d) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the long section plot, it doesn't have to be drawn on the long section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter `primary_string`.

The colour of the primary string in the plot is the actual primary string colour.

Sometimes the primary string is only required to define chainages or the horizontal path for tin sections. In this case, the primary string would not be drawn on the long section plot.

If the primary string is drawn, it is automatically labelled.

Also the drawing of crosses at the vertical intersection points can be controlled from the ppf file.

**Draw and label the primary string  primary_string tick box**

*if ticked, the primary string will be drawn and labelled.*

**Draw crosses at VIPs primary_draw_vips tick box**

*if ticked, crosses will be draw at the vertical intersection points.*

The position of the primary string label box can be either straight after the chainage box, or after the tin and offset boxes but before the blank boxes.

Placing the primary string label before the bank boxes or just after the chainage box in controlled by the parameter `primary_label_mode`.

**Primary string location  primary_label_mode choice box**
in last box before blank boxes
in first box above chainages

*position of the primary string label.*

Although the order of the boxes may appear to be fixed, in practice they can be in any order. This is possible because for each box, there is a parameter to set the height in millimetres from the bottom of all the boxes that the text in the box is drawn at (the `_y_pos` parameters).

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

Section: Boxes - Title area parameters

The title area starts at the co-ordinate (left_margin, bottom_margin).

The size of the title text is given by the \texttt{title\_box\_text\_size} parameter.

The width of the title area is either given by the \texttt{space\_for\_titles} parameter, or if omitted, the required width is automatically calculated.

\begin{itemize}
  \item \textbf{Size of titles (mm)} \texttt{title\_box\_text\_size} \textit{input}
  \item \textit{size of offset, height label and values}
  \item \textbf{Space for titles (mm)} \texttt{space\_for\_titles} \textit{input}
  \item \textit{size of title area.}
\end{itemize}

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

\begin{itemize}
  \item \textbf{X adjustment (mm)} \texttt{box\_titles\_x} \textit{input}
  \item \textit{distance to move the title text from the left hand side of the boxes}
\end{itemize}

The y position of the title text can be set separately for each type of title. The parameters are given later under each of the title types (e.g. chainages, primary string, tins, depths \textit{etc}.).

After the title area there can be a user defined gap, followed by the heights area

\begin{itemize}
  \item \textbf{Distance between title and values area (mm)} \texttt{box\_gap} \textit{input}
  \item \textit{distance between title and values area in mm.}
\end{itemize}

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (\texttt{box\_justification}).

Continue to the next section \texttt{26.4.8.2 Boxes - Values Area} or return to \texttt{26.4.8 Boxes}. 

26.4.8.2 Boxes - Values Area

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>

**Section: Boxes - Value area parameters**

The **values area** starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (box_text_justification).

The number of decimal places (number_of_decimals), and the size of the heights text (box_text_size) can be specified globally but there is a parameter for each box which overrides these defaults for each box of heights.

**Justification**

- box_text_justification
- choice box
- bottom of individual boxes
- top of individual boxes

justification of height text.

**Number of decimals**

- number_of_decimals
- input

number of decimal places in the height boxes. If <0, the absolute value is taken as the number of decimal places i.e. no trailing zeros are removed for the values in the heights area.

**Text size (mm)**

- box_text_size
- input

distance to move the title text from the left hand side of the boxes

**Horizontal line spacing (mm)**

- horizontal_line_spacing
- input

height of the individual height boxes.

A global height for the individual boxes is either given by the horizontal_line_spacing parameter, or if omitted, a height to fit the largest height or depth value is calculated and used as the default box height.

However, the height of each box can be individually set by parameters box_size_n where the boxing numbering, n. starts from the bottom box. The value of horizontal_line_spacing is used for any of the box_size_n parameters not specified.

**Label tin/offset string heights by default**

- label_heights
- tick box

**Label tin/offset string depths by default**

- label_depths
- tick box

**Box #**

- input

specifying the nth value

**Size (mm)**

- box_size_n
- input

height of the nth box, numbered from bottom up.

The total height of the boxes area is simply given by the sum of the heights of each box.
The width of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the title area plus box_gap, plus the width of the heights area.

Many distance definitions in the plot parameter file are given in terms of distance above the top of the boxes area so that the distances are independent of the number of boxes and box sizes.

Continue to the next section 26.4.8.3 Boxes - Outside Linework or return to 26.4.8 Boxes.
26.4.8.3 Boxes - Outside Linework

The drawing of the box line work, the box colour, the position of the primary string labels and the number of blank boxes are all set by parameters.

The columns for the fields documented in the sections are for.

Section: Boxes - Inside linework parameters

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters `box_line_draw_mode` and `box_line_mode_n`.

The separation lines can be drawn just in the title area, just in the heights area or in both areas.

The parameter `box_line_draw_mode` can be set to control all the separation lines but there are additional parameters, `box_line_mode_n`, which override `box_line_draw_mode` for each of the individual boxes where \( n = 1, \ldots \) number of boxes -1.

The top of the top box is not controlled by `box_line_mode_n` but is controlled by the parameters `draw_box_side_2` and `draw_box_side_6`.

**Separation line mode**

- **box_line_draw_mode**
  - choice box: Do not draw any separation
  - choice box: Draw the separation lines in both areas
  - choice box: Draw the separation lines in the title area only
  - choice box: Draw the separation lines in the heights area only

**Box #**

Where box \( # = 1 \) to number of boxes \( (n) \). Box 1 is the bottom box, increasing upwards.

**Line mode**

- **box_line_mode_n**
  - choice box: No top line for title or area (mode=0)
  - choice box: Draw top line for title or height area (mode=1)
  - choice box: Draw top line for title area only (mode=2)
  - choice box: Draw top line for height area only (mode=3)

*Line mode for top of title and height areas for box number specified.*

26.4.8.6 Boxes - Primary String Titles/Heights

Sometimes the primary string is only required to define chainages or the horizontal path for tin sections. In this case, the primary string would not be drawn on the long section plot.

If the primary string is drawn, it is automatically labelled.

Also the drawing of crosses at the vertical intersection points can be controlled from the ppf file.

The columns for the fields documented in the sections are for.

</tr>
</tbody>
</table>

The depth from the primary string to a tin, at a particular offset is defined as
\[ \text{depth} = \text{tin height value} - \text{height of the primary string} \]

That is, the depth that the primary string is \textbf{below} the tin.

Before plotting, the value of depth is multiplied by either the \textit{depth\_positive\_factor} or \textit{depth\_negative\_factor}.

\[
\begin{align*}
\text{if (depth} \geq 0) & \quad \text{plotted\_depth\_value} = \text{depth} \times \text{depth\_positive\_factor} \\
\text{if (depth} < 0) & \quad \text{plotted\_depth\_value} = \text{depth} \times \text{depth\_negative\_factor}
\end{align*}
\]

Hence the definition of depth can be modified by the parameters:

- \text{depth\_positive\_factor value} \quad // multiplier for positive depths
- \text{depth\_negative\_factor value} \quad // multiplier for negative depths

For example, if the opposite sign is required for depth, that is,

\[
\text{depth} = \text{height of the primary string} - \text{tin height value}
\]

simply set

\[
\begin{align*}
\text{depth\_positive\_factor} & = -1 \\
\text{depth\_negative\_factor} & = 1
\end{align*}
\]

Continue to the next section \textbf{26.4.8.7.4 Boxes - Offset String Titles/Heights/Depths} or return to \textbf{26.4.8 Boxes}. 
26.4.8.7.4 Boxes - Offset String Titles/Heights/Depths

<td><strong>Section:</strong></td>
<td><strong>Offset string titles/heights/depths parameters</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Each string in the offset model given can be automatically projected onto the primary string and drawn on the long section plot.

The offset model has been modified to allow strings to be projected onto the primary string to be specified by model and name, rather than just projecting all the strings in a given model. The string can also be labelled with either the string name, its model name or both.

The string is specified by

```
offset_n_mask = "model_name->string_name"
```

For each n, a set of plot parameters determine if the string’s heights and/or depths from the primary string are labelled in the boxes area.

If only the `string_name` is given, then the model given in the Offset model field of the Section Long Plot panel.

If there is **more than one string** with the given model and name, then it will be considered to be one string and at any primary string chainage, the closest of the strings will be the part used for projecting. For example, strings of the same name on either side of a road intersection will be considered to be the one string for projecting.

If any `offset_n_mask` is used, then the Offset option expects all the strings to be specified by an `offset_n_mask`. Then if no mask exists for any value of n, then that parameter set is ignored and no string projected.

If no offset masks are used (that is, no `offset_n_mask`'s are used), then the plot parameters determine whether each string in the offset model is plotted and labelled is the same as the order of the strings in the offset model.

For the following sets of parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth string given by `offset_n_mask` or, if no offset masks are given, the nth string in the Offset model.

26.4.8.9 Boxes - Super Elevation Diagram

The optional super-elevation diagram draws the values of the cross-fall (x-fall) between two strings using the primary string as the reference string. The cross-fall at a given chainage on the primary string is calculated by sectioning perpendicular to the reference string at that chainage and cutting the two strings. The cross-fall is defined as the cross-fall between the two cuts points on the strings.

The diagram has levels for the cross fall for a pair of strings on the left of the primary string, and a pair of strings on the right of the primary string. The diagram also has uprights in the super-elevation box with chainage values at the change of super values.

For the left hand side, the cross-fall is calculated at right angles to the primary string between the user given left hinge string and the left edge string.

The columns for the fields documented in the sections are for.

The values of calculated cut and fill volumes (cut and fill earth works) can be read from a file and then interpolated to produce cut and fill volumes for a given interval along the primary string.

**Draw a volume diagram**  volume_draw_mode  tick box
if ticked, draw a volume diagram.

**Cut and fill text position**  volume_text_centre_mode  choice box  along the uprights
position of cut and fill text relative to the uprights.

**Sample interval**  volume_sample_interval  input
interval to display volumes.

**Report file**  volume_file_name  report box
name of volumes report file.

**Box Y position (mm)**  volume_y_pos  input
if set, the volume box is positioned at this height from the bottom of the first box

**Box size (mm)**  volume_box_size  input
if set, upright, volumes and titles box height.

**Horizontal cut/fill dividing line linestyle**
volume_cl_linestyle  linestyle box
linestyle of the cut/fill dividing line.

**Horizontal cut/fill dividing line colour**
volume_cl_line_colour  colour box
colour of the cut/fill dividing line.

Sub upright X position (mm) | volume_sub_uprights_x | input | the x distance to move from the default sub uprights position.

Sub upright title X position (mm) | volume_sub_title_x | input | the distance to move the sub title text from the volume sub uprights

Continue to the next section 26.4.8.11 Boxes - X,Y or return to 26.4.8 Boxes.
26.4.8.11 Boxes - X,Y

The values of the X and Y coordinate for selected chainages can be labelled as separate boxes. The chainages specified are limited to the base set of chainages already defined in the chainage selection and staggering section. i.e. an upright must exist for the X and Y value to be labelled. Not all of the uprights have to be labelled, just those specified in this section. There are plot parameters to control all aspects of the X and Y labelling. Chainages are used for positioning X and Y labels. The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

The columns for the fields documented in the sections are for:

*size of the Y values*

| Text y position (mm) | y_label_y_pos | input | |

*if set, the height in mm above the bottom of all the boxes that the Y values are drawn. If not set, then the text is placed at a height that puts it inside the default box for the Y labels.*

Please continue to the next section [26.4.9 Chainage/Staggering](#).
26.4.9 Chainage/Staggering

Chainages are used for positioning height labels, uprights (leader lines) and bubbles. The chainages for the long section plot relate to the primary string.

The columns for the fields documented in the sections are as follows:

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section: Chainage/Staggering - Chainage parameters</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Chord/arc chainage mode</td>
<td>chord_arc</td>
<td>choice box</td>
<td>Do not use chord/arc chainages</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Use chord/arc chainages</td>
</tr>
</tbody>
</table>

Chainage mode to include chord/arc chainages.

Chainage interval: chainage_interval input
the regular interval (0=no regulars).

Include start and end chainages
chainage_label_ends tick box
if ticked, include the start and end chainages.

Include tangents, spirals
chainage_label_hcp tick box
if ticked, include the tangents and spirals.

Include horizontal intersection points
chainage_label_hip tick box
if ticked, include horizontal intersection points.

Include horizontal tangent points
chainage_label_hcp tick box
if ticked, include horizontal tangent points.

Include vertical intersection points
chainage_label_vip tick box
if ticked, include vertical intersection points.

Include vertical tangent points
chainage_label_vtp tick box
if ticked, include vertical tangent points.

Include crest points
chainage_label_crest tick box
if ticked, include crest points.

Include sag points
chainage_label_sag tick box
if ticked, include sag points.

Include change of vertical grade
chainage_label_grade_change tick box
if ticked, include changes in vertical grade.

Include chord/arc tolerance chainages
chainage_label_grade_change tick box.

Chainage weeding tolerance
chainage_label_tolerance input
if >0 then use as a weeding tolerance, if <=0 don’t weed.

Merge in bubble chainages
chainage_merge_bubbles tick box
if ticked, merge in bubble chainages.

Weeding tolerance after bubble merge
chainage_merge_tolerance input
if > 0, weed after merge using specified weeding tolerance. If <= 0, don’t weed after merge.

Files of special chainages
chainage_special_n_file file box
n = 1 to 20 - include chainages from the file (one chainage per line)

Continue to the next section 26.4.9.1 Chainage/Staggering - Staggering or return to 26.4.9.
26.4.9.1 Chainage/Staggering - Staggering

If the real chainage position is used for the horizontal position of the chainage/height/depth text, text over writing can easily occur.

To prevent over writing, the text can be staggered.

If the `stagger_mode` parameter is set to 1, the text position is adjusted so that the text does not over write.

The real chainage position is then indicated by the chainage markers which are drawn at the top of the text boxes from the staggered text position back to the actual chainage position of the text.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section: Chainage/Staggering - Staggering parameters</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Stagger mode</td>

</tbody>
</table>

**Uprights text offset factor**

<table>
<thead>
<tr>
<th>Uprights text offset factor</th>
<th>uprights_text_offset_factor</th>
<th>input</th>
</tr>
</thead>
<tbody>
<tr>
<td>move the text by this factor*size.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave
room for the height text.

Please continue to the next section 26.4.11 Datum Area.
26.4.11 Datum Area

The **datum area** is the region between the boxes area and the graph area.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>

**Section: Datum area - datum value mode**

- **Use manual datum** manual_datum tick box
  
  If ticked the datum will be calculated internally, else use the datum_value parameter for the datum.

- **Datum value** datum_value input
  
  The value to be used for the datum.

- **Datum roundoff** datum_roundoff input
  
  The value to roundoff the datum value.

- **Decimal places for datum** datum_decimals input
  
  *If* > 0, trailing zeros are **removed** after the decimal point.
  
  *If* < 0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

**Section: Datum area - other parameters**

- **Datum name** datum_name input
  
  Text to write before the datum value

- **Graph area to datum line gap (mm)** datum_above_gap real box
  
  Distance from the bottom of the graph area to the datum line.

- **Datum line gap to top of boxes (mm)** datum_below_gap real box
  
  Distance from datum line to top of boxes.

The **datum line** is positioned the distance **datum_below_gap** above the top of the boxes area and the graph area is positioned the distance **datum_above_gap** above the datum line.

Hence the graph area is distance (datum_below_gap + datum_above_gap) above the top of the boxes area.

The **datum_below_gap** and **datum_above_gap** can be zero or positive.

- **Datum linestyle** datum_linestyle linestyle box
  
  Datum line linestyle (default solid)

- **Datum textstyle** datum_textstyle text box
  
  Textstyle for datum information

- **Datum text size (mm)** datum_text_size input
  
  Size of datum text and value (mm)

- **Datum colour** datum_colour colour box
  
  Colour of the datum text and line.

- **X adjustment (mm)** datum_x input
  
  Distance to move the datum text along the datum line

- **Y adjustment (mm)** datum_y input
  
  Distance to raise the datum text above the datum line
26.4.11.1 Datum Area - Offset String Datum Labels

</thead>
</table>

*extra distance to add before the bottom of plot area starts.*

Please continue to the next section [26.4.13 Corridors - Long Section](#).
26.4.13 Corridors - Long Section

A corridor around the primary string is defined by giving a left and right corridor width. Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, it is drawn on the cross-section plot. To be drawn, strings do not have to cross the primary string, but just be in the corridor. This is documented for all the PPF Editors in 26.2.7 Corridors.

Please continue to the next section 26.4.14 Bubbles.
26.4.14 Bubbles

Circles with the string name and a unique number (bubbles) can be drawn on the long section plot. Bubbles are normally used for lip profiles.

The chainages used for the bubbles are given by a set of parameters similar to the chainage parameters. The resulting set of bubbles are sequentially numbered (starting with one) in chainage order.

Although many bubbles can be defined by the bubble parameters, a bubble is only drawn on the plot if there is a labelled chainage to draw it above.

Hence not all bubbles given by the bubble chainage parameters are drawn but for the ones that are drawn, the bubble number is taken from the full bubble set.

The columns for the fields documented in the sections are for.

Please continue to the next section 26.4.16 Extensive Horizontal Geometry.
26.4.16 Extensive Horizontal Geometry

The standard horizontal geometry arrows can be drawn at a given distance above the top of the boxes area.

For complicated horizontal geometry labelling, there are sets of horizontal geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the horizontal geometry of alignment strings other than the primary string. To plot such a string on the same plot, the chainage position of the horizontal geometry for the non-primary alignment strings is projected onto the primary string to give a primary string chainage for plotting. The values of the horizontal geometry (such as radius and spiral length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting horizontal geometry, the user can give up to twenty sets of these labels and they can be used to label spirals, curves and tangent information for the primary string and/or additional alignment strings.

Each label set consists of three parts:
(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

The columns for the fields documented in the sections are for.

Please continue to the next section 26.4.18 Extensive Vertical Geometry.
26.4.18 Extensive Vertical Geometry

For complicated vertical geometry labelling of the primary alignment string, there are sets of vertical geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the vertical geometry of alignment strings other than the primary string. To plot such a string on the same plot, the chainage position of the vertical geometry for the non-primary alignment strings is projected onto the primary string to give a primary string chainage for plotting. The values of the vertical geometry (such as grade and curve length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting vertical geometry, the user can give up to twenty sets of these labels and they can be used to label grades or vertical curve information for the primary string and/or additional alignment strings.

Each label set consists of three parts:
(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>

<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section:</td>
<td>Extensive</td>
<td>vertical geometry parameters</td>
<td></td>
</tr>
</tbody>
</table>

**Define set #**

Input where \( n = 1 \) to \( ...20 \). The set enables the specification of a number of parameters for a number of specified extensive horizontal geometry.

For the following parameters, \( n \) takes the value 1 to 20 and specifies the \( n \)th parameter set.

**Geometry to label**

\[ v_{g\_n\_type} \]

**Choice box**

Label grades

**Value to label**

\[ v_{g\_n\_value\_mode} \]

**Choice box**

Nothing

%grade | or | parabola length, arc length

1 in grade | or | radius

mm grade | or | K value

ch length between curve points per chord (QR) | or | curve constant (QR).

Specifies the value to label. This will be dependant on the \( v_{g\_n\_type} \) chosen.

**Vertical curve points to draw the arrows between** (for grade labelling only)

**Points to draw arrows between**

\[ v_{g\_n\_between\_mode} \]

**Choice box**

Between chainages at the vips between chainages at the vtps
specifies where to draw the arrows between (for grade labelling only).

Y offset (mm) \( v_{g_n\_label\_y} \) input
distance of arrow line above top of the boxes. This value can be negative

If the set of parameters is to apply to the vertical geometry of an alignment string other than the primary string, then the following parameter can define the other alignment string

**Offset string** \( v_{g_n\_offset\_string} \) select box
the name of the non-primary string. i.e.

\[ v_{g_n\_offset\_string} \quad \text{model->string\_name} \]

or

\[ v_{g_n\_offset\_string} \quad \text{string\_name} \]

and the model is the **defined by offset\_model**. offset\_model has been defined in the section 26.4.8.7.4 Boxes - Offset String Titles/Heights/Depths.

If the \( v_{g_n\_offset\_string} \) parameter does not exist, then the set of vertical geometry parameters is applied to the primary string.

`draw mode for symbol`
Please continue to the next section 26.4.21 Hatching Cut/Fill.
26.4.21 Hatching Cut/Fill

This option is used to hatch cut and/or fill areas between sets of tins.

The Hatching Cut/Fill section is common to the PPF Editors and is fully documented in 26.2.8 Hatching Cut/Fill.

**Section: Hatching cut/fill - Tin parameters** - see 26.2.8 Hatching Cut/Fill

**Section: Hatching cut/fill - Cut parameters** - see 26.2.8.1 Hatching Cut/Fill - Cut

**Section: Hatching cut/fill - Fill parameters** - see 26.2.8.2 Hatching Cut/Fill - Fill

Please continue to the next section 26.4.22 Cuts.
26.4.22 Cuts

The cuts that the longsection string makes though strings in any user-specified model, can be automatically labelled on the x-section plots.

The Cuts section is common to the PPF Editors and is fully documented in 26.2.9 Cuts.

Section: Cuts - Model/Name mask parameters - see 26.2.9 Cuts.

Section: Cuts - Chainage parameters - see 26.2.9.3 Cuts - Chainage - Long Sections Only

Section: Cuts - Height parameters - see 26.2.9.4 Cuts - Heights

Section: Cuts - Diameter parameters - see 26.2.9.5 Cuts - Diameters

Section: Cuts - Label parameters - see 26.2.9.6 Cuts - Labels

Section: Cuts - Symbol parameters - see 26.2.9.7 Cuts - Symbols

Continue to the next section 26.4.23 Paired Cuts - Long Section.
26.4.23 Paired Cuts - Long Section

Paired cuts uses pairs of strings and where both strings cut the primary string, the cuts on the long plot can be labelled with information such as:
(a) the name of the first and second cut strings
(b) attributes from the first and second cut string
(c) plan distance between the two cuts of the pair
(d) 3d length between the two cuts of the pair
(e) the chainage on the long section of the first and second cuts of the pair

Symbols can be drawn at the chainages of the first and second cuts (at a height specified when defining the Cut sets), and a line drawn between the symbols. Using both the line and a symbol of an arrow head makes an arrow between the two cuts.

The method for specifying which strings are to be checked for paired cuts is by first specifying the models (using wild cards and characters) that contains the strings, and then a start name mask to select the all the strings that are to be the first strings in a cut pair, and an end name mask to select all the strings that are the second strings in a cut pair.

For a long section, all the cuts of the selected start strings are found and the cuts ordered by the chainage of the cut with the primary string of the long section. Then all the cuts of the selected
end strings are found and the cuts ordered by the chainage of the cut with the primary string of the long section.

The start cuts are then processed and each start cut is paired with the next end cut with a larger chainage than the start cut. It is possible that there are end cuts before the first start cut (orphaned end cuts) and start cut with no following end cut (orphaned start cuts).

Up to twenty five different sets of models and name masks can be used so that different paired cut sets can be labelled in different ways.

See

Section: Pairing - Model/Name mask parameters

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define Set #</td>
<td>pairing_n_set</td>
<td>input</td>
</tr>
</tbody>
</table>

*set number to be used to define different model/mask sets.*

<table>
<thead>
<tr>
<th>Model</th>
<th>pairing_n_model</th>
<th>model box</th>
</tr>
</thead>
</table>

*models (the name can include wild cards (*) and wild characters (?)) from which start and end cut masks are derived.*

<table>
<thead>
<tr>
<th>Start name mask</th>
<th>pairing_n_start_mask</th>
<th>input</th>
</tr>
</thead>
</table>

*text string containing the name masks to select the start strings, each separated by one or more spaces, to test the string names against. If the name include spaces then it must be enclosed in the quotes " (eg "bench 2").

Each mask can include wild cards (*) and wild characters (?).

For example: 
"ke*" or, 
"?bank*" or, if both masks are required, 
"ke* ?bank***"

<table>
<thead>
<tr>
<th>End name mask</th>
<th>pairing_n_end_mask</th>
<th>input</th>
</tr>
</thead>
</table>

*text string containing the name masks to select the end strings, each separated by one or more spaces, to test the string names against. If the name include spaces then it must be enclosed in the quotes " (eg "bench 2").

Each mask can include wild cards and wild characters.

For example: 
"ke*" or, 
"?bank*" or, if both masks are required, 
"ke* ?bank***"

**Note**

*If Start name mask is blank and End name mask is not blank, then all strings in the models that are not used as end strings, are used as start string.*

*If End name mask is blank and Start name mask is not blank, then all strings in the models that are not used as start strings, are used as end string.*

*This is currently not operational: If Start name mask and End name mask are both blank, then all strings in the models are used. All the strings that cut the primary string of the long section are ordered by offset, and successive pairs of cuts taken to be the cut pairs. There could be one remaining cut point (it has the largest chainage) and if so, it is taken to be orphaned start point.*
where to get the z-values to use for the two cut positions. This is used in conjunction with the choice in the Adopted height field.

If left blank, at cut string height is used.

Adopted height pairing_n_height choice box lower position, higher position
for the choice selected in the Position field, there will be a z-value at the first cut and another z-value at the end cut. The Adopted height says which of the two z-value to use for placing symbols, lines between cuts, text from Attributes and the Offsets of the first cut and the second cut.

If lower (higher) position, the smaller (greater) of the two z-values will be used.
If start (end), the z-value of the first (second) cut of the cut point pair will be used.
If left blank, lower position is used.

Include orphaned start ? pairing_n_orphan_start choice box yes, no
if Yes and there are start cuts after the last end cut (and so can’t be paired), then the last start cut (i.e. the one with the largest chainage) is taken as an orphaned start and it is labelled as though there is a matching end at the end of the long section.
if No and there are start cuts after the last end cut, then those start cut are ignored.
If left blank, No is used.

Include orphaned ends ? pairing_n_orphan_end choice box yes, no
if Yes and there are end cuts before the first start cut, then the first end cut (the one with the smallest chainage) is taken as an orphaned end and it is labelled as though there is a matching start at the beginning of the long section.
if No and there are end cuts before the first start cut, then those end cut are ignored.
If left blank, No is used.

Continue to the next section 26.4.23.2 Paired Cuts (Long Section) - Lines and Symbols or return to 26.4.23 Paired Cuts - Long Section.
26.4.23.2 Paired Cuts (Long Section) - Lines and Symbols

Symbols can be placed at the start and end cut chainages (at the z-value given by the Position and Adopted height columns when defining the Sets), and a line can also be drawn between the cuts at that z-value. Having both the line and a symbol forms an arrow between the cuts pair.

<td>set number as specified in the Define set #.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Mode</td>
<td>pairing_label_n_mode</td>
<td>choice box</td>
<td></td>
</tr>
</tbody>
</table>

*Type of label to write between the start and end points of the cuts pair*

The height used for the label is given by the **Position** and **Adopted height** columns in the Set definition.

**Attribute name**

- **pairing_label_n_attribute**

  if **Mode** is **attribute of first string** or **attribute of second string**, this is the name of the attribute to use as the label

**Offset**

- **pairing_label_n_offset**

  the text is raised by this amount above the line between the cut pair

**Colour**

- **pairing_label_n_colour**

  colour of the text

**Size (mm)**

- **pairing_label_n_size**

  size of the text in millimetres. A value of 0 means no text.

**Textstyle**

- **pairing_label_n_textstyle**

  the textstyle for the text

**Pre-text**

- **pairing_label_n_pre_text**

  text to draw before the label. This can include spaces, including one or more spaces after the last non blank character of **Pre-text**.

**Post-text**

- **pairing_label_n_post_text**

  text to draw after the label. This can include spaces, including one or more spaces before the first non blank character of **Post-text**.

**Decimals**

- **pairing_label_n_no_decimals**

  if the label is a number, then **Decimals** is the number of decimal places to write the number out to.

  If > 0, trailing zeros are **removed** after the decimal point.

  If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

**Leave gap for text**

- **pairing_label_n_??**

  if ticked then a gap in the line between the cuts pair is left large enough for the label and the pre-text and post-text.

  If not ticked then no gap is left in the line between the cuts pair.

**Rotate text to fit**

- **pairing_label_n_rotate_text**

  if ticked, then if the label and the pre-text and post-text will not fit between the start cut and end cut of...
the cut pair, the text is rotated through ninety degrees.

If not ticked, then the label text is drawn even though it will run over the ends of the cut pair.

Continue to the next section 26.4.23.4 Paired Cuts (Long Section) - Start Chainage or return to 26.4.23 Paired Cuts - Long Section.
26.4.23.4 Paired Cuts (Long Section) - Start Chainage

The Chainage (on the long section) of the first point of the cut pair can be labelled.

The text for the label consists of pre-text followed by Chainage value followed by post-text.

**Section: Pairing - Start Chainage parameters**

<table>
<thead>

set number as specified in the Define set #.

The height used for the text is given by the Position and Adopted height columns in the Set definition. This is then adjusted by the field Y (mm).

X (mm)  pairing_start_chainage_n_x  measure box

for placing the text: horizontal adjustment from the chainage of the first cut.

Y (mm)  pairing_start_chainage_n_y  measure box

for placing the text: the vertical adjustment to the height given by the Position and Adopted height columns in the Set definition

Angle (dms)  pairing_start_chainage_n_angle  measure box

angle (measured counterclockwise from the positive x-axis with units of degrees in 4.17.1 HP Notation) to rotate the text

Colour  pairing_start_chainage_n_colour  colour box

colour of the text

Size (mm)  pairing_start_chainage_n_size  measure box

size of the text in millimetres. A value of 0 means no text.

Textstyle  pairing_start_chainage_n_textstyle  textstyle box

the textstyle for the text

Pre-text  pairing_start_chainage_n_pre_text  text box

text before the Chainage value. This can include spaces, including one or more spaces after the last non blank character of Pre-text.

Post-text  pairing_start_chainage_n_post_text  text box

text after the Chainage value. This can include spaces, including one or more spaces before the first non blank character of Post-text.
Justification          pairing_start_chainage_n_justification          justification box

Decimals               pairing_start_chainage_n_no_decimals       number box
the number of decimal places for the offset value
If > 0, trailing zeros are removed after the decimal point.
If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Continue to the next section 26.4.23.5 Paired Cuts (Long Section) - End Chainage or return to 26.4.23 Paired Cuts - Long Section.
26.4.23.5 Paired Cuts (Long Section) - End Chainage

The Chainage on the long section of the second point of the cut pair can be labelled. The label consists of pre-text then the Chainage value followed by post-text.

Section: Pairing - End Chainage parameters

<table>
<thead>
<tr>

<td>input</td>
<td></td>
</tr>
</tbody>
</table>

  set number as specified in the Define set #.

The height used for the text is given by the Position and Adopted height columns in the Set definition. This is then adjusted by the field Y (mm).

X (mm)  pairing_end_chainage_n_x  measure box

for placing the text: horizontal adjustment from the offset of the second cut.

Y (mm)  pairing_end_chainage_n_y  measure box

for placing the text: the vertical adjustment to the height given by the Position and Adopted height columns in the Set definition.

Angle (dms)  pairing_end_chainage_n_angle  measure box

angle (measured counterclockwise from the positive x-axis with units of degrees in 4.17.1 HP Notation) to rotate the text.

Colour  pairing_end_chainage_n_colour  colour box

colour of the text.

Size (mm)  pairing_end_chainage_n_size  measure box

size of the text in millimetres. A value of 0 means no text.

Textstyle  pairing_end_offset_n_textstyle  textstyle box

the textstyle for the text.

Pre-text  pairing_end_chainage_n_pre_text  text box

text before the Offset value. This can include spaces, including one or more spaces after the last non blank character of Pre-text.

Post-text  pairing_end_chainage_n_post_text  text box

text after the Offset value. This can include spaces, including one or more spaces before the first non blank character of Post-text.
### Justification

**pairing_start_chainage_n_justification**

Justification of the text.

### Decimals

**pairing_start_chainage_n_no_decimals**

The number of decimal places for the Offset value

*If* > 0, trailing zeros are **removed** after the decimal point.

*If* <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Please continue to the next section **26.4.24 Primary String Name Label**.
26.4.24 Primary String Name Label

The plot can be labelled with a name under the boxes area.

The name is made up of a concatenation of the text string names.

**Section: Primary string name label parameters**

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

The plot name is positioned under the boxes.

The plot_name_x_offset is measured from the beginning of the height boxes.

The default for plot_name_x_offset is centred on heights area.

The plot_name_y_offset is measured from the bottom of the box area with positive being down.

Please continue to the next section 26.4.25 Scale Labelling.
26.4.25 Scale Labelling

The plot can be labelled with the horizontal and vertical scale under the boxes area. The scale label is made up of a concatenation of the text strings:

scale_horizontal_pre_text horizontal scale value scale_horizontal_post_text
and
scale_vertical_pre_text vertical scale value scale_vertical_post_text

The horizontal scale value is the value given by the scale parameter. The scales are positioned under the boxes.

  *If > 0, trailing zeros are removed after the decimal point.*
  *If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.*

Please continue to the next section **26.4.26 Plan Plotting.**
26.4.26 Plan Plotting

**Section: Plan parameters**

The Plan Plotting section is for generating a combined long section and plan plot on the one plot sheet. The chainage interval for the long section plots (as set up in the Pagination section 26.4.7 Pagination) is used to define the chainage interval for the plan plot.

The total sheet size is given by the Sheet size parameter (see the section 26.4 Long Plot PPF Editor), and the position of the long section plot on the sheet is defined in the section 26.4.6 Plot Sheet Layout - Long Section. What is left to be defined is the area on the sheet for the plan plot.

Hence sheets of long sections and the associated plan plots are automatically generated.

The fields and buttons used in this section have the following functions.

<table>

26.4.27 PPFs To Include - Long Section

This is documented for all the PPF Editors in 26.2.10 PPFs To Include.
Please continue to the next section 26.4.28 Buttons at Bottom of Panel - Long Section.

26.4.28 Buttons at Bottom of Panel - Long Section

This is documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

Return to 26.4 Long Plot PPF Editor.
26.5 Drainage Long Plot PPF Editor

**Position of option on menu:** Plot => Plot and PPF Editors => Drainage long

The **Drainage Plot PPF Editor** is for creating and/or editing a (binary) drainage and sewer long section ppf file and for creating a drainage and/or sewer long section plot.

**Note:** Binary and text PPFs are stored within the project (not in the folder containing the project).

On selecting the Drainage long option, the **Drainage Plot PPF Editor** panel is displayed.

The plot parameters for controlling the cross section plots are accessed by expanding to the appropriate node in the **Drainage Plot** tree (click on the + to expand to node or - to collapse the node) and then clicking on the required node, and the required information to fill in is displayed on the right hand side of the panel.

For information on all the different nodes see:

26.5.1 General Information on Drainage Long Section Plots

The Drainage Long Section Plot generates the longsection plots for all lines in a drainage network.

Given the plot sheet size and the horizontal and vertical scales, the long sections for the drainage lines are plotted in string name alphabetical order starting at the top of the sheet and moving across the sheet. Once one row is full, if there is room the plot moves down the page and begins a new row. When a plot sheet is full, a new plot sheet is automatically begun.

Hence the drainage lines are plotted one after another on one or more plot sheets.

Each individual drainage long section plot consists of eleven areas.

From the bottom up, they are

1. The **drainage string name area** is where the name of the drainage string can be plotted.
2. The **boxes area** is where the chainages and various values for the drainage strings are labelled.
3. The **below datum area** is a region between the boxes area and the datum line.
4. The **arrow 1 area** is for drawing arrows where the arrows go between the staggered uprights and below the graph area. The datum line is at the bottom of the arrow 1 area.
5. The **bottom stagger area** is where the upright line staggers occur before going up from the boxes area to the graph area.
6. The **arrow 2 area** is for drawing arrows below the graph but where the arrows go between non-staggered uprights.
7. The **graph area** is the area where the actual plots of the strings are drawn.
8. The **arrow 3 area** is for drawing arrows above the graph area and where the arrows go between non-staggered uprights.
9. The **top stagger area** is where the upright line staggers occur above the graph area.

10. The **arrow 4 area** is for drawing arrows where the arrows go between the staggered uprights and above the graph area.

11. The **top area** is an annotation area above the arrow 4 area and is used for bubbles, manhole names (pit names), junctions, deflection angles etc.

The areas and the information in them will now be described in more detail.

The drainage longsection plot includes:
(a) the manholes, drainage pipe and any house connections
(b) the height of the finished surface at the manhole
(c) manhole names and cover types
(d) distances between manholes
(e) the invert depth of the pipe on either side of a manhole
(f) the grades and types of the pipes
(g) any services in the corridor - including their name, invert level and distance from the nearest downstream manhole
(h) if the information exists, the velocity, flow, HGL values and diagram

All the required parameters for controlling the drainage long section plot are set up in the **Drainage Plot PPF Editor** and will be described in detail in the following sections.

Please continue to the next section **26.5.2 Drainage Plot - Front Page** or return to **26.5 Drainage Long Plot PPF Editor**.
26.5.2 Drainage Plot - Front Page

The drainage long plot itself consists of the three regions - boxes, datum and graph areas. The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled. The **datum area** is the region between the boxes area and the graph area. The **graph area** is the area where the actual plots of the strings are drawn.

**Section: Plot parameter file**

A *plot parameter file* can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

This section is documented for all the PPF Editors in **26.2.1 Plot Parameter File**.

**Section: Section: View to load details from AND Global variables**

A *section view* can be selected to load certain values into fields of the PPDF Editor. For example,
Vertical exaggeration and Corridor models. And there are variables to use if some values aren’t given.

These sections are documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

The columns for the fields documented in the sections are for.

26.5.7 Boxes

The Boxes Area on the drainage long section plot is used to label points on the drainage strings with the following information: chainages, road centre line chainages, natural surface heights, finished surface heights, before pit and after pit invert levels, before pit and after pit hgl values, and before pit and after pit depths to inverts.

The default order of the boxes is as shown in the diagram, below.

![Diagram of Boxes Area](image)

The chainage box is hardwired to always appear first (at the bottom) in the order of boxes. If, you wish to change the order of any of the other boxes, or wish to omit any of the other boxes, you can do so by specifying the following box order parameters.

<table>
<thead>

Or return to 26.4 Long Plot PPF Editor.
26.5.8.1 Chainages/Uprights - Services

Any services crossing the drainage strings (defined by specifying corridor service models in the Corridors section) can be automatically labelled with an upright, chainage and invert level labels (of the drainage string, placed within the appropriate boxes in the Boxes area), and a name label (that includes the crossing service string name, its diameter, and its invert level at the point of crossing).

Note: crossing services may also be labelled (independently) by utilising the parameters in the Cuts section.

*service_name_decimals*  
**input**

decimal places for the crossing service invert levels that make up part of the crossing service name labels (required only if different from default number_of_decimals).

*If > 0, trailing zeros are removed* after the decimal point.

*If < 0, the absolute value is taken as the number of decimal places to report* i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Continue to the next section [26.5.8.2 Chainages/Uprights - Finished Surface/Top of MH Values](#) or return to [26.5.8 Chainages/Uprights](#).
26.5.8.2 Chainages/Uprights - Finished Surface/Top of MH Values

In addition to the finished surface level labels within the Boxes area, more detailed vertical labels representing finished surface levels at the pits, can be added to accompany the pit uprights within the Graph area.

### Panel Field Parameter name Type Pop-Up

**Finished surface draw mode**
- **draw_fs_vertical** choice box
  - do not draw fs values
  - always draw fs values
  - only draw if different

whether to label the finished surface levels within the Graph area. Additional control is provided to only draw the labels if the finished surface level is different from the level at the top of the maintenance hole.

**Finished surface value mode**
- **draw_fs_vertical_mode** choice box
  - value from fs tin
  - value from top of mh

whether the finished surface level label values come from the fs tin or the top of the maintenance holes.

**Pre text**
- **fs_vertical_pre_text** input
  
  label text before the finished surface level.

**Post text**
- **fs_vertical_post_text** input
  
  label text after the finished surface level.

**Decimal places**
- **fs_vertical_decimals** input
  
  decimal places for finished surface level values (required only if different from default number_of_decimals).

  *If > 0, trailing zeros are removed after the decimal point.*

  *If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.*

**Colour**
- **fs_vertical_colour** colour box
  
  text colour of finished surface level labels (required only if different from default box_text_colour).

**Size (mm)**
- **fs_vertical_size** input
  
  text size of finished surface level labels (required only if different from default box_text_size).

**Textstyle**
- **fs_vertical_textstyle** font box
  
  font of finished surface level labels (required only if different from default global_textstyle).

**X adjustment (mm)**
- **fs_vertical_x** input
  
  horizontal adjustment to position of finished surface level labels.

**Y adjustment (mm)**
- **fs_vertical_y** input
  
  vertical adjustment to position of finished surface level labels.

Continue to the next section 26.5.8.3 Chainages/Uprights - Staggering or return to 26.5.8 Chainages/Uprights.
26.5.8.3 Chainages/Uprights - Staggering

Because the pit and service uprights are sometimes too close together to fit all the desired information in the Boxes and Arrows areas, the uprights can be staggered (widen) in such a way as to provide more space in these areas, below and above the Graph area, whilst still maintaining the correct upright spacing within the Graph area itself. Specifically, the staggering of the uprights occurs below the Graph area between Arrow areas 1 and 2, and above the Graph area between Arrow areas 3 and 4. As such, it is recommended that Arrow areas 2 and 3 be used only for information requiring minimal space.

Please continue to the next section **26.5.10 Arrows.**
26.5.10 Arrows

The Arrow areas on the drainage long section plot, are used to label segments (individual pipes) on the drainage strings with the following information: grades, diameters and types, flow velocities, flow volumes, drainage line names, and any user-defined pipe attribute values.

There are four separate Arrow areas on the plot, any of which can be used to label the above information. From plot bottom to top, the Arrow areas are:

- Arrow area 1: staggered arrows below the Graph area,
- Arrow area 2: unstaggered arrows below the Graph area,
- Arrow area 3: unstaggered arrows above the Graph area,
- Arrow area 4: staggered arrows above the Graph area.

**Set #**

a unique integer $n$, greater than 0, to identify the $n$th set of pipe attribute plot parameters.

**Draw pipe attribute mode**

draw_pipe_attr_n choice box don't draw pipe attribute draw pipe attribute

whether to draw the $n$th set of pipe attribute data in one of the Arrow areas.

**Pipe attribute name**

pipe_attr_n_name input

name of the $n$th pipe attribute.

**Arrow area for the arrow**

pipe_attr_n_arrow_area choice box Area 1 Area 2 Area 3 Area 4

the desired Arrow area for the $n$th set of pipe attribute data.

**Y offset (mm)**

pipe_attr_n_y input

vertical offset of the $n$th set of pipe attribute data, measured upwards from the bottom of the selected Arrow area.

Whether to draw a horizontal line at the bottom of the Top area.

Please continue to the next section 26.5.13 Corridors - Drainage Long.

26.5.13 Corridors - Drainage Long

A corridor around the primary string is defined by giving a left and right corridor width.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, it is drawn on the cross-section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.

This is documented for all the PPF Editors in 26.2.7 Corridors.

Please continue to the next section 26.5.14 Maintenance Holes.
26.5.14 Maintenance Holes

The drainage string name, the maintenance hole name (pit number) and maintenance hole type (pit type) can be drawn on the drainage long section plot as MH label, with or without a bubble around it.

The MH label text is made up of

```
pre_text line_name / pit_name pit_type post_text
```

where each bit of the MH label is controlled by parameters.

The bubble may or may not exist.

The MH label (and bubble) can be positioned at the bottom of the top area, or can be placed a fixed distance above the top of the corresponding manhole.

If the bubble text is drawn at the bottom of the top area, the upright is automatically drawn up to the bubble text.

If the bubble text is drawn above the pit, it is positioned by the distance_above_pit parameter plus the top stagger distances, stagger_gap_top, stagger_height_3 and stagger_height_4.

This is necessary because the bubble text may need to be staggered.

The columns for the fields documented in the sections are for.

vertical adjustment to position of MH name label.

**Pre text**

*bubble_pre_text*  text box

text to go before MH name label.

**Post text**

*bubble_post_text*  text box

text to go after MH name label.

**Text angle (dms)**

*bubble_text_angle*  angle box

text angle of MH name label.

**Text justification**

*bubble_text_justify*  justification box

text justification of MH name label.

**Bubble radius (mm)**

*bubble_radius*  real box

radius of bubble around MH name label. Zero (0) for no bubble.

**Bubble colour**

*bubble_colour*  colour box  available colours

colour of bubble around MH name label.

**Bubble length (mm)**

*bubble_length*  input

length of bubble around MH name label. Zero (0) for circular bubble.

**Bubble text position**

*draw_text_at_pit*  choice box  draw bubble&text in top area
draw bubble&text above pit

whether to position the MH name labels and bubbles in the Top area, or directly above the pits.

**Distance to add to place bubble above the pit (mm)**

*distance_above_pit*  real box

for *draw_text_at_pit* set to draw bubble & text above pit, distance to add between top of pit and bottom of bubble.

See

- 26.5.14.1 Maintenance Holes - Line/Junction Deflection Angles
- 26.5.14.2 Maintenance Holes - Symbols
- 26.5.14.3 Maintenance Holes - Attribute Labels

Or return to 26.5 Drainage Long Plot PPF Editor.
26.5.14.1 Maintenance Holes - Line/Junction Deflection Angles

If there is a change of direction of the pipes of the plotted drainage string going through the pit, the **deflection angle** (pit angle) is drawn above the MH label.

The **deflection angle text** is made up:

```
angled_pre_text  deflection angle  angled_post_text
```

Also **any junctions** at a pit in the plotted drainage string can be labelled with the name of the drainage strings coming into the pit, and the angle of the pipes at the junction.

Hence the **junction text** for each junction at the pit is made up of two lines:

```
junction_pre_text  line_name  junction_post_text
junction_angle_pre_text  junction_angle  junction_angle_post_text
```

Note that there may be more than one junction at the pit.

If bubbles are drawn around the MH label, the deflection angle and junction name and angle are drawn at the distance (**angled_text_x_offset**, **angled_text_y_offset**) above the bubble and with the distance **angled_text_gap** between the lines of information.

If bubbles are not drawn, **MH label** and the deflection angle and junction names and angles are placed the distance (**angled_text_x_offset**, **angled_text_y_offset**) above the bottom of the top area. Each line of text is separated by the distance **angled_text_gap**.

The deflection angle and junction name and angle are drawn at an angle of **angled_text_angle**.

The columns for the fields documented in the sections are for:

<table>
<thead>

</tbody>
</table>

**Angled text x offset (mm)** | angled_text_x_offset | real box |
--|-------------------------|---------|
distance in mm that the text is offset in x from the centre of the top of the bubble.

**Angled text y offset (mm)** | angled_text_offset | real box |
--|-------------------------|---------|
distance in mm that the text is offset in y from the centre of the top of the bubble.

**Angled text horiz gap (mm)** | angled_text_gap | real box |
--|-------------------------|---------|
perpendicular distance in mm between the pit angle text and the junction texts.

**Angled text angle (dms)** | angled_text_angle | angle box |
--|-------------------------|---------|
angle of the text in degrees minutes and seconds in hp notation.
Angled text justification  choice box  left, right
justification of the pit angle text and the junction texts. It can only be "left" and "right".

Degrees mode  choice box  DDDMMSS.s
DDDM
DDD
Decimal degrees

if DDDMMSS.s the angle is given in degrees, minutes and seconds and tenths of a second
if DDDMMSS.s the deflection angle is given in degrees, minutes and seconds and tenths of a second.
If DDDMM the deflection angle is given in degrees and minutes.
If DDD the deflection angle is given in degrees.
If Decimal degrees the deflection angle is given in decimal degrees with the number of decimal places
given by Degrees decimals.

Degrees decimals  integer box
if Degrees mode is Decimal degrees the it will be written out t this many decimal places.

Section: Drainage line deflection angles
this section defines the pre and post text, textstyle, size and colour for the deflection angle (pit angle) text.

Pre text  text box
text to go before the pit deflection angle text.

Post text  text box
text to go after the pit deflection angle text.

Colour  colour box available colours
colour of the pit deflection angle text.

Size (mm)  real box
size in millimetres of the pit deflection angle text.

Textstyle  textstyle box available textstyles
textstyle of the pit deflection angle text.

</thead>
</table>

**Section: Maintenance hole symbols**

This section defines the pre and post text, textstyle, size and colour for the junction name text.

The fields for each row form one set of controls for the placement of MH symbols on the plot. Normally, the grid will contain one row for each MH type/symbol used.

**Symbols Grid**

**All MH types**

- **tick box**

  If **ticked**, then all MH types are labelled with the fields in this row.

  If **not ticked**, then all maintenance holes with the given **MH Type** are labelled with the fields in this row.

**MH type**

- **manhole_symbol_n_type**

  available MH types

  maintenance holes with this **MH type** are labelled with the fields in this row.

**MH symbol mode**

- **manhole_symbol_n_mode**

  cross (0)

  up from centre of box (1)

  up&down from box centre (2)

  square (3)

  triangle, base at bottom (4)

  circle (5)

  use a 12d symbol (6)

  for the MH type for this row, whether to use one of the hard-wired symbols (1-5), or a symbol from the 12d symbols list.(6)

**MH symbol position**

- **manhole_symbol_n_position**

  choice box

  at top of mh

  above top of boxes

  above highest point

  to primary string

  to first found tin

  for the MH type for this row, the desired position of the symbol.

**Stagger**

- **tick box**

**Size (mm)**

- **manhole_symbol_n_size**

  for the MH type for this row, the symbol size.

**X (mm)**

- **manhole_symbol_n_x**

  for the MH type for this row, the horizontal adjustment to the selected MH symbol position.

**Y (mm)**

- **manhole_symbol_n_y**

  for the MH type for this row, the vertical adjustment to the selected MH symbol position.
Symbol manhole_symbol_n_style symbol box available symbols
for the MH type for this row, and with Manhole symbol mode set to use a symbol, the symbol to use from the 12d symbols list.

Angle (dms) manhole_symbol_n_angle angle box
for the MH type for this row, the symbol angle in degrees minutes and seconds in hp notation.

Colour manhole_symbol_n_colour colour box available colours
for the MH type for this row, the symbol colour.

Continue to the next section 26.5.14.3 Maintenance Holes - Attribute Labels or return to 26.5.14 Maintenance Holes.
26.5.14.3 Maintenance Holes - Attribute Labels

The text for Maintenance Holes attributes can be drawn on the plots.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>
| Section: Maintenance hole attribute labels

This section defines the pre and post text, textstyle, size and colour for displaying the attributes as text.

The fields for each row form one set of controls for the placement of the given attribute on the plot.

Attributes Grid

Label MH attribute

if ticked, this row is used and the attribute is labelled.

If not ticked, this row is ignored.

Attribute name

the full path name of the attribute to be labelled.

From primary string at junction pits (non-standard) tick box

if ticked.:

Text size (mm)

the text size for this attribute label.

Label position choice box

at top of mh
at ds il of mh
at sump of mh
at first found tin
at top of boxes
at highest point

position to place attribute label

Stagger tick box

the text size for this attribute label.

X off (mm) real box

the horizontal adjustment to the selected label position.

Y off (mm) real box

the vertical adjustment to the selected label position.

Angle (dms) angle box

the angle of the attribute label in degrees minutes and seconds in hp notation.

Pre text text box

text to go before the attribute label.

Post text text box

text to go after the attribute label.

Decimal places integer box

number of decimal places to use when it is a real attribute.

If > 0, trailing zeros are removed after the decimal point.

If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.
Units factor

for real and integer attributes, the value is multiplied by the **Units factor**.

Colour

the colour of the attribute label.

Textstyle

the textstyle of the attribute label.

Justification

the justification of the attribute label.

Please continue to the next section 26.5.17 Cuts - Drainage/Sewer Long.
26.5.17 Cuts - Drainage/Sewer Long

The cuts that the primary string (drainage or sewer line) makes though strings in any user specified model can be automatically labelled on the drainage/sewer long section plots.

The Cuts section is common to the PPF Editors and is fully documented in 26.2.9 Cuts.  

Section: Cuts - Model/Name mask parameters - see 26.2.9 Cuts.  
Section: Cuts - Chainage parameters - see 26.2.9.3 Cuts - Chainage - Long Sections Only  
Section: Cuts - Height parameters - see 26.2.9.4 Cuts - Heights  
Section: Cuts - Diameter parameters - see 26.2.9.5 Cuts - Diameters  
Section: Cuts - Label parameters - see 26.2.9.6 Cuts - Labels  
Section: Cuts - Symbol parameters - see 26.2.9.7 Cuts - Symbols  

Continue to the next section 26.5.18 Primary String Name Label.
26.5.18 Primary String Name Label

The plot can be labelled with a name under the boxes area.

The name is made up of a concatenation of the text string names:

<table>

</tbody>
</table>

The plot name is positioned under the boxes.
The plot_name_x_offset is measured from the beginning of the height boxes.
The default for plot_name_x_offset is centred on heights area.
The plot_name_y_offset is measured from the bottom of the box area with positive being down.

Please continue to the next section 26.5.19 PPFs to include - Drainage Long Section.
26.5.19 PPFs to include - Drainage Long Section
This is documented for all the PPF Editors in 26.2.10 PPFs To Include.
Please continue to the next section 26.5.20 Buttons at Bottom of Panel.

26.5.20 Buttons at Bottom of Panel
This is documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.
Return to 26.5 Drainage Long Plot PPF Editor.
26.6 Melbourne Water Plot PPF Editor

**Position of option on menu:**  Plot => Plot and PPF Editors => Melbourne Water

The Melbourne Water plot PPF editor is for creating and/or editing a (binary) Melbourne Water sewer long section PPF and for creating a Melbourne Water sewer long section plot. An text version of the file is also produced.

**Note:** Binary and text PPFs are stored within the project (not in the folder containing the project).

On selecting the Melbourne Water option, the Sewer Plot Melbourne Water PPF Editor panel is displayed.

The plot parameters for controlling the cross section plots are accessed by expanding to the appropriate node in the Sewer Plot Melbourne Water tree (click on the + to expand to node or - to collapse the node) and then clicking on the required node, and the required information to fill in is displayed on the right hand side of the panel.

For information on all the different nodes see:

- 26.6.1 Melbourne Water Plot - Front Page
- 26.6.2 Notes - Melbourne Water
- 26.6.3 Plot to Models - Melbourne Water
- 26.6.4 Title Block - Melbourne Water

26.6.14 Cuts - Melbourne Water Long
26.6.16 PPFs to include - Melbourne Water
26.6.17 Buttons at Bottom of Panel - Melbourne Water
26.6.1 Melbourne Water Plot - Front Page

The Melbourne Water sewer long plot itself consists of the three regions - boxes, datum and graph areas.

The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

Section: Plot parameter file

A plot parameter file can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

This section is documented for all the PPF Editors in **26.2.1 Plot Parameter File**.

Section: Section: View to load details from AND Global variables
a section view can be selected to load certain values into fields of the PPDF Editor. For example, Vertical exaggeration and Corridor models. And there are variables to use if some values aren’t given.

These sections are documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

The columns for the fields documented in the sections are for.

26.6.12 Property Controls/House Connections - Melbourne Water

Continue to the next section 26.6.13 Hatching Cut/Fill - Melbourne Water.

26.6.13 Hatching Cut/Fill - Melbourne Water

This option is used to hatch cut and/or fill areas between sets of tins.

The Hatching Cut/Fill section is common to the PPF Editors and is fully documented in 26.2.8 Hatching Cut/Fill.

**Section: Hatching cut/fill - Tin parameters -** see 26.2.8 Hatching Cut/Fill

**Section: Hatching cut/fill - Cut parameters -** see 26.2.8.1 Hatching Cut/Fill - Cut

**Section: Hatching cut/fill - Fill parameters -** see 26.2.8.2 Hatching Cut/Fill - Fill

26.6.14 Cuts - Melbourne Water Long

The cuts that the primary string (drainage or sewer line) makes though strings in any user specified model can be automatically labelled on the drainage/sewer long section plots. The Cuts section is common to the PPF Editors and is fully documented in 26.2.9 Cuts.

Section: Cuts - Model/Name mask parameters - see 26.2.9 Cuts.

Section: Cuts - Chainage parameters - see 26.2.9.3 Cuts - Chainage - Long Sections Only

Section: Cuts - Height parameters - see 26.2.9.4 Cuts - Heights

Section: Cuts - Diameter parameters - see 26.2.9.5 Cuts - Diameters

Section: Cuts - Label parameters - see 26.2.9.6 Cuts - Labels

Section: Cuts - Symbol parameters - see 26.2.9.7 Cuts - Symbols

Continue to the next section 26.6.16 PPFs to include - Melbourne Water.
26.6.15 Paired Cuts - Melbourne Water

Paired cuts uses pairs of strings and where both strings cut the primary string, the cuts on the long plot can be labelled with information such as:

(a) the name of the first and second cut strings
(b) attributes from the first and second cut string
(c) plan distance between the two cuts of the pair
(d) 3d length between the two cuts of the pair
(e) the change on the long section of the first and second cuts of the pair

Symbols can be drawn at the chainages of the first and second cuts (at a height specified when defining the Cut sets), and a line drawn between the symbols. Using both the line and a symbol of an arrow head makes an arrow between the two cuts.

The method for specifying which strings are to be checked for paired cuts is by first specifying the models (using wild cards and characters) that contains the strings, and then a start name mask to select the all the strings that are to be the first strings in a cut pair, and an end name mask to select all the strings that are the second strings in a cut pair.

For a long section, all the cuts of the selected start strings are found and the cuts ordered by the chainage of the cut with the primary string of the long section. Then all the cuts of the selected end strings are found and the cuts ordered by the chainage of the cut with the primary string of
the long section.

The start cuts are then processed and each start cut is paired with the next end cut with a larger chainage than the start cut. It is possible that there are end cuts before the first start cut (orphaned end cuts) and start cut with no following end cut (orphaned start cuts).

Up to twenty five different sets of models and name masks can be used so that different paired cut sets can be labelled in different ways.

26.6.16 PPFs to include - Melbourne Water

This is documented for all the PPF Editors in 26.2.10 PPFs To Include.

Continue to the next section 26.6.17 Buttons at Bottom of Panel - Melbourne Water.

26.6.17 Buttons at Bottom of Panel - Melbourne Water

This is documented for all the PPF Editors in 26.2.11 Buttons at the Bottom of the PPF Editors.

Return to 26.6 Melbourne Water Plot PPF Editor.
26.7 Pipeline Plot PPF Editor

**Position of option on menu:** Plot => Plot and PPF Editors => Pipelines

**Position of option on menu:** Design => Pipeline => Plots

The Pipeline Plot PPF Editor is for creating and/or editing a (binary) pipeline long section pff file and for creating a pipeline long section plot for all the pipeline strings in a given model.

The pipeline long section plot will break an individual plot up if it doesn’t fit across the sheet. There can be one or more rows of plot on the same sheet.

The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

When a sheet is full, a follow on sheet is created.

As soon as one pipeline string is completed, the next pipeline string in the network model is plotted beginning on the same row as the previous pipeline string and with a horizontal gap of size horizontal_plot_gap between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

**Note:** Binary PPFs are stored within the project (not in the folder containing the project as the text PPFs were).

On selecting the **Pipelines** option, the Pipeline Plot PPF Editor panel is displayed.

The plot parameters for controlling the cross section plots are accessed by expanding to the appropriate node in the Pipeline Plot tree (click on the + to expand to node or - to collapse the node) and then clicking on the required node, and the required information to fill in is displayed on the right hand side of the panel.
For information on all the different nodes see:

26.7.15 Paired Cuts - Pipeline
26.7.16 PPFs to include - Pipeline
26.7.17 Buttons at Bottom of Panel - Pipeline
26.7.1 General Information on Pipeline Long Section Plots

The pipeline plot makes special long section plots for a **network** of pipeline strings.

The pipeline long section plot will break an individual plot up if it doesn't fit across the sheet. There can be one or more rows of plot on the same sheet.

The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

When a sheet is full, a follow on sheet is created.

As soon as one pipeline string is completed, the next pipeline string in the network model is plotted beginning on the same row as the previous pipeline string and with a user given horizontal gap between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

---

Each pipeline long plot consists of seven areas. From the bottom up, they are:

1. **The boxes area** is where the chainages and various values for the pipeline strings are labelled.
2. **The below datum area** is a region between the boxes area and the datum line.
3. **The bottom stagger area** is where the upright line staggers occur before going up from the boxes area to the graph area.
4. **The graph area** is the area where the actual plots of the strings are drawn.
5. **The top stagger area** is where the upright line staggers occur above the graph area.
6. **The arrow 4 area** is an extension of the uprights above the top stagger area to allow for the drawing of arrows where the arrows go between the staggered uprights above the graph area.
7. **The top area** is an annotation area above the arrow 4 area (the top of the plot) and is used for...
pegs and deflection angles.

Apart from information labelled in the boxes and top areas, the pipeline long section plot can place arrows between ips for other information such as:

(a) pipe grade  
(b) vertical geometry  
(c) horizontal geometry  

Also the chainages where services cross the pipeline line are automatically labelled.

For each pipeline plot, the labelling of pipe invert levels, depth to invert, pipe grade and natural surface level are done at the chainages:

(a) pegs given by a user given peg interval  
(b) horizontal and vertical deflection points  
(c) points in the specials model  
(d) crossing services  

All the required parameters for controlling the pipeline long section plot are set up in the Pipeline Plot PPF Editor and will be described in detail in the following sections.

Please continue to the next section 26.4.2 Section Long Plot - Front Page or return to 26.4 Long Plot PPF Editor.
26.7.2 Pipeline Longsection Plot - Front Page

The pipeline long plot itself consists of the three regions - boxes, datum and graph areas. The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled. The **datum area** is the region between the boxes area and the graph area. The **graph area** is the area where the actual plots of the strings are drawn.

---

**Section: Plot parameter file**

A plot parameter file can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

*This section is documented for all the PPF Editors in [26.2.1 Plot Parameter File](#).*

**Section: View to load details from AND Global variables**

A section view can be selected to load certain values into fields of the PPDF Editor. For example,
Vertical exaggeration and Corridor models. And there are variables to use if some values aren’t given. These sections are documented for all the PPF Editors in 26.2.2 View to Load and Global Variables.

The columns for the fields documented in the sections are for.

**Note:** When creating Drainage Plan Plot overlays, all distances and sizes (including text sizes, offsets, rises, etc) are specified in world units.

---

**Section: Plot parameter file**

A *plot parameter file* can be used to load values into the fields of the PPF Editor, or as a file to write out all current values in a PPF Editor to.

This section is documented for all the PPF Editors in 26.2.1 Plot Parameter File.

The columns for the fields documented in the sections are for:

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>model box</td>
<td>model</td>
<td>available models</td>
</tr>
</tbody>
</table>

**Section: Load design details from**

Model of drainage design strings to create Annotation for.

**Section: Save plot annotations to**

Model to write the drainage annotations to.

Clean plot model beforehand  plot_model_clean  choice box  smart clean
full clean
determines how to clean (delete the elements in) the output model, if it exists, before generating the plot annotations.

For **smart clean**, any existing text, flow arrow and bubble annotation elements found that match the annotations about to be generated, will retain their pre-existing positions.

For **full clean**, no information about the pre-existing plot annotation is used, and the new plot annotation is created from scratch.

**Plot rotation (dms)** plot_rotation measure box
At Point, Point to Point,
String from Point, String to
Point

**Set colours as string names** naming_mode tick box
if ticked, the names all created plot annotation strings will be their colour names. This will override any user specified string names defined in other sections.

---

26.8.2 Notes - Drainage Plan Plot

This is documented for all the PPF Editors in **26.2.4 Notes**.

Continue to the next section **26.8.3 Pipes** or return to **26.8 Drainage Plan Plot PPF Editor**
26.8.3 Pipes

The pipes in a plan of a drainage network are often not drawn as they appear but with different linestyles etc to represent different pipe diameters etc.

The pipe diameter, invert levels and attributes can all be labelled in plan.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td></td>
<td>Draw multi pipes</td>
<td>pipe_multi</td>
<td>tick box</td>
</tr>
</tbody>
</table>

**Pipe Diameters Label grid**

The fields in this section are grid column fields that may each have up to 20 rows (sets) defined.

All pipes with diameters that fall between the minimum diameter Min pipe diam and the maximum diameter Max pipe diam for a row (set), will be represented according to the values of the other fields in this row. Note that the Pipe diameters are defined in the drainage design strings.

Min pipe diam (m) pipe_dia_min_n input minimum pipe diameter in metres for the nth row of pipe representations.

Max pipe diam (m) pipe_dia_max_n input maximum pipe diameter in metres for the nth row of pipe representations.

All pipes with diameters that fall between the min and max diameters of this row, will be represented according to the values of the other fields in this row.

Pipe type mask pipe_dia_mode text box

determines whether to represent pipes as linestyles and/or solid pipes for the nth row of pipe representations.

Representation mode pipe_dia_mode choice box none linestyle pipe linestyle and pipe

determines whether to represent pipes as linestyles and/or solid pipes for the nth row of pipe representations.

Trim mode trim_edge_mode choice box don't trim strings trim pipes trim linestyles trim pipes and linestyles

determines whether to trim pipe and/or linestyle strings around maintenance holes for the nth row of pipe representations.

Multi-pipe spacing real box the distance to space the pipes when multiple pipes are drawn.

Colour pipe_dia_colour_n colour box available colours colour to use for the nth row of pipe representations.
Linestyle pipe_dia_linestyle_n linestyle box available linestyles
   linestyle to use for the nth row of pipe representations.
Linestyle string name pipe_dia_name_n input
   string name of linestyles for the nth row of pipe representations.
Pipe string name pipe_edge_name_n input
   string name of pipes for the nth row of pipe representations.

Section: Pipe labels

Label Rise mode rise_mode choice box rise from centre of pipe
   rise from edge of pipe
determines where all pipe label text rise values are measured from.

See
  26.8.3.0.1 Pipes - Pipe Diameter Labels
  26.8.3.0.2 Pipes - Pipe IL Labels
  26.8.3.0.3 Pipes - Pipe Attribute Labels

Or return to 26.8 Drainage Plan Plot PPF Editor.
26.8.3.0.1 Pipes - Pipe Diameter Labels

The diameter of the pipes can be labelled in plan.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

Continue to the next section 26.8.3.0.3 Pipes - Pipe Attribute Labels section or return to 26.8.3 Pipes.
26.8.3.0.3 Pipes - Pipe Attribute Labels

The values of any pipe attributes can be labelled in plan.

The columns for the fields documented in the sections are for:

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
</table>

**Section: Pipe attribute labels**

Pipe attribute label grid

Each row of the grid defines how a pipe attribute is labelled. There may be up to 20 rows.

- **Label pipe attribute**
  - tick box
  - *if ticked*, the pipe attribute for this row will be labelled.
  - *If not ticked*, the pipe attribute for this row will *not* be labelled.

- **Attribute name**
  - text box
  - full path name of the pipe attribute for this row that may be labelled.

- **Text size**
  - pipe_attribute_text_size_n real box
  - text size of the pipe attribute for this row.

- **Text offset**
  - real box
  - distance to move the pipe attribute labels for this row along the pipe, from the ends of the pipe. Positive values are towards the mid position of the pipe segment.

- **Text rise**
  - real box
  - distance to move the pipe attribute labels for this row away from the pipe edge. A negative value will place the labels on the other side of the pipes.

- **Text colour**
  - colour box available colours
  - colour of the pipe attribute labels for this row.

- **Text style**
  - textstyle box available textstyles
  - textstyle of the pipe attribute labels for this row.

- **Pre text**
  - text box
  - text to be placed before the pipe attribute labels for this row.

- **Post text**
  - text box
  - text to be placed after the pipe attribute labels for this row.

- **Units factor**
  - real box
  - if the pipe attribute for this row is real or integer, it is multiplied by the *Units factor* for this row.

- **Decimal places**
  - integer box
  - if the pipe attribute for this row is real, this is the number of decimal places in the pipe attribute label for this row.
  - *If > 0, trailing zeros are removed* after the decimal point.
  - *If < 0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed*. For example -3 means that there is always 3 figures after the decimal place.

- **Text string name**
  - pipe_attribute_text_name_n name box
  - name of the text string of the pipe attribute label for this row.

Continue to the next section 26.8.4 Maintenance Holes or return to 26.8.3 Pipes or 26.8 Drainage Plan Plot PPF Editor.
26.8.4 Maintenance Holes

The maintenance holes in a plan of a drainage network are often not drawn as they appear but with different symbols etc to represent different manhole types etc.

The manhole name, diameter, depth, chainage, attributes and setout points can all be labelled in plan.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Section: Maintenance hole representation</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MH symbol direction mode</td>
<td>mh_symbol_dir_mode</td>
<td>choice box</td>
<td>use symbol angle</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>left</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>right</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>average</td>
</tr>
</tbody>
</table>

Determines what mode of direction is used to place the MH symbols.

MH symbol angle (dms) | mh_symbol_angle | angle | angle of MH symbol placement in degrees, minutes and seconds in hp notation. This is only used depending on the setting of mh_symbol_dir_mode.

Use road direction where possible | tick box |

Use MH label direction for Text mode | tick box |

Group symbols with text labels | tick box |

If ticked,

MH Grid

The rows in the grid contain information for placing symbols at maintenance holes. There can be up to 20 rows in the grid.

MH type | mh_type_n | MH cell | available MH types |

MH type that will be drawn by information in this row of the grid. All MHs of this type will be represented according to the values of the other fields in this row. MH types are defined in the drainage design strings.

MH mode | mh_mode_n | choice cell | none |
|        |           |              | text |
|        |           |              | symbol |
|        |           |              | circle |

Determines whether a text string, a symbol, or a circle is to be used to represent the maintenance holes in this row.

Insertion point | choice cell | mh centre, setout point |

Where to place the representation of the maintenance hole.

MH Symbol or Text | mh_symbol_n | symbol cell | available symbols |

Symbol or text string to use to represent the nth set of maintenance holes.

If mh_mode_n is set to text, a text string can be typed in.

If mh_mode_n is set to symbol, the symbol name can be chosen from the pop-up list.

If mh_mode_n is set to circle, then it is ignored.

MH Symbol mirror image
Justification

Justification mode of the MH text for this row of maintenance holes. It is relative to the centres of the MHs. This will only be relevant if \texttt{mh\_mode\_n} is set to \texttt{text}.

Size

Size of the MH symbols or text strings for this row of maintenance holes. The symbols, circles or text strings will only be created if the size is greater than zero.

In the case of a circle, the size is determined to match the diameter of the MH.

Offset

distance to move the MH symbols, circles or text strings to the left or right of the MH centres, for this row of maintenance holes. Positive values are to the right. The direction of movement is parallel to the angle of the MH symbols (see \texttt{mh\_symbol\_dir\_mode} and \texttt{mh\_symbol\_angle}).

Rise

distance to move the MH symbols, circles or text strings above or below of the MH centres, for this row of maintenance holes. Positive values are upwards. The direction of movement is perpendicular to the angle of the MH symbols (see \texttt{mh\_symbol\_dir\_mode} and \texttt{mh\_symbol\_angle}).

Colour

colour of the MH symbols, circles or text strings, for this row of maintenance holes.

Text style

font of the MH text for this row of maintenance holes. This will only be relevant if \texttt{mh\_mode\_n} is set to \texttt{text}.

MH Symbol string name

string name of the MH symbols, circles or text strings for this row of maintenance holes.

Section: Maintenance Hole Labels

MH label direction mode

determines what angle is to be used to position the maintenance hole label text.

MH label angle

angle of MH label text in degrees, minutes and seconds using hp notation.

This is only used depending on the setting of \texttt{mh\_text\_mode}.

MH label justification

justification mode of all MH label text strings, relative to the MH centres.

**Section: MH name labels**

this section defines how a MH name is labelled.

**Draw name labels** tick box

- if **ticked** the name of the maintenance hole is labelled.
- If **not ticked** the name of the maintenance hole is not labelled.

**Text size** mh_text_size real box

- if >0, the text size of the MH name labels.
- If zero, the MH name will not be labelled.

**Text offset** mh_text_offset real box

distance to move the MH name labels to the left or right of the MH centres. Positive values are to the right. The direction of movement is parallel to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

**Text rise** mh_text_rise real box

distance to move the MH name labels above or below the MH centres. Positive values are above. The direction of movement is perpendicular to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

**Text colour** mh_text_colour colour available colours

colour of the MH name labels.

**Text style** mh_text_textstyle textstyle available textstyles

textstyle of the MH name labels.

**Pre text** mh_text_pre text box

text to be placed before the MH name in the MH name labels.

**Post text** mh_text_post text box

text to be placed after the MH name in the MH name labels.

**Text string name** mh_text_name text box

text string name of the MH name labels.

Continue to the next section 26.8.4.2 Maintenance Holes - MH diameter Labels or return to 26.8.4 Maintenance Holes.
26.8.4.2 Maintenance Holes - MH diameter Labels

The diameter of each maintenance hole is defined in the drainage strings.

The columns for the fields documented in the sections are for.

</thead>
</table>

**Section: MH depth labels**

This section defines how a **MH depth** is labelled.

**Draw depth labels**

TICK box

If **ticked** the depth of the maintenance holes are labelled.

If **not ticked** the depth of the maintenance holes are not labelled.

**Text size**

mh_text_size_depth real box

If >0, the text size of the MH depth labels.

If zero, the MH depths are not labelled.

**Text offset**

mh_text_offset_depth real box

distance to move the MH depth labels to the left or right of the MH centres. Positive values are to the right. The direction of movement is parallel to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

**Text rise**

mh_text_rise_depth real box

distance to move the MH depth labels above or below the MH centres. Positive values are above. The direction of movement is perpendicular to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

**Text colour**

mh_text_colour_depth colour box available colours

colour of the MH depth labels.

**Text style**

mh_text_textstyle_depth textstyle available fonts

text style of the MH depth labels.

**Pre text**

mh_text_pre_depth text box

text to be placed before the depth in the MH depth labels.

**Post text**

mh_text_post_depth text box

text to be placed after the depth in the MH depth labels.

**Units factor**

mh_text_factor_depth real box

multiplier of depth values. A Units factor of 3.281 will result in the depths being labelled in feet.

**Decimal places**

mh_text_decimals_depth integer box

number of decimal places in labelled depth values.

If > 0, trailing zeros are removed after the decimal point.

If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

**Text string name**

mh_text_name_depth name box

string name of the MH depth labels.

Continue to the next section **26.8.4.4 Maintenance Holes - MH Chainage Labels** or return to **26.8.4 Maintenance Holes**.
26.8.4.4 Maintenance Holes - MH Chainage Labels

The chainage of each maintenance hole is defined in the drainage strings.

The columns for the fields documented in the sections are for.

<table>
<thead>
<tr>
<th>Panel Field</th>
<th>Parameter name</th>
<th>Type</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section: MH chainage labels</td>
<td>this section defines how a MH chainage is labelled.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Draw chainage labels | tick box |
if >0, the text size of the MH chainage labels.
If zero, the MH depths are not labelled.

Chainage mode | mh_text_mode_ch | choice box |
runtime: chainage
previous chainage
next chainage

determines what the chainage is that is labelled at the MHs.

If running chainage, the chainage is given with reference to the start of the drainage design string.
If previous chainage, the chainage is from the previous maintenance hole.
If next chainage, the chainage is from the next maintenance hole.

Text size | mh_text_size_ch | real box |
if >0, the text size of the MH chainage labels.
If zero, the MH depths are not labelled.

Text offset | mh_text_offset_ch | real box |
distance to move the MH chainage labels to the left or right of the MH centres. Positive values are to the right. The direction of movement is parallel to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

Text rise | mh_text_rise_ch | real box |
distance to move the MH chainage labels above or below the MH centres. Positive values are above. The direction of movement is perpendicular to the angle of the text, specified by parameters mh_text_mode and mh_text_angle. The justification of the text is specified by parameter mh_text_justify.

Text colour | mh_text_colour_ch | colour box |
colour of the MH chainage labels.

Text style | mh_text_textstyle_ch | textstyle |
font of the MH chainage labels.

Pre text | mh_text_pre_ch | text box |
text to be placed before the chainage in the MH chainage labels.

Post text | mh_text_post_ch | text box |
text to be placed after the chainage in the MH chainage labels.

Units factor | mh_text_factor_ch | real box |
multiplier of chainage values. A Units factor of 3.281 will result in the chainages being labelled in feet.

Decimal places | mh_text_decimals_ch | integer box |
number of decimal places in labelled chainage values.

If > 0, trailing zeros are removed after the decimal point.
If <0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

Text string name | mh_text_name_ch | name box |
string name of the MH chainage labels.

Continue to the next section 26.8.5 House Connections or return to 26.8 Drainage Plan Plot PPF Editor
26.8.5 House Connections

The maintenance holes in a plan of a drainage network are often not drawn as they appear but with different symbols etc to represent different manhole types etc.

The manhole name, diameter, depth, chainage, attributes and setout points can all be labelled in plan.

The columns for the fields documented in the sections are for.

Panel Field | Parameter name | Type | Pop-Up
--- | --- | --- | ---
Section: Maintenance hole representation
Panel field | Parameter name | Type | Pop-Up
Section: Maintenance hole representation

Draw house connections | hc_draw_mode | tick box

**HC linestyle** | hc_line_style | linestyle | available linestyles
linestyle with which to represent the house connections to the pipes. The HCs will be represented as lines perpendicular to the pipe, from the pipe centreline, to the sides of the pipe that the HCs are on.

**HC colour** | hc_colour | Colour | available colours
colour of the house connection linestyles

**HC string name** | hc_line_name | Input
string name of the HC lines.

The remaining fields in this section are grid column fields that may each have up to 6 sets (rows) defined.

Panel field | Parameter name | Type | Pop-Up
--- | --- | --- | ---
**HC Type** | hc_types_n | Input
HC type of the nth set of house connections. All HCs of this type will be represented according to the values of the other fields in this set (row). HC types are defined in the drainage design strings. There are only 6 different HC types used in 12d Model.

**HC Type label** | hc_type_text_n | Input
text label to be associated with the HC type of the nth set of house connections.

**Label HC Name and Type** | hc_type_tp_n | Tick box
label the names and types of the HCs of the nth set of house connections. Depending on the HC type, it may not be desired to label the type.

**Label HC IL** | hc_type_il_n | Tick box
label the ILs of the HCs of the nth set of house connections. Depending on the HC type, it may not make sense to label the IL.

**Label HC Chainage** | hc_type_ch_n | Tick box
label the chainages of the HCs of the nth set of house connections. Depending on the HC type, it may not make sense to label the chainages.

**Label HC Additional Text** | hc_type_at_n | Tick box
label the Additional text of the HCs of the nth set of house connections. Depending on the HC type, it may not be desired to label the Additional text.

</tbody>
</table>

Text size of the HC type labels. The labels will only be created if the size is greater than zero and the parameter hc_type_tp_n is set to on for the nth set of house connections. The HC type labels are associated with the HC types are defined by the parameter set hc_type_text_n.

Text offset  

Input

distance to move the HC type labels away from the pipe centreline. Negative values are converted to positive. HC label text is always placed perpendicular to the pipe (or parallel to the HC line) and on the same side of the pipe as the HC. The text will be automatically left justified or right justified, depending on the side.

Text rise  

Input

distance to move the HC type labels above or below the HC lines. Positive values are above. The direction of movement is parallel to the pipe (or perpendicular to the HC line). The text will be automatically bottom justified.

Text colour  

Colour

colour of the HC type labels.

Text style  

Textstyle

font of the HC type labels.

Text string name  

Input

string name of the HC type labels.

</tbody>
</table>

determines what chainage values will be labelled at the HCs. The **running chainage** option refers to the start of the drainage design string. The **previous chainage** and **next chainage** options refer to the previous and next MHs respectively. The **hc lot offset** option is a special one that looks for a user-defined attribute called "<hc_name> hc lot offset" in the house connections along the drainage design strings. If the attribute is found, its value is set as the HC chainage label. If the attribute is not found, the value of the HC chainage label is set to a default HC Lot Offset of 5.0.

**Text size**

**hc_chain_size**

*input*

text size of the HC chainage labels. The labels will only be created if the size is greater than zero and the parameter **hc_type_ch_n** is set to **on** for the nth set of house connections.

**Text offset**

**hc_chain_offset**

*input*

distance to move the HC chainage labels away from the pipe centreline. Negative values are converted to positive. HC label text is always placed perpendicular to the pipe (or parallel to the HC line) and on the same side of the pipe as the HC. The text will be automatically left justified or right justified, depending on the side.

**Text rise**

**hc_chain_rise**

*input*

distance to move the HC chainage labels above or below the HC lines. Positive values are above. The direction of movement is parallel to the pipe (or perpendicular to the HC line). The text will be automatically bottom justified.

**Text colour**

**hc_chain_colour**

colour available colours

colour of the HC chainage labels.

**Text style**

**hc_chain_textstyle**

textstyle available fonts

*font* of the HC chainage labels.

**Pre text**

**hc_chain_pre**

*input*

text to be placed before the chainage in the HC chainage labels.

**Post text**

**hc_chain_post**

*input*

text to be placed after the chainage in the HC chainage labels.

**Units factor**

**hc_chain_factor**

*input*

multiplier of chainage values. A Units factor of 3.281 will result in the chainages being labelled in feet.

**Decimal places**

**hc_chain_decimals**

*input*

number of decimal places in labelled chainage values.

*If* > 0, trailing zeros are **removed** after the decimal point.

*If* < 0, the absolute value is taken as the number of decimal places to report i.e. no trailing zeros are removed. For example -3 means that there is always 3 figures after the decimal place.

**Text string name**

**hc_chain_name**

*input*

string name of the HC chainage labels.

</tbody>
</table>
27 Reports

Position of menu: It is on the main menu as Report

The Reports menu contains options to report on the strings in a model, polygon details (area, centroid), string set outs, string names, crest and sag points and x-falls.

The Reports menu is

For the option/menu Edit, go to

- 27.1 Edit
- 27.2 Strings
- 27.3 Functions
- 27.4 Length and Area
- 27.5 Set-Out Reports
- 27.6 Services
- 27.7 Quantities
- 27.8 X-Fall and Offset Report
- 27.9 Report Utilities
- 27.10 QA Reports
- 27.11 More Reports

Each menu option will now be discussed.
27.1 Edit

**Position on menu:** Report => Edit

The Edit option is used to edit any (printer) reports ending in *.rpt.

On walking right on Edit, the list of files ending in *.rpt are displayed.

Double clicking on the report name will bring up the report in the system editor.

Clicking on the Edit at the top of the menu brings up the **Edit a file** panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Folder</strong></td>
<td>folder box</td>
<td>folder box</td>
<td>current folder</td>
<td>folder browser</td>
</tr>
</tbody>
</table>

  * the folder to look for the report file.

| **File to edit** | file box | * .rpt |

  * name of the file to bring up in the system editor.
27.2 Strings

Position of menu: Report => Strings

The Strings menu contains options to report on selected strings, report the crest/sag points for a string and create a list of all the unique string names in a model or view.

The Strings walk-right menu is

For the option Coords/Brg-Dst, go to 27.2.1 Coordinates or Bearing-Distance Report

Crest/sag points 27.2.2 Crest/Sag Points Report
Names 27.2.3 Names Report
Super alignment 27.2.4 Super Alignment Report
Chainage Equalities 27.2.5 Chainage Equalities Report
Super strings 27.2.6 Report for Super Strings
More 27.2.7 More Strings Reports.
27.2.1 Coordinates or Bearing-Distance Report

Position of option on menu:  Report => Strings => Coords/Brg-Dst

The Coords/Brg-Dst option is used to generate a report on selected items defined by a source box. The report can be of the form of coordinates of each point of a string, or the co-ordinates of the first point of a string and the bearings and distances from each other point of the string to the first point of the string.

For a Super Alignment string it will report the solved horizontal and vertical geometry (the horizontal and vertical Segments that make up the Super Alignment). If there is a non-zero separation value, then at each chainage that is a multiple of the separation value, the report also includes the chainage, x, y, z, and in and out bearings at the chainage.

For an Alignment string it will report on the HIP’s and VIPS. If there is a non-zero separation value, then at each chainages that are multiples of the separation value, the report also includes the chainage, x, y, z, bearing for horizontal and chainage, height (z), grade for vertical.

On selecting the Coords/Brg-Dst option, the Report on Selected Item panel is displayed.

![Report on Selected Item panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>data selection type - for a full description go to <a href="#">4.19.3 Data Source</a>.</td>
</tr>
<tr>
<td>Data source</td>
<td>input</td>
<td></td>
<td>source of data to be processed.</td>
</tr>
<tr>
<td>Report file</td>
<td>input</td>
<td>* .rpt</td>
<td>name of the file to report to.</td>
</tr>
<tr>
<td>Coordinates(x,y)</td>
<td>tick box</td>
<td>tick</td>
<td></td>
</tr>
</tbody>
</table>
if tick, the coordinate report parameters will be displayed which will determine what other information as well as the coordinate values will be placed in the report. **NOTE:** If an alignment string is part of the selection, the report will include all relevant details about the alignment. In this case the report will not use the coordinate report parameters as specified, for the alignment string.

**Bearing and Distances** tick box

if tick, the bearing and distance report parameters will be displayed which will determine what other information as well as the bearing and distance values will be placed in the report.

**Coordinate report parameters**

if the Coordinates(x,y) option is selected, the following parameters will be displayed

- **Point ids** tick box
  
  if selected, any valid point ids will be shown in the report.

- **Vertex indices** tick box
  
  if selected, vertex indices will be shown in the report.

- **Z Values** tick box
  
  if selected, any valid z values will be shown in the report.

- **Radius values** tick box
  
  if selected, any valid radius values will be shown in the report.

- **Vertex Text** tick box
  
  if selected, any valid vertex text values will be shown in the report.

- **Separation for Alignment** tick box
  
  if selected, the separation for alignment box will be enabled.

  **Separation** input box 10
  
  if enabled by ticking the previous tick box, the alignment string information will be reported at a chainage interval given by the separation value.

- **Report** button
  
  run the option and create the report.

For a Super Alignment, the report is the same as Reports => Strings => Super alignment (see 27.2.4, Super Alignment Report).
27.2.2 Crest/Sag Points Report

Position of option on menu:  Report => Strings => Crest sag points

The crest/sag points option is used to generate a (printer) report on the crests and sags points of a string.

A number of strings can be reported on by selecting them in turn.

On selecting the crest/sag points option, the string crest/sag points report panel is displayed.

The fields and buttons in this panel are used as follows:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>

</table>

data selection type - for a full description go to 4.19.3 Data Source.

data source type of data source.

name of the file to contain the reports on the crest and sag points of strings.

Pick & Report button

as strings are selected, the crest and sag points report is generated and appended to the report file.

The cycle is terminated by clicking RB to raise the pick ops menu and selecting cancel from it.
27.2.3 Names Report

The names option is used to report on all the unique strings in a model or on a view.

If the report button is selected, then all the strings in the model/view given by the model/view to report field will be checked and all unique names, plus a frequency count, will be written to the report file.

Selecting Names displays the String Names Report for panel.

![String Names Report for Panel]

</tbody>
</table>
27.2.4 Super Alignment Report

Report on the Super Alignment that gives information on the horizontal and vertical components.

For a Super Alignment string it will report the solved horizontal and vertical geometry (the horizontal and vertical Segments that make up the Super Alignment).

If there is a non-zero separation value, then at each chainages that are multiples of the separation value, the report also includes the chainage, x, y, z, in and out bearing for horizontal vertices, and chainage, height (z) and in and out grade for vertical vertices.

On selecting the Super alignment option, the Super Alignment Report panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

</tr>
<tr>
<td>Report file</td>
<td>input</td>
<td>*.rpt</td>
<td>name of the file to report to. See below for definition of the report and an example.</td>
</tr>
</tbody>
</table>

The Super Alignment report is made up of 5 parts:

(a) General Information
   The type of transition curve.
Whether the super alignment is closed or not.

The start chainage for the string and the chainage length (2d length) of the string.

(b) Horizontal Vertex Data

The Horizontal Vertex Data section of the report gives information about each of the horizontal vertices of the underlying horizontal segment geometry.

Note: "Solving" a super alignment takes all the constraints and produces a string of vertices with segments of type Line, Arc or Transition between each pair of adjacent vertices.

So the Horizontal Vertex Data report gives the (x,y,z) coordinates of each of the vertices of the solved horizontal geometry with the type of segment going into the vertex (In Seg), and the type of segment going out of the vertex (Out Seg).

The In Direction is the angle at the vertex of the segment going into the vertex, and the Out Direction is the angle at the vertex of the segment going out of the vertex.

If the In and Out Direction are the same, then the two segments are tangential at the vertex and there will be a Yes in the Tan column, otherwise there will be a No in the Tan column.

In Seg

The type of the segment going into the critical point (In Segment) at the chainage - Line, Arc, Leading Spiral (L.Spiral), Trailing Spiral (T.Spiral)

Out Seg

The type of the segment going out of the critical point (Out Segment) at the chainage - Line, Arc, Leading Spiral (L.Spiral), Trailing Spiral (T.Spiral)

Tan - yes or no

yes if the In Segment and Out Segment are tangential. That is, the In Direction and Out Direction are the same.

no if the In Segment and Out Segment are not tangential. That is, the In Direction and Out Direction are different.

Chainage

chainage of the critical point

X, Y and Z Coordinates at that chainage

In Direction

the angle of the In Segment at the critical point. Measured in dms, counterclockwise from the positive x-axis.

Out Direction

the angle of the Out Segment at the critical point. Measured in dms, counterclockwise from the positive x-axis.

In Radius

the radius of the In Segment at the critical point (or blank if on a Line).

Out Radius

the radius of the Out Segment at the critical point (or blank if on a Line).

(c) Horizontal Geometry Data

How each of the horizontal parts is defined.

(d) Vertical Vertex Data

The Vertical Vertex Data section of the report gives information about each of the vertical vertices of the underlying vertical segment geometry.

Note: "Solving" the vertical of a super alignment takes all the constraints and produces a 2d string in the (Chainage, height) plane, of vertices with segments of type Line, Arc or Parabola between each pair of adjacent vertices.
So the **Vertical Vertex Data** report gives the (ch,z) coordinates of each of the vertices of the solved vertical geometry with the type of segment going into the vertex (**In Seg**), and the type of segment going out of the vertex (**Out Seg**).

The **In Grade** is the grade at the vertex of the segment going into the vertex, and the **Out Grade** is the grade at the vertex of the segment going out of the vertex.

If the **In** and **Out Grade** are the same, then the two segments are **tangential** at the vertex and there will be a **Yes** in the **Tan** column, otherwise there will be a **No** in the **Tan** column.

**In Seg**

The type of the segment going into the critical point (**In Segment**) at the chainage - Line, Arc, Parabola

**Out Seg**

The type of the segment going out of the critical point (**Out Segment**) at the chainage - Line, Arc, Parabola

**Tan - yes or no**

- **yes** if the **In Segment** and **Out Segment** are tangential. That is, the **In Grade** and **Out Grade** are the same.
- **no** if the **In Segment** and **Out Segment** are not tangential. That is, the **In Grade** and **Out Grade** are different.

**Chainage**

chainage of the critical point

**Level**

height (z value) at that chainage

**In Grade**

the grade of the **In Segment** at the critical point.

**Out Grade**

the grade of the **Out Segment** at the critical point.

**In VCL Radius**

the radius of the parabola or arc of the **In Segment** at the critical point (or blank if on a Line).

**Out VCL Radius**

the radius of the parabola or arc of the **Out Segment** at the critical point (or blank if on a Line).

(e) **Vertical Geometry Data**

How each of the vertical parts is defined.
Super Alignment to Report

Horizontal Geometry

Vertical Geometry
The Super Alignment report is made up of 5 parts:

(a) General Information
   - The date the report was produced
   - The string and model name for the string
   - The type of transition curve
   - Whether the super alignment is closed or not
   - The start chainage for the string and the chainage length (2d length) of the string

---

</tr>
</tbody>
</table>
(b) A report for the critical points, and the horizontal chainage increment of the string giving the
Point Type at the chainage (eg Straight, Tangent-Curve, Curve, Spiral-Curve etc)
Chainage at that point.
X, Y and Z Coordinates at that chainage
Instantaneous Bearing at that chainage
Instantaneous Radius at that chainage (or blank if on a straight)

(c) Horizontal Vertex Data
The Horizontal Vertex Data section of the report gives information about each of the horizontal vertices of the underlying horizontal segment geometry.
Note: "Solving" a super alignment takes all the constraints and produces a string of vertices with segments of type Line, Arc or Transition between each pair of adjacent vertices.
So the Horizontal Vertex Data report gives the (x,y,z) coordinates of each of the vertices of the solved horizontal geometry with the type of segment going into the vertex (In Seg), and the type of segment going out of the vertex (Out Seg).
The In Bearing is the bearing at the vertex of the segment going into the vertex, and the Out Bearing is the bearing at the vertex of the segment going out of the vertex.
If the In and Out Bearings are the same, then the two segments are tangential at the vertex and there will be a Yes in the Tan column, otherwise there will be a No in the Tan column.

(d) Horizontal Geometry Details
How each of the horizontal parts is defined.

(e) Vertical Vertex Data
The Vertical Vertex Data section of the report gives information about each of the vertical vertices of the underlying vertical segment geometry.
Note: "Solving" the vertical of a super alignment takes all the constraints and produces a 2d string in the (Chainage, height) plane, of vertices with segments of type Line, Arc or Parabola between each pair of adjacent vertices.
So the Vertical Vertex Data report gives the (ch,z) coordinates of each of the vertices of the solved vertical geometry with the type of segment going into the vertex (In Seg), and the type of segment going out of the vertex (Out Seg).
The In Grade is the grade at the vertex of the segment going into the vertex, and the Out Grade is the grade at the vertex of the segment going out of the vertex.
If the In and Out Grade are the same, then the two segments are tangential at the vertex and there will be a Yes in the Tan column, otherwise there will be a No in the Tan column.

(f) Horizontal Geometry Details
How each of the vertical parts is defined.
27.2.5 Chainage Equalities Report

Position of option on menu:  Report => Strings => Chainage equalities
This option is under development.

On selecting the Chainage equalities option, the Chainage Equality Report panel is displayed.

27.5 Set-Out Reports

**Position of menu:** Report => Set-out

The Set out report options are for reporting the bearing and distance from a selected instrument station to individual points, strings, models of strings or views of strings.

In the Setout report, a backsight stations can be selected and the bearing of the line from the instrument station to the backsight station reported. Individual backsight points or strings of backsight points can be selected for reporting.

In the Radial report, the report can be sorted by point number, bearing or distance.

The set outs walk-right menu is

```
Set-Out Report
Old Setout Report
Setout Report
Radial Report
```

old set out report from V5.0
set out report for strings
set out report sorted by name, distance or bearing

For the option Old setout report, go to

- Old Setout Report 27.5.1
- Setout Report 27.5.2
- Radial Report 27.5.3

The menu options will now be discussed.
27.5.1 Old Setout Report

**Position of option on menu:** Report => Set out => Old setout report

The setout report from 12d Model V5. This option has been rewritten for 12d Model V6 and is called **Setout Report**.

On selecting the **Old setout report** option, the **Old Setout Report** panel is displayed.

The fields and buttons in this panel are used as follows:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Instrument XYZ/name output
co-ordinates/name of the current instrument station

Bearing decimal places input
number of decimal places to report the bearings to

Instrument button
the required instrument station is selected and its name and position are reported in the instrument XYZ and instrument name panel fields.

Backsight button
a backsight is selected and written to the report file.

Pick button
After pick is chosen, a set out report is written to the report file for any selected strings. If the report mode is report point, only the individual point is reported. If the report mode is report string, all the points in the string are reported.
The cycle is terminated by clicking RB to raise the pick ops menu and selecting cancel from it.

Setouts button
produce a set out report for all the strings in the model/view given in the model/view field.

How to Use the Panel and Panel Messages
(a) Enter the report file name and maximum distance.
(b) The instrument station is chosen by activating the station button and selecting the required station point. It will then be reported in the file.
(c) Any backsight points to be reported can then be chosen by picking the backsight button and selecting the backsight point.
(d) To report on individual strings or points, set the report mode to either point or string. The pick button is then activated and the individual points or strings selected. The cycle is terminated by clicking RB to raise the pick ops menu and selecting cancel from it.
To report on all the strings in a model/view, give the model/view in the model/view field, and select the setout button.

Note
The instrument station can be changed at any time by selecting the station button and picking the new station.
All backsight and set outs will then be taken from the new instrument station.
27.5.2 Setout Report

**Position of option on menu:**  Report => Set out => Setout report

In the Setout report, a backsight stations can be selected and the bearing of the line from the instrument station to the backsight station reported. Individual backsight points or strings of backsight points can be selected for reporting.

The instrument station can be changed at any time and new backsight and set outs reported.

The setout option prints the following information:

- **instrument station**
  - string name, point number, x, y, z

- **backsight point**
  - string name, point number, x, y, z, bearing to the line joining the instrument and backsight, horizontal distance, height difference between instrument station and the backsight

- **point set-out point**
  - string name, point number, x, y, z, bearing, horizontal distance, height difference between instrument station and the point

On selecting the Setout report option, the Setout Report panel is displayed.

Report mode  choice box  report points, report string
   if report points, report selected points. Otherwise report on all points in the selected string.

Maximum distance  input
   if non-blank, any points further that the maximum distance from the instrument station will not be reported on. If blank, all selected points will be reported on.

Report file  file box
   file for the backsight and setout reports

Instrument XYZ/name  output
   co-ordinates/name of the current instrument station

Bearing decimal places  input
   number of decimal places to report the bearings to

Instrument  button
   the required instrument station is selected and its name and position are reported in the instrument XYZ and instrument name panel fields.

Backsight  button
   a backsight is selected and written to the report file.

Pick  button
   After pick is chosen, a set out report is written to the report file for any selected strings. If the report mode is report point, only the individual point is reported. If the report mode is report string, all the points in the string are reported. The cycle is terminated by clicking RB to raise the Pick ops menu and selecting Cancel from it.

Setouts  button
   produce a set out report for all the strings in the model/view given in the model/view field.

How to Use the Panel and Panel Messages
(a) Enter the report file name and maximum distance.
(b) The instrument station is chosen by activating the station button and selecting the required station point. It will then be reported in the file.
(c) Any backsight points to be reported can then be chosen by picking the backsight button and selecting the backsight point.
(d) To report on individual strings or points, set the report mode to either point or string. The pick button is then activated and the individual points or strings selected. The cycle is terminated by clicking RB to raise the pick ops menu and selecting cancel from it. To report on all the strings in a model/view, give the model/view in the model/view field, and select the setout button.

Note
The instrument station can be changed at any time by selecting the station button and picking the new station.

All backsight and set outs will then be taken from the new instrument station.
27.5.3 Radial Report

Position of option on menu: Report => Set out => Radial report

The radial report reports the bearing and distance from the Instrument to selected vertices. The report can be sorted by point id, bearing or distance.

Selecting Radial report brings up the Radial Report panel.

![Radial Report panel](image)

The fields and buttons in this panel are used as follows:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>

</table>

*data selection type - for a full description go to 4.19.3 Data Source.*

Data source

*type of data source.*
Scaled radial  
  radio button  
  if selected, the report uses a fixed scale factor.

Scale factor  
  input 1  
  if scaled radial is selected, the fixed scale factor to use

Projection radial  
  radio button  
  if selected, the report uses a projection for calculating distances

Projection  
  projection box  
  if projection radial is selected, the selected projection is used when calculating distances

Instrument setup  
  when the instrument point is selected, the **Instrument co-ordinates** and **name** is displayed in the Instrument xyz and Instrument name fields.

Report settings

Include points without id  
  tick box  
  if tick, vertices with a non blank point id are included in the report.  
  if not tick, only vertices with non blank point id are included in the report.

Zero padding for bearing  
  tick box  
  if tick, include extra zeros for minutes and seconds.

Sort by  
  choice box  
  point id, bearing, distance  
  if point id, the report is sorted by the point id’s on the vertex.  
  bearing, the report is sorted by the bearing to the point.  
  distance, the report is sorted by the distance to the point.

Number of decimals  
  input 3  
  number of decimal places for reporting co-ordinates

Maximum distance  
  input  
  if non-blank, any vertices further that the maximum distance from the instrument station will not be reported on. If blank, all vertices points will be reported on

Search tolerance  
  input  
  when a vertex is found, any vertices with the same point id within the search distance of the vertex are not reported. Also no vertices closer to the instrument point that this distance will be reported.

Report file  
  file box  
  file for the setout reports

Report  
  button

27.8 X-Fall and Offset Report

**Position of option on menu:** Report => Xfall/offset

The x-fall report option reports on the horizontal and vertical offsets and the cross-fall between two strings.

The offsets are calculated as follows:

(a) a reference string is selected which is used to define chainages.

(b) lines perpendicular to the reference string are taken at regular chainages and intersected (in plan) with the first and second strings.

(c) the horizontal and vertical offsets and the cross-fall between the two strings is calculated at the intersection points.

On selecting the X-fall option, the X-Fall Report panel is displayed.

The fields and buttons in this panel are used as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start/End chainage</td>
<td>input&lt;br&gt;&lt;br&gt;if blank, the start/end chainage of the reference string is used.&lt;br&gt;if non-blank, the given chainage is used as the start/end chainage.</td>

Compare name strings 27.10.7 Compare Named Strings
27.10.1 Check As built String vs Design String

**Position of option on menu:**  Report => QA Reports => Check asbuilt string vs design string

This panel is used to check the horizontal and vertical differences between two strings (usually “as built” and design). A control string is selected to provide the chainage and line to cut the two strings and calculate the difference along. The control string can be one of the two strings.

The corridors are an optional setting for where multiple cuts of the as built and design strings are possible.

E.g. If string crosses over itself or turns through more than 90° a section normal to the control string could cut it more than once.

If the user sees warning messages such as “> 1 cut” then use these settings to filter out the multiple cuts.

Selecting the Check asbuilt string vs design string brings up the **Check As Built String vs Design String** panel.

![Check As Built String vs Design String panel](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>

</tr>
</tbody>
</table>

The fields and buttons used in this panel have the following functions:

- **As built string**
  - string select
- **Design string**
  - string select
Control string

string to use to define chainage and right angles. The line at right angles cuts the “as built” and “design” strings and is used to calculate the horizontal and vertical differences.

Report horizontal difference choice box Right +ve None, Right +ve, Right -ve

if None Don’t report horizontal distances.

if Right +ve Horizontal differences are reported with differences to the right reported as +ve

if Right -ve Horizontal differences are reported with differences to the right reported as -ve

Report vertical difference choice box Above +ve None, Above +ve, Above -ve

if None Don’t report horizontal distances.

if Above +ve Vertical differences are reported with differences above reported as +ve

if Above -ve Vertical differences are reported with differences above reported as -ve

Report at asbuilt string’s vertices tick box

if tick, the differences are reported at the vertices of the as built string.

Report at regular control line interval tick box

if tick, the differences are reported at the chainage interval given in the “Report interval” box.

Difference units choice box Millimetres (0 dp), Millimetres (1 dp), Millimetres (2 dp), Millimetres (3 dp), Millimetres (4 dp)

if Millimetres (0 dp) In the report, differences are printed out as Millimetres with 0 decimal places

if Millimetres (1 dp) In the report, differences are printed out as Millimetres with 1 decimal place

if Metres (3 dp) In the report, differences are printed out as Metres with 3 decimal places

if Metres (4 dp) In the report, differences are printed out as Metres with 4 decimal places

Report interval input box

chainage interval of the control string to report the differences at.

Start chainage input box

start chainage of the control string to start reporting differences.

End chainage input box

end chainage of the control string to stop reporting differences.

Offset Corridor input box

If this value is set a cut offset greater than this from the design string is ignored.

Hgt diff Corridor input box

If this value is set a cut hgt difference greater than this from the design string is ignored.

Report file input box

name of the report file.

Report button

run the option.
27.10.2 Check Asbuilt String vs Wall Tin

Position of option on menu: Report => QA Reports => Check asbuilt string vs wall tin

This panel is used to check the horizontal difference between a string (usually the “as built”) and a tin (usually a wall tin). A control string is selected to provide the chainage and bearing to project a horizontal line to cut the string and the tin and calculate the horizontal difference along. The control string can be the “as built” string.

Points that are different by a given inner and outer tolerance are flagged in the report.

![Check As Built String vs Wall Tin]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>

</table>

As built string string to compare against the wall tin.

Control string string to use to define chainage and right angles. The horizontal line at right angles cuts the “as built” string and “tin to check against” tin that is used to calculate the horizontal differences.

Start chainage start chainage of the control string to start reporting differences.

End chainage end chainage of the control string to stop reporting differences.

Tin to check against tin to compare the as built string with.
Report at as built string's vertices tick box tick
if tick, the differences are reported at the vertices of the as built string.

Report at regular control line interval tick box tick
if tick, the differences are reported at the chainage interval given in the “Report interval” box.

Report interval input box 5
chainage interval of the control string to report the differences at.

Inner tolerance (mm) input box 100
if the inner horizontal distance between the string and the wall is greater than this value (in units times 1000) then it is flagged in the report.

Outer tolerance (mm) input box 100
if the outer horizontal distance between the string and the wall is greater than this value (in units times 1000) then it is flagged in the report.

Report File input box
name of the report file.

Report button
run the option.
27.10.3 Check Points Above a Tin

**Position of option on menu:** Report => QA Reports => Check points above tin

This panel is used to check the z-value of points against the z-value of a tin at the same (x,y) locations and only report on those above the tin. To check points above and below a tin, go to the next section 27.10.4 Check Points vs Tin.

A z-tolerance above the tin is given and all points above the tin and outside the tolerance are especially flagged in the report.

Optionally the report can also include the chainage and offset of the points from a selected alignment string.

![Check Tolerance Above Design Tin](image)

if ticked design coordinates will be written to the report file

**Report as CSV?**

*If Report as CSV? is ticked then the column width settings are ignored and the report written as a comma delimited 'CSV' file suitable for exports to spreadsheets and others.*

*If Report as CSV? is not ticked then the reported is formatted with the column width figures in mind.*

Run button

**run the option.**
27.10.7 Compare Named Strings

Position of option on menu:  Report => QA Reports => Compare named strings

The **compare named strings** panel is a utility to check for changes in a string and highlights these changes. It would typically be used when a revised design is released to highlight where the actual changes are.

Strings are matched by name, there must only be one string of the same name in each of the data sources.

Selecting **Compare named strings** brings up the **Compare Named Strings** panel.

![Compare Named Strings panel](image)

The fields and buttons used in this panel have the following functions:

<table>

**Data 1st Strings**

the data source for the 1st set of strings.

data selection type - for a full description go to [4.19.3 Data Source](#).

**Data 2nd Strings**

the data source for the set of strings to compare to the 1st set of strings.

data selection type - for a full description go to [4.19.3 Data Source](#).

**Exact comparison?** tick box

if ticked the strings are compared vertex by vertex

if unticked the points in the 2nd string are dropped to the first string and the comparison is done by offset and height difference.
**Pos/xy Tol** measure box

*The distance between vertices or the difference in offset before the point is considered different.*

**Z Tol** measure box

*The height difference between the strings before the point is considered different.*

**Report file** file box

*The file to which the results of the comparison are written, contains the strings compared, the number of name matches if not matched or unique and the details of differing points.*

**Out of Tolerance Model** model box

*Any points outside the nominated tolerances can be written to this model.*

**Symbol size** input

*Points in the out of tolerance model have a diamond of this real world size drawn around them to highlight the points.*

**Compare** button

*Compares the two data sources*
27.11 More Reports

**Position of menu:**  Report => More

More miscellaneous reports.

</table>

select the alignment string to report on.

name of the report file.

run the option.
27.11.5 Alignment Table - IP’s, TC’s

Position of option on menu: Report => More => Alignment table - IP’s and TC’s

Create table of IP and CT points for an alignment string.

This panel has already been documented.

See 24.16.15 Tabulate Alignment - IP’s and CT’s in 24 Drafting
27.11.6 Alignment Table - Elements

Position of option on menu:  Report => More => Alignment table - elements

Create table of horizontal elements for an alignment string.

This panel has already been documented.

See 24.16.16 Tabulate Alignment - Elements in 24 Drafting
27.11.7 Total of Plan Area by String Colour

Position of option on menu:  Report => More => Area by string colour

This panel is used to calculate the sum of the plan area of all strings of the same colour. This is especially useful for calculating the plan areas of faces produced for slope areas, volumes etc. A report giving the total plan area for each different colour is produced.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
27.11.9 Quarter Points Report

**Position of option on menu:** Report => More => Quarter points bubbles and table

This option is used to create bubbles and/or a report for the critical horizontal and vertical points and quarter points (by chord or by chainage) for any arcs in an alignment string.

This option has already been documented as Survey => Setout => Setout lip line in the section 17.18.3 Setout Lip Line.
27.11.10 Report Minimums Z-Value on a Cross Section

Position on menu: Report => More => Report min z

This panel creates a report giving the minimum z-value on a cross section.

![Minimum Section Level Panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>

</tbody>
</table>
28 Utilities

Position of menu: It is on the main menu as Utilities.

The Utilities menus contain a collection of useful operations that don't easily fit under any of the other menus.

For ease of selection, the frequently used utilities are placed on the first level of the menu. All the other utilities are split alphabetically between two walk-right menus - the utilities walk-right menus for A-G and H-Z.

For the option/menu:

- **Snaps**, go to 28.1 Snaps
- **Attributes**, go to 28.2 Attributes
- **Chains**, go to 28.3 Chains
- **Functions**, go to 28.4 Functions
- **Macros**, go to 28.5 Macros
- **Measure**, go to 28.6 Measure
- **Recalc**, go to 28.7 Recalc
- **Fence**, go to 28.8 Fence
- **Super strings**, go to 14.12.9 Super Strings
- **A-G**, go to 28.9 Utilities A-G
- **H-Z**, go to 28.10 Utilities H-Z
- **Old**, go to 28.11 Old
28.1 Snaps

**Position of menu:**  Utilities => Snaps

The snaps option allows the user to set snapping modes for use during pick operations. The snapping modes have been discussed in detail in the 4.13 Snaps section.

The Snaps walk-right menu provides a full snap menu, abbreviated snap menus laid out either horizontally or vertically, and a snaps cogo menu for creating special point positions using coordinate geometry commands.

For the option
- **Snaps**, go to 28.1.1 Snaps
- **Snaps (Vert)** 28.1.2 Snaps (Vert) and H Toolbar
- **Cogo** 28.1.3 Snaps Cogo
- **New** 28.1.5 Snaps New
- **Select accept button** 28.1.4 Select accept button
28.1.1 Snaps

**Position of option on menu:** Utilities => Snaps => Snaps

The Snaps menu provides tick boxes to turn the various snap modes on or off and options to set tin, string and model names. Any combination of snap modes and names can be set.

<table>
<thead>
<tr>
<th>Snaps menu</th>
<th>Snaps V menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>point snap on/off</td>
<td>V</td>
</tr>
<tr>
<td>line snap on/off</td>

<td>M</td>
</tr>
<tr>
<td>turns data tips on/off</td>
<td></td>
</tr>
<tr>
<td>turns fast pick on/off</td>
<td></td>
</tr>
<tr>
<td>turns fast accept on/off</td>
<td></td>
</tr>
<tr>
<td>K - accept results of snaps CAD</td>
<td></td>
</tr>
<tr>
<td>picks bring up selection grid</td>
<td></td>
</tr>
</tbody>
</table>

The snaps are set on or off using the toggles on the Snaps H toolbar, or the tick boxes on the Snaps or Snaps V menu.

For more information on what all the snaps in the Snaps menu are, go to the 4.13 Snaps and 4.13.2 Setting Snaps section.
28.1.2 Snaps (Vert) and H Toolbar

Position of option on menu: Utilities => Snaps => Snaps (Vert)

The Snaps (vert) menu provides the same tick boxes as the Snaps menu to turn the various snap modes on or off, however the snap descriptions are abbreviated to one character to reduce the menu size. There is also the H toolbar which is a horizontal version of the Snaps menu.

The H toolbar and Snaps (vert) menu are H toolbar which is

![Snaps Menu]

The Snaps are

- P  Point snap (on)
- L  Line snap (on)
- X  Text snap (off)
- G  Grid snap (off)
- C  Cursor snap (on)
- H  Height snap (off)
- T  Tin snap (off)
- S  Segment snap (off)
- I  Info snap (on)
- D  Data tip (off)
- F  Fast accept (on)
- A  Fast accept (off)
- K  Construction snap (on)
- M  Show selection grid on picks

For more information on snaps, go to the 4.13 Snaps and 4.13.2 Setting Snaps section.
28.1.3 Snaps Cogo

Position of menu: Utilities -> Snaps -> Cogo

The Snaps cogo options are used to create the point required for any 12d Model select operation. For example, selecting the next point in append in an editor. The result of the Snaps cogo is returned to the select operation as the selected point.

Walking right on the cogo option brings up the Snaps cogo menu

and the walk-right menus for each of the Snaps cogo menu items are

Note on Combining Snaps Cogos

When using a snaps cogo option, another select is often required and it is permissible to use other snaps cogo option to create the point for that select.

For example, the required point is the point halfway between two other points dropped perpendicularly onto an arc.

Such a combined result can be achieved using Snaps cogo however the order of selecting the snaps cogo options may at first seem to be the reverse of what is required.

For the above example, the snaps cogo perpen must be selected before the between option.

This is because when the perpen snap cogo option is selected, it asks the user to select the point to drop and it is then that the snaps cogo between option is used to find the midpoint of two selected point. The result of the between then becomes the point to drop for the perpen.

If the between option had been selected first, the resultant midpoint would have been returned as the selected point and that select completed.
28.1.4 Select accept button

**Position of menu:** Utilities => Snaps => Select accept button

Instead of selecting (MB) to accept a string selection, you can click (LB) on the **Accept** button. This option is usually used for tablet computers without a middle mouse button.

LB = the left mouse button

MB = the middle mouse button

![Select Accept Button](image_url)
28.1.5 Snaps New

Position of menu: Utilities => Snaps => New

The XTRA Snaps menu is currently under development.
28.2 Attributes

**Position of menu:** Utilities => Attributes

This section of documentation is a work in progress and will be updated in subsequent releases.

The Attributes walk-right menu is:

For the Attribute definitions editor, go to 28.2.1 Attribute Definitions Editor

Custom attribute editor 28.2.2 Custom Attribute Editor
28.2.1 Attribute Definitions Editor

Position of option on menu: Utilities => Attributes => Attributes Edits => Attribute definitions editor

This section of documentation is a work in progress and will be updated in subsequent releases.
28.2.2 Custom Attribute Editor

**Position of option on menu:** Utilities => Attributes => Attributes Edits => Custom attribute editor

This section of documentation is a work in progress and will be updated in subsequent releases.
Chapter 28 Utilities

28.3 Chains

Position of menu:  Utilities => Chains

12d Model has many different built in objects, from simple strings, through to complex super alignments with computators, drainage networks, super tins and Apply MTF functions. However as complex as these objects are, no software can foresee every situation met in surveying and civil design, both now and into the future.

12d Model provides two tools to help users extend the supplied 12d Model functionality and automate simple and complex tasks within a company. They are the

(a) the 12d Model Programming Language (12dPL) - a full programming language so users can write complex tailored options and functions (called macros)

and

(b) chains.

Chains are a relative simple method for users to combine and run existing 12d Model functions and options. Anyone who can use 12d Model can create and run a chain.

In its simplest form, a Chain is a list of items that are run in the order that they appear in the list. Things that can be run in a Chain include:

(a) 12d Model functions
(b) other chains
(c) super alignment resolves
(d) plot parameter files
(e) most 12d Model options
(f) most screen layout files
(g) most macros, and certainly those that don’t have a panel
(h) an external command line
(i) some special hardwired chain commands such as delete a tin, delete all tins, delete a model, delete all models, clean a model, delete a file and compare files.

For more sophisticated applications, chains can also

(a) create 12d Model views and add and remove models from the views
(b) minimise, maximise, redraw and delete views
(c) include flow control using tests, labels and go to’s
(d) be parametrised and run with user supplied parameter values

So a chain can be as simple as running a list of functions or as complex and making decisions inside the chain, thus creating user defined Super Objects.
The **Chains** walk-right menu is

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create</strong></td>
<td>create a chain</td>
</tr>
<tr>
<td><strong>Edit</strong></td>
<td>edit a chain</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
<td>parameterise a chain</td>
</tr>
<tr>
<td><strong>Copy</strong></td>
<td>copy a chain</td>
</tr>
<tr>
<td><strong>Convert</strong></td>
<td>convert a chain</td>
</tr>
<tr>
<td><strong>Rename</strong></td>
<td>rename a chain</td>
</tr>
<tr>
<td><strong>Run</strong></td>
<td>run a chain</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>delete a chain</td>
</tr>
</tbody>
</table>
28.3.1 Create/Edit a Chain

**Position of option on menu:** Utilities => Chains => Create

The **Create/Edit** option creates new chains but can also edit an existing chain, or run an existing chain.

Selecting **Create** brings up the **Create/Edit Chain** panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain file</td>
<td>name of the file for the chain.</td>
<td>file box</td>
<td>blank</td>
<td>available *.chain, *.rcn files</td>
</tr>
<tr>
<td>Parameter value file</td>
<td>file defining parameters for the chain.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Prompt for parameters</td>
<td>if ticked, prompt for parameter values when running a chain</td>
<td>checkbox</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Always record parameters</td>
<td>if ticked, create parameters when recording</td>
<td>checkbox</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Run chain in interactive mode</td>
<td>if ticked, will run the chain in interactive mode</td>
<td>checkbox</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Warning prompt</td>
<td>if ticked, validate each chain command</td>
<td>checkbox</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The icons across the middle are:

- **Insert a command**
- **Delete commands**
- **Copy commands**
- **Move commands up**
- **Move commands down**
- **Activate commands**
- **Deactivate commands**
- **Record options**
- **Paste commands**
- **Run the chain**
- **Activate commands**
- **Deactivate commands**

The **Read** button when pressed, read in the given chain file.

To **create** a new chain, a unique name is typed into the **Chain file** box and the **Write** button clicked.

To **edit** an existing chain, enter the name of the existing chain into the **Chain file** box and then click on the **Read** button.

The chain is then built up by inserting commands using the **Insert** icon.

Chains
Write button
when presses, write out all the chain commands in the list to the given chain file. After each item is added to the chain, click on Write to save the updated chain.

Parameter value file file box blank existing parameter files
if not blank, the file to use for mapping parameters and values in the Chain.
If blank, no parameter file is used
For more information, go to the section 28.3.4 Chain Parameters.

Prompt for parameters tick box
if ticked, when a with parameters chain is run, the table of parameters is displayed on the screen before running the chain so that any required modifications can be made before the chain is run.
If not ticked, any values for parameters are taken from the parameter value file.

Always record parameters tick box
If ticked and the user records panels or options, the recorder will attempt to record parameters.

Run chain in interactive mode tick box
if ticked, run the chain in Interactive Mode. See 28.3.2 Interactive Mode.
If not ticked, the chain runs normally.

Important Note and Warning
Run chain in interactive mode has no connection to the Run in interactive mode that is available when many panels are recorded in a chain. When a recorded panel in the chain has Run in interactive mode ticked on, then when that panel runs in the chain, the panel is displayed and the user can change values in the panel fields and then run/not run the panel. When the panel is closed the chain continues running.

Warning prompt tick box
if not ticked, validations of the inserted commands are not performed straight away. For example, if you press Insert many times, you won’t get the warning prompt “Some changes you have made are invalid. Do you wish to change nodes and discard your changes?”. Also a confirmation prompt does not come up when you delete commands from the chain.
if ticked, inserted commands are validated and warning messages and error messages will be generated.

Icons
Insert icon
inserts commands into the chain. For more information on the commands, go to 28.3.1.1 Inserting a Chain Command

Delete icon
deletes the highlighted commands in the chain

Copy icon
copies the highlighted commands in the chain so that they can be pasted back into this chain or another chain.

Paste icon
pastes the copied commands into this chain, or into another opened chain.

Move up icon
move the highlighted commands up one position in the chain

Move down icon
move the highlighted commands down one position in the chain
Activate icon
activate any of the highlighted commands that are deactivated

Deactivate icon
deactivate all of the highlighted commands

Record icon
record one or more options. For more information on Record, go to 28.3.1.2 Record Icon and the Recorder Toolbar

Button at Bottom

Run button
run the chain.

Continue to the next subsection 28.3.1.1 Inserting a Chain Command or the next section 28.3.3 Edit a Chain or return to 28.3 Chains.
28.3.1.1 Inserting a Chain Command

The chain is built up by *inserting commands* using the **Insert** icon.

Clicking on the **Insert** icon inserts a new command with the default name of **New** into the chain. The **Type** of the command is then selected on the right hand side of the panel. The specific information needed for defining that type of new command is then displayed on the right hand side of the panel.

![Image of Create/Edit Chain interface with instructions on inserting a chain command](image)

- Click on the **Insert** icon to create a new command with the default name of **New**.
- Click on the **Type** pop-up to see what **Chain** commands can be inserted.
- The information displayed on the right hand side is then modified to suit the selected command.
Selecting a command will update the right hand side of the panel with information for that particular command. For example, for the **Resolve SA** command:

After each Command is added to the chain, or a Command modified, click on **Write** to save the updated chain.
For all the available Chain Commands that can be Inserted, see 28.3.1.1 Chain Commands.

Continue to the next section 28.3.1.1 Chain Commands or return to 28.3 Chains.
28.3.1.1.1 Chain Commands

For the Chain commands under the group
- Execution, go to 28.3.1.1.2 Execution
- Elements 28.3.1.1.3 Elements
- Files 28.3.1.1.4 Files
- Views 28.3.1.1.5 Views
- Drainage 28.3.1.1.6 Drainage
- Other 28.3.1.1.7 Other
- Conditionals 28.3.1.1.8 Conditionals
28.3.1.1.1 Common Fields in Commands

The common fields used in the right hand side of the Create/Edit Chain panel for the Chain commands are:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use parameters</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>If ticked,</em> parameters can be used within the commands.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>Note that only some chain commands have a Use Parameters tick.</em></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command name</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>the name to give the command - this is what is displayed in the Chain list.</em></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>As information is filled in for a command, a default Command name composed of the command and some extra information from the command fields (for example the name of the super alignment) is created and written into the Command name field.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>The Command name does not have to be unique and can be changed at any time.</em></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Clicking on the abc icon on the end of the Command name field will regenerate the automatic Command name and write it in the Command name field.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>When you rerecord a command, the Command name is not modified but left as it was before rerecording.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Active</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>If ticked,</em> the command is run when the chain is run.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>If not ticked,</em> the command is not run when the chain is run.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Continue on failure</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>If ticked</em> and there is an error when running the command, processing continues to the next command in the Chain.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>If not ticked</em> and there is an error when running the command then the Chain terminates.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Comments</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>any information typed into this box is kept as a Comment for current Chain command being displayed.</em></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a comment on the command in the chain. The comment can be many lines. And contain blank lines.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Execute</th>
<th>button</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>run the current chain command. This button is not on all commands.</em></td>
<td></td>
</tr>
</tbody>
</table>

When a chain is running, messages and error messages are written to the **Output window**.

**Important Note** - each time a command is inserted or modified, the **Write** button must be clicked to write out the modified chain.
Return to 28.3.1.1 Chain Commands or 28.3 Chains.
28.3.1.1.2 Execution

For the description of the common fields on most Chain Command panels, see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Option
run a 12d Model option. Note that not all options can be run in a chain.
Option is also used to record the option that it runs.
For more information, go to 28.3.1.2.1 Execution >Option.

Option - Manual
run a 12d Model option in Manual Mode. Note that not all options can be run in a chain.
Option - Manual is also used to record the option that it runs.
For more information, go to 28.3.1.2.2 Execution >Option - Manual.

Screen layout file
run an existing screen layout file. Note - not all slf’s can be run.
For more information, go to 28.3.1.2.3 Execution >Screen Layout File.

Function
recalc a 12d function
For more information, go to 28.3.1.2.4 Execution >Function.

Delete function
delete a function.
It will optionally clean all the strings created by the function.

Delete all functions
delete all functions
It will optionally clean all the strings created by all the functions.

Chain
run an existing chain.

Macro
run a 12d Model macro that doesn’t have a panel
For more information, go to 28.3.1.2.5 Execution >Macro.

Plot
run a plot parameter file.
For more information, go to 28.3.1.2.6 Execution >Plot.

Shell command
run an external program, Microsoft command line etc.
For more information, go to 28.3.1.2.7 Execution >Shell Command.

Continue to the next section 28.3.1.1.3 Elements or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.3 Elements

For the description of the common fields on most Chain Command panels, see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Resolve SA
resolve a selected super alignment.
Clicking on the Resolve command highlights the selected super alignment.

Delete string
delete a selected string

Clean model
clean the given model

Create model
creates a new model of the specified name

Delete tin
delete the given tin

Delete model
delete the given model

Delete all tins
delete all tins in the project

Delete all models
delete all models in the project

Delete all templates
delete all templates in the project

Delete all empty models
delete all empty models in the project

Continue to the next section 28.3.1.1.4 Files or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.1.4 Files

For the description of the common fields on most Chain Command panels see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Copy file

copy the given file to a user given file name (which included the full path name).

![Copy file dialog](image)

The file being copied will overwrite an existing file.

Delete file

deletes the specified file

Compare

compare two text files and write the results out to a Report file.

If the Report file already exists, the Write mode determines if it is overwritten or appended to.

![Compare dialog](image)

Continue to the next section 28.3.1.1.5 Views or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.5 Views

For the description of the common fields on most Chain Command panels see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Redraw all views
  redraws all views.

Redraw a view
  redraws a given view.

Fit view
  do a fit on a given view.

Minimise view
  minimise a given view.

Maximise view
  maximise a given view.

Restore a view
  restore a minimised view.

Create view
  creates a new view of the given name and optionally position in the View Area.
  For more information, go to 28.3.1.1.2.8 Views >Create view.

Delete view
  delete a view of a given name.

Add model to view
  adds the given model to a given view.

Remove model from view
  remove a given model from a given view.

Remove all from view
  removes all the models from a given view.

Dump view image
  dump an image of a given view.
  For more information, go to 28.3.1.1.2.9 Views >Dump view image.

Change view colour
  change the background colour of a given view.

Continue to the next section 28.3.1.1.6 Drainage or return to 28.3.1.1 Chain Commands or 28.3.1 Inserting a Chain Command.
28.3.1.1.6 Drainage

For the description of the common fields on most Chain Command panels see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Drainage analysis

runs drainage analysis on a given model

Drainage analysis- dynamic

runs dynamic drainage analysis on a given model

Set pit details

sets the pit details for a given model

Regrade pipes

regrades the pipes in a given model

Continue to the next section 28.3.1.1.7 Other or return to 28.3.1.1 Chain Commands or 28.3.1 Inserting a Chain Command.
28.3.1.1.1.7 Other

For the description of the common fields on most Chain Command panels see 28.3.1.1.1 Common Fields in Commands. These include the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute.

Comment

creates a cosmetic comment - no action is performed.

Halt

stop running the chain

Prompt

places a Prompt and returns a value to a chain parameter.

For more information, go to 28.3.1.2.10 Other >Prompt.

Sleep

puts the chain asleep for a given number of seconds.

Write output window

writes a one line message to the Output Window.

Clear output window

clears the Output Window.

Dump slx image

writes out the image of the panel than an SLX creates.

For more information, go to 28.3.1.2.11 Other >Dump slx image.

Print parameter

prints out information about a chain parameter to the Output Window.

For more information, go to 28.3.1.2.12 Other >Print parameter.

Save project

save the current project to disk.

Continue to the next section 28.3.1.1.8 Conditionals or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.1.8 Conditionals

How the Conditionals work is described in 28.3.1.1.9 Chain Flow Control and Conditional Commands.

Label

create a labelled line in the chain. See 28.3.1.1.9 Chain Flow Control and Conditional Commands.

Goto

jump to a labelled line. See 28.3.1.1.9 Chain Flow Control and Conditional Commands.

If Model Is Empty

test if a model of a given name is empty.

If Model Exists

test if a model of a given name exists

If Tin Exists

test if a tin of a given name exists

If Function Exists

test if a function of a given name exists

If File Exists

test if a file of a given name exists

If View Exists

test if a view of a given name exists

If Parameter Equals

test if a given parameter has a certain value

For more information, go to 28.3.1.1.2.13 Conditionals >If Parameter Equals.

Return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.9 Chain Flow Control and Conditional Commands

The commands in a Chain are normally processed in the order that they are listed in the Chain. However this order can be changed by using the Goto and Label commands, and the commands given in the Conditionals group (see 28.3.1.1.8 Conditionals).

**Label**

The Label command has a user given name and acts as a reference line in a chain. Goto’s and Conditionals can change the processing order of the Chain so that the next command processed is the one after the Label and processing continues on from there.

The name of a Label must be unique within the Chain.

When run the Label command doesn’t do anything and processing moves onto the command after the Label command.

**Goto**

The Goto command changes the processing order of the Chain so that next command processed is the one after the given Label.

**Conditionals**

A Conditional consists of a test and the two nodes On pass and On fail.

Each Conditional commands performs a specific test and

(a) if the test is passed then the action on the On pass line is performed
(b) if the tests fails then the action on the On fail line is performed
The choices for both the **On pass** and **On fail** are the same and are:

- **Continue** - run the next command in the Chain
- **Goto Label** - the next command to run is the one after the given Label.

**Run chain** - run the given Chain. The next command in the Chain is then run.

**Halt** - stop running the chain.

Return to [28.3.1.1 Chain Commands](#) or [28.3.1 Inserting a Chain Command](#).
28.3.1.1.2 Additional Information on Some Chain Commands

See

28.3.1.1.2.1 Execution >Option
28.3.1.1.2.2 Execution >Option - Manual
28.3.1.1.2.3 Execution >Screen Layout File
28.3.1.1.2.4 Execution >Function
28.3.1.1.2.5 Execution >Macro
28.3.1.1.2.6 Execution >Plot
28.3.1.1.2.7 Execution >Shell Command
28.3.1.1.2.8 Views >Create view
28.3.1.1.2.9 Views >Dump view image
28.3.1.1.2.10 Other >Prompt
28.3.1.1.2.11 Other >Dump sli image
28.3.1.1.2.13 Conditionals >If Parameter Equals
28.3.1.2.1 Execution >Option

The Option command records any 12d Model panel or 12d PL’s (macros) that can be recorded.

After this command is selected, the Record button must then be pressed to start a "one option" record cycle. The option to be recorded is then started up and run so that it is recorded.

The fields and buttons have the following functions.

Field Description  Type  Defaults  Pop-Up

Type  
chain command box
the chain command - this command is Option

Run in interactive mode  tick box
if ticked, when the command runs, the panel will be displayed.
At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.
Note that it is the responsibility of the user to only make sensible changes.
If not ticked, the command will run without being displayed and allowing for changes to be made.

Important Note and Warning
The Run in interactive mode for a panel has no connection to the Run chain in interactive mode for the Chain.

For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Buttons at bottom
See Record button
Preview button
Execute button
Record button

Clicking on the Record button starts a “one option” record cycle.

The Recorder toolbar is placed on the screen but no button has to be pressed because the Record is already running. However the buttons Stop and Cancel can be pressed to terminate the recording.

Now run the 12d Model panel option or macro that you wish to record.

Once the option has run, the Recorder panel is automatically removed, and the recorded option’s details recorded in the Option command and the Command name of the Option is set to the name of the option that was run.

The Create/Edit Chain panel is then opened and displayed the Option command that was just recorded.

Click on the Write button at the bottom of the Create/Edit Chain panel to save the modified chain.

Important Notes on Recording
1. CAD commands can not be recorded.
2. Many Macros can not be recorded. But if Option won’t work, then Option - Manual may. See 28.3.1.2.2 Execution >Option - Manual.
3. Not all 12d panels can be recorded. For example, if a screen layout file can not be created for an option, then it can’t be recorded. When recording, the 12d Model panel option must be filled in and run. This may restrict what options can be recorded. But if Option won’t work, Option - Manual may. See 28.3.1.2.2 Execution >Option - Manual. If you still find a panel won’t record, please leave a note about that panel on the 12d Model Forum.
Preview button

The Preview button brings up the panel with all the information filled in for those panel fields that can be validated. So sometimes Preview can not display all the command information.

Preview is for display only and on its own can’t be used to modify the details of the command.

However, if it is a recorded option and there is a Record button on the command, it can be done in conjunction with the Record button.

So to change the values in a recorded option, select Preview to bring up the recorded option with all the information filled in.

Then hit the Record button on the Option command, make the required changes to the displayed option, and run the panel again.

This will record the new information in place of the existing information.

Click on the Write button at the bottom of the Create/Edit Chain panel to save the modified chain.

Execute button

run the current chain command.

Option Parameters

To define or modify parameters used in an option, click on the + beside the option name in the chain (or double click on the option name) and the Parameters node for the option will be displayed.

For more details on option parameters, go to 28.3.4.3 How to Create Chain Parameters.

Special Notes on Recording Options

1. Use Unique String Names for String Selects

String selects on panels record the ID and the name of the string, and the model ID and the name of the model containing the string.

When the option is run in the chain, the string is first searched for using the model and string id’s but if that fails then a string of the recorded name is searched for in the recorded model name.

If the string name is unique in the model then the correct string will be selected. If there is more than one string with the same name in the model, then the first string of that name that is found will be used.

2. Polygon Selects

String selects can be recorded for a Polygon box but Rectangle, Parallelogram or Lasso can not be recorded.

Continue to the next section 28.3.1.2.2 Execution >Option - Manual or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.2.2 Execution >Option - Manual

The Option - Manual command records an option but with additional information that is used when the command is run in the chain. For example, recording that certain buttons are to be pressed in a certain order.

This is useful for more complex panels, or panels that require multiple button presses. It is also useful for recording macros.

Unlike the Option command, the panel must already be on the screen with the appropriate fields filled in before it can be recorded.

The Option - Manual command records an option in two parts:

1. The panel to use (the data)
2. The buttons to press and the order they should be pressed

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

the chain command - this command is Option - Manual

Buttons to press

grid

displays the list of buttons in the panel that are to be pressed and in the order that they are to be pressed. The buttons are added to the list by using the Capture button button.
For information about grids, see 4.19.6 Grids in Panels.

Automatically close panel  tick box

if **ticked**, when the panel is run in the chain, the panel is automatically closed after all the captured buttons are pressed.

if **not ticked**, the panel is not automatically closed. If a Finish button has not been captured and hence not pressed when the panel is run in the chain, the panel will remain on the screen (open) after the command is finished.

Run in interactive mode  tick box

if **ticked**, when the command runs, the panel will be displayed.

At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

If **not ticked**, the command will run without being displayed and allowing for changes to be made.

**Important Note and Warning**

The Run in interactive mode for a panel has no connection to the Run chain in interactive mode for the Chain.

For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Capture data  button

after pressing Capture data, the cursor is moved over the panel that is to be captured. The panel will be highlighted with a yellow border to indicate which panel will be selected.

Clicking LB will select the highlighted panel and the panel and all the panel field values will be recorded.

Unlike the Option command, the panel must already be on the screen with the appropriate fields filled in before pressing Capture data.

Also unlike the Option command the panel is not run.

Instead after the panel has been selected, the panel buttons that need to be pressed for running the panel are recorded in the order that they need to be pressed.

Capture buttons  button

after pressing Capture buttons, the cursor is moved over the panel buttons on the selected panel, and the panel button will be highlighted with a yellow border to indicate which button will be selected.

Clicking LB will select the highlighted button and the name of the button will be added to the bottom of the Buttons to press grid.

To select another panel button, click on Capture buttons again.

Continue to the next section 28.3.1.2.3 Execution >Screen Layout File or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
### 28.3.1.2.3 Execution > Screen Layout File

The Screen layout file command displays the first panel stored in an SLF file and runs it by pressing the panels designated 'run button'.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td>the chain command - this command is Screen layout file.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SLF</td>
<td>file</td>
<td>the slf file to run the first panel from.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Run in interactive mode**  
- tick box
  - *if ticked*, when the command runs, the panel will be displayed.
  - *At this point all the data in the panel field may be changed. Once the panel is closed, the chain will continue.*
  - *Note that it is the responsibility of the user to only make sensible changes.*
  - *If not ticked*, the command will run without being displayed and allowing for changes to be made.

**Important Note and Warning**

*The Run in interactive mode for a panel has no connection to the Run chain in interactive mode for the Chain.*

For the description of the fields **Use Parameters, Command name, Active, Continue on failure and Comments**, and the button **Execute** see [28.3.1.1.1 Common Fields in Commands](#).

Continue to the next section [28.3.1.2.4 Execution >Function](#) or return to [28.3.1.1 Chain Commands](#) or [28.3.1.1 Inserting a Chain Command](#).
28.3.1.1.2.4 Execution >Function

The Function command recalcs an existing function.

If Use parameters is not ticked, the Function field is displayed. This requires the selection of an existing function to recalc.

If Use parameters is ticked, the Function parameter field is displayed. This requires the selection of a function parameter. See 28.3.4 Chain Parameters for more details.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Function</td>
<td>the chain command - this command is Function.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command name</td>
<td>function box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Active</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Continue on failure</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Run in interactive mode</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Comments</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

At this point all the data in the panel fields may be changed. Once the panel is closed, the chain will continue.
Note that it is the responsibility of the user to only make sensible changes.

If not ticked, the command will run without being displayed and allowing for changes to be made.

**Important Note and Warning**

The Run in interactive mode for a panel has no connection to the Run chain in interactive mode for the Chain.

**Preview** button

The **Preview** button brings up the panel with all the information filled in for those panel fields in the function that can be validated. So sometimes **Preview** can not display all the command information.

**Preview** is for display only and on its own can’t be used to modify the details of the command.

For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** and **Comments**, and the buttons **Execute** see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.5 Execution >Macro or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.2.5 Execution >Macro

The Macro command runs a macro with a set of optional arguments.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Macro</strong></td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Command name</strong></td>
<td>New</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Continue on failure</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Run in interactive mode</strong></td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Comments</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The chain command - this command is *Macro*.

The macro to run.

An optional set of arguments to pass to the macro.

*Note* that Chain Parameters can be passed as argument to the Macro. See [28.3.5.5 Chain Parameters as Macro (12dPL's) Arguments](#).

**Run in interactive mode**

Tick box

If ticked, if it is a panel macro (i.e. brings up a panel), the macro will be run in Interactive mode and the panel will be displayed. If it is not a panel macro, the macro will run as normal.

At this point all the data in the panel fields may be changed. Once the panel is closed, the chain will continue.

Note that it is the responsibility of the user to only make sensible changes.

If not ticked, the command will run without being displayed and allowing for changes to be made.

**Important Note and Warning**

The Run in interactive mode for a panel has no connection to the Run chain in interactive mode for the Chain.
For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.2.6 Execution >Plot or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.2.6 Execution >Plot

The Plot command plots a given pff file.

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><em>the chain command - this command is Plot</em></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Plot type</strong></td>
<td>Plot type box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>PPF file</strong></td>
<td>PPF file box</td>
<td>available PPF's for the Plot type</td>
<td></td>
</tr>
<tr>
<td><strong>Command name</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Continue on failure</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Comments</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Click on **Plot type** choice box and select the required plot type.

Then type or select the **PPF file** of that type to plot.

Continue to the next section 28.3.1.2.7 Execution >Shell Command or return to 28.3.1.1 Chain Commands or 28.3.1 Inserting a Chain Command.
### 28.3.1.2.7 Execution >Shell Command

The Shell command commands run an external program, Microsoft command line etc.

![Shell Command Setup](image)

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>The chain command box</td>
<td>chain command box</td>
<td>Shell command</td>
<td></td>
</tr>
<tr>
<td><strong>Executable</strong></td>
<td>Name of the file to execute.</td>
<td>file browse box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| **Arguments**  | If not blank, the text is passed as arguments to theExecutable. Also the value of a Chain parameter can be used as an argument passed to the Executable program. The parameter name is enclosed in square brackets ([ and ]) and then surrounded by double quotes ("), 

"[parameter_name]" and this is entered in the Arguments field in the place of the argument of the Executable that it replaces. |

For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.2.8 Views >Create view or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.1.2.8 Views >Create view

The Create view command creates view of a given name and type. It can also optionally give the Top Left and Bottom Right to position and size the view.

The fields and buttons have the following functions.

Field Description | Type | Defaults | Pop-Up
---|---|---|---
Type | chain command box |

*the chain command - this command is Create view*

View name | text box | name of the view to create. If the name already exists then it is an error.

View type | view types box | available view types | the type of view to create

Top/Left/Bottom/Right | integer box | if not blank, the value in pixels of the top left hand and bottom right corners of the of the created view.

The coordinate system has (0,0) at the Top Left of the 12d Model View area, and the X-axis going across the screen and the Y-axis going down the screen. The units are pixels.
For the description of the fields **Use Parameters**, **Command name**, **Active**, **Continue on failure** and **Comments**, and the button **Execute** see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.1.2.9 Views >Dump view image or return to 28.3.1.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.2.9 Views >Dump view image

The Dump view image command write out an image of the given view.

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td>Dump view image</td>
<td></td>
<td></td>
</tr>
<tr>
<td>View</td>

<td>available views</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Include title</td>
<td>tick box</td>
<td></td>
<td>if ticked, the title of the view and the icons on the view are included in the image.</td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>choice box</td>
<td></td>
<td>If not ticked, the title of the view and the icons on the view are not included in the image.</td>
<td></td>
</tr>
<tr>
<td>Image file</td>
<td>file box</td>
<td>check_progress_2.jpg</td>
<td>the image is written out to this file.</td>
<td></td>
</tr>
</tbody>
</table>
For the description of the fields **Use Parameters, Command name, Active, Continue on failure and Comments**, and the button **Execute** see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.2.10 Other >Prompt or return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.2.10 Other >Prompt

The **Prompt** command is used to display a user defined Prompt or panel, with user defined text, optional widgets and buttons.

Each button assigns a value to a given parameter, which may be used later in the chain to provide flow control or change data.

All Prompts come up in the same place.

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Prompt title</strong></td>
<td>text box</td>
<td></td>
<td></td>

<tr>
<td><strong>Comments</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

![Prompt Command Interface](image)
the title to display at the top of the Prompt

**Prompt message**  
the message to display

**Parameter for result**  
the parameter to store the result of the Prompt in

**Widgets to display - grid**
An optional list of widgets to display on the panel to capture more information. The widget must be stored in an existing parameter, defined in the chain's PVF file. The type of parameter will determine the type of widget displayed.

For information about grids, see [4.19.6 Grids in Panels](#).

**Name**  
the name of the widget

**Parameter**  
list of parameters for the chain

the parameter that the widget is created for and will set once the prompt is closed. The parameter must be one of the parameters for the chain.

**Mode**

**Optional?**
tick box

if yes, the widget will be optional and the user will not need to fill it in when the prompt is displayed.

if no or blank, the widget will not be optional and the user will be required to fill in the widget.

For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see [28.3.1.1.1 Common Fields in Commands](#).

**Buttons to display - grid**
a set of buttons to display on the Prompt panel, each with a name and a return value.

For information about grids, see [4.19.6 Grids in Panels](#).

**Name**
the name of the button

**Value**

if the button is pressed, the value to assign to the parameter Parameter for result.

Continue to the next section [28.3.1.1.2.11 Other >Dump slx image](#) or return to [28.3.1.1 Chain Commands](#) or [28.3.1.1 Inserting a Chain Command](#).
28.3.1.2.11 Other >Dump slx image

The Dump slx image command write out an image of the panel that the SLX creates.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box - the chain command is Dump slx image</td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SLX File</td>
<td>file box - name of the slx file to read in and display the panel it describes, and then write out an image for.</td>
<td>file box</td>
<td>available *.slx commands</td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>choice box - image format to use</td>
<td>choice box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Image file</td>
<td>file box - the image is written out to this file.</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command name</td>
<td>Dump file ADAC_Reader_slx</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The fields and buttons have the following functions.

For the description of the fields Use Parameters, Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Continue to the next section 28.3.1.2.12 Other >Print parameter or return to 28.3.1.1 Chain Commands or 28.3.1 Inserting a Chain Command.
28.3.1.1.2.12 Other >Print parameter

The **Print parameter** command writes out information about a chain parameter to the Output Window.

It prints out in the format

\[
\text{parameter_name [type:parameter_type]} = \text{parameter_value}
\]

(a) the name of the parameter  
(b) the type of the type  
(c) the value of the parameters where the **Print parameter** command is processed in the Chain

As an example, for a parameter **design_map_file**, this would print to the **Output Window**:

---

**Starting chain**: ADAC_design_base.chain  
**Executing print parameter command**: New  
**design_map_file [type: Text]** = $USER_LIB\ADAC_GCCC_Map_Design_to_ADAC_40.mapfile  
**Executing Comment command**: Clean out the models used in processing  
**Executing Clean model command**: Clean design mapped data

---

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>chain command box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

<tr>
<td><strong>Command name</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Continue on failure</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Comments</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

The chain command - this command is **Print parameter**

For the description of the fields **Command name**, **Active**, **Continue on failure** and **Comments**, and the button **Execute** see [28.3.1.1.1 Common Fields in Commands](#).

Continue to the next section [28.3.1.2.13 Conditionals >If Parameter Equals](#) or return to [28.3.1.1 Chain Commands](#) or [28.3.1.1 Inserting a Chain Command](#).
28.3.1.2.13 Conditionals >If Parameter Equals

The If Parameter equals command tests if a Chain Parameter has a certain value.

The fields and buttons have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>chain command box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The chain command - this command is If Parameter Equals</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter name</td>
<td>parameter box</td>
<td>parameters in this chain</td>
<td></td>
</tr>
<tr>
<td>The name of a parameter from the Parameter value file that is to be tested for having a user given value. The pop-up lists all the parameters in the Parameter value file for the Chain.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The action of the On Pass and On fail nodes are described in 28.3.1.1.9 Chain Flow Control and Conditional Commands.

For the description of the fields Command name, Active, Continue on failure and Comments, and the button Execute see 28.3.1.1.1 Common Fields in Commands.

Return to 28.3.1.1 Chain Commands or 28.3.1.1 Inserting a Chain Command.
28.3.1.2 Record Icon and the Recorder Toolbar

Clicking on the Record icon removes the Create/Edit Chain panel and brings up the Recorder toolbar with icons to Pause, Stop and Cancel the recording.

The Recording process is already underway and you simply run the 12d Model panels and recordable macros that you wish to record and then press the Stop icon.

Pressing Pause causes the recording process is interrupted and the Pause icon on the Recorder toolbar changes to Record. Other options can be run and recording only resumes when Record is pressed on the Recorder toolbar.

For each recorded panel or macro, an Option command is added to the list of commands in the chain and its Command name is the name of the recorded panel or macro.

When Stop is pressed, the Recorder toolbar is removed and the Create/Edit Chain panel for the chain is opened on the screen with the new Option commands added to the command list.

Click on the Write button at the bottom of the Create/Edit Chain panel to then update the chain.

Note that in Create/Edit Chain panel the Command name can be modified by clicking on the command in command list in the Create/Edit Chain panel and then changing its Command name.
field. Click on the **Write** button at the bottom of the **Create/Edit Chain** panel to update the chain.

For more information on recording panel and the buttons **Record**, **Preview** and **Execute**, go to 28.3.1.2.1 **Execution >Option**.
28.3.2 Interactive Mode

Chains support an **Interactive Mode**, meaning that the user is allowed to influence the flow of commands or the data input into the chain.

There are two types of Interactive Mode: **Chain Interactive Mode** and **Command Interactive Mode**:

(a) **Chain Interactive Mode:**

This is toggled via the Run chain in interactive mode tick box on the **Chain Edit/Create panel**. See 28.3.1 Create/Edit a Chain

Then when the chain is run, the **Interactive toolbar** is displayed and the chain will pause for user input. See 28.3.2.1 Interactive Toolbar and Chain Interactive Mode for more details.

(b) **Command Interactive Mode:**

Several commands now support and interactive mode which means that instead of running without the user seeing the command, a command with interactive mode ticked on will pause the chain, display the panel, and allows the user to change panel values and be run or not run. This applies in the case of panels, functions and macros.

So in these cases, any panels associated with them, and the data they were recorded with, will be displayed and the panel will wait for user input before continuing. See 28.3.2.2 Commands Interactive Mode.

**Important Note**

The **Chain Interactive Mode** and the **Command Interactive Mode** are totally separate and not related in any way. However when running a **Chain in Interactive Mode**, for each command that supports **Command Interactive Mode**, the user can run the command as is, or force it to run in **Command Interactive Mode**.
28.3.2.1 Interactive Toolbar and Chain Interactive Mode

When running a Chain in Interactive Mode, the Interactive toolbar is placed on the screen and the chain pauses and waits for the user to say run the command. The user can even choose a different command to run, and continue running from that command on.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choice box</td>
<td>choice box</td>
<td>all commands in the Chain</td>
<td></td>
</tr>
</tbody>
</table>

- **Choice box**: choose the command from the Chain that is placed in the Interactive toolbar ready to be run next.

- **Play button**: plays the command displayed in the Interactive toolbar.

- **Play + i button**: plays the command displayed in the Interactive toolbar in the Command Interactive Mode regardless of the commands own Run in interactive mode field. See 28.3.2.2 Commands Interactive Mode.

  *This button is only available when the command can be run in Command Interactive Mode. For example a Comment command can not be run in Command Interactive Mode.*

- **Stop button**: stops running the Chain but the Create/Edit Chain panel for the Chain is left on the screen.

- **Fast forward button**: runs the chain to the end. The Create/Edit Chain panel for the Chain is left on the screen.
Bring up the Chain Parameters Editor panel with the Parameter value file for the Chain loaded into it.

Help button

Display the context sensitive help.

28.3.2.2 Commands Interactive Mode

Running a command in Command Interactive Mode will do one of several things, depending on the type of the command:

1. If it is a recorded Option, the panel will be presented to the user and the user can change values in the panel fields.
   The user either runs the panel or doesn’t run the panel, and then selects the Finish button or closes the panel with the X icon.
   If the chain is being run from the Interactive toolbar, the Chain then moves on and displays the next command in the Chain in the Interactive toolbar.
   If the chain is not being run from the Interactive toolbar, the Chain then moves on and runs the next command in the Chain.

2. If it is a Function command, the chain will attempt to open the function editor.
   The user either runs the function or doesn’t run the function, and then selects the Finish button or closes the panel with the X icon.
   If the chain is being run from the Interactive toolbar, the Chain then moves on and displays the next command in the Chain in the Interactive toolbar.
   If the chain is not being run from the Interactive toolbar, the Chain then moves on and runs the next command in the Chain.
28.3.3 Edit a Chain

**Position of option on menu:** Utilities => Chains => Edit

**Position of option on menu:** Utilities => Recalc => Edit chain

Editing an existing chain on either menu can be done two ways.

The **Edit** walk-right menu displays all the chains in the project and double clicking on a chain in the list will bring up the Create/Edit Chain panel (see 28.3.1 Create/Edit a Chain for more information).

Another way of editing a chain is by using the **Recalc Chain** panel (yes the **Recalc Chain** panel) that comes up by:

(a) If the **Chain** menu is being displayed by walking right on Utilities => Chains => Edit on the top Main Menu then the Edit menu will be displaying with [Edit] written on the top. Clicking on [Edit] will bring up the **Recalc Chain** panel

(b) If the **Chain** or **Recalc** menu has been torn from the Main Menu on the top then the **Recalc Chain** panel comes up if you click on Utilities => Chains => Edit without walking right or Utilities => Recalc => Edit chain without walking right.

The **Recalc Chain** panel can run an existing chain, edit an existing Chain or create a new chain. For information on the **Recalc Chain** panel see 28.3.9 Run a Chain.

Continue to the next section 28.3.4 Chain Parameters or return to 28.3 Chains.
28.3.4 Chain Parameters

The basic usage of chains is to record and playback a set of panels and other chain commands. The user can have interactive with the command running in the chain by running the Chain in Interactive Mode (see 28.3.2 Interactive Mode) and/or running selected commands in Command Interactive Model (see 28.3.2.2 Commands Interactive Mode).

However even though these options allow you to change values in some panels as the chain runs, this has to be done again every time the chain is run.

To allow for more power and in the way values in the panels fields are changed, Chain Parameters were introduced.

Chain Parameters can be used in place of actual values in the panels and the parameters can be given different values each time the chain is run.

For example, you may have a chain that triangulates a data set and creates and labels contours for the created tin. And to make the chain more flexible, you want to give the name of the created tin and contour models each time the chain is run but don’t want to do it by hand.

Or you may want to just give the name of the tin and have the names of the contour models derived from the given tin name.

Chain Parameters are used to give the chain this added flexibility.

When Chain Parameters are created, the actual values for the parameters used are stored in a separate parameter value file (*.pvf) and so the values of all the parameters can be changed by running the chain with a different parameter value file.

The Chain Parameters and their values can be defined when the panel is created using the Option command, or done separately within the chain itself. Or a combination of both.

To create parameters straight away, have the Always record parameters field ticked on before starting to record an Option.

After the option is finished and the recording stops, the Record Option Parameters panel is displayed and is used to select the fields you wish to parameterise. See 28.3.4.2 Record Option Parameters Panel.

For information on how to create parameters separately to the recording process, or how to modify existing parameters, see 28.3.4.1 Creating and Modifying Parameters Outside the Recording Process.
28.3.4.1 Creating and Modifying Parameters Outside the Recording Process

For a command in the Create/Edit Chain panel, to create parameters separately to the recording process, or to modify existing parameters, click on the + to the left of the command in the command list and then on the Parameter line. The Parameters are then displayed on the right hand side of the panel.

The fields and buttons used in this panel have the following functions.
### Field Description

<table>
<thead>
<tr>
<th><strong>Parameter grid</strong></th>
<th><strong>Type</strong></th>
<th><strong>Defaults</strong></th>
<th><strong>Pop-Up</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>the parameter grid holds information about each defined parameter in the chain.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Field name</strong></td>
<td>display only</td>
<td></td>
<td></td>
</tr>
<tr>
<td>the name of the panel field to be parameterised. This is written to when a field is selected by the <strong>Pick parameters</strong> buttons. This is read only.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>the name the user gives the parameter. This can also be modified.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Note that the parameter name can only be alphanumeric and underscores. No spaces are allowed in the name</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>if <strong>ticked</strong>, this row is used.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>If <strong>not ticked</strong>, the row is not used and acts like a comment.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Buttons at Bottom

**Pick parameters**

this is used to define more parameters for the option by picking a field from the recorded panel to use as a parameter.

To create a new parameter for the command, click on the **Pick parameters** button. This will bring up the **Record Options Parameter** panel which is used to pick new parameters.

For a description of the **Record Options Parameter** panel and information on how to use it to pick parameters, see 28.3.4.2 **Record Option Parameters Panel**.

Highlighted rows in the grid can be deleted using the **X** icon.

New rows are created using the **Pick parameters** button.

If a **Parameter** is not to be used at this time, **untick** the **Active** column.

Parameters within options are defined as **Parameter Mappings**.

A parameter mapping maps from a specific field to a named parameter. When an option command runs and fills out a particular field, it will look for the appropriate parameter mapping to that field to use as the value for the field.

To create parameters without recording, or modify them, click on the Parameters under the expanded Option command in the chain editor. All the mappings from parameters to the fields they represent will be listed here.
28.3.4.2 Record Option Parameters Panel

The Record Option Parameters panel is displayed:

(a) as soon as a recording is finished if the Always record parameters field ticked on in the Create/Edit Chain panel.

or

(b) by clicking on the Pick parameters button when the Parameters line is clicked on for a command in the Create/Edit Chain panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter value file</td>
<td>parameter value file box</td>
<td>available *.pvf files</td>
<td></td>
</tr>
<tr>
<td>Parameter stem</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The fields and buttons for this panel will now be described but how you use the panel to select parameters is given in the section 28.3.4.3 How to Create Chain Parameters

The fields and buttons used in this panel have the following functions.

Parameter value file

the name of the field on the panel that is being parameterised.

Parameter stem

pretext and postext written in the form pre_text*post_text and it is used on the value that is going to be written in the Parameter column in the grid when it is created by the Generate button.
Note that if there are any spaces in the pre_text*post_text, then each space will be replaced by an underscore in the parameter name.

**Parameter grid name**
the parameter grid holds information about each defined parameter in the chain.

**Field name** display only
the name of the panel field to be parameterised. This is written to when a field is selected by either the **Pick** or **Pick all** buttons. This is read only.

**Field type** display only
the type of the parameterised field. This is written to when a field is selected by either the **Pick** or **Pick all** buttons. This is read only.

**Current value** display only
the value that the panel field had at the time of recording. This is read only.

**Parameter** text box
the name of the parameter. If **Generate** is pressed, then this is automatically created from the **Parameter stem** and the name of the Field in the panel.

Note that the parameter name can only be alphanumeric and underscores. Not spaces are allowed in the name.

**Save in PVF** tick box
if **ticked**, this row is saved in the **parameter value file**.
If **not ticked**, the row is not saved in the **parameter value file**.

However in both cases the information is saved with the chain.

**Buttons at Bottom**

**Pick**
pick a field from the recorded panel to use as a parameter

**Pick all**
automatically pick all fields to be used as parameters

**Generate**
generate names for the parameters, using the optional parameter stem

**Set and finish**
save the recorded parameters and finish the panel.

For information on how to use this panel to select parameters is given in the section 28.3.4.3, **How to Create Chain Parameters**.
28.3.4.3 How to Create Chain Parameters

The Record Option Parameters is used to create Chain Parameters and this section describes that process in detail.

Note - information on each field and button in the panel is given in the section 28.3.4.2 Record Option Parameters Panel.

The Pick or the Pick All buttons can then be used to select the fields that are to be parameterised.

After Pick is pressed, as you move over the panel that was just recorded, the fields of the panel that the cursor is over is highlighted with a yellow rectangle.
Clicking when a particular field is highlighted writes the name, type and current value of the field to the next blank line in the grid of the Record Option Parameters panel.

The name that you want to call the parameter is then typed into the Parameter column and the Save in PVF column ticked or not ticked.

If another panel field is to be parameterised, then press the Pick button and repeat the process.

When all the fields to be parameterised have been selected, click on Set and finish.

The Record Option Parameters panel is then removed from the screen. Click on Finish to remove the panel that was recorded.

Click on the Write button on the top right hand side of the Create/Edit Chain panel to update the chain in the file, and also if there is one, update the Parameter value file.

Note that sometimes the name of the command is not updated until Write is pressed.

Another way to create the Parameter names is to click on Generate. The Parameter stem is then applied to the name of the field on the panel to create the Parameter name.
Note that a parameter name can not contain spaces so any spaces are replaced by underscores.

Finally if all panel fields are to be selected as parameters then press the Generate all button.
Also if you want to do most parameters but not all, it is often quicker to click on Generate all and then delete the few that you don’t want from the Record Option Parameters panel.

The parameters for a command can be seen by clicking on the + to the left of the command in the command list and then clicking on the Parameter line that is displayed. The Parameters are then displayed in the right hand side of the panel.

If the Parameter is not to be used at this time, untick the Active column.

Return to 28.3.4.2 Record Option Parameters Panel or 28.3.4.3 How to Create Chain Parameters.
28.3.5 Creating/Editing Parameter Value Files

**Position of option on menu:** Utilities => Chains => Parameters

These options Create, Edit and Copy Chain pvf files (parameter value files).

- **Create**
  - 28.3.5.1 Creating a Chain Parameters Value File
  - selecting Create opens the parameter editor
  - walk right on Edit, lists parameter files to edit
  - used to copy a Chain Parameter Value File from one file to another.

- **Edit**
  - 28.3.5.2 Editing a Chain Parameters Value File

- **Copy**
  - 28.3.5.3 Copy a PVF

Chains can also be used
28.3.5.1 Creating a Chain Parameters Value File

Position of option on menu: Utilities => Chains => Parameters => Create

Selecting Create brings up the Chain Parameters Editor panel which is used to both create and edit chain parameters.

For information about this panel, see 28.3.5.2 Editing a Chain Parameters Value File
28.3.5.2 Editing a Chain Parameters Value File

**Position of option on menu:** Utilities => Chains => Parameters => Edit

The **Edit** option is a walk-right which lists the existing parameter files. Clicking on a file in this list, brings it up in the Chain Parameters Editor panel with the selected pvf file already loaded into the panel.

Or if the Parameter menu is a floating menu, clicking on **Edit** without walking right will bring up the Chain Parameters Editor panel without a pvf file already loaded. This can then be used to create a new pvf file or selected and load an existing pvf file.
See:

Inserting a parameter  28.3.5.2.1 Inserting a Parameter
Searching  28.3.5.2.2 Searching for Parameter Values
28.3.5.2.1 Inserting a Parameter

Clicking on the **Insert** icon inserts a new parameter into the list of parameters under the current highlighted parameter. The new parameter is given the default **Type** Text and name **New**.

![Insert icon and parameter editor](image)

The correct type for the new parameter is then selected in the **Type** field and the information required for that type of parameter is then displayed in the right hand side of the panel.

The types of parameters available are:

- **Integer**
- **Real**
- **Text**
- **String**
- **Tin**
- **Model**
- **Function**
- **True/False**
- **Colour**
- **Grid**

The information on the right hand side will be updated when a different **Type** is selected.

See:

- **Integer** [28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters](#)
- **Real** [28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters](#)
- **Text** [28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters](#)

### 28.3.5.2.1.1 Integer, Real, Text, Function, True/False and Colour Parameters

The information needed for all these parameter types is virtually the same.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>choice box parameter types</td>
<td>the type of the parameter. In this case it will be Integer, Real, Text, Function, True/False or Colour.</td>
<td></td>
</tr>
</tbody>
</table>

The icon displayed on the left of the parameter name in the Parameter list under the Parameter node will match the Type.
Name  text box
the name of the parameter. This must be unique within the pvf file.
The name becomes the name displayed in the Parameter list under the Parameter node.
The name in this list may not change until the Write button is pressed.

Value  integer, real, text, function, tick box, colour
the value of the parameter. This must match the type of the parameter (integer, real, text, function, true/false tick box, colour).
For Type True/False, Value is a tick box and ticked means True and unticked means False.

Comment  comment box
user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.2 String Parameter or return to 28.3.5.2.1 Inserting a Parameter.
28.3.5.2.1.2 String Parameter

The information needed for the parameter of type String is given on the right hand side of the panel when String is selected for Type.

The fields and buttons used in the right hand side of the panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>choice box parameter types</td>
<td>choice box</td>
<td>parameter types</td>
<td></td>
</tr>
<tr>
<td>The type of the parameter. In this case it is String.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>text box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>the name of the parameter. This must be unique within the pvf file.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Lookup mode</td>
<td>choice box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>if Lookup by name and id, the string to use is searched for by string id first and if the string id does not exist, then by string name. If the search becomes by name and there is more than one string with the name then the first one found is selected. THIS NEEDS TO BE EXTENDED FOR name and model</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Comment</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
and model

if **Lookup by id only**, the string to use is searched for by id only. THIS NEEDS TO BE EXTENDED FOR name and model

**Value**

string select box

A string is selected by clicking on the string select icon on the right of the field and then selecting a string. The string name and id, and the model name and id that the string is in, are saved with the parameter.

**Comment**

comment box

User comments to be stored with the parameter.

Continue to the next section **28.3.5.2.1.3 Tin Parameter** or return to **28.3.5.2.1 Inserting a Parameter**.
28.3.5.2.1.3 Tin Parameter

The information needed for the parameter of type Tin is given on the right hand side of the panel when Tin is selected for Type.

The fields and buttons used in the right hand side of the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>choice box</td>
<td>parameter types</td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Lookup mode</strong></td>
<td>choice box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Type**: the type of the parameter. In this case it is Tin.
- **Name**: the name of the parameter. This must be unique within the .pvf file.
- **Lookup mode**: if Lookup by name and id, the tin to use is searched for by tin id first and if the tin id does not exist, then by tin name.
- if Lookup by name only, the tin to use is searched for by tin name only.
- if Lookup by id only, the tin to use is searched for by id only.
**Value**

tin box

the name of the tin. The tin name and id are saved with the parameter.

**Comment**

comment box

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.4 Model Parameter or return to 28.3.5.2.1 Inserting a Parameter.
28.3.5.2.1.4 Model Parameter

The information needed for the parameter of type `Model` is given on the right hand side of the panel when `Model` is selected for `Type`.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>choice box</td>
<td>parameter types</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Lookup mode</td>
<td>choice box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The fields and buttons used in the right hand side of the panel have the following functions.

- **Type**
  - The type of the parameter. In this case it is `Model`.
  - The `Model` icon displayed on the left of the parameter name in the Parameter list under the Parameter node.

- **Name**
  - The name of the parameter. This must be unique within the pvf file.
  - The name becomes the name displayed in the Parameter list under the Parameter node.
  - The name in this list may not change until the Write button is pressed.

- **Lookup mode**
  - If `Lookup by name and id`, the model to use is searched for by model id first and if the model id does not exist, then by model name.
  - If `Lookup by name only`, the model to use is searched for by model name only.
  - If `Lookup by id only`, the model to use is searched for by id only.
Value  

tin box  

the name of the model. The model name and id are saved with the parameter.

Comment  

comment box  

user comments to be stored with the parameter.

Continue to the next section 28.3.5.2.1.5 Grid Parameter or return to 28.3.5.2.1 Inserting a Parameter.
28.3.5.2.1.5 Grid Parameter

The information needed for the parameter of type Grid is given on the right hand side of the panel when Grid is selected for Type.

The fields and buttons used in the right hand side of the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>choice box</td>
<td>parameter types</td>
<td>Grid</td>
</tr>
<tr>
<td>Name</td>
<td>text box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CSV mode</td>
<td>choice box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Grid parameter file</td>
<td>file box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Modify mode</td>
<td></td>
<td>Clear All</td>
<td></td>
</tr>
<tr>
<td>Comment</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Grid icon is displayed on the left of the parameter name in the Parameter list under the Parameter node.

The name becomes the name displayed in the Parameter list under the Parameter node.

The name in this list may not change until the Write button is pressed.

If CSV file, a CSV (comma separated value) file, which defines the values to fill a grid.

The name of the CSV file.
Modify mode  choice box

if Clear All, all the existing values in the grid are deleted and are replaced by those in the CSV file.
If Append, any existing value in the grid in the panel that has the same name as one in the CSV file is replaced by the one in the CSV file. All values in the CSV file that do not already exist in the grid in the panel are added to the grid in the panel.

Comment  comment box
user comments to be stored with the parameter.

Return to 28.3.5.2.1 Inserting a Parameter.
28.3.5.2.2 Searching for Parameter Values

The Chain Parameters Editor panel has a search facility to find any parameter names that contain some user given text.

Text is entered into the search field and if the button for:

- **Backward** search is pressed then the parameter names are searched backwards from the current highlighted node until a name containing the text is found. The parameter node of the found name is highlighted so that information for it is displayed in the right hand side of the panel. The search stops when the beginning of the parameter nodes is reached.

- **Forward** search is pressed then the parameter names are searched forward from the current highlighted node until a name containing the text is found. The parameter node of the found name is highlighted so that information for it is displayed in the right hand side of the panel. The search stops when the end of the parameter nodes is reached.

Return to 28.3.5.2 Editing a Chain Parameters Value File.
28.3.5.3 Copy a PVF

Position of option on menu: Utilities => Chains => Parameters => Copy

Copy a PVF is used to copy a Chain Parameter Value File. Selecting Copy brings up the Copy a PVF panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source File</td>
<td>file box</td>
<td>available *.pvf files</td>
<td><em>original PVF file to copy</em></td>
</tr>
<tr>
<td>Target File</td>
<td>file box</td>
<td>available *.pvf files</td>
<td><em>name of the new copied PVF file</em></td>
</tr>
<tr>
<td>Copy</td>
<td>button</td>
<td></td>
<td><em>copies the PVF file</em></td>
</tr>
</tbody>
</table>

Continue to the next section 28.3.5.4 Running Chains from User Menus and Toolbars or return to 28.3.5 Creating/Editing Parameter Value Files.
28.3.5.4 Running Chains from User Menus and Toolbars

Chain can be run from a user menu or a user toolbar by using the **Command**:

Command: "chain chain_file_name"

where `chain_file_name` is the name of the chain.

For User Menus and Toolbars, it is also possible to substitute the name of the parameter value file (pvf) to use for the chain `chain_file_name` in place of the pvf mentioned in the chain `chain_file_name` itself.

The command is

Command: "chain -pvf pvf_file_name chain_file_name"

where `pvf_file_name` is the name of the pvf file to use when the chain `chain_file_name` is run from this User Menu or Toolbar.

**Note** that the

```
-pvf pvf_file_name
```

is still inside the double quotes (".").

Using the `-pvf` means that the one base chain can be easily used in user menus and toolbars but with different pvf files.

For example, the chain `ADAC_Survey_base.chain` occurs many times in the "ADAC Survey 4.0 Chains" menu but each time it is run with a different pvf file.

For more information on User Menus and User Toolbars, see 41.2 User Defined Menus and 41.3 User Defined Toolbars in the Appendix 41 Functions Keys, Menus, Toolbars.

Continue to the next section 28.3.5.5 Chain Parameters as Macro (12dPL's) Arguments or return to 28.3.5 Creating/Editing Parameter Value Files.
28.3.5.5 Chain Parameters as Macro (12dPL’s) Arguments

When the Chain Command

**Execution >Macro**

is used to run a 12dPL program (also known as 12PL's or **12d Model** macros), the **value** of a **Chain parameter** can be used as an argument passed to a 12dPL program.

This is done via the **Arguments** field in the Macros Command.

The Parameter Name is enclosed in square brackets ([ and ]) and then surrounded by double quotes ("")

"[parameter_name]"

and this is entered in the **Arguments** field in the place of the argument that it replaces.

For information on the chain command **Macro**, see 28.3.1.2.5 **Execution >Macro**.

Return to 28.3.5 Creating/Editing Parameter Value Files or 28.3 Chains.
28.3.6 Copy a Chain

Position of option on menu: Utilities => Chains => Copy

This option copies a chain.

Selecting Copy bring up the Copy a Chain panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source file</td>
<td>name of the chain to be copied.</td>
<td>file</td>
<td>available *.chain, *.rcn files</td>
<td></td>
</tr>
<tr>
<td>Target file</td>
<td>new name for the copied chain.</td>
<td>file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Copy</td>
<td>Copy the chain.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Continue to the next section 28.3.7 Chain Conversion or return to 28.3 Chains.
28.3.7 Chain Conversion

Position of option on menu: Utilities => Chains => Convert

This option converts a pre-v10 chain rcn file to the .chain format.

Selecting Convert brings up the Chain Conversion panel.

![Chain Conversion panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source file</td>
<td>file</td>
<td>available *.rcn files</td>
<td></td>
</tr>
<tr>
<td>Destination file</td>
<td>file</td>
<td>available *.chain files</td>
<td></td>
</tr>
<tr>
<td>Convert sub chains</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>if ticked, all sub chains will be converted.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>if not ticked, no sub chains will be converted.</td>
<td></td>
</tr>
<tr>
<td>Convert SLF files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>if ticked, all slf files included in the chain will be converted to the new SLX format.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>if not ticked, no slf files will be converted.</td>
<td></td>
</tr>
<tr>
<td>Convert</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>converts the source rcn file into the new .chain file format.</td>
<td></td>
</tr>
</tbody>
</table>

Continue to the next section 28.3.8 Rename a Chain or return to 28.3 Chains.
28.3.8 Rename a Chain

Position of option on menu: Utilities => Chains => Rename

This option renames an existing chain.

Selecting Rename brings up the Rename a Chain panel.

![Rename a Chain panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain to rename</td>
<td>file box</td>
<td>available *.chain, *.rcn files</td>
<td></td>
</tr>
<tr>
<td>New name</td>
<td>text box</td>
<td>available *.chain, *.rcn files</td>
<td></td>
</tr>
<tr>
<td>Rename</td>
<td>button</td>
<td>Change the name of the chain.</td>
<td></td>
</tr>
</tbody>
</table>

Continue to the next section 28.3.9 Run a Chain or return to 28.3 Chains.
28.3.9 Run a Chain

Position of option on menu: Utilities =>Chains =>Run

Position of option on menu: Utilities =>Recalc =>Run chain

These options can run an existing chain and also create a new chain or edit an existing chain.

Running an existing chain on either menu can be done two ways.

The Run or Run chain walk-right menu displays all the chains in the project and double clicking on a chain in the list will run the chain.

Another way of running a chain is by using the Recalc Chain panel that comes up by:

(a) If the menu is being displayed by walking right on Utilities =>Chains =>Run on the top Main Menu then the Run menu will be displaying with [Run] written on the top. Clicking on [Run] will bring up the Recalc Chain panel.

(b) If any of the menus getting to the Chain or Recalc menus have been torn from the top Main Menu then the Recalc Chain panel comes up by clicking on Utilities =>Chains =>Run without walking right or Utilities =>Recalc =>Run chain without walking right.

The Recalc Chain panel can run an existing chain, or edit an existing chain, or create a new chain.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain file</td>
<td>the name of the chain file to create/edit or run.</td>
<td>file box</td>
<td>available *.chain and *.rcn files</td>
<td></td>
</tr>
<tr>
<td>Run</td>
<td>if the chain exist then the chain will be run.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edit</td>
<td>if the chain exist then it will be brought up in the Create/Edit Chain panel for editing.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Editing an existing chain on either menu can be done two ways.

The Edit walk-right menu displays all the chains in the project and double clicking on a chain in the list will bring up the Create/Edit Chain panel (see 28.3.1 Create/Edit a Chain for more information).

Another way of editing a chain is by using the Recalc Chain panel that comes up by:

(a) If the Chain menu is being displayed by walking right on Utilities =>Chains =>Edit on the top Main Menu then the Edit menu will be displaying with [Edit] written on the top. Clicking on [Edit] will bring up the Recalc Chain panel.

(b) If any of the menus getting to the Chain or Recalc menus have been torn from the top Main Menu then the Recalc Chain panel comes up by clicking on Utilities =>Chains =>Edit without walking right or Utilities =>Recalc =>Edit chain without walking right.
Main Menu then the Edit menu will be displaying with [Edit] written on the top. Clicking on [Edit] will bring up the Recalc Chain panel.

If the Chain menu is being displayed by walking right on Utilities => Recalc => Edit chains on the top Main Menu then the Edit menu will be displaying with [Edit chain] written on the top. Clicking on [Edit chain] will bring up the Recalc Chain panel.

(b) If the Chain or Recalc menu has been torn from the Main Menu on the top then the Recalc Chain panel comes up if you click on Utilities => Chains => Edit without walking right or Utilities => Recalc => Edit chain without walking right.

The Recalc Chain panel can edit an existing Chain or create a new chain.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain file</td>
<td>file box</td>
<td>available *.chain, *.rcn files</td>
<td>the name of the chain file to create.</td>
</tr>
<tr>
<td>Run</td>
<td>button</td>
<td>if the chain exist then the chain will be run.</td>
<td></td>
</tr>
<tr>
<td>Edit</td>
<td>button</td>
<td>if the chain in Chain file exist then it will be brought up in the Create/Edit Chain panel for editing.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the chain in Chain file does not exist then it is created and then brought up in the Create/Edit Chain panel for editing.</td>
<td></td>
</tr>
</tbody>
</table>

Continue to the next section [28.3.10 Delete a Chain] or return to [28.3 Chains].
28.3.10 Delete a Chain

Position of option on menu: Utilities => Chains => Delete

This option deletes a chain.

Selecting Delete brings up the Delete a Chain panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain to delete</td>
<td>name of the chain to delete</td>
<td>folder box</td>
<td>available *.chain, *.rcn files</td>
<td></td>
</tr>
</tbody>
</table>

Delete button delete the chain given in the Chain to delete field.

Return to 28.3 Chains.
28.4 Functions

Position of menu: Utilities => Functions

Functions are used in the template and interface options to collect special data together. This allows 12d Model to recognise when some of the data has been modified and that some of the data is no longer valid. It is then possible to re-run the functions (re-calc the functions) and update the modified data.

The Functions walk-right menu is

- list of functions in the project
- modify an existing function
- lock a function so it won’t recalc
- modify the recalc order of functions
- recalculate functions
- rename a function
- change the name of tins in functions
- add functions to the project
- save a functions to disk
- edit attributes of a function
- delete functions from disk

The Functions walk-right simply lists all the functions that have been defined in the project. The other options in this menu will now be described in more detail.

For the option Editor, go to
- 28.4.1 Editor
- 28.4.2 Lock
- 28.4.3 Order
- 28.4.4 Recalc
- 28.4.5 Rename
- 28.4.6 Change all Tins
- 28.4.7 Add
- 28.4.8 Save
- 28.4.9 Attributes
- 28.4.10 Delete
- 28.4.10.2 Delete Many Functions
28.4.1 Editor

On walking right on the Editor menu option, a list of defined functions appears.

By selecting the highlighted name of a function to be edited, the appropriate function panel filled with the information from the selected function, is displayed.

The information in the selected function can then be modified.

Important Note
The defined functions menu also has a [Same as] option which is used to select the function to be edited by simply picking any string that was created by the function.
28.4.2 Lock

Position of option on menu: Utilities => Functions => Lock

The function lock option is used to lock a function so that it can’t be re-calculated. On selecting the Lock option, the Function Lock Status panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>name of the function to lock/unlock.</td>
<td>input</td>
<td>available functions</td>
<td></td>
</tr>
<tr>
<td>Lock model</td>
<td>display and modifies the lock status for the given function.</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Set</td>
<td>set the lock mode for the selected function.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
28.4.3 Order

Position of option on menu: Utilities => Functions => Order

The default recalculation order for functions is the order in which the functions were created. However, the Order option is used to modify the function recalc order.

On selecting the Order option, the Function Recalc Order panel is displayed.

![Function Recalc Order Panel]

The fields and buttons used in this panel have the following functions.

Field Description                Type             Defaults   Pop-Up

Functions                        table            available functions

list of functions in their recalculation order. Functions should only appear once in the list.

Set                              button

record the order of functions in the table.

Note - all functions must still exist somewhere in the re-arranged recalc order.
28.4.4 Recalc

Position of option on menu: Utilities => Functions => Recalc

The recalc menu is the same as the menu.

Utilities => Recalc

For more information, please go to the section 28.7 Recalc.
28.4.5 Rename

**Position of option on menu:** Utilities =>Functions =>Rename

On selecting the rename option, the **function rename** panel is displayed. This panel can be used to change the names of existing functions.

![Function Rename Panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Old function</td>
<td>name of the function to be renamed.</td>
<td>input</td>
<td>available functions</td>
<td></td>
</tr>
<tr>
<td>New function</td>
<td>new name for the function</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rename</td>
<td>button</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Change the name of the function in the old function field to the name given in the new function field.*
28.4.6 Change all Tins

Position of option on menu: Utilities => Functions => Change all tins

Selecting the Change all tins option, displays the panel Change Tin Name in All Functions. This panel is used to change the name of a tin in all functions to another tin name.

![Change Tin Name in All Functions Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Old tin name</td>
<td>Tin box</td>
<td>Available tins</td>
<td>name of the tin to be renamed</td>
</tr>
<tr>
<td>New tin name</td>
<td>Tin box</td>
<td>Available tins</td>
<td>new name for the tin in all functions</td>
</tr>
<tr>
<td>Rename</td>
<td>button</td>
<td></td>
<td>Change the name of the tin in the Old tin name field in all functions to the name given in the New tin name field</td>
</tr>
</tbody>
</table>
28.4.7 Add

**Position of menu:** Utilities => Functions => Add

The function add option brings up the walk-right menu, function adds:

```
Function Adds
Add all to project
```

**Position of option on menu:** Utilities => Functions => Add => Add all to project

On selecting the Add all to project option, the Add All Functions To Project panel is displayed. This panel is used to add all removed functions to the project.

```
Add All Functions To Project
```

```
Add Finish Help
```
28.4.8 Save

Functions can be saved on disk so that they can be used for future project work.

The **Function save** walk-right menu is

![Function Save Menu]

**Note** - Modified or new functions are automatically saved when a project is saved.

For the option **Save a function**, go to 28.4.8.1 **Save a Function**

For the option **Save all functions**, go to 28.4.8.2 **Save All Functions**

28.4.8.1 Save a Function

On selecting the **Save a function** option, the **Save Function** panel is displayed.

![Save Function Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>input</td>
<td>available functions</td>
<td>name of the function to be saved.</td>
</tr>
<tr>
<td>Save</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

After selecting this button, the function given in the function field will be saved to disk.

28.4.8.2 Save All Functions

On selecting the **Save all** option, the **Save All Functions** panel is displayed.

![Save All Functions Panel]

By selecting the **save** button, all functions in the working project will be saved to disk. Unless an error occurs, the panel will be removed after the saving is completed.
28.4.9 Attributes

Position of menu: Utilities => Functions => Attributes

This section of documentation is a work in progress and will be updated in subsequent releases.
28.4.10 Delete

Position of menu: Utilities => Functions => Delete

Using the Delete option, functions can be deleted from disk so that they no longer can be accessed or take up disk space.

To help protect the user against disasters, when a function is selected for deletion, a yes-no pop-up menu is used to confirm that the user did intend deleting the function.

If deletion is confirmed, the selected function is removed from the project and deleted from the disk.

The Function Delete walk-right menu is

![Function Delete Walk-right Menu]

For the option Delete a function, go to
- 28.4.10.1 Delete a Function
- 28.4.10.2 Delete Many Functions
- 28.4.10.3 Delete All Functions

28.4.10.1 Delete a Function

Position of option on menu: Utilities => Functions => Delete => Delete a function

The Delete a function option can be used to delete a function in the working project.

On selecting the Delete a function option, the Delete Function panel is displayed.

![Delete Function Panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>function box</td>
<td>all project functions</td>
<td>name of the function to be deleted.</td>
</tr>
<tr>
<td>Clean function strings</td>
<td>tick box</td>
<td></td>
<td>if ticked, delete all the strings created by the function</td>
</tr>
<tr>
<td>Delete</td>
<td>button</td>
<td></td>
<td>after selecting this button, the function given in the function field will be deleted from the computer disk. A yes-no pop-up is used to confirm that deletion is required.</td>
</tr>
</tbody>
</table>

28.4.10.2 Delete Many Functions

Position of menu: Utilities => Functions => Delete many
The Delete many option deletes one or more functions in the working project. Selecting the Delete many, displays the Delete many functions panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>if ticked, delete the selected function listed after the tick</td>
</tr>
<tr>
<td>Function</td>
<td>input</td>
<td>all project functions</td>
<td>name of all the functions in the project</td>
</tr>
<tr>
<td>Delete function strings</td>
<td>tick box</td>
<td></td>
<td>if ticked, delete all the strings created by the selected functions</td>
</tr>
<tr>
<td>Delete</td>
<td>button</td>
<td></td>
<td>delete all the ticked functions in the function field</td>
</tr>
</tbody>
</table>
28.4.10.3 Delete All Functions

Position of option on menu: Utilities => Functions => Delete => Delete all functions

The Delete all functions option will delete all of the functions in the working project.

On selecting the Delete all functions option, the Delete All Functions panel is displayed.

![Delete All Functions panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean function strings</td>
<td>tick box</td>
<td>if ticked, delete all the strings created by all the function</td>
<td></td>
</tr>
</tbody>
</table>

After selecting the Delete button, a yes-no pop-up is used to confirm that deletion is required. If it is, all functions in the working project will be deleted from disk and unless an error occurs, the panel will be removed.
28.5 Macros

Position of menu: Utilities -> Macros

The 12d Solutions Programming Language (12dPL) is a powerful programming language designed to run from within 12d Model. Its main purpose is to allow users to enhance the existing 12d Model package by writing their own programs (12dPLs or macros).

12dPL programs can be compiled from within or outside 12d Model but can only be run from within 12d Model.

The Macros menu has options to compile macros, compile and run or just run macros. A full description of macros is given in the 12d Model Programming Language manual.

The Macros walk-right menu is

For the option Compile, go to 28.5.1 Compile

Compile/run 28.5.2 Compile and Run
Create 28.5.3 Create
Edit 28.5.4 Edit
Run 28.5.5 Run
Create prototypes file 28.5.6 Create Prototype File
Version 28.5.7 Version
Kill 28.5.8 Kill

The options will now be described.
28.5.1 Compile

Position of option on menu:  Utilities => Macros => Compile

The Compile option is used to compile the 12dPL program source code into a executable program which can then be run from within 12d Model.

On selecting the option, the **Compile a Macro** panel is placed on the screen.

![Compile a Macro panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Macro source</strong></td>
<td>input</td>
<td>* .4dm files</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>* .4dm files</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>* .4dm files</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>* .4dm files</td>
</tr>
<tr>
<td>Compile</td>
<td>button</td>
<td></td>
<td>* .4dm files</td>
</tr>
</tbody>
</table>

* compile the code file given in the **Macro source** field.
28.5.2 Compile and Run

Position of option on menu: Utilities => Macros => Compile/Run

The Compile/Run option compiles the 12dPL program (macro) source code into an executable program, and if there are no errors, runs the program.

When a macro is run, a macro console panel is placed on the screen to provide an i/o and message area for the macro. It is possible to bring up the macro console with or without the restart, abort and finish buttons.

When the macro finishes, the macro console can be left on the screen or removed.

Selecting the Compile/Run menu option, brings up the Compile/Run a Macro panel:

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro source</td>
<td>input</td>
<td>*.4dm files</td>
<td></td>
</tr>
<tr>
<td>Macro arguments</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Show buttons</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Retain on exit</td>
<td>tick box</td>
<td>tick</td>
<td></td>
</tr>
<tr>
<td>Show console</td>
<td>tick box</td>
<td>tick</td>
<td></td>
</tr>
<tr>
<td>Allow defaults</td>
<td>tick box</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

* the name of the macro source file.

If non-blank, a text line which is passed to the program as an argument line.

If ticked, the macro console panel remains on the screen after the macro has finished running.

If ticked, the macro console panel is placed on the screen.

If ticked, the default value for a prompt is displayed in the macro console panel.
Compile/Run button

compile the code file given in the macro source field and if the compile is successful, run the program.
28.5.3 Create

The Macros=>Create option is used to create macro files (*.4dm) with the editor pointed to by the EDIT_4D environment variable.

Selecting Macros=>Create brings up the Create Macro File *.4dm panel.

```
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Folder</td>
<td>name of the folder to create</td>
<td>input</td>
<td>current folder</td>
<td></td>
</tr>
<tr>
<td>File to create</td>
<td>name of the file, in folder</td>
<td>input</td>
<td>*.4dm files</td>
<td></td>
</tr>
<tr>
<td>Create</td>
<td>create the file given by the file to create in folder</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

create the file given by the folder and file to create panel fields. A macro header is set up in the file.
28.5.4 Edit

**Position of option on menu:** Utilities => Macros => Edit

The Macros=>Edit option is used to edit macro files (*.4dm) with the editor pointed to by the EDIT_4D environment variable.

The Macros=>Edit option has two modes of operation - selecting the macros=>edit itself, or by activating the Macros=>Edit option's walk-right menu, folder *.4dm.

Selecting Macros=>Edit itself brings up the Edit Macro File *.4dm panel.

![Edit Macro File *.4dm panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Folder</td>
<td>name of the folder for the .4dm file.</td>
<td>input</td>
<td>current folder</td>
<td></td>
</tr>
<tr>
<td>File to edit</td>
<td>name of the file, in folder, to edit.</td>
<td>input</td>
<td>*.4dm files</td>
<td></td>
</tr>
<tr>
<td>Edit</td>
<td>edit the file given by the folder and file to edit panel fields. If the file given in the file to edit field does not exist, then a new file is created which already has each of the macro header set up.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Macros=>Edit walk-right menu provides a list all the many template files (files ending in .mtf) in the current folder. When a file is selected from the list, it is automatically loaded into the editor.
28.5.5 Run

Position of option on menu: Utilities => Macros => Run

The Run option runs an existing macro executable program (produced by the compile process).

Like the Compile/Run option, the Run options can run the macro executable with or without buttons on the macro console, and leave or remove the macro console once the macro has been executed.

Selecting the Run menu option brings up the Run a Macro panel

![Run a Macro panel]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro object</td>
<td>input</td>
<td></td>
<td>* .4dm files</td>
<td></td>
</tr>
<tr>
<td></td>
<td>the name of the macro object or executable program.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Macro arguments</td>
<td>input</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if non-blank, a text line which is passed to the program as an argument line.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Show buttons</td>
<td>tick box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if ticked, the macro console panel has abort, restart and finish buttons on it.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Retain on exit</td>
<td>tick box</td>
<td></td>
<td>tick</td>
<td></td>
</tr>
<tr>
<td></td>
<td>if ticked, the macro console panel remains on the screen after the macro has finished running.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Show console</td>
<td>tick box</td>
<td></td>
<td>tick</td>
<td></td>
</tr>
<tr>
<td></td>
<td>if ticked, the macro console panel is placed on the screen.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if not ticked, the macro console panel is not displayed - used mainly with panels.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Allow defaults</td>
<td>tick box</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>if ticked, the default value for a prompt is displayed in the macro console panel.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Run</td>
<td>button</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>run the executable given in the macro object field.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
28.5.6 Create Prototype File

**Position of option on menu:** Utilities => Macros => Create prototype file

The **Create prototype file** option creates a list of the function prototypes for all the *12dPL* functions in the **12d Programming Language** compiler that is available on your computer.

Selecting the **Create prototypes file** brings up the **Create Macro Prototype File** panel.

![Create Macro Prototype File panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output prototype file</td>
<td>File Box</td>
<td>*.txt files</td>
<td>the name of the file to write the macro function prototypes out to.</td>
</tr>
<tr>
<td>Create</td>
<td>button</td>
<td></td>
<td>create the file of macro function prototypes.</td>
</tr>
</tbody>
</table>

*Note:* The image shows a window titled "Create Macro Prototype File" with fields for "Output prototype file" and buttons labeled "Create," "Finish," and "Help."
28.5.7 Version

**Position of option on menu:** Utilities => Macros => Version

The Version option simply brings up a panel giving information about the macro process.
28.5.8 Kill

Position of option on menu: Utilities => Macros => Kill

The Kill option is used to terminate selected running macros.

This option is useful in situations such as when the macro writer has omitted a Finish button on the macro or has unintentionally made the macro panel invisible.

It cannot be used to terminate a macro in an infinite loop because there is no way of getting to the Kill option.

On selecting Kill, the Kill Macros panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro Grid</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Macro name</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Kill</td>
<td>choice cell</td>
<td>yes</td>
<td>yes, no</td>
</tr>
</tbody>
</table>

if yes, the macro will be terminated when the Kill button is selected.
**Kill button**

terminates all macros in the grid with *yes* in the **Kill** column.
28.6 Measure

Position of menu: Utilities => Measure

The Measure menu contains two options to display the
delta x, delta y, horizontal distance, angle and bearing
between points, and for a section view, the
delta chainage, delta height, slope distance and % grade
between points are calculated and displayed.

There are also options to calculate the plan area of polygons, the surface area of a tin within a
polygon, run measures and dynamic measures and dynamically calculate and display the x-fall
between two strings.

The Measure walk-right menu is

Note

The Measure option has another mode of operation. Rather than moving onto the walk-right
arrow, if LB is clicked when the Measure button is highlighted on the 12d Model=>utilities menu, the
distance/bearing panel is displayed on the screen.

For the option Angle x 3 pts, go to 28.6.1 Angle by 3 Points
Bearing/distance 28.6.2 Bearing and Distance
Plan area 28.6.3 Plan Area
Surface area 16.11.4 Surface Area
Value 28.6.5 Value
String 28.6.6 String
String dynamic 28.6.7 String Dynamic
Xfall by strings 28.6.8 X Fall by Strings
Xfall by strings (advanced) 28.6.9 X Fall by Strings (Advanced)

The options in the menu will now be described.
28.6.1 Angle by 3 Points

**Position of option on menu:** Utilities => Measure => Angle x 3 pts

The Angle by 3 pts option is used to calculate the angle formed by selected three positions. The angle can be expressed as a clockwise or anti-clockwise angle.

On selecting the Angle x 3 pts option, the Measure Angle panel is displayed.

![Measure Angle panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mode</strong></td>
<td>Input</td>
<td>input</td>
<td>disjoint</td>
<td>disjoint, continuous</td>
</tr>
<tr>
<td></td>
<td>In disjoint mode, only the angle between the three selected positions is reported. After the angle is reported, the user can select the 1st point in the sequence.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>In continuous mode, after the initial reporting of the angle, the user is prompted for the 3rd point of the new angle to be measured. By default, the previous 2nd point becomes the first point and the previous 3rd point becomes the 2nd point. This allows just one point (the third point) to be selected and the angle reported will change accordingly.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Clockwise angle</strong></td>
<td>Tick box</td>
<td>tick box</td>
<td>if ticked, then the angle is measured in the clockwise (forward) direction.</td>
<td></td>
</tr>
<tr>
<td><strong>Anti-clockwise angle</strong></td>
<td>Tick box</td>
<td>tick box</td>
<td>if ticked, then the angle is measured in the anti-clockwise direction.</td>
<td></td>
</tr>
<tr>
<td><strong>Clear</strong></td>
<td>Button</td>
<td>button</td>
<td>when this button is selected, the sequence is re-initialised.</td>
<td></td>
</tr>
</tbody>
</table>

**Note** - after two positions are selected, the angle to the cursor position is dynamically calculated and displayed as the cursor moves around the view.
28.6.2 Bearing and Distance

**Position of option on menu:** Utilities => Measure => Bearing/Distance

The **Bearing/Distance** option is used to calculate

(a) the bearing measured in a clockwise direction between the positive y-axis and the (imaginary) line joining two selected points (when the bearing tick box is selected)

or

the bearing measured in an anticlockwise direction between the positive x-axis and the (imaginary) line joining two selected points (when the **Math angle** tick box is selected)

(b) the distance between two user selected points.

On selecting the **Bearing/Distance** option, the **Measure Bearing/Distance** panel is displayed.

```
Measure Bearing/Distance

Mode [ ] disjoint [ ] Scale factor [ ]

Bearing [ ] Math angle [ ] Special for same string [ ] XY grades [ ]

Clear Finish Help
```

This panel is principally used to display the distances between, and bearing of the line joining, pairs of user selected points.

message area 1 : \[ \text{brg} = \text{plane dist} = \text{ellipsoid dist} = \]

where \( \text{brg} \) is the angle measured clockwise from north and is calculated using the coordinate values (Inverse value)

\( \text{plane dist} \) is the distance calculated using the coordinate values (Inverse value)

\( \text{ellipsoid dist} \) is the distance calculated by dividing the plane distance by the current scale factor

message area 2: \[ \text{dx} = \text{dy} = \text{dht} = \text{(if applicable)} \]

where \( \text{dx} \) is the difference in x value between the two coordinates

\( \text{dy} \) is the difference in y value between the two coordinates

\( \text{dz} \) is the difference in z value between the two coordinates

If valid height values exist for two consecutive points the grade and slope is also reported

message area 3: \[ \text{grade \%} = \text{slope} = \]

If the measurement mode is set to continuous, the sum distances will be shown for the route taken

message area 4: \[ \text{Sum plane dist} = \text{Sum ellip dist} = \]

where \( \text{Sum plane dist} \), is the accumulative length of the route taken calculated using plane distances.

\( \text{Sum ellip dist} \), is the \( \text{Sum plane dist} / \text{scale factor} \).

The fields and buttons used in this panel have the following functions.
Field Description | Type | Defaults | Pop-Up
--- | --- | --- | ---
**Mode** | input | disjoint | disjoint, continuous

In disjoint mode, only the distance between the two points and the bearing (in degrees, minutes and seconds) of the (imaginary) line connecting the two points are displayed.

In continuous mode, after the initial reporting of the bearing/distance, the user is prompted to select the next point (2nd point). In this case the previously selected second point becomes the first point.

**Scale** | input/output | 1.0

The scale factor which will be used to convert plane distances to ellipsoid distances.

i.e ellipsoid distance = plane distance / scale factor

**Bearing** | tick box | ticked

If ticked, the measured vectors can be displayed as bearings (angles measured from north, clockwise).

**Math angle** | tick box | un-ticked

If ticked, the measured vectors can be displayed as a mathematical angle (measured from east in a anti-clockwise direction).

**Clear** | button

When this button is selected, the selection sequence is re-initialised.

Note

When in **continuous** mode, each time the next screen position is added to the highlighted figure, the **plan area** is calculated for the closed figure that is constructed by joining the first and last selected screen positions.
28.6.3 Plan Area

**Position of option on menu:** Utilities => Measure => Plan area

The Plan area option is used to calculate the plan areas enclosed by strings. If a string is not closed, the first and last points are considered to be connected to form a polygon. On selecting the option, the Measure Plan Area panel is placed on the screen.

![Measure Plan Area panel](image)

This panel is principally used to display the plan areas of strings selected by the user. The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>input</td>
<td>disjoint</td>
<td>disjoint, continuous</td>
</tr>
</tbody>
</table>

If disjoint, only the area of the selected string is displayed. If continuous, the total of the areas is also displayed.

**Clear button**  
When this button is selected, the total-to-date of the area is reset to zero and the selection sequence began.

**How to Use the Panel and Panel Messages**

The measure area cycle consists is as follows:

(a) the string is selected with the mouse.

- message area 1: select string for area calcs
- message area 2

(b) repeat step (a) to find more areas and accumulate them. If the accumulator is to be zeroed, simply select the clear button again.

The area of the selected string is displayed in message area 2. If the mode is set to continuous, the accumulated areas (sum) of the selected strings is also displayed.

- message area 1: select string for area calcs
- message area 2: area = value, sum = value

The cycle can then be repeated for as many strings as needed without leaving the option. The accumulated total is reset to zero (cleared) by selecting the clear button again.
28.6.4 Surface Area

**Position of option on menu:** Utilities => Measure => Surface area

The **Surface area** option calculates and reports the surface area of a tin restricted to a user specified polygon.

This option has already been documented as Tins => Tin analysis => Surface area.

See the section 16.11.4 Surface Area.
28.6.5 Value

**Position of option on menu:**  Utilities => Measure => Value

The *Value* option is used to calculate and display any of the measures available in the *Measures* pop-up menu.

The *Measures* are documented under 4.21 Measures.

On selecting the option, the *Measure Value* panel and the *Measures* menu are placed on the screen.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Value</strong></td>
<td>output</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

the value calculated by the selected measure option.
28.6.6 String

Position of option on menu:  Utilities => Measure => String

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting String, the Measure String From Point panel is placed on the screen.
28.6.7 String Dynamic

**Position of option on menu:**  Utilities => Measure => String dynamic

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting **String dynamic**, the **Measure String Dynamic** panel is placed on the screen.
### 28.6.8 X Fall by Strings

**Position of option on menu:** Utilities => Measure => XFall by strings

In this option, the user selects a reference string to define what is meant by chainage and right angles, and then selects two strings to calculate the x-fall between.

Once the three strings are selected, as the cursor moves around in a plan view, the cursor position is dropped perpendicularly onto the reference string.

At the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts the two selected strings. The xfall, delta width and delta z is then calculated between the cut points on the strings.

Then the chainage and the xfall are dynamically displayed in the panel message area.

The line joining the two strings is dynamically displayed on the plan view.

The chainage, xfall, delta width and delta z are dynamically displayed in the message area.

- **Reference string**: The selected string is used to defined the meaning of chainage and bearing for the inquire. The cursor is dropped perpendicularly onto the reference string and at the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts string 1 and string 2. The xfall, delta width and delta z between the two cut points are then calculate and displayed.

- **String 1/2**: The two strings to calculate x-fall between.

On selecting the Xfall by strings option, the XFall Between 2 strings Inquire panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference</td>
<td>string-select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>String 1/2</td>
<td>string-select</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reference**

The selected string is used to defined the meaning of chainage and bearing for the inquire. The cursor is dropped perpendicularly onto the reference string and at the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts string 1 and string 2. The xfall, delta width and delta z between the two cut points are then calculate and displayed.

**String 1/2**

The two strings to calculate x-fall between.
If **pick all** is selected, the user is asked to sequentially select the three strings: reference string, string 1 and string 2. The strings are automatically assigned to the appropriate string-select panel fields.
28.6.9 X Fall by Strings (Advanced)

**Position of option on menu:** Utilities => Measure => X Fall by strings (advanced)

In this option, the user selects a reference string to define what is meant by chainage and right angles, and then selects two strings to calculate a variety of values for the reference string and the two strings, and the differences between the values for the two strings.

Once the three strings are selected, as the cursor moves around in a plan view, the cursor position is dropped perpendicularly onto the reference string.

At the dropped chainage, a line is taken at right angles to the reference point and extended until it cuts the two selected strings. The xfall is then calculated between the cut points on the strings.

Then the chainage and the xfall are dynamically displayed in the panel message area.

The line joining the two strings is dynamically displayed on the plan view.

Various values for the cut points on the two strings, and the differences of the values between the strings dynamically displayed in the grid.

![Plan View Diagram]

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>

button

For example,
28.7 Recalc

Position of menu:  Utilities => Recalc

Once a function has been applied, the calculated information is only correct whilst the initial data is not modified in any way. If any modifications are made to the data, then the function must be re-run and all the associated information recalculated and redrawn, and any perspective views associated with the function set with the new eye and target positions, and redrawn.

There are date and time stamps for all string, tin and template information in 12d Model and this enables 12d Model to determine what information has been modified since a function was last run and what re-calculation are required.

The Recalc option is designed to re-run functions

If LB is clicked whilst the Recalc menu option is highlighted, all the template functions with auto recalc set on, and that have had their initial data modified since their last re-run, will be recalculated and all appropriate information updated. The data will be redrawn on any views that is was on before the recalc.

The Recalc walk-right menu has four options:

- Auto
- Edit func
- Edit data
- Recalc
- Recalc all
- User
- Edit chain
- Run chain

For the option Auto, go to 28.7.1 Auto

For the option Edit func, go to 28.7.2 Editor

For the option Edit data, go to 28.7.3 Edit Data from String

For the option Recalc, go to 28.7.4 Recalc

For the option Recalc all, go to 28.7.5 Recalc All

For the option Edit chain, go to 28.7.6 Edit Chain

For the option Run chain, go to 28.7.7 Run Chain
28.7.1 Auto

Position of option on menu: Utilities => Recalc => Auto

The Auto option allows the user to specify whether a function is automatically recalced if another function, tin, template or string that it depends upon, is modified or recalced.

Individual functions or all functions can have auto-recalcalc mode turned on or off and the default for a new function is off.

The Function Auto menu is

For the option Auto, go to 28.7.1 Auto
Auto all 28.7.1.2 Auto all

28.7.1.1 Auto

Position of option on menu: Utilities => Recalc => Auto

Selecting Auto displays the Auto Recalc Mode for a Function panel.

The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up
--- | --- | --- | ---
Function | input | available functions | name of the function to be have auto recalc mode set on/off.
Auto recalc | tick box | tick | If the tick is on, the specified function will have its auto recalc value changed to on.
 | | | If the tick is off, the specified function will have its auto recalc value changed to off.
Set | button | | Set the auto recalc mode for the selected function.

28.7.1.2 Auto all

Position of option on menu: Utilities => Recalc => Auto => Auto all

Selecting Auto all displays the Auto Recalc Mode For All Functions panel.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto recalc</td>
<td>tick box</td>
<td>tick</td>
<td></td>
</tr>
</tbody>
</table>

*If the tick is on, all functions within the project will have their **auto recalc** value changed to on.*

*If the tick is off, all functions within the project will have their **auto recalc** value changed to off.*

*Note: the tick is not a global setting within 12d. The use of the option changes every function within the project.*

**Set** button

*Set the **auto recalc** mode for all functions.*
28.7.2 Editor

Position of option on menu: Utilities => Recalc => Editor

The Recalc => Editor option is used to edit functions.

The Recalc => Editor walk-right menu provides a list all the defined functions in the project.

When a function is selected from the list, it is automatically loaded into the appropriate function panel for the selected function, and displayed.

The information in the selected function can then be modified.

Important Note

The defined functions menu also has a [Same as] option which is used to select the function to be edited by simply picking any string that was created by the function. This is documented in the next section 28.7.2.1 Edit Function from String.

28.7.2.1 Edit Function from String

Position of option on menu: Utilities => Recalc => Editor => [Same as]

The Edit Function from String option allows the user to start up the Function editor by simply selecting a string that was created by the function.

On selecting the option, the Edit Function From String panel is displayed.

The fields and buttons used in this panel have the following functions.

Field Description | Type | Defaults | Pop-Up
--- | --- | --- | ---
Pick Edit button |  |  |  

select data that was created by a function and the appropriate function editor is then opened.
28.7.3 Edit Data from String

Position of option on menu: Utilities =>Recalc =>Edit data

The Edit data option allows the user to start up the MTF editor by simply selecting a string that was created using an Apply Templates function (and hence an MTF file). The MTF file used in the Apply Templates function is automatically loaded into MTF editor (go to 20.4.1.1 MTF Edit).

Similarly the Edit data option also allows the user to start up the Survey Field Data editor by simply selecting a string that was created using a Survey Data Reduction function. All the data produced by the Survey Data Reduction function is automatically loaded into the Survey Field Data editor (go to the section 17.7.5 Survey Field Data Editor).

On selecting the Edit data option, the Edit MTF/Survey Function Data panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pick Edit button</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

select data that was created by applying an MTF file or a Survey Data Reduction function. The appropriate MTF editor or Survey Field Data editor that created the selected data, is then opened.

For information on the Survey Field Data Editor, go to the section 17.7.5 Survey Field Data Editor.

For information on the MTF Editor, go to 20.4.1.1 MTF Edit.
28.7.4 Recalc

**Position of menu:** Utilities => Recalc => Recalc

The Recalc option is used to recalculate a user selected function, and all functions that depend on the function that have auto recalc set on.

The Recalc walk-right menu lists all the existing functions and by selecting a function name, the function will be forced to re-run and all appropriate information and views for that function will be updated.

The existing functions menu also has a [Changed] option which recalcs all changed functions.

The existing functions menu has a [Same as] option which is used to select the function to be recalced by simply picking any string that was created by the function. This is documented in the next section 28.7.4.1 Recalc Function from String

28.7.4.1 Recalc Function from String

**Position of option on menu:** Utilities => Recalc => Recalc => [Same as]

The Recalc Function from String option allows the user to recalc a function by simply selecting a string that was created by the function.

On selecting the option, the Recalc Function From String panel is displayed.

![Recalc Function From String Panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pick Edit</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The fields and buttons used in this panel have the following functions.

- **Pick Recalc** button: select data that was created by a function and the appropriate function will be recalced.
28.7.5 Recalc All

Position of option on menu:  Utilities => Recalc => Recalc all

The Recalc all option re-runs all functions regardless of their date and time stamps.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore auto recalc</td>
<td>tick box</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If not ticked, all functions that have the auto-recalc flag set on are re-calculated.
If ticked, the auto-recalc flag is ignored and all functions are re-calculated.
28.7.6 Edit Chain

**Position of option on menu:** Utilities => Recalc => Edit chain

The Recalc => Edit chain option is used to edit chains.

The Recalc => Edit chain walk-right menu provides a list all the defined chains in the project. When a chain is selected from the list, it is automatically loaded into the Edit/Create Chain panel ready for editing.
28.7.7 Run Chain

Position of option on menu: Utilities => Recalc => Run chain

The Recalc => Run chain option is used to run chains.

The Recalc => Run chain walk-right menu provides a list all the defined chains in the project. When a chain is selected from the list, it is automatically run.
28.8 Fence

Position of menu: Utilities => Fence

It is often necessary to divide strings into those parts that are within a certain region and those parts that are outside the region. In 12d Model, the Fence option is the method of achieving this result.

Given a string to be used as a fence, the 12d Model fencing options will process strings in a model/view against the fence and break the strings into the parts inside the fence string and those parts outside the fence string.

Any 2d, 3d or interface line-strings that cut the fence polygon will have points inserted at the intersections with the fence polygon. The z-value at the intersection point will be interpolated from the adjacent points in the line-string.

Point strings do not have any extra points added to them.

Restrictions
- only 2d, 3d and interface strings can be split using the fence option.
- 4d strings are treated as though they were point strings.
- arcs are considered to be inside the fence if the minimum bounding rectangles of the fence and arc overlap.
- alignment, pipeline, drainage, sewer strings are not processed by the fence option

Notes
1. if the fence string is not closed, the first and last points are joined together to form a closed polygon as the fence.
2. a string may be broken into a number of pieces if it wanders in and out of the fence string.
3. the fence string is not processed against itself even if it is in the model or view being fenced.
4. unpredictable results will occur if any strings being fenced lie on top of the fence. If problems occur, parallel the fence in or out by a millimetre.

The fence options allows the user to choose a single string to be used as the polygon fence or a number of strings to be used as polygons and process the data against all the strings in one operation.

The fence walk-right menu is

For the option Fence, go to
- 28.8.1 Fence
- 28.8.2 Fence Stem
- 28.8.3 Multi Fence
- 28.8.4 Multi Fence Stem
28.8.1 Fence

**Position of option on menu:** Utilities => Fence

In this option, the user selects a single string to be used as a polygon fence. If the string is not closed, the first and last points are joined together to form a polygon.

The Fence option will process a selected string or all the strings in a model/view/string against this fence and break the strings into the parts inside the fence string and those parts outside the fence string.

On selecting the Fence option and then the appropriate Data Source in the panel, the Fence panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>
Fence button

on selecting fence, the appropriate strings in the data source will be divided by the fence string (selected by the poly button) into the parts of the strings inside the fence string and the parts of the string outside the fence string. Any line-strings that cut the fence string will have a point inserted at the intersection with the fence string and the z-value for this point interpolated from the points on either side of it in the line-string.

How to Use the Panel and Panel Messages

(a) Select a fence polygon string by choosing Polygon to fence
(b) Fence processing begins on selecting the Fence button.

Progress messages - sent to the panel message area
- calculating inside-outside
- calculating inside
- calculating outside
- fencing string name

Completion message - sent to the panel message area
- finished fence

<esc> can be used to abort the fence option.
28.8.2 Fence Stem

Position of option on menu: Utilities => Fence => Fence stem

As for the Fence option, the user selects a single string to be used as a polygon fence. If the string is not closed, the first and last points are joined together to form a polygon.

The Fence Stem option will process a selected string or all the strings in a model/view against this fence and break the strings into the parts inside the fence string and those parts outside the fence string. The inside and outside will then be put into models of the same name as the original model modified by a prefix and/or postfix.

This means that unlike the Fence option, when fencing a view with the Fence Stem option, the inside/outside for each model on the view goes to distinct models using the prefix/postfix for the inside/outside model names.

On selecting the Fence Stem option and then the appropriate Data Source in the panel, the Fence Stem panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>

</table>

* data selection type - for a full description go to 4.19.3 Data Source.

Data source

data source for strings to fence.

Prefix for fence inside

input available models

if non-blank, prefix*postfix to adjust the data model name to be the model to contain the data inside of the fence string.

If blank, then no fence inside will be calculated.

Prefix for fence outside

input available models

if non-blank, prefix*postfix to adjust the data model name to be the model to contain the data outside of the fence string.

If blank, then no fence outside will be calculated.
Polygon for fence string-select
the selected string will be used as the polygon to act as a fence to separate data into an inside and an outside.

Exclude model containing fence tick box tick
if ticked, no data in the model containing the fence string will be fenced.
if not ticked, all the appropriate data in the model containing the fence string will be fenced.

Fence button
on selecting Fence, the appropriate strings in the data source will be divided by the fence string into the parts of the strings inside the fence string and the parts of the string outside the fence string. Any line-strings that cut the fence string will have a point inserted at the intersection with the fence string and the z-value for this point interpolated from the points on either side of it in the line-string.

<esc> can be used to abort the fence option.
28.8.3 Multi Fence

Position of option on menu: Utilities => Fence => Multi fence

It is often necessary to fence data against more than one polygon.

In the Multi fence option, the user provides a model containing all the polygons to be used as fences. The Multi fence option will process the selected string or all the strings in a model/view against all the polygons in the polygon model.

The data will be clipped and the outside is considered to be those bits are outside all of the polygons and the inside is the remainder, i.e. the bits inside any one of the polygon.

On selecting the Multi fence option and then the appropriate Data Source in the panel, the Multi Fence String/Model/View panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

For general information on *Affine* and *Helmert* Transformations, go to [28.9.1 Coordinate Transformations - Helmert and Affine](#).
28.9.1 Coordinate Transformations - Helmert and Affine

A **2D Helmert** transformation is a two dimensional linear transformation consisting of a scaling, a rotation (of both the x-axis and y-axis about the vertical axis) and a 2D-translation (shift) of data. Hence there are four parameters to be specified.

A **3D Helmert** transformation is a three dimensional linear transformation consisting of a scaling, three rotations (about the 3 axes), and a 3D-translation (shift) of data. Hence there are 7 parameters to be specified.

A **2D affine transformation** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and rotations of the x-axis (about the vertical axis) and of the y-axis (about the vertical axis). Hence there are six parameters to be specified. Unlike the Helmert transformations, rectangles can be skewed by an affine transformation.

A **2D orthogonal affine transformation** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and the same rotation (of both the x-axis and y-axis like the Helmert). Hence there are five parameters to be specified. Unlike the standard affine transformations, rectangles are not skewed by the orthogonal affine transformation.

These types of transformation are often used in civil projects for converting data between a local coordinate system (observed coordinates) and another coordinate system.

The most frequent method of defining all these transformations is not by explicitly giving the transformation parameters but by having both the observed and the final coordinates for three or more points (known as the control points) and then trying to calculate the transformation parameters from these sets of coordinates.

If the transformation parameters can be successfully calculated from the observed-final coordinate pairs for the control points, then the transformation parameters are then be used to convert the coordinates of any other object in the observed coordinate system to the new final coordinates.

So for this method, the first step is to select control points for which the coordinates are known in the final coordinate system and in the local (observed) coordinate system.

And in the diagram above, the observed coordinates of the control point A are to be mapped by the transformation to the coordinates of the control point A in the final coordinate system. And similarly for the points B, C and D.

Note that A is the same point on the ground - it just has a different coordinate in a different coordinate system and hence will appear in a different place in a diagram for each coordinate system.
Usually each control point is selected because
(a) its final coordinates are already known
(b) there is a marker on the ground indicating the exact position of the control point
and
(c) the control point is the area that is being surveyed (observed).
The control point is then surveyed to get its observed coordinates.

Because the final coordinates of the control points are known in advance, the final coordinates of
the control point are referred to as the Control Coordinates, or Control Easting and Control
Northing and the control point coordinates often referred to as the Control Point. The surveyed
coordinates of the control point are called as the Observed Coordinates or Observed Easting
and Observed Northing (of the control point).

**IMPORTANT NOTE** - the control points must be selected so that they are spread throughout the
area, and the control points must not all be on the one straight line.

The number of parameters to be determined for the transformation ranges from three in a fixed
scale 2D Helmert up to seven for a 3D Helmert so there must be enough control points to provide
sufficient independent equations to be able to solve for the parameters. Also all survey
measurements have errors in them and it is best to have more than the minimum number of
required control points to help control errors.

However when there are four or more control-observed point pairs, the system will be over
determined. That is, by taking different subsets of the control-observed point pairs, different
transformation parameters will result.

In this situation, **12d Model** uses Least Squares to calculate the transformation parameters
from the over determined systems.

Once the transformation parameters have been calculated by Least Squares, for each of the
control points the transformation can be applied to the observed coordinates of the control point.
The difference between the Control Coordinates and the transformed Observed Coordinates for
a control point is called the residuals for the transformation.

The residuals for the least squares solution gives a measure of how good the Least Squares
solution was, and for checking purposes, the residuals are displayed in the transformation panel
for each of the control-observed point pairs.

As an example of the meaning of the transformation parameters, we’ll look at the 2D Helmert
transformation.

The 2D Helmert has four parameters:
(a) the scale factor for the existing coordinates with respect to the new coordinates
(b) the (z axis) rotation of the existing coordinates to align it with the new coordinates axis
(c) the two (x and y) translations of the existing coordinates after the scalings and rotations
have been applied

and the operations to be performed on observed coordinates are:
