1. Scale the observed coordinates about (0,0) by the Scale factor
2. Then rotate the resulting coordinates about (0,0) in a clockwise direction by the Clockwise
rotation degrees.
3. Then translate the resulting coordinates by ((X translation, Y translation).
28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations

For the **Affine** and **Helmert** transformations, the parameters can be either typed in or calculated from control-observed point pairs using the method of least squares.

If the **Parameters by** choice box is set to **Pt Selection** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels.

For information about how to select control and observed points in the Affine and Helmert panels, go to the next section [28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations](#).

For Example

The Helmert parameters for the example are:

- **Scale**: 0.5
- **Clockwise rotation**: 45 deg
- **X translation**: -1.5
- **Y translation**: 1.38

### Grid for 2D transformations
If the Pt selection method is chosen, the selection of points is started by selecting the Control button.

**Note** - the default is to select the Control Point (the coordinates of the control point in the transformed coordinate system) and then its associated Observed Point (the coordinates of the control point in the observed system).

Neither point is accepted until the second point is selected. However, the order of selection can be reversed by setting the environment variable PICK_ORDER_OBSERVED_FIRST_4D (see 7.6.3 env.4d). The order can then be Observed Point first and then its associated control point with Control Coordinates.

To help reduce errors, after a control point - observed point pair is selected, the position of the Control Point is shown as a triangle and the position of the associated Observed Point as a circle with a line drawn between the control-observed point pair for clarity.

---

### Grid for 3D transformations

<table>
<thead>
<tr>
<th>Use pt</th>
<th>Control Easting</th>
<th>Control Northing</th>
<th>Control Level</th>
<th>Observed Easting</th>
<th>Observed Northing</th>
<th>Observed Level</th>
<th>Residual Easting</th>
<th>Residual Northing</th>
<th>Residual Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

After selecting the Control button, the selection starts with the Control (Observed) Point, accepting that point then selecting the corresponding Observed (Control) Point.
After selecting the first pair of points, the second pair is then selected and so on.
The picking is terminated by clicking **RB** and selecting **Cancel** when the next control (observed) point is to be selected.

The coordinates of the Control Points and Observed Points are added to the grid on the selection of two valid points. The **Use pt** field is ticked by default.

<table>
<thead>
<tr>
<th>Use pt</th>
<th>Control Easting</th>
<th>Control Northing</th>

<td>73829.0734</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If **Use pt** is set to tick, the corresponding control-observed point pair is used in the calculations. If **Use pt** is not ticked, the corresponding control-observed point pair is ignored and not used.

The **Calculate** button calculates the transformation parameters based on all the control-observed point pairs in the grid with the **Use pt** tick box ticked on.

The residuals are placed into the residual columns of the grid and the calculated parameters are placed into the parameters section of the panel.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

For information on how the **Affine Transformation works with Rasters**, go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

### 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

12d Rasters (including ECW rasters) may have transforms applied with any transformation panel with the following constraints:

1. "Replace existing data" is the only output option supported.
2. The set of parameters supplied for the transformation, when applied to the four corners of the
original raster, results in a rectangle.

3. The raster cannot be selected as a string to be transformed, it should be placed in a model on its own and the model selected as the 'Data to change'.

The raster images themselves will not be altered, only the model information which maps them into world coordinates is changed.

For the Affine panel, this means that different x and y scaling factors may be used, however the two axis rotations must be identical.
28.9.2 Add VIP to SA From File

Position of option on menu: Utilities => A-G => Add VIP to SA from file

This section of documentation is a work in progress and will be updated in subsequent releases.

On selecting Add VIP to SA from file, the Add VIP to SA from file panel is displayed.
28.9.3 2D Affine

Position of option on menu: Utilities => A-G => Affine

An affine transformation is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two perpendicular directions and a rotation of the x-axis and the y-axis. Hence there are six parameters to be specified. Unlike the Helmert transformations, rectangles can be skewed by an affine transformation.

So the affine parameters are:
(a) the x-scale factor for the observed co-ordinates with respect to the control coordinates
(b) the y-scale factor for the observed co-ordinates with respect to the control coordinates
(c) the rotation of the x-axis of the observed co-ordinates to align it with the control x co-ordinates axis
(d) the rotation of the y-axis of the observed co-ordinates to align it with the control y co-ordinates axis
(e) the x and y translation of the existing co-ordinates after the scalings and rotations have been applied

For information on the affine transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine.

For information on how the Affine Transformation works with Rasters, go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters.

On selecting Affine 2D, the Affine 2d panel is displayed.
If the Parameters by choice box is set to **Pt Selection** then control-observed point pairs are selected by the user and the pairs are written to the grid on the panel. See the section [28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations](#) for information on picking control and observed points.

If the Parameters by choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

    - source of data to be processed.
Affine parameters by choice Pt selection Pt selection Direct entry

the parameter entry method.

Pt selection - the control points and their matching observed points are selected by the user after clicking the control button.

Direct entry - the transformation parameter fields are used to type in the parameter data.

Report file *.rpt files
if not blank, write a report on the Affine transformation.

Rotation x angle box
the rotation of the x-axes of the existing points with respect to the transformed x-axis.

Rotation y angle box
the rotation of the y-axes of the existing points with respect to the transformed y-axis.

Scale x input/output
the x-scale factor for the existing coordinates with respect to the transformed coordinates

Scale y input/output
the y-scale factor for the existing coordinates with respect to the transformed coordinates

X Translation input/output
the x translation of the existing coordinates with respect to the transformed coordinates

Y Translation input/output
the y translation of the existing coordinates with respect to the transformed coordinates

Control button
starts the selection process for choosing more control points. The process is terminated when the calculate button is used.

Calculate button
calculate the Affine parameters from the selected points shown in the grid.

Target type
Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input
extra information required for the target.

Affine button
apply the affine transformation to the data specified in the source box, and put it into the appropriate target area.
28.9.4 2D Affine - Orthogonal

**Position of option on menu:** Utilities => A-G => Affine 2D orthogonal

A **2D orthogonal affine transformation** is a two dimensional linear transformation consisting of a 2D-translation (shift) of the data, a scaling of the data in two different directions and the same rotation of both the x-axis and y-axis (about the z axis, like the Helmert). Hence there are five parameters to be specified. Unlike the standard affine transformations, rectangles can not be skewed by the orthogonal affine transformation.

Hence the orthogonal affine parameters are

(a) the x-scale factor for the observed co-ordinates with respect to the control coordinates
(b) the y-scale factor for the observed co-ordinates with respect to the control coordinates
(c) the same rotation of the x-axis and y-axis of the observed coordinates to align it with the control x and coordinate axis
(d) the x and y translation of the observed coor dinates after the scalings and rotations have been applied

For information on the affine transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the Affine Transformation works with Rasters, go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

On selecting Affine 2D orthogonal, the Orthogonal Affine panel is displayed.
If the **Parameters by** choice box is set to **Pt Selection** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1, Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the **Parameters by** choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions.

**Field Description** | **Type** | **Defaults** | **Pop-Up**
--- | --- | --- | ---
**File** | file box | *.ortho_aaf files | 
*Filename can be specified for reading or writing a file to restore the panel contents for re-use.*

**Read** | button | 
*If a valid file exists, the file contents can be loaded into the panel.*

**Write** | button | 
*If a valid name is specified, the user can write the input data to a file.*

**Data to change**
Data source type
data selection type - for a full description go to 4.19.3 Data Source.

Data source input
source of data to be processed.

Parameters by choice Pt selection Pt selection Direct entry
the parameter entry method.

Report file *.rpt files
if not blank, write a report on the orthogonal affine transformation.

Clockwise rotation angle box
the rotation of both x and y axes of the existing points with respect to the transformed x and y axes.

Fixed scale? tick box
if ticked, the x and y scales are typed into the X/Y Scale fields and are held fixed when the orthogonal affine parameters are calculated from the selected control-observed point pairs.

Scale x input/output
the x-scale factor for the existing co-ordinates with respect to the transformed coordinates

Scale y input/output
the y-scale factor for the existing coordinates with respect to the transformed coordinates

X Translation input/output
the x translation of the existing coordinates with respect to the transformed coordinates

Y Translation input/output
the y translation of the existing coordinates with respect to the transformed coordinates

Origin method choice box Pick Pick, Obs’d centroid Ctrl centroid
the translation can be reported against another origin than the default (0,0).

Origin X/Y coordinate input
the translation parameters are written out with respect to this origin.

Control button
restarts the selection process for choosing more control points.

Calculate button
calculate the orthogonal affine parameters from the selected points shown in the grid.

Target type
Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input
extra information required for the target.

Affine button
apply the orthogonal affine transformation to the data specified in the source box, and put it into the appropriate target area.
28.9.5 Archive Models

**Position of option on menu:** Utilities => A-G => Archive models

This option saves all models matching a specified model mask, to 12da files named in the style:

<model name/prefix>[YYYYMMDD HHMMSS].12da

On selecting the Archive models option, the Archive models panel is displayed.

![Archive Models panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model mask</td>
<td>input text</td>
<td></td>
</tr>
<tr>
<td>specifies the model(s) to archive. Use '*' and '?' wildcards to specify multiple models.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Folder for archive files</td>
<td>folder</td>
<td></td>
</tr>
<tr>
<td>a pre-existing folder to write the 12da files to. If unspecified, will write to backups.4d or working folder, depending on the environment variable $USE_BACKUPS_4D_FOLDER_4D.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Decimal places</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>Number of decimal places to use when writing the 12da files. If unspecified, 15 decimal places are used.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Group multiple models per 12da file</td>
<td>tick box</td>
<td>ticked</td>
</tr>
<tr>
<td>if ticked, multiple models may be archived per 12da file, based on the matching first word of each model name. (The first word is the prefix of the model name, before the first space.) If not ticked, one model is archived per 12da file.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Skip existing archives with matching file names</td>
<td>tick box</td>
<td>ticked</td>
</tr>
<tr>
<td>if ticked, existing 12da files with matching names are left untouched and not re-archived. If not ticked, existing files are overwritten.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Include time stamp in file names</td>
<td>tick box</td>
<td>not ticked</td>
</tr>
<tr>
<td>if ticked, include archive date and time stamp in the file names, in the style:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>YYYYMMDD HHMMSS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Run</td>
<td>button</td>
<td></td>
</tr>
<tr>
<td>runs the option</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Special Note**
The Archive Models option is a macro, which may optionally be run from a chain via arguments, rather than via an interactive panel. The details of the argument syntax are written to the Output Window, whenever the macro is run without valid arguments, namely:

```
128 Macro: "model Archive panel.48d" started...

Saves all models matching <model mask> to 128-ascii files named: "<model name>/prefno/YYYYMMDD HHMMSS.126a".

Usage with no arguments: macro is run with a panel interface.

Usage with arguments: model Archive panel <model mask> [4 <folder> [ -group -skip -timestamp]

Arguments:
<model mask> - Models to be archived. Use "*" and "?" wildcards to specify multiple models.
[4 <folder>] - Existing folder to write 126a files to. If unspecified, will write to backups.4d or working folder, depending on USE_BACKUPS.4D_FOLDER.4D.
-group - Group multiple models per 126a file, based on matching first word of model names. If unspecified, one model is archived per 126a file.
-skip - Existing 126a files with matching names are left untouched and not re-archived. If unspecified, existing files are overwritten.
-timestamp - Include archive date and time stamp in file names ("YYYYMMDD HHMMSS" format).

eg1: model Archive panel 047* 4",survey archive" -group -skip
eg2: model Archive panel "CONTROL" -timestamp
```
28.9.6 Cartographic Projections

**Position of option on menu:** Utilities => A-G => Cartographic

The Cartographic option is used to transform data based on the same datum between

(a) two different cartographic projections (based on the same datum)

(b) longitude and latitude and a cartographic projection (based on the same datum)

(c) a cartographic projection and longitude and latitude (based on the same datum).

The Cartographic option has already been documented in the section 17.10.2 Cartographic.
28.9.7 Change

**Position of option on menu:** Utilities => A-G => Change

This Change option is similar to the Change option from the Strings edits menu.

For the selected strings, Change can modify the colour, name, breakline type, style and model of each string.

On selecting the Change option, the Change String Info panel is displayed.

![Change String Info Panel](image)

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data source type</strong></td>
<td>Model</td>
<td></td>

<tr>
<td><strong>New pt-line type</strong></td>
<td>leave as is</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>New weight</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The source of data to be changed.

If non-blank, then the name of the selected strings will be changed to the name given in the new name field.

If non-blank, then the colour of the selected strings will be changed to the colour given in the new colour field.

If non-blank, then the linestyle of the selected strings will be changed to the given in the new style field.
New pt-line type input leave as is leave as is, point, line
if leave as is, then the point-line type of the selected string will be not be changed.
If point string or line string, then the point-line type of the selected string will be changed to that type.

New weight input leave as is leave as is, point, line
if non-blank, then the weight of the selected strings will be changed to the
given in the new weight field.

Target type
Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info input
extra information required for the target.

Change button
process the Data source of selected strings.
28.9.8 Change String Chainage

**Position of option on menu:** Utilities => A-G => Change string chainage

Change string chainage sets the start chainage of the selected strings to a given chainage value.

Selecting the Change string chainage brings up the Change string chainage panel.

![Change String Chainage Panel](image)

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data to change</td>
<td></td>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Change</td>
<td>button</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The fields and buttons used in the panel have the following functions.

**Data to change**

- **Data source type**: Model
  - *data selection type* - for a full description go to [4.19.3 Data Source](#).
- **Data source**: input
  - source of data to be processed.
- **Cut through string**: string select
  - if selected, the position on each string from the "Data to change" source box intersects the selected string will have the chainage from "New Chainage" at that position.
  - if no string is selected, the field is displayed as optional and the "New Chainage" value becomes the start chainage of each string selected from the source box.
- **New chainage**: input
  - value to set the start chainage of all the selected strings to.

**Target type**

- **Data target type**: where to put the processed strings. For a full description go to [4.19.4 Data Target](#).

**Target info**: input
- extra information required for the target.

**Change**
- button
  - process the selected Data source of strings.
28.9.9 Check/Clash

Position of menu: Utilities => A-G => Check/clash

Check/clash options run checks on strings, and clashes between strings.

The Check/Clash walk-right menu is

- check for clashing pipes, drainage strings, etc.
- check for crossing breaklines, duplicate vertices, etc.
- run checks on a polygon
- check strings against a Map File, etc.
- check strings clashing in 3d

For

- Clash detection 28.9.9.1 Clash Detection
- Check breaklines, go to 16.3 Check Breaklines, Duplicate Vertices, Identicals
- Check polygon 28.9.9.2 Check Polygon
- Check strings 28.9.9.3 Check Strings
- 3d service clash 28.9.9.4 Strings Clash in 3d
28.9.9.1 Clash Detection

**Position of menu:** Design => Check/clash => Clash detection  
Utilities => A-G => Check/clash => Clash detection

**Clash detection** checks whether strings clash with each other, and trimeshes of the clash zones can be created. **Rules** can be defined specifying what is a clash.

The **Check/Clash** menu is:

![Check/Clash menu](image)

For the options, see

- **Detection** 28.9.9.1.1 Clash Detection
- **Rules** 28.9.9.1.2 Clash Detection Rules

---

Utilities A-G

Page 6543
28.9.9.1.1 Clash Detection

Position of option on menu: Design => Check/clash => Clash detection => Detection
Utilities => A-G => Check/clash => Clash detection => Detection

Service Clash detection checks whether strings clash with each other, and trimeshes of the clash zones can be created. Rules can be defined specifying what is a clash. For example, you may only want to know about a horizontal clash, but not a vertical clash, or you may want to know if anything clashes not only with a string but within a user given corridor around the string.

Clashes can be detected between strings of the types Super Pipe with straight line segments and Drainage with straight line segments.

Selecting Detection brings up the Service Clash panel

![Service Clash Detection Panel]

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>

*If blank, no report is created.*

**Check**

button

perform the clash checks. Error messages are written to the Output Window as Intelligent Log Lines to help find the problems.
28.9.9.1.2 Clash Detection Rules

Position of option on menu: Design => Check/clash => Clash detection => Rules
Utilities => A-G => Check/clash => Clash detection => Rules

The Service Clash Rules define what is meant by a "clash".

The Service Clash Rules is a tree of Clash Rule Sets and each set has a unique name. The Service Clash Detection panel specifies which of the Clash Rule Sets is to be used for a particular clash detection run.

The Service Clash Rules are loaded from a file called service_clash_rules.xml that is searched for as a standard Set_UPs file. See 39.2 Files for Setting Up 12d.

Selecting Rules brings up the Service Clash Rules panel.

The Service Clash Rules panel

- Each Clash Rule Set is at the first level of the Clash Rule Sets tree
- A Rule in the Clash Rule Set Water vs Gas
- This is at the second level of the tree.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clash Rule Sets Tree</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(a) Clash Rule Set</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A Clash Rule Set is defined at the first level of the Clash Rule Sets tree and each Clash Rule Set must have a unique name. One Clash Rule Set is selected in the Service Clash Detection panel to provide the rules to be used for a particular clash detection run</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A new Clash Rule Set is created by clicking and highlighting the top level Clash Rules Sets and then pressing the Add Child button, or by clicking on and highlighting a first level Clash Rule Set and then pressing the Add button.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A new Clash Rules Set with the dummy name service_clash_rule_set is then created and a new name must be entered in the Name field on the right hand side of the tree. The Description is optional.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(b) Rules in a Clash Rule Set

The rules for a named Clash Rule Set as defined as second level items under the Clash Rule Set. The rules define what is meant by a particular clash.

A new Rule is created by clicking and highlighting the named Clash Rules Set and then pressing the Add Child button, or by clicking on and highlighting a Rule already in the named Clash Rule Set and then pressing the Add button.

A new Rule with the dummy name service_clash_rule is then created and a new name must be entered in the Name field on the right hand side of the tree. The Description is optional.
There must be at least one clash rule in a Clash Rule Set otherwise there is nothing to do. If such a Clash Rule Set is used then no results will be reported.

The Rule defines two separate datasets for each rule - the **Source dataset** containing the elements being checked, and the **Target dataset** containing the elements being checked against. Elements cannot exist in both. They are in either one or the other or neither.

The **Model to check** and **Object name to check** defines the elements that are in the Source data set. Both fields can contain wild cards and wild characters and blank fields will match all elements. That is, blank fields are taken as the wild character *.

The **Model to check against** and **Object name to check against** defines which of the remaining elements (where remaining = all elements minus source data) are in the **Target dataset**. Both fields can contain wild cards and wild characters.

Elements in the **Source dataset** will **only be checked** against elements in the **Target dataset**. Any other objects not in the **Source dataset** or **Target dataset** are ignored.

So you should be specific for the **Source dataset** and cannot be too generic, since being too generic will mean that there are few elements left to be in the **Target dataset** leaving little or nothing to check against.

Hence you should be fairly specific in your **Source dataset** filters, but can be totally generic in the **Target dataset** filters.

To see this in a diagram, if the yellow region represents all the elements in the project and the green region the elements in the **Source dataset**, then the Target dataset (red region) can only be totally outside the green region. So if the green region is very large, then there are not many elements left to be in the red region. The elements in the yellow region that aren’t in the red or green regions are the objects in the project that are totally ignored by that rule.

**Recommendations for Using the Service Clash Detection:**

(a) Model each type of utility in its own model, *e.g.* GAS, WATER, ELEC, TELECOM.

(b) As a minimum create a rule for each service type.

(c) If there are different clearances for different target services being checked, create a rule for each case. *e.g.* Gas vs Water, Gas vs Elec, Gas vs Other.

(d) If you need to check for clashes between utilities of the same type, place these in different models or name them differently so that they can be selected by name, *e.g.* WATER TRUNK and WATER CONNECTIONS or ELEC LEFT and ELEC RIGHT.
(e) Be as narrow and specific with the Source filters as you can be. There is a trade-off, however, between being specific and needing to create multiple rules. Find a balance.

(f) Use standard naming for models and strings and develop standard clash detection rule sets.

(g) You can use map files to help filter out or map strings to certain models to match existing rule sets.

Write Button

When the Write button is selected, a Write Setup File panel comes up to specify where the services_clash_rules.xml file is to be written out to.

For the choices on the panel, see 39.2.6 Writing Out Setup Files

A project restart is required for the new file to take effect
28.9.9.2 Check Polygon

Position of option on menu: Utilities => A-G => Check/clash => Check polygon

Check polygon checks to see if a polygon passes the polygon checks performed by a polygon box. The checks are to try and ensure that the polygon is suitable for use in some 12d options.

For example, a polygon that crosses over itself, or has duplicate vertices, or has edges partially on top of other edges, or in parts consists of a single line, are not usable in most options requiring a polygon (fence) for calculations.

The Exact Volumes options in particular are very sensitive to having a well formed polygon whereas other options can use polygons that are unsuitable for Exact Volumes.

Some of the things that make a polygon unsuitable (and will produce the message "bad polygon" or "bad poly") are:

(a) self intersects in the polygon
(b) multiple vertices at the same (x,y) location
(c) sides being partially on top of other sides
(d) corners just touching other sides or vertices
(e) parts of the polygon that contain no area. For example, a loop at one end and then a line going out from the loop. The line does not enclose any area. This may be created by contouring a surface that contains has a ridge line of constant height.

Errors in the polygon are reported in the Output Window with intelligent log lines to help find the section of the polygon with the error.

Selecting Check polygons brings up the Check Polygon panel

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polygon</td>
<td>select a polygon to check</td>
<td>polygon box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Output model</td>
<td>if non blank, the resolved polygon is added to this model</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Check</td>
<td>perform the polygon checks. Error messages are written to the Output Window as Intelligent Log Lines to help find the problems.</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
28.9.9.3 Check Strings

**Position of option on menu:** Utilities => A-G => Check/clash => Check strings

Check strings compares selected strings against a Map File and also checks distances between vertices on strings.

Selecting Check strings brings up the Check Strings panel.

![Check Strings panel](image)

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data source type</strong></td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Data source</strong></td>

<td></td>
</tr>
<tr>
<td><strong>Min height</strong></td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Max height</strong></td>
<td>input</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Min length**: report if any distance between adjacent vertices in a string is less than Min length.
- **Max length**: report if any distance between adjacent vertices in a string is greater than Max length.
- **Min height**: report if any vertex height is less than Min height.
- **Max height**: report if any vertex height is greater than Max height.
Zero heights tick box
   if ticked, any vertex heights equal to 0.0 will be reported. It is very rare that any height is exactly 0.0

Report file
   if non blank, any failures are reported in this file.

Check button
   process the selected strings
28.9.9.4 Strings Clash in 3d

Position of option on menu: Utilities => A-G => Check/clash => 3d service clash

3d service clash compares selected models of strings and checks to see if they intersect each other.

Selecting 3d service clash brings up the Service Clash panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service clearance file</td>
<td>file box</td>
<td>*.csv files</td>
<td></td>
</tr>
</tbody>
</table>

Service clearance file

- csv file containing a list of model names and clearances. This file is read in as soon as the option starts and fills out the Service and Clearance grid.

Grid - Service model and Clearance

For a row in the grid:

- any string in the model of name Service model must have the clearance given in the Clearance column. That is, any other string must be at least the Clearance distance from the string from the Service model.

When the option starts, the grid is loaded from the Service clearance file. The grid can be modified and whenever the Process button is selected, the contents of the grid is written to the file name given by Service clearance file.

Data source type

- Model

Data source type - for a full description go to 4.19.3 Data Source.
source of data to be processed.

Each string in the data source is processed against all other strings selected by the Data source.

If a string is from a model listed in the Service model and Clearance grid, then the corresponding clearance is used for the string, otherwise the default clearance given in the Clearance panel field is used.

Clash model model box available models

the lines of clash between any two strings is placed in the Clash model.

Clash report

a report is generated for any clashes

Clearance input

the default clearance to use for a string that is not in any of the Service models given in the Service model and Clearance grid

Process button

process the selected strings and check for clashes
28.9.10 Classify Conduits

Position of option on menu: Utilities => A-G => Classify conduits

This option sets attributes on “conduit strings”, i.e. strings of the following type only: Super (with conduit dimensions), Drainage, Pipeline, Pipe.

String attributes set are:
- "justification" (text) on all strings - values set to "invert", "obvert" or "centre".
- "pipe size" (text) on constant-size Super string conduits, Pipeline and Pipe strings.
- "diameter" (real) on constant-size Super string conduits, Pipeline and Pipe strings.
- "width" (real) on constant-size Super string box conduits.

Segment attributes set are:
- "pipe size" (text) on all Super string conduit segments.
- "diameter" (real) on all Super string conduit segments.
- "width" (real) on all Super string box conduit segments.

Notes:
1) Drainage and Pipeline strings are always invert justified.
2) Pipeline and Pipe strings are always circular with a constant diameter.
3) Super string conduits may be circular or box. Drainage strings may be circular, box, vee or trapezoid.
4) For non-circular conduit shapes, attribute "diameter" represents height of conduit.
5) Attribute "pipe size" is in mm (base units x 1000) and supports shapes: circular, box, vee, trapezoid - eg: "600", "1200x600", "V2000x600", "T2000B1200x600".
6) Drainage strings already have Pipe attributes "diameter" and "pipe size" (and potentially "width" and/or "top width") set via the Drainage Network Editor.

On selecting the Classify conduits option, the Classify Conduit Strings panel is displayed.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>

<td></td>
</tr>
<tr>
<td><strong>Run</strong></td>
<td>button</td>
<td>remove/delete the string names from the selected strings</td>
<td></td>
</tr>
</tbody>
</table>
28.9.12 Convert

**Position of menu:** Utilities => A-G => Convert

The convert options are designed to convert large numbers of strings between string types. There is also a global convert option which will convert even more string types.

The convert walk-right menu is

![Convert Menu]

- convert bulk strings
- convert 2d strings to 3d strings
- convert 3d strings to 2d strings
- convert 4d strings to 3d strings
- convert text to 3d points
- convert polylines to alignments
- convert closed strings to closed super strings
- convert strings to super alignments

For the option **Convert**, go to the section

- **28.9.12.1 Convert**
- **28.9.12.2 2d to 3d**
- **28.9.12.3 3d to 2d**
- **28.9.12.4 4d to 3d**
- **28.9.12.5 Text to 3d**
- **28.9.12.6 Poly to alignment**
- **28.9.12.7 Same start/end point strings**
- **28.9.12.8 Convert to super alignments**
28.9.12.1 Convert

Position of option on menu: Utilities => A-G => Convert => Convert

The Convert option converts strings to a selected string type.

On selecting the Convert option, the Convert String Types panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

- *button* convert all the selected strings to the type given in the New type field.
28.9.12.2 2d to 3d

Position of option on menu: Utilities => A-G => Convert => 2d to 3d

The main difference between a 2d and a 3d string is that all the points in a 2d string have the same height. Hence to modify the z-values at individual points, a string must be 3d.

The 2d to 3d option is used to turn 2d (contour) strings into 3d strings.

This option is especially useful when a large number of strings have been read in with constant z-values (for example, cadastre) and the user then wants to modify the heights at each point on the string.

On selecting 2d to 3d and then the appropriate Data Source in the panel, the Convert 2d to 3d Strings in panel is displayed.

![Convert 2d to 3d Strings in panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>

</tr>
</tbody>
</table>

Extra information required for the target.

| Convert             | button                                                                                           |

Convert all the 2d string in the Data source to 3d strings.
28.9.12.3 3d to 2d

Position of option on menu: Utilities => A-G => Convert => 3d to 2d

The difference between a 3d and a 2d string is that all the points in a 2d string have the same height. The 3d to 2d option turns 3d string with a constant height into 2d strings. That is, it only converts 3d strings that have the same height at each point.

This option is useful when contours strings have come from another system as 3d strings, not 2d strings.

On selecting 3d to 2d and then the appropriate Data Source in the panel, the Convert 3d to 2d Strings in panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>

<tr>
<td>Convert</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Convert all the 3d strings with constant height in the Data source to 2d strings.
28.9.12.4 4d to 3d

Position of option on menu: Utilities => A-G => Convert => 4d to 3d

The difference between a 4d and a 3d string is that a 4d string can have a text label at each point on the string. The 4d to 3d option turns 4d string into 3d strings by stripping off the text labels at each point of the 4d string.

On selecting 4d to 3d and then the appropriate Data Source in the panel, the Convert 4d to 3d Strings in panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<thead>
<tr>
<th>Target info</th>
<th>input</th>
<th></th>
</tr>
</thead>
</table>

extra information required for the target.

<table>
<thead>
<tr>
<th>Convert</th>
<th>button</th>
<th></th>
</tr>
</thead>
</table>

convert all the 4d strings in the Data source to 3d strings.
28.9.12.5 Text to 3d

Position of option on menu: Utilities => A-G => Convert => Text to 3d

Sometimes when data for points is received from a CAD systems, all that is received is the text of the z-value of the point and no actual point.

The Text to 3d option will find text representing a z-value and create a new point using the justification point of the text as the (x,y) position and the value of the text as the z-value.

On selecting Text to 3d, the Convert Text Strings to 3d Strings panel is displayed.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data source</td>

28.9.12.7 Same Start/End Point Strings

Position of option on menu: Strings => Properties => Same start/end point strings
Position of option on menu: Utilities => A-G => Convert => Same start/end point strings
Position of option on menu: Utilities => Super strings => Same start/end point strings

When non super string strings are closed, an extra vertex identical to the first vertex is added to the end of the string. For super strings, there is a closed string flag and no duplication of the first and last vertices is required.

This option converts closed non super strings to closed super strings and deletes the duplicated vertex.

Selecting Same string/end point strings brings up the Convert Same Start/End Point Strings panel.

![Convert Same Start/End Point Strings Panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>

<td></td>
</tr>
</tbody>
</table>

Data source type - for a full description go to 4.19.3 Data Source.

Data source - source of data to be processed.

Pass other strings - if ticked, copy all other strings and pass them through to the target model.

Target type - Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target.

Target info - extra information required for the target.

Convert - convert all the closed strings to closed super strings with duplicated end point.
28.9.12.8 Convert to Super Alignment

Position of option on menu: Utilities => A-G => Convert => Convert to super alignments

The Convert option converts strings to super alignments, either with just IPs or using Elements.

Note - conversion to Elements is only possible if you have the Alignment module.

Selecting Convert to super alignments brings up the Convert to Super Alignment panel.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>

<td></td>
</tr>
</tbody>
</table>

Field Description and Type:
- **Data source type**: Model data selection type - for a full description go to 4.19.3 Data Source.
- **Data source**: input source of data to be processed.
- **Convert mode**: choice box IPS, Elements
  - If **IPs**, the strings are converted to super alignments with IPs.
  - If **Elements**, the strings are converted to super alignments using Elements.
  - Note - if the user does not have the Alignment module, then the Convert mode is automatically set to IPs.
- **Target type**: Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target.
- **Target info**: input extra information required for the target.
- **Convert**: button convert all the selected strings to either super alignments with IPs or super alignments with Elements.
28.9.13 Cuts

Position of menu:  Utilities => A-G => Cuts

Cuts is used to create intersections through string data rather than tins.

That is, it calculates the cuts that a plan string makes with each of the strings in a model or view, and creates cut points with the z-value from the cut strings.

The cut points that the plan string creates are connected as a 4d string - the x-section of cuts through a model or view - with the z value coming from the cut string, and the text at the point being the name of string that was cut.

There are two methods for generating the cuts x-sections

(a) by taking sections along selected strings or all the strings in a model or view

(b) by taking sections at regular intervals and perpendicular to a selected centre line string.

The Cuts walk-right menu contains these two methods

For the option by strings, go to the section 28.9.13.1 Cuts by Strings.

For the option by centreline, go to the section 28.9.13.2 Cuts by Centreline.
28.9.13.1 Cuts by Strings

Position of option on menu: Utilities => A-G => Cuts => by strings

by strings generates cuts through a Data source of strings, for all the strings in a user specified model.

For each string in the Model of strings, the plan representation of the string is cut through the all the string in Data to cut through, to generate cut x-sections.

Selecting by strings displays the Cuts Through panel.

The fields and buttons used in this panel have the following functions:

</tr>
</tbody>
</table>
28.9.13.2 Cuts by Centreline

Position of option on menu: Utilities => A-G => Cuts => by centreline

For by centreline, a centre line string is selected by the user and temporary plan lines are created at regular intervals perpendicular to the selected string.

Cut x-sections are then generated for the temporary plan section lines by taking cuts through the Data source Data to cut through.

Selecting by centreline displays the Cuts from CL for panel.

The fields and buttons used in this panel have the following functions:

<table>
<thead>

</tbody>
</table>

The fields and buttons used in this panel have the following functions:

Field Description      | Type | Defaults | Pop-Up |
------------------------|------|----------|--------|
Data source type        | Model|          |        |
Data source              | input|          |        |
Section separation       | input| 10.0     |        |
data source.

Special chainages input *.spf files
a file containing chainages, one per line, that are also used as chainages to create cross sections at.

Gather vertical points of interest tick box
whether or not to create cuts at vertical points of interests (sags, crests, vertical tangent points etc)

Chord/arc tolerance input default chord/arc tolerance
the chord to arc tolerance to use on the selected string for determining how many plan sections are created around horizontal curves.

Left/Right cut width input 50
the left/right distance to go out from the centre line for creating a section to cut through the strings.

Model for cuts input available models
model to place the cut x-section strings into.

Clean cuts model beforehand tick box
if ticked, the model is cleaned of all data before new sections are created.

Colour for cuts colour box available colours
colour for the cut section strings

Keep null levels tick box
if ticked, then if a null level exists on the string being cut, then a null level point is created.

Select cl string-select
the selected cl string is used to create plan section lines at regular intervals and perpendicular to the centre line string. These strings are cut though the model/view of strings.

Start/End chainage input
if non-blank then sections for the cuts are restricted to between the given start and end chainage of the selected cl string.

End Area Calculations

Tin tin box available tins
if non-blank, the cut and fill areas for the section against the tin are calculated and added as attributes to the section.

Strip depth input
if non-zero, then a strip depth is removed from the tin before the cut and fill areas for the section against the tin are calculated.

Cut button
each plan section line generated down the selected centre line string is processed against all the strings in the Data source. The 4d strings of cuts are placed in the Model for cuts.
28.9.14 Delete

Position of option on menu: Utilities => A-G => Delete

The Delete option deletes all the selected strings.
On selecting the Delete option, the Delete panel is displayed.

![Delete Panel]

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
28.9.15 Draw a Perpendicular from Centreline to a Point

Position of option on menu:  Utilities => A-G => Draw perpendicular cl to points

This option creates strings drawn perpendicular from reference alignments to selected points, and output a Special Chainage (SPC) file of the reference chainages that the points are perpendicular to. The user has the choice of either output, or both.

Typical uses are to create a model of cut strings which can be used to for cut labelling on long section plots where features such as property access locations occur along the road corridor, or to write SPC files that can be used to create cross sections through the dropped points when running Apply MTF functions.

Selecting Draw perpendicular cl to points displays the Draw a Perpendicular from Centreline to a Point panel.

The fields and buttons used in this panel have the following functions...
### Data Points To Drop

Gathers a list of all the points on the selected strings.

*For a full description of data source go to 4.19.3 Data Source*

### Data Reference Strings

Selects the reference strings that the above points will be dropped onto. Reference strings must be of type Alignment or Super Alignment.

*For a full description of data source go to 4.19.3 Data Source*

### Drop all points from chosen strings?

**tick box**

*The default is to calculate chainages and/or strings from every point in the selected strings. Turning this tick box off will restrict the calculation to the end points only. E.g. It can be used to create cut strings for use with the paired cuts functionality in long section plotting.*

### Offset Tolerance

**input**

*Will restrict the search to points that fall within the specified width from the reference string.*

### Outputs

#### Name mode

**choice box**

*For the From point text mode, the name of the new string is set by the text attached to the points. For the From string names mode, the name of the new string is set by the selected strings. For the Typed mode, the name is given in the Name field.*

**name box names.4d file**

*This only needs to be filled in when using the Typed name mode. This field is not required for the other Name mode choices.*

**model box available models**

*The model to store the new strings on. This field is optional and no strings will be created if left blank. E.g. if you only want Special Chainage Files.*

**colour box available colours**

*The colour to draw the new strings with.*

**linestyle box available linestyles**

*The linestyle to draw the new strings with.*

#### Z value mode

**choice box**

*The method by which z values are assigned to the points on the new string.*

*For the 2d from point mode, all points have the same z value as the point being dropped. For the 2d from reference mode, all points have the same z value as the reference string. For the 3d reference to point mode, the new string is drawn from the z value at the reference to the z value of the dropped point.*

**measure box**

*At point, Point to Point, String from Point, String to Point*
End extension measure box 1 At point, Point to Point, String from Point, String to Point

Write SPC Files(s)? tick box ticked

The writing of Special Chainage Files is optional. If ticked, the names of the files are automatically derived from the combination of Model name and Reference string name and a user defined file stem (given in the SPC file stem field) may be added to the name.

SPC File Stem text box

An optional user entered text value that is added to the automatically derived file name.

Process button

run the option.
28.9.16 Duplicate

**Position of option on menu:** Utilities => A-G => Duplicate

Duplicate makes duplicates of strings.

Selecting Duplicate displays the Duplicate panel.

![Duplicate panel](image)

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>

</tbody>
</table>

<esc> can be used to abort the duplicate option.
28.9.17 Explode

Position of option on menu: Utilities => A-G => Explode

The Explode option explodes point strings into individual one vertex strings and line strings into individual segments.

Super alignment, Alignment, pipeline, sewer and drainage strings are not exploded.

On selecting Explode and then the appropriate Data Source in the panel, the Explode Strings in panel is displayed.

![Explode Strings in panel](image)

28.9.18 Explode Text

**Position of option on menu:** Utilities =>A-G => Explode (text)

**Explode (text)** explodes text in text strings and the text from 4d strings, into its component arcs and lines. The exploded arcs and lines are placed in one new model.

Selecting **Explode (text)** displays the **Explode Text in** panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

<td></td>
</tr>
</tbody>
</table>
28.9.19 Factor

**Position of option on menu:** Utilities => A-G => Factor

Factor multiplies the x, y and z values of selected strings by user supplied factors. The option is useful for changing the units of any data in a model (e.g. Imperial to metric). Selecting Factor displays the Factor panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

* multiply the (x,y,z) values of the selected strings by the x,y and z factors given in the appropriate panel fields.*

**WARNING** - if the x factor and y factor are not equal, then arcs in arcs, circles, alignment and polyline strings can not be factored. For these cases, the y factor will be set the x-factor and then applied to the arcs.
28.9.20 Filter

**Position of menu:** Utilities => A-G => Filter

The Filter options are used to remove surplus points from strings.

Three types of filters are currently supported in 12d Model:

- a string filter, which removes points from 2d and/or 3d line strings that do not deviate by more than a specified offset tolerance from straight lines joining successive string points (in three dimensions for 3d strings)
- a vertex-filter which removes adjacent vertices closer than a given user defined (x,y) and z distance
- a z-filter which eliminates points not contained within a specified z-range

The Filter walk-right menu is

![Filter menu]

For the option **String filter**, go to

- **28.9.20.1 String Filter**
- **28.9.20.2 Vertex Filter**
- **28.9.20.3 Z Filter**
28.9.20.1 String Filter

**Position of option on menu:** Utilities => A-G => Filter => String filter

The String filter option is used to remove surplus vertices from 2d strings (contours) and 3d strings.

The string filter option tries to drop out vertices that if left out, don't make "too much difference". So for a user defined tolerance:

if you have successive vertices A, B and C, and by leaving out vertex B, then the lines AB and BC don't go outside a tube of radius tolerance around the lines AC, then vertex B is dropped.

![String Filter - Vertex B Can Be Dropped](image1)

![String Filter - Vertex B CAN'T be Dropped](image2)

![String Filter - Working from A, the vertices from A to E will be Dropped](image3)

The filter starts at the first vertex of the string and looks ahead, dropping out vertices until it finds one that can't be removed. That vertex then become the new second vertex and the process is repeated but starting at the new second vertex. This process is repeated for the new third vertex.
and so on until the end of the string.

The tolerance value used normally depends on the data set and the job that the data is being used for.

So the string filter removes vertices from 2d and/or 3d line strings that do not deviate by more than a specified offset tolerance from straight lines joining successive string vertices (in three dimensions for 3d strings).

**NOTE** - string filter does not apply to point strings.

Selecting String filter displays the Filter Strings in panel.

The fields and buttons used in this panel have the following function:

<table>

filter all the selected strings.
28.9.20.2 Vertex Filter

Position of option on menu: Utilities => A-G => Filter => Vertex filter

The Vertex filter option is used to remove close adjacent vertices from selected strings. The strings can be point or line strings.

The option can remove adjacent string vertices that are equal to a given tolerance either in plan position only (i.e. have similar x and y co-ordinates) or equal to a given tolerance for x, y and z co-ordinates.

Selecting Vertex filter displays the Filter adjacent vertices in panel.

- extra information required for the target.

**Filter**

- **button**
- filter the selected strings.
28.9.20.3 Z Filter

Position of option on menu: Utilities => A-G => Filter => Z filter

It is often necessary to remove data which is not within a certain z range. For example, all points with z-values below 0.0. The z filter option allows the user to define a z-range by specifying a minimum and maximum z value.

Strings of type 2d, 3d and 4d can then be processed against the z-range and new strings created containing only those points that are

(a) within the z-range - accepted points

or

(b) outside the z-range - rejected points

For all other string types, the entire string is accepted if any part of the string is within the z-range, otherwise it is rejected.

Selecting Z filter displays the Z Filter Strings in panel:

![Z Filter Strings in panel](image)

28.9.21 Grid setout

**Position of option on menu:** Utilities => A-G => Grid setout

*Grid setout* creates a set of points from the intersections of lines and/or arc strings. The strings to intersect normally form a grid.

It is assumed that the strings to intersect are named with letters along one axis of the grid and numbers in the other so that a point may be named in the following manner: 1a or a1.

Selecting *Grid setout* displays the *Grid Setout* panel.

![Grid setout panel]

*Data source* - source of data to be processed.

*New height* - the new height to set all the z-values in the selected strings to.

*Do null heights* - if ticked, null heights are set to the new height. If not ticked, null heights are not modified.

*Target type* - Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

*Target info* - extra information required for the target.

*Set* - process the selected string.
28.10.4 Helmert Transformations

See 28.10.4.1 2D Helmert (Advanced)  
28.10.4.2 3D Helmert

28.10.4.1 2D Helmert (Advanced)

Position of option on menu: Utilities => H-Z => Helmert 2D (Advanced)

A 2D Helmert transformation is a two dimensional linear transformation consisting of a scaling, rotation and a 2D- translation (shift) of data. That is, there are four parameters to be specified.

Hence the 2D Helmert parameters are

(a) the one scale factor for both the x and y axes
(b) the same rotation of the x-axis and y-axis of the existing coordinates to align it with the control x and coordinate axis
(c) the x and y translation of the observed coordinates after the scalings and rotations have been applied

The 2D Helmert (Advanced) option calculated and applied a Helmert transformation, and also allows the user to fix the scale for the transformation. That is, the scale is user defined and not determined by the least squared calculations.

For information on the 2D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the Affine Transformation works with Rasters, go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

Selecting 2D Helmert (Advanced) brings up the Helmert 2D (Advanced) panel.
If the Parameters by choice box is set to **Pt Selection** then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 *Selecting Control and Observed Points for the Helmert and Affine Transformations* for information on picking control and observed points.

If the Parameters by choice box is set to **Direct entry**, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>

Target info

input

extra information required for the target.

Helmert

button

apply the helmert transformation to the data specified in the source box, and put it into the appropriate target area.

Inverse

button

applies the inverse transformation to the one defined in the panel.

Finish

button

end the option, remove the panel from the screen.
28.10.4.2 3D Helmert

Position of option on menu: Utilities => H-Z => Helmert 3D

A 3D Helmert transformation is a three dimensional linear transformation consisting of a scaling, three rotations, and a 3D-translation (shift) of data. Hence there are 7 parameters to be specified.

For information on the 3D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

For information on how the Affine Transformation works with Rasters, go to the section 28.9.1.2 Affine and Helmert Transformations Applied to Rasters

Selecting Helmert 3D brings up the 3D Helmert panel.

If the Parameters by choice box is set to Pt Selection then control-observed point pairs are selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the Parameters by choice box is set to Direct entry, the transformation parameters are
manually entered into the panel and the grid section is not used.

**Change** | button | | 
*Change all the null z-values in the selected strings to the value in the New height field.*
28.10.7 Parallel String

**Position of option on menu:** Utilities => H-Z => Parallel string

This option parallels horizontally one or more strings (the option Strings => Strings edit => Parallel only parallels one string at a time).

It is a macro and runs in two ways:

1. from the menu or
2. via a command line interface that does not require user interaction.

**Note:** the command line interface is available so that the option can be run in a chain if the macro cannot be recorded in a chain. If the macro is called without any command line arguments, then it will assume it is being run in the graphical, interactive manner and will display a panel to the user. Otherwise, the macro will parse the relevant command line arguments and run without user interaction.

Selecting `Parallel` brings up the **Parallel Strings** panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data source</td>
<td>input</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Offset</td>
<td>measure box</td>
<td>0</td>
<td>available measures</td>
<td></td>
</tr>
<tr>
<td>Target type</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The direction of the source string is used to determine the left and right side of the string in the parallel operation. A positive offset parallels the string to the right with respect to the string direction. A negative offset parallels to the left with respect to the string direction.
Data target type - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info

input
extra information required for the target.

Process

button
processes the selected data.

Note When Using the Option With Command Line Arguments:

When calling the macro using the command line interface, it must be called according to the following format:

parallel_strings_panel.4do "SOURCE MODEL" offset "TARGET MODEL"

The first argument passed must be the name of a model containing the data to process. The source model of data to process must be the first argument provided to the macro.

The second argument must be the offset distance to parallel the source strings. This can be negative or positive, but it must be a valid real number (e.g. 1.234, -567.00, 0).

The third and final argument must be the name of the model in which to place the resultant paralleled strings.

If any of the fields contain spaces, they must be enclosed in quotes

For example:  "SOURCE DATA"

When using the command line interface, there must be 3 and only 3 arguments. Any fewer or more will be considered an error and will stop the macro from progressing any further.

Refer to the description of the fields in the Graphical User Interface section for further details, including restrictions on fields and expected behaviour

The macro uses the Parallel() function made available through the macro language. As such, the string types supported and behaviour of the macro is dependent on the implementation of that function.
28.10.8 Polygon Discovery

**Position of option on menu:** Utilities => H-Z => Polygon discovery

Polygon discovery takes a selected position/point on a plan view and from the data displayed on the view, finds the polygon enclosing the selected position/point from the line and arc segments in strings around the position/point.

The name, colour and model for the created polygon are taken from the CAD Tool bar.

Selecting Polygon discovery brings up the **Polygon Discovery** panel.

![Polygon Discovery Panel](image)

The fields and buttons used in the panel have the following functions.

<table>

</tbody>
</table>

  extra information required for the target.

<table>
<thead>
<tr>
<th>Reverse</th>
<th>button</th>
</tr>
</thead>
</table>

  reverse the direction of the selected strings.
28.10.11 Rotate

**Position of option on menu:** Utilities => H-Z => Rotate

*Rotate* rotates all the selected strings about a central point (the rotation centre). The strings are rotated through a user supplied angle and can be moved or copied to their new rotated position.

The difference between a copy and a move is that if a string is **copied**, a copy of the string is rotated and the original string left untouched, whereas for a **move**, the actual string is moved from its original position to the new rotated position.

Selecting **Rotate** displays the **Rotate** panel.

![Rotate panel](image)

The centre of the rotation is defined by selecting the **Centre** button and picking a point as the new centre. The centre can be changed at any time by using the **Centre** button to select another centre.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

Target info  
input

extra information required for the target.

Rotate  
button

rotate the selected data.
28.10.12 Rotate Relative

Position of option on menu: Utilities => H-Z => Rotate relative

Rotate Relative allows multiple strings to be rotated in the XY plane by a user given angle and about various base points (rotation centres).

The simpler Rotate option (Utilities => H-Z => Rotate) only rotates the selected strings about a single point.

Rotate Relative is more flexible and has many methods for defining the base points (rotation centres), even allowing individual strings to have their own base point. In this case, the base point for rotation is calculated for each string in the Data Source and the rotation applied to each string individually. For example, Relative Rotate can rotate strings where the base point for each string is the start vertex of each string.

Allowing various base point modes allows greater flexibility in rotating many strings at once.

Rotate Relative performs a 2d rotation of strings. That is, the rotation is only in the XY plane.

The strings can be moved or copied to their new rotated position. The difference between a copy and a move is that if a string is copied, a copy of the string is rotated and the original string left untouched, whereas for a move, the actual string is moved from its original position to the new rotated position.

Selecting Rotate Relative displays the Relative Rotate panel.

The fields and buttons used in the panel have the following functions.
<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>source box</td>
<td>Model</td>
<td></td>
</tr>
<tr>
<td>Rotation angle (dms)</td>
<td>angle box</td>
<td>0°</td>
<td></td>
</tr>
<tr>
<td>Direction</td>
<td>choice box</td>
<td>Clockwise</td>
<td>Clockwise, Counter-clockwise</td>
</tr>
<tr>
<td>Pick Angle by 3 points</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Upon clicking the button, the user will be asked to pick the:

1. Base point about which the angle is measured (A);
2. Reference point (B); and
3. New point (C).

The Rotation angle and Direction will be calculated based on the 3 picked points.

Base point mode | choice box | Start of string | Start of string, End of string, Middle of string, Middle Vertex, Vertex Number, Chainage, Chainage & Offset, Coordinates, Angle by 3 pts Vertex, Justification point (Text only!) |

allows the user to define how the base point for the rotation is determined for the data. Valid options include:

- Start of string – the base point is the start of each string
- End of string – the base point is the end of each string
- Middle of string – the base point is the middle (based on chainage) of each string
• Middle Vertex – the base point is the middle vertex of each string. In the case of a string with an even number of vertices, the behaviour of this routine can be varied. Refer to the Middle Vertex Mode in the Advanced tab.

• Vertex Number – the base point is a specific vertex of each string, specified by the vertex number. The start vertex is 1, the next vertex 2 and so on for a string with n vertices. The vertex number may also be specified as a negative number to count vertices from the end of the string back towards the start. In this case, for a string with n vertices, a vertex number of -1 is the last vertex (nth vertex), -2 the 2nd last vertex (n-1), and so on until the first vertex number is ~n. If the specified vertex number exceeds the string extents, then an error will be produced and the string skipped.

• Chainage – the base point is calculated at a specific chainage along each string. Where the chainage is beyond either end of a string, the behaviour of this routine can be varied. Refer to the Base point chainage extend mode in the Advanced tab.

• Chainage & Offset – the base point is calculated at a specific chainage along and offset from each string. The standard convention of a negative offset to the left of the string and positive offset to the right of the string applies.

• Coordinates – the base point is specified by a set of coordinates. In this mode, the routine behaves in the same way as the normal Rotate routine- the same base point is used for all strings. The Z coordinate is not optional and must be entered, even if it is zero. The Z coordinate, however, does not affect the rotation.

• Angle by 3pts Vertex – the base point is the set of coordinates selected when the Angle by 3 pts was picked. This is the coordinates of point A in the diagram above.

• Justification point (Text only!) – the base point is the justification point of a Text object. Note that this only applies to Text objects- all other objects will be skipped in this mode.

The fields displayed on the panel will change depending on the base point mode chosen.

**Vertex number**
integer box 1
the vertex number to be used as a base point. Enabled for Vertex Number mode only.

**Chainage**
real box 0
the chainage to be used for calculating the base point. Enabled for Chainage and Chainage & Offset modes only.

**Offset**
real box 0
the offset to be used for calculating the base point. Enabled for Chainage & Offset mode only.

**Base Point**
xyz box 0,0,0
the coordinates (X, Y, Z) to be used as the base point. Enabled for Coordinates mode only.
Advanced Tab

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base point chainage extend mode</td>
<td>choice box</td>
<td>Limit to end of string</td>
<td>Skip with error,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Limit to end of string</td>
<td>Limit to end of string,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Extend beyond string</td>
</tr>
</tbody>
</table>

controls the behaviour of the routine when the base point mode is Chainage and the specified chainage is beyond the string extents.

- *Skip with error* – the string will be skipped, with an error written to the output window
- *Limit to end of string* – the base point will use the chainage of the nearest end point
- *Extend beyond string* – the base point will be calculated based on a projection beyond the string to the specified chainage and based on the bearing of the nearest end.
Middle vertex mode choice box Lower vertex Skip with error, Lower vertex< Higher vertex

controls the behaviour of the routine when the base point mode is Middle Vertex and the string has an even number of vertices. Where the string has an even number of vertices, the middle vertex can be one of two possibilities.

Skip with error – the string will be skipped, with an error written to the output window

Lower vertex – the lower-numbered vertex will be used as the middle vertex

Higher vertex – the higher-numbered vertex will be used as the middle vertex

Add attributes tick box ticked

writes the various relative rotate settings to the rotated string as string attributes.

Output messages tick box ticked

writes various output messages when run. If not ticked, no output messages will be produced by the routine, including critical warning and error messages.

Use log lines tick box ticked

use intelligent log lines for the certain output messages. If not ticked and output messages are enabled, the messages will be normal messages.

data selection type - for a full description go to 4.19.3 Data Source

Target info
input
extra information required for the target.

Rotate
button
rotate the selected data.
28.10.13 Set Constant Z-Values

Position of option on menu: Utilities => H-Z => Set constant z-values

This option sets all the points on a string to the same elevation - the average, highest, or lowest z-value of each selected string's z-values.

For example, the option can be used to set a starting value for building pads.

The user can drape a string then average the z-values to get close to a volumes balance. Alternatively, the user can opt for the highest z-value calculated by the drape, i.e. the entire platform is in fill, or select the lowest z-value so the entire platform is in cut.

Selecting Set constant z-values brings up the Set Constant Z-Value panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td>data selection type - for a full description go to 4.19.3 Data Source</td>
<td></td>
</tr>
<tr>
<td>Data source</td>
<td>input</td>
<td>source of data to be processed.</td>
<td></td>
</tr>
<tr>
<td>Z value mode</td>
<td>choice box</td>
<td>Average, Highest, Lowest</td>
<td></td>
</tr>
</tbody>
</table>

if Average, the string is given the Z value that is the average of all the vertex Z values.

If Highest, the string is given the Z value that is the highest of all the vertex Z values.

If Lowest, the string is given the Z value that is the lowest of all the vertex Z values.

Process button

sets the constant z-value for the selected strings.
28.10.14 Set Strings Directions

**Position of option on menu:** Utilities => H-Z => Set strings directions

Set strings directions attempts to set the direction of select strings to be the same as the direction of a selected reference string.

On selecting Set strings directions, the Set Strings Directions panel is displayed.

![Set Strings Directions Panel]

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>

</tr>
</tbody>
</table>

*Data source type - for a full description go to 4.19.3 Data Source*

*Data source - for a full description go to 4.19.3 Data Source*

*Reference string - the string that is used as the reference direction. This is the direction that, if possible, the selected strings are given.*

*Target type - for a full description go to 4.19.4 Data Target*

*Target info - extra information required for the target.*

*Change - change the direction of the selected strings.*
28.10.15 Set Heights for 2d/Super Strings

Position of option on menu: Utilities => H-Z => Set heights for 2d/super strings

Set heights for 2d/super strings is used to quickly change the height of selected 2d strings or 2d super strings (super strings with a constant z value). It is especially useful when you have a lot of contours without z-values and you wish to give them z-values.

An initial height and increment is given and as each string is selected, it is given the current height and the height then incremented for use when picking the next string.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Height increment</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Colour</td>
<td>input</td>
<td>available colours</td>
<td></td>
</tr>
<tr>
<td>Target type</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Target info</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Update string</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Height** to used as the height for the next selected string. This is incremented by the **Height increment** after each string is accepted.

As each string is accepted and given the **Height**, **Height** is incremented by this value.

If not blank, the selected strings are given this colour when their z-value is changed.

If blank, the selected strings keep their original colour.

**4.19.4 Data Target**

Where to put the processed string - for a full description go to

Update string

After clicking on the **Update string** arrow icon, 2d strings are selected and when accepted, have their z-value changed to the value in **Height**. The height value is then automatically incremented by **Height increment**. The next string is then selected and accepted (without needing to click on **Pick** again). This continues until **Cancel** is selected from the **Pick Ops** menu.
28.10.16 Smooth Strings

Position of option on menu: Utilities => H-Z => Smooth strings

The Smooth options are used to add extra points into 2D or 3D strings to make a smoother string.

Selecting Smooth strings displays the Smooth Strings panel.

The fields and buttons used in this panel have the following function:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model data selection type - for a full description go to 4.19.3 Data Source.</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data source</td>
<td>Data source to be smoothed.</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Model for smoothed strings</td>
<td>Model for the smoothed strings to go to</td>
<td>available models</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Preserve string points</td>
<td>Tick box</td>
<td>tick box</td>

<td></td>
</tr>
<tr>
<td>Pass other strings</td>
<td>Tick box</td>
<td>tick</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Smooth</td>
<td>Button</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- If ticked, the smoothed strings will still contain all the original points.
- If not ticked, the smoothed strings may deviate from the original string points.
- If ticked, any strings that can’t be smoothed are copied and added to the smoothed strings model.
28.10.17 Swap XY

Position of option on menu: Utilities => H-Z => Swap XY

The Swap xy option is used to swap the (x,y) coordinates of selected strings. Selecting Swap XY displays the Swap XY String/Model/View panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data source</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Target info</td>
<td>input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Swap XY</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

data selection type - for a full description go to 4.19.3 Data Source.

source of data to be have the XY coordinates swapped.

Data target - where to put the processed string. For a full description go to 4.19.4 Data Target.

extra information required for the target.

swap the selected strings and add them to the target.
28.10.18 Test Wildcards

Position of option on menu: Utilities => H-Z => Test wildcards

Test wildcards is used to test the effect of pattern expressions and regular expressions on text.

Selecting Test wildcards displays the Pattern/Regular Expression Tester panel.

The Search/Replace criteria and the Pattern expression or Regular expression are applied to the data in the Input column and the results are placed in the Output column.
28.10.19 Text

Position of option on menu: Utilities => H-Z => Text

The Text option is used to change the text style, units, height, offset, justification, angle and text for text, 4d strings and super strings.

For this option the selection process is extended from the standard Data Source.

After the data is selected as defined by the Data Source, the two extra parameters, Old text and the Textdata parameters in Info, are used to further specify which text is to be selected and modified.

Selecting Text displays the Change Text Info panel.

The fields and buttons used in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td></td>
</tr>
</tbody>
</table>

Data selection type - for a full description go to 4.19.3 Data Source.

Data source input

source of data to be processed.
Use regular expressions  
tick box  
not ticked  
if ticked, then Regular expressions given in the Old and New fields are used to modify the text.

Ignore case  
tick box  
ticked  
if ticked, the search for Old text will make a match independent of upper or lower case.  
If not ticked, the search for Old text will treat upper or lower case as being different.

Any matched text is replaced by new text.

Old text  
input  
if the Old text field is non-blank, then any text in 4d or text strings will be checked for a match against this value. Wild cards and characters can be used.

Info  
input  
if non-blank, then only strings which match these Textdata parameters will be selected.

New text  
input  
if non-blank, then any selected text the selected strings will be modified to this value. Wild cards and characters can be used.

Info  
input  
if non-blank, then the select text on the selected strings will be given these Textdata parameters.

Target type  
Data target - where to put the processed strings. For a full description go to 4.19.4 Data Target

Target info  
input  
extra information required for the target.

Convert  
button  
run the option and change the selected text.
28.10.20 Translate

Position of option on menu: Utilities => H-Z => Translate

Translate is used to translate the selected strings through a user supplied translation vector (dx,dy,dz).

The strings can be translated in the x,y and z directions and be moved or copied to their new translated positions.

The difference between a copy and a move is that if a string is copied, a copy of the string is translated and the original string left untouched, whereas for a move, the actual string is moved from its original position to the new translated position.

Selecting Translate displays the Translate panel.

![Translate Panel](image)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source type</td>
<td>Model</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Data source type - for a full description go to 4.19.3 Data Source

Data source

input

source of data to be processed.

dx dy dz

input

the translation vector (dx,dy,dz). This vector is added to all points in the strings.

The translation (dx dy dz) can be typing into the dx dy dz field or by picking the dx dy dx button and then selecting two points with the cursor. When two points are selected, the difference vector of the two selected points is taken as the translation vector (dx,dy,dz). The (dx,dy,dz) value is piped into the dx dy dz field.

Target type

Data target - where to put the processed string. For a full description go to 4.19.4 Data Target
Target info input
extra information required for the target.
Translate button
translate the selected strings.

How to Use the Panel
(a) Enter the Data source for the strings to be translated.
(b) Define the translation vector \((dx \ dy \ dz)\) by either typing the value into the \(dx \ dy \ dz\) field or by selecting the \(dx \ dy \ dz\) button and picking two points to define the translation vector. The resulting \((dx \ dy \ dz)\) values are piped into the \(dx \ dy \ dz\) field.
(c) Select the target mode.
(d) Selecting the Translate button then does the required translations (moves or copies).
28.11 Old

Position of option on menu: Utilities => Old

The Old Utilities contains superseded options. They should no longer be used.

For Check breaklines, go to
  Check breaklines (advanced)  28.11.1 Check Breaklines
  Helmert 2D  28.11.2 Check Breaklines (Advanced)
  28.11.3 2D Helmert
28.11.1 Check Breaklines

Position of option on menu: Utilities => Old => Check breaklines

For information on this option please go to the section 16.4 Check Breaklines - Old
28.11.2 Check Breaklines (Advanced)

**Position of option on menu:** Utilities => Old => Check breaklines (advanced)

This section of documentation is a work in progress and will be updated in subsequent releases.

The fields and buttons in the panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>

</table>
Data set 2

Data set 2 source type  Model
  data selection type - for a full description go to 4.19.3 Data Source.

Data set 2 source  input
data to be processed.

Intersecting strings with valid heights  model box  available models
  if non-blank, check for any crossing line segments and place either a copy of the crossing segments into
  the model given in this field or a diamond depending on the state of Simple crosses.

Duplicate vertices of different heights  model box  available models
  if non-blank, copies of any strings that are completely duplicated are placed in the model given in this
  field and circles are placed in this model at any duplicate points that aren't from an entire string.

Identical strings in all details  model box  available models
  if non-blank, the duplicates of any strings are moved to model given in this field. That is, if any strings
  are identical in all ways, then the second and subsequent identical strings are moved to the this model.
  This is especially for the case when a second copy of some data has been supplied.

Self check strings  tick box  tick
  if ticked, a string is not check against itself for crossing breaklines etc.
  If not ticked, a string is not checked against itself for crossing breaklines. This speeds up processing.

Colour for intersections  colour box  available colours
  colour for the copies of the crossing segments.

Clean models beforehand  tick box  tick
  if ticked, the models for intersecting string, duplicate points, identicals are cleaned before the option is
  run.

Report file  file box
  if non-blank, a report file of this name is created giving details of all the crossing breaklines and
  duplicate plan points with different z-values.

Simple crosses  tick box  tick
  if ticked, create diamonds at the position where strings cross, otherwise create a string in the shape of
  a cross with parts of the crossing strings.

Check  button
  after selecting the check button, all the strings in the model/view are tested for any crossing line
  segments or duplicate points. If requested, a report is generated.

<esc> can be used to abort the checking option.
28.11.3 2D Helmert

Position of option on menu:  Utilities => Old => 2D Helmert

NOTE - this option has been superseded and should not be used. It is for upward computability only.

A 2D Helmert transformation is a two dimensional linear transformation consisting of a scaling, rotation and a 2D- translation (shift) of data. Hence there are four parameters to be specified:

Hence the 2D Helmert parameters are
(a) the one scale factor for both the x and y axes
(b) the same rotation of the x-axis and y-axis of the existing coordinates to align it with the control x and coordinate axis
(c) the x and y translation of the observed coordinates after the scalings and rotations have been applied

For information on the 2D Helmert transformation, please go to the section 28.9.1 Coordinate Transformations - Helmert and Affine

This case of a fixed scale is not allowed in this option but is in the 28.10.4.1 2D Helmert (Advanced) option.

Selecting Helmert brings up the Helmert 2D panel.

If the Parameters by choice box is set to Pt Selection then control-observed point pairs are
selected by the user and the pairs are written to the grids on the panels. See the section 28.9.1.1 Selecting Control and Observed Points for the Helmert and Affine Transformations for information on picking control and observed points.

If the Parameters by choice box is set to Direct entry, the transformation parameters are manually entered into the panel and the grid section is not used.

The fields and buttons used in this panel have the following functions

applies the inverse transformation to the one defined in the panel.

**Finish** button
end the option, remove this panel and the Helmert control points table from the screen.
29 User

12d Model allows options to be placed on User menus.

Go to

- 29.1 User Defined Menus
- 29.2 User on the Main Menu
- 29.3 Miscellaneous
- 29.4 Beta
- 29.5 Console
- 29.6 Polygon
- 29.7 Undocumented User Menus
- 29.8 Obsolete Options

29.1 User Defined Menus

To help customise 12d Model, there is a pull down menu User on the Main menu and User menus on each of the pull down menus on the Main menu.

The User menus can run 12d Model macros, external programs, chains, and bring up 12d Model screen layout files, panels and menus.

For the full definition and format for user defined menus, see 41.2 User Defined Menus in the Appendix 41 Functions Keys, Menus, Toolbars.
29.2 User on the Main Menu

All the options under User and User menus are either customers own macros or unsupported macros from 12d Solutions which may not be documented. For more information on defining User menus, go to 29.1 User Defined Menus.

The User walk-right menu on the Main menu is:

For the option Miscellaneous, go to 29.3 Miscellaneous
Beta 29.4 Beta
Console 29.5 Console
Polygon 29.6 Polygon
29.3 Miscellaneous

All the options under User and User menus are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on User menus, go to 29.1 User Defined Menus

The walk rights User =>Miscellaneous menu is:

A to C
- Attribute editor

</table>
29.3.3 XXX Create Building for a Tin

**Position of option on menu:** User => Miscellaneous => A to C => Create buildings for tin

**Note** - This is an unsupported option which may not be fully documented.
29.3.4 Create Points for Centre of Circles

Position of option on menu: User => Miscellaneous => A to C => Convert circles to points

Note - This is an unsupported option which may not be fully documented.
This option creates points at the centres of circles.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>Model</td>
<td>string, model, view</td>
<td></td>
</tr>
<tr>
<td>Model/View/string of circles</td>
<td></td>
<td>source of the circles to create centre points for.</td>
<td></td>
</tr>
<tr>
<td>Model for centres</td>
<td>model box</td>
<td>available models</td>
<td></td>
</tr>
<tr>
<td>Run</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

run the option.
29.3.5 XXX Create Control Stations

**Position of option on menu:**  User => Miscellaneous => A to C => Create control stations

*Note* - This is an unsupported option which may not be fully documented.
29.3.6 XXX Create 2d String from Two Points

**Position of option on menu:**  User =>Miscellaneous =>A to C =>Create 2 point - 2d strings

*Note* - This is an unsupported option which may not be fully documented.
29.3.7 XXX Create 3 Point 2d Strings

Position of option on menu: User =>Miscellaneous =>A to C =>Create 3 point - 2d strings

Note - This is an unsupported option which may not be fully documented.
29.3.8 XXX Drop Bubbles

Position of option on menu:  User => Miscellaneous => D to K => Drop bubbles

Note - This is an unsupported option which may not be fully documented.
29.3.9 XXX Drop Points onto Alignment

**Position of option on menu:** User => Miscellaneous => D to K => Drop points onto alignment

**Note** - This is an unsupported option which may not be fully documented.
29.3.10 XXX Drop z-value onto Centreline

**Position of option on menu:** User => Miscellaneous => D to K => Drop points on centreline

*Note* - This is an unsupported option which may not be fully documented.
29.3.11 Extrapolate Point

Position of option on menu: User => Miscellaneous => D to K => Extrapolate

Note - This is an unsupported option which may not be fully documented.

This option is used to select two points and then creates a new point a given distance from the second point along the line from the first point to the second point. The z-value for the point is the extrapolated z-value from the two selected points.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select first point</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>and second point</td>
<td>string select</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Distance</td>
<td>output box</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>button</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Undo</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

select the first point to use in the extrapolation.
select the second point to use in the extrapolation.
distance to project from the second point along the line from the first to the second point.
run the option.
undo the last extrapolated point created since the panel has been up.
29.3.12 XXX Create VicRoad Pipe

*Position of option on menu:* User => Miscellaneous => D to K => Extend pipe

*Note* - This is an unsupported option which may not be fully documented.
29.3.13 XXX Fencing Models

Position of option on menu: User => Miscellaneous => D to K => Fencing models

*Note* - This is an unsupported option which may not be fully documented.
29.3.14 Length in 3d

**Position of option on menu:**  User => Miscellaneous => D to K => Get length in 3d

**Note:** This is an unsupported option.

This panel is used to calculate the 3d length of a selected string.

![Length in 3D panel](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pick button</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*select the string to calculated the 3d length for.*
29.3.15 XXX Head to Tail Closest Points

Position of option on menu: User => Miscellaneous => D to K => Head to tail closest points

Note - This is an unsupported option which may not be fully documented.
29.3.16 XXX Label Alignment

Position of option on menu: User => Miscellaneous => L to Q => Label alignment

Note - This is an unsupported option which may not be fully documented.
29.3.17 XXX Label Alignment Radius

**Position of option on menu:**  
User => Miscellaneous => L to Q => Label alignment radius/ip (rail)

*Note* - This is an unsupported option which may not be fully documented.
29.3.18 XXX Label Sewer Plan (old)

Position of option on menu:  User =>Miscellaneous =>L to Q =>Label sewer plan

Note - This is an unsupported option which may not be fully documented.

This option has been superseded.
29.3.19 XXX Name Strings by Nearby Text

Position of option on menu:   User =>Miscellaneous =>L to Q =>Label strings with name

Note - This is an unsupported option which may not be fully documented.

![Label String By Name dialog box](image)
29.3.20 XXX Name Strings by Model Name

Position of option on menu:  User => Miscellaneous => L to Q => Model to name

Note - This is an unsupported option which may not be fully documented.
29.3.21 XXX Name Section Strings by Picking Text

**Position of option on menu:**  User =>Miscellaneous =>L to Q =>Name strings using text strings

*Note* - This is an unsupported option which may not be fully documented.
29.3.22 XXX Overlay Optimiser

**Position of option on menu:** User => Miscellaneous => L to Q => Overlay optimiser

*Note* - This is an unsupported option which may not be fully documented.
29.3.23 XXX Read EEBY Sections

Position of option on menu:  User =>Miscellaneous =>R to Z =>Read EEBY sections

Note - This is an unsupported option which may not be fully documented.
29.3.24 XXX Read USGS DEM Data

Position of option on menu: User => Miscellaneous => R to Z => Read USGS DEM data

Note - This is an unsupported option which may not be fully documented.
29.3.25 Remove Null VIP Points

**Position of option on menu:**  User =>Miscellaneous =>R to Z =>Remove null VIP’s

*Note* - This is an unsupported option which may not be fully documented.

This option is used to remove any null vertical intersection points from alignment strings.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>data source</td>
<td>Model</td>
<td>String, Model, View</td>

<td></td>
</tr>
</tbody>
</table>

*Type of data to remove null vips for.*

*Data source for all the alignment strings to remove all null vips from.*

*Run the option.*
29.3.26 XXX Remove Tinability

**Position of option on menu:** User => Miscellaneous => R to Z => Remove tinability

*Note* - This is an unsupported option which may not be fully documented.
29.3.27 XXX Restore Fenced Model

Position of option on menu: User => Miscellaneous => R to Z => Restore fenced model

Note - This is an unsupported option which may not be fully documented.

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model name</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>View to Add</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
29.3.28 XXX Scale Text Values

Position of option on menu: User => Miscellaneous => R to Z => Scale text values

Note - This is an unsupported option which may not be fully documented.

<table>
<thead>
<tr>
<th>Text model</th>
<th>labels</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delimiter</td>
<td></td>

</tr>
<tr>
<td>New pre text</td>
<td></td>
</tr>
</tbody>
</table>

**Error** Model <labels> does not exist

[Image of text converter interface]
29.3.29 XXX Scale String Names

Position of option on menu:  User =>Miscellaneous =>R to Z=>Scale string names

Note - This is an unsupported option which may not be fully documented.
29.3.30 XXX Set String Names by Number

Position of option on menu: User => Miscellaneous => R to Z => Set string names by number

*Note* - This is an unsupported option which may not be fully documented.
29.3.31 XXX String Operations

Position of option on menu: User => Miscellaneous => R to Z => Set string properties

Note - This is an unsupported option which may not be fully documented.
29.3.32 Set Contour Levels from String Names

Position of option on menu: User => Miscellaneous => R to Z => Set contour level from contour name

Note - This is an unsupported option which may not be fully documented.

This operates on contour strings and sets the contour z-value to be the value of the name of the contour string. The z-values may need to be factored to bring them into the correct units.

![Z-values from Names panel](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>data source</td>
<td>Model</td>
<td>Model, View</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Undo</td>
<td>button</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Type of data to set contour z-values for:

Data source to of contours to set z-values for:

Run the option

Undo the last set of contours labelled since the panel was up.
29.3.33 Set Contour Names From Contour Levels

**Position of option on menu:** User => Miscellaneous => R to Z => Set contour names from contour levels

*Note* - This is an unsupported option which may not be fully documented.

This option operates on contours only and sets the string name to be the contour z value multiplied by the given factor.

![Name From Contour Level](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data source</strong></td>
<td>data source</td>
<td>Model</td>
<td>String, Model, View</td>
</tr>
<tr>
<td><strong>Model/View/String</strong></td>

</tbody>
</table>

*Type of data to label contours strings for.*

*Data source to calculate label the contours for.*

*Value to multiply the z values by before creating the string name.*

*Number of decimals places to use in the string name.*

*Run the option.*
29.3.34 XXX Sort XYZs Data File

Position of option on menu: User => Miscellaneous => R to Z => Sort xyz data file

Note - This is an unsupported option which may not be fully documented.
29.3.35 String Clipboard

**Position of option on menu:** User => Miscellaneous => R to Z => String attributes-properties to-from clipboard

**Position of option on menu:** File I/O => User => String attributes-properties to-from clipboard

*Note* - This is an unsupported option which may not be fully documented.

On selecting the String attributes-properties to-from clipboard option, the String clipboard panel is displayed.

This panel can be used to export string properties and attributes to the windows clipboard and import the properties to update the same strings.

The following properties are always exported when **copy** is selected:

<table>
<thead>
<tr>
<th>String id</th>
<th>Name</th>
<th>Type</th>
<th>Breakline</th>
<th>Style</th>
<th>Colour</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>3322187D1</td>
<td>Drainage</td>
<td>3</td>
<td>1</td>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

**String id. Type and Length** are for export only and cannot be changed on an import. **Name, Breakline, Style and Colour** may be changed to update the string when **paste** is selected. **Style** (linestyle order number from linestyl.4d) and **Colour** (colours.4d) numbers are used.

Starting in the 8th column, all of the string attributes are exported unless the **Att prefix selection** and/or the **Att prefix exclusion** filters are used. The first row is the string attribute name and the second row contains a number indicating the type of attribute. Attribute type numbers are:

1. integer numbers (no decimals)
2. real numbers (decimals allowed)
3. text (characters allowed)

The fields and buttons used in this panel have the following functions.

**String model**
- **model box**
  - name of the model to select strings from.

**Att prefix selection**
- **input**
  - last data used
  - (copy only) if blank all attributes will be selected prior to the exclusion. If text is entered then only attributes with this exact text (case sensitive) will be selected prior to the exclusion.

**Att prefix exclusion**
- **input**
  - last data used
  - (copy only) if blank all attributes matching the selection above will be exported. If text is entered then attributes with this exact text (case sensitive) will be excluded from the export.
Copy button

Copies the data from the string to the Windows clipboard.

Paste button

Pastes the data from the Windows clipboard. The string id is used to locate the string in the given model and then the properties/attributes are created and/or updated. If the attribute name is prefixed by DELETE followed by a space this string attribute will be deleted from all strings listed in the import.
29.3.36 Total Length of Strings

**Position of option on menu:**  User => Miscellaneous => R to Z => Sum length of all strings

**Note** - This is an unsupported option which may not be fully documented.

This panel is used to calculate the total length of the strings in a selected model or view.

![Total Length of Strings](image)

The fields and buttons used in this panel have the following functions:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>data source type</td>
<td>model, view, string</td>
<td></td>
<td></td>

</tr>
</tbody>
</table>
29.3.37 XXX Super String Dimension Occurrences

Position of option on menu: User => Miscellaneous => R to Z => Super string dimension occurrences

Note - This is an unsupported option which may not be fully documented.
29.3.38 XXX Transform V4 to V3.2

**Position of option on menu:** User => Miscellaneous => R to Z => Super string to V3.2 strings

*Note* - This is an unsupported option which may not be fully documented.

This panel converts a super string from 12d *Model* V4.0 format to V3.2 strings.
29.3.39 XXX Section Move

**Position of option on menu:** User => Miscellaneous => R to Z => Translate string in section view

*Note:* This is an unsupported option which may not be fully documented.

This panel is used to translate a string on a section view.

![Section Move Panel](image)
29.3.40 XXX Output XYZ and Chainage

Position of option on menu:  User =>Miscellaneous =>R to Z=>XYZ chainage

Note - This is an unsupported option which may not be fully documented.
29.4 Beta

All the options under User and User menus are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on User menus, go to 29.1 User Defined Menus.

The walk rights Beta menu is:

- 12d block insert
- Alignment labels
- Alignment label table
- Airfield Runway Calculator
- Catchment definer
- Check duplicate point numbers
- Create culverts
- Liquid Measure
- Make cuts
- Plot symbol / title block creation
- Read SDRMap feature codes
- Read SDRMap symbols
- Reformat CivilCAD Ascii 5 File
- Remove super string tinability
- Triangulate by selection set
- Update z value from points
- Create extrusions
- Extrusions tutorials

For the option Alignment labels, go to 29.4.1 XXX Alignment Labels
- Alignment label table 29.4.2 XXX Table of Alignment Labels
- Airfield Runway Calculator 29.4.3 Airfield Runway Calculator
- Catchment definer 29.4.4 XXX Catchment Definer
- Check duplicate point numbers 29.4.5 XXX Check Duplicate Point Numbers
- Create culverts 29.4.6 XXX Create Culvert
- Liquid measure 29.4.7 XXX Liquid Measure
- Make cuts 29.4.8 XXX Make Cuts Through Strings
- Plot symbol/title block 29.4.9 XXX Plot Symbol and Title Block

Creation (old)
- Read SDRMap feature codes 29.4.10 XXX Read SDRMap Feature Code
- Read SDRMap symbols 29.4.11 XXX Read SDRMap Symbols
- Reformat CivilCAD Ascii 5 file 29.4.12 XXX Reformat CivilCAD Ascii 5 file
- Remove super string tinability 29.4.13 XXX Remove Super String Tinability
- Triangulate by selection set 29.4.14 XXX Triangulate by Selection Set
- Update z values from points 29.4.15 XXX Update Z Values from Points
29.4.1 XXX Alignment Labels

**Position of option on menu:** User => Beta => Alignment labels

*Note* - This is an unsupported option which may not be fully documented.
29.4.2 XXX Table of Alignment Labels

Position of option on menu: User => Beta => Alignment label table

*Note* - This is an unsupported option which may not be fully documented.
29.4.3 Airfield Runway Calculator

Position of option on menu: User => Beta => Airfield Runway Calculator

This option is under development
29.4.4 XXX Catchment Definer

Position of option on menu:  User => Beta => Catchment definer

Note - This is an unsupported option which may not be fully documented.
29.4.5 XXX Check Duplicate Point Numbers

Position of option on menu: User => Beta => Check duplicate point numbers

Note - This is an unsupported option which may not be fully documented.
29.4.6 XXX Create Culvert

**Position of option on menu:** User => Beta => Create culvert

*Note* - This is an unsupported option which may not be fully documented.
29.4.7 XXX Liquid Measure

Position of option on menu:  User => Beta => Liquid measure

*Note* - This is an unsupported option which may not be fully documented.
29.4.8 XXX Make Cuts Through Strings

Position of option on menu:  User => Beta => Make cuts

Note - This is an unsupported option which may not be fully documented.
29.4.9 XXX Plot Symbol and Title Block Creation (old)

Position of option on menu: User => Beta => Plot symbol/title block creation

Note - This is an unsupported option which may not be fully documented.
29.4.10 XXX Read SDRMap Feature Code

Position of option on menu:  User => Beta => Read SDRMap feature codes

Note - This is an unsupported option which may not be fully documented.
29.4.11 XXX Read SDRMap Symbols

Position of option on menu: User => Beta => Read SDRMap symbols

Note - This is an unsupported option which may not be fully documented.
29.4.12 XXX Reformat CivilCAD Ascii 5 file

Position of option on menu: User => Beta => Reformat CivilCAD Ascii 5 file

Note - This is an unsupported option which may not be fully documented.
29.4.13 XXX Remove Super String Tinability

**Position of option on menu:**  User => Beta => Remove super string tinability

*Note* - This is an unsupported option which may not be fully documented.
29.4.14 XXX Triangulate by Selection Set

*Position of option on menu:*  User => Beta => Triangulation by selection set

*Note* - This is an unsupported option which may not be fully documented.
29.4.15 XXX Update Z Values from Points

**Position of option on menu:** User => Beta => Update z value from points

*Note* - This is an unsupported option which may not be fully documented.

![Update Z-value From Point](image_url)

29.5 Console

All the options under User and User menus are either customers own macros or unsupported macros from 12D Solutions which may not be documented. For more information on User menus, go to 29.1 User Defined Menus

All the macros on the Console menu only use the console panel and so do not support a F1 key for help.

The User => Console rights menu is:

![Console Rights Menu](image_url)
29.6 Polygon

The Polygon walk-right menu is

```
Polygon
Create polygon by picking point inside
Create polygon by picking sides
Colour polygon by range file
Remove polygon colour
Read polygons
```

and each option in this menu will now be discussed.

For Create polygon by picking point inside area, go to 14.6.18 Surrounding Polygon
Create polygon by picking sides 29.6.1 Create Polygon by Picking Sides
Colour polygons from range file 29.6.2 Colour Polygons by Range File
Remove polygon colour 29.6.3 Remove Polygon Colour
Road polygons 20.8.12.3 Road Polygons
29.6.1 Create Polygon by Picking Sides

**Position of option on menu:** User => Polygon => Create polygon by picking sides

This option creates a polygon by picking each segment in its order (and with direction) around the polygon. Segments will be automatically extended or clipped to form the polygon.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model for polygon</td>
<td>model box</td>
<td>available models</td>
<td></td>
</tr>
<tr>
<td>Lot colour</td>
<td>colour box</td>
<td>available colours</td>
<td></td>
</tr>
<tr>
<td>Join first and last segment</td>
<td>tick box</td>
<td>if tick, join the end of the last selected segment to the start of the first selected segment to form the final</td>
<td></td>
</tr>
</tbody>
</table>
side of the polygon. The segments may be automatically trimmed/extended.

Pick sides
string select
pick, with direction, the segments to be joined together to form the sides of the polygon.

Process
button
create the polygon from the selected segments.
29.6.2 Colour Polygons by Range File

**Position of option on menu:**  User => Polygon => Colour polygons by range file

This option creates a polygon by picking each segment in its order (and with direction) around the polygon. Segments will be automatically extended or clipped to form the polygon.

![](image.png)

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>

</table>
29.7 Undocumented User Menus

The options on a User menu are either customer’s macros or unsupported macros from 12D Solutions and may not be documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8 Obsolete Options

These options are now obsolete and may not be documented.
To return to the start of the documentation on the User menu, click on User.
29.8.1 Triangulate a Model List

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.2 Triangulate a Model

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.3 MicroStation/ArcView/MapInfo Map File

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.4 Old Head to Tail Strings

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.5 String Movie CL for View

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.6 String Report

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.7 Write Binary XYZ File For

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.8 Write BIPS File For

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.9 Write Title Block File

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.8.10 Old Clip String

This is an obsolete option which is not documented.

To return to the start of the documentation on the User menu, click on 29 User.
29.9 Drainage Options

These options are part of the Drainage-Sewer menu.
For the option *Downhill strings*, go to 29.9.1 Downhill Strings
Raindrop 29.9.2 Raindrop/Teardrop
Aquaplaning risk 29.9.3 Aquaplaning Risk Assessment
Extract sewer controls 29.9.4 Extract Sewer Controls
Convert to pts and lines 29.9.5 Convert to Points and Lines
29.9.1 Downhill Strings

Position of option on menu: Design=>Drainage-Sewer=>Downhill strings

This option copies selected Super strings to a target model, where the strings are split at their crests and sags, and set in the downhill direction.

On selecting the **Downhill strings** option, the **Downhill Strings** panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source model mask</td>
<td>input text</td>
<td></td>
<td></td>

</tbody>
</table>

Specifies the model(s) from which to select Super strings to process. Use '*' and '?' wildcards to specify multiple models. Note: the target model cannot be specified.

| Source string mask                       | input text  |          |        |

Specifies the string name(s) to process from within the selected model(s). Use '*' and '?' wildcards to specify multiple string names. Note: if blank, the option will match all string names in the selected model(s).

| Colour for downhill strings              | colour box  | available colours |        |

Drainage Options

Chapter 29  User

Colour to apply to all strings in the target model (optional).

Linestyle for downhill strings  linestyle box  “FLOW LINE”  available linestyles

Linestyle to apply to all strings in the target model (optional).

Levee tolerance  input real  0.025

Localised uphill portions will be allowed to rise up within this vertical tolerance.

Discard tolerance  input real  0.1

Resultant strings shorter than this tolerance will be discarded from the target model.

Join resultant strings head-to-tail  tick box  ticked

Whether to join strings in the target model in a head-to-tail fashion.

Head-to-tail tolerance  input real  0.005

If joining strings head-to-tail, the head must be within this tolerance of the tail.

Matching number of leading characters in string names  input integer0

If joining strings head-to-tail, this number of leading characters in both string names must match.

Split resultant strings at drainage inlets  tick  not ticked

Whether to split strings in the target model at nearby drainage inlets.

Drainage model  model box  available models

If splitting strings at drainage inlets, strings will be split at all nearby drainage inlet pits found in this model. Drainage inlets (i.e. on-grade and sag pits only) must be within one pit diameter of the string, and may not be closer than the Discard tolerance from either end of the string.

Model of downhill strings  model box  available models

Target model. All matching source strings are copied to and processed in this model.

Clean model beforehand  tick box  ticked

Whether to clean the target model beforehand.

Run  button

Runs the option.

Special Note:
The Downhill Strings option is a macro, that may optionally be run from a chain via arguments, rather than via a panel. The details of the argument syntax are written to the Output Window, whenever the macro is run without valid arguments, viz:
12d Macro: "downhill_strings_panel.4do" started ...

Credits: AECOM Australia Pty Ltd developed the original, non-panel version of this macro.

Copies Super strings matching (string mask) from all models matching (model mask) to (target model).
All strings copied to (target model) are split at create and a gap and set in downhill direction.

Usage with no arguments: macro is run with a panel interface.

Usage with arguments: downhill_strings_panel <model mask> <string mask> <target model>
	[clean] [-C <colour name>] [-L <linestyle name>]
	[-t <tlevel tol> [-d <discard tol>]] [-j <ch2 tol> <prefix len>]

Optional flags:
-<clean> = Clean <target model> beforehand.
-<C <colour name>> = Colour for resultant strings.
-<L <linestyle name>> = Linestyle for resultant strings.
-<t <tlevel tol>> = Allow localised uphill portions rising less than <leveld tol>. Default is 0.025 without -t flag.
-<d <discard tol>> = Discard resultant strings shorter than <discard tol>. Default is 0.1 without -d flag.
-<j <ch2 tol> <prefix len>> = Join <target model> strings head-to-tail when head is within <ch2 tol> of tail ... ...
and when first <prefix len> characters in string names match.

cgl: downhill_strings_panel "down* stra" DL, "down stra", clean t 6.025 -d 0.1
cgl2: downhill_strings_panel "down* stra" DL, "down stra", C cyan t L "FLOW LINE", j 0.005 2

target model cleaned ...
added 30 downhill strings to target model ...
joined 18 string pairs head-to-tail in target model ...
split 14 strings in target model at nearby drainage inlets ...
discarded 6 short strings from target model ...

12d macro "downhill_strings_panel.4do" processed 24 strings from 15 models, to target model "drainage kerb inverts downhill"
29.9.2 Raindrop/Teardrop

Position of option on menu: Design=>Drainage-Sewer=>Raindrop
Position of option on menu: Tins=>Tin Analysis=>Rain drop

This section of documentation is a work in progress and will be updated in subsequent releases.
On selecting the Raindrop option, the Teardrop Macro panel is displayed.

The fields and buttons used in this panel have the following functions.

29.9.3 Aquaplaning Risk Assessment

Position of option on menu: **Design=>Drainage-Sewer=>Aquaplaning risk**

This option performs an aquaplaning risk assessment using the *Gallaway Equation*. The user need only supply flow path strings as 2d Super strings in the areas of concern on the road pavement tin (typically at the transitions in the road cross-fall). The option then re-creates these flow path strings in 3d, with evenly spaced vertices, then applies the *Gallaway Equation* to determine a water film depth at each vertex (where all parameters considered are set as vertex attributes). It then assesses the risk of aquaplaning at each vertex by associating a risk level and segment colour with the water film depth calculated at each vertex. In addition, a report file is written to the *Windows* clipboard, and optionally to file.

The *Gallaway Equation* is defined as follows:

\[
d = \frac{0.103 T^{0.11} L^{0.43} I^{0.59}}{S^{0.42}} - T
\]

- d = water film depth above top of pavement texture (mm)
- L = length of flow path (m)
- S = slope of the flow path (%)
- T = average pavement texture depth (mm)
- I = rainfall intensity (mm/hr)

On selecting the *Aquaplaning risk* option, the *Aquaplaning Risk Assessment* panel is displayed.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field Description</th>

Warn if 

\[
\frac{\text{water film depth}}{\text{flow path length}}
\]

is excessive (optional).

**Warning flow path length (m)**

60

Warn if flow path length is excessive (optional).

**Report**

**Report file**

Report will be written in tab-delimited format to the Windows clipboard, and optionally to this file.

**Overwrite existing report file**

Whether to overwrite or append to an existing report file.
Run button

Runs the option.

Additional Notes:

1) The **Aquaplaning Risk Assessment** option writes auxiliary help information to the *Output Window* every time it is run, *viz*:

```
12d macro "aquaplaning_risk_panel.4dm"

Performs an aquaplaning risk assessment using the Gallaway equation.
User need only draw flow paths as 2d Super strings in the areas of concern on the road pavement tin.

Report:
*Written in tab-delimited format to Windows clipboard and optionally to file.
Flow Path Strings:
*re-created in 3d with evenly spaced vertices.
*segments are individually colour coded to indicate the risk of aquaplaning.
*vertices are set with attributes of all variables considered at each vertex.

Reference:

Credits:
*NECIM Australia Pty Ltd developed the original version of this macro.
```

2) The tab-delimited report is always written to the *Windows* clipboard, even if a report file is not specified. A pre-formatted *Excel* report template is installed and available in the library – **SLIB/aquaplaning_report_template.xlsx** – and after running the aquaplaning option, the contents of the clipboard may be pasted directly into a copy of this template file, as shown here:
3) Combined plan and profile plots of the analysed flow path strings, for inclusion in reports, may be generated from the Section Long Plot PPF Editor. A PPF file set specifically for this purpose is installed and available in the library – SLIB\aquaplaning_longsection_A4.lplotppf – as shown here:
29.9.4 Extract Sewer Controls

Position of option on menu: **Design=>Drainage-Sewer=>Extract sewer controls**

The sewer property control strings are a sub string of the drainage string and therefore may only be profiled using a right mouse click of the profile button. To include these control strings on plots or export to other packages they need to be converted to super strings.

On selecting the **Extract Sewer Controls** option, the **Extract Sewer Property Controls** panel is displayed.

The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>

|--------------------------------|----------| Create the super strings representing the property controls. |
29.9.5 Convert to Points and Lines

Position of option on menu: **Design=>Drainage-Sewer=>Convert to pts and lines**

This option converts a drainage network into simple points and lines.

Pits will be created as single point super strings with the pit attributes set as string attributes.

Pipes will be created as single or multiple segment super strings with pipe attributes set as string attributes.

This may be useful for uploading to external GIS systems via the GIS module.

Selecting **Convert to pts and lines** brings up the **Drainage convert to points and lines** panel.

![Drainage convert to points and lines panel](image)

</tbody>
</table>
```

The fields and buttons used in this panel have the following functions.

- **Turn off modules**: Turn off modules
- **Finish**: Finish and close the panel
- **Help**: Help
Dongle output only
number of the dongle for this licence.

Version output only
12d Model version number.

Days remaining output only
number of days left for the authorisation.

Modules tab

Base module output only
number of allowed points in the Base module. If this number is exceeded then the project cannot be saved until enough points are deleted to bring the point count below the allowed number of points.

Alignment, Pipeline, Volumes, etc. choice boxes yes, no, maintenance.

if yes, the module is authorised. If it is yes then it can be changed to no and when the Turn off modules button is pressed, the module will no longer be authorised until you exit the project and restart it.

If no, the module is not authorised.

If Maintenance, the module is included whilst you are on Maintenance.

Turn off modules button
for any modules with yes, you can turn off modules by setting the choice to no and then clicking this button.

You can NOT turn modules back on. To get the module back you need to restart the project and then the modules that are authorised in the nodes.4d file will again have yes displayed, and hence be turned on.
Program tab

If the Email button does not send an email, the Save button can be used to write the information out to a file called 12d_auth.txt. This file can then be emailed to support@12d.com.

Continue to the next section 31.6 Dongles Administration or return to 31 Help.
31.6 Dongles Administration

Position of option on menu:  Project => Management => Dongles => Administration
Position of option on menu:  Help => Dongles

This option is documented in 7.6.5.2 Dongles Administration.

Continue to the next section 31.7 Check for Updates or return to 31 Help.
31.7 Check for Updates

Position of option on menu: Help => Check for updates

Selecting Check for updates will check if there are any newer versions and/or builds of 12d Model than the one currently being run.

The 12d Update Checker panel will give a link to the new versions or display the message that there is no update available if the current version and build of 12d Model is the latest one.

Continue to the next section 31.8 Microsoft 7 or return to 31 Help.
31.8 Microsoft 7

Position of option on menu: Help => Windows 7

12d Model has a context sensitive reference help system which can be accessed directly from most menus and panels:

(a) For most menus in 12d Model, when the menu is on the screen and has the Windows focus, simply press F1 and the 12d Help will open automatically at that menu

(b) For most panels in 12d Model, when the panel is on the screen and has the Windows focus, simply press F1 and the 12d Help will open automatically at that panel

(c) Most panels in 12d Model have a Help button on them and clicking on the Help button opens the 12d Help at that panel

(d) By clicking on the option Help => 12d Model

The 12d Model context sensitive help uses Microsoft’s WinHlp.

For Win 7 and 8, Microsoft no longer ships the WinHlp.exe executable and Microsoft will no longer allow it to be installed by the 12d Model installation DVD.

So if you are running Win 7 or Win 8, you need to download and install WinHlp.exe from Microsoft’s website to access the 12d Model Help files.

The link to the area for the download is Walking right on Microsoft 7 displays the Help on Windows 7 Not Working panel which has a link to the Microsoft web site to download Winhel32.exe.

![Help on Windows 7 not Working](image)

Try the hyperlinks below.

They are current as of 03 April 2014 but are subject to change by Microsoft

If the links become inactive, use the "Knowledge Base Search" and search on, Windows 7 winhlp32.exe download.

Note that we are not allowed to distribute Winhlp32.exe, so you must have a legal copy of Windows 7 to access this download from Microsoft.

- [Microsoft Knowledge Base Search](#)
To return to the start of the documentation on the Help menu, click on 31 Help.
32 Save and Exit

Save and Exit are available from both the Main Menu under Project or on the floating 12d Model menu.
32.1 Save and Exit from Main Menu

Selecting Save from the Main Menu=>Projects menu simply saves all data in the project modified since the last save.

When Exit is selected from the bottom of the Main Menu=>Projects menu and a save is not needed, 12d Model exits the project.

If Exit is selected from the bottom of the Main Menu=>Projects menu and a save is needed, then the Save Project? yes-no panel is placed on the screen.

If Yes is selected, then 12d Model saves the project and exits.
If No is selected, then 12d Model does not save the project and exits.
If Cancel is selected, then the Exit is aborted and 12d Model stays in the project.

Note: when exiting 12d Model, the user is reminded if any mtf files modified by the 12d Model mtf editor have not been saved, or any string editors are still running.

32.2 Save/Exit from Floating 12d Model Menu

When Save is selected from the left hand side of the bottom of the 12d Model menu (Save / Exit menu option), all the information modified since the last save is written to disk.

When Exit is selected from the right hand side of the bottom of the 12d Model menu (Save / Exit menu option), an Exit 12d Model panel is fired up.

Selecting No removes the yes-no pop-up and leaves the user in 12d Model.
If Yes is selected and a modification to the project has been made since the last project save, a Save Project panel is fired up.
If yes is selected, the project is saved and 12d Model terminates.
If no is selected, the project is not saved and 12d Model terminates.
If cancel is selected, the exit option is aborted and the user is left in 12d Model.

Note: When exiting 12d Model, the user is reminded if any mtf files modified by the 12d Model mtf editor have not been saved, or any string editors are still running.

Selecting No removes the yes-no pop-up and leaves the user in 12d Model.
If Yes is selected and a modification to the project has been made since the last project save, a Save Project panel is fired up.
Appendices
33 BIM

See

33.1 What is BIM ?
33.2 The 12d Approach to BIM
33.3 The UK Government and BIM
33.4 Common Terms in BIM
33.5 What is Wrong with Local Coordinates ?

33.1 What is BIM ?

What BIM is seems to depend on who you are talking to. And the various participants in the design, construction and management of the asset (building or infrastructure) also emphasise different aspects of BIM.

If a wide search of the literature for BIM and ISO Standards is made, and all the marketing fluff is ignored, one quickly sees that almost universally the BI in BIM is Building Information and although BIM is about the process, all the objects are for a Building on a site. The other constant is that the International Standard for transferring BIM data is the vendor independent format of IFCs. For more information on IFCs, see 8.2.19 IFC Output.

In 2011 the BIM movement received a major boost when the UK Government released the Government Construction Strategy which aimed to reduce he cost of government construction projects by 15-20% and BIM was identified as one of the strategies to achieve help the savings.

The Strategy contained an Action Plan that included the objective for BIM to introduce a progressive programme of mandated use of fully collaborative Building Information Modelling for Government projects by 2016.
One early outcome of the Strategy was for BuildingSMART to develop a national BIM standard with the principles of interoperability. This will be key to future delivery of Level 3 “Open & Shared” BIM.

buildingSMART is now the International group looking after the development of the Industry Foundation Classes (IFCs) which is the data model for the Open Standard for BIM. See http://www.buildingsmart-tech.org.

For more information, see 33.3 The UK Government and BIM and for some common BIM terms and the Levels of BIM outlined by the UK Government, see 33.4 Common Terms in BIM.

Under the umbrella of buildingSMART there are a number of International Committees currently grappling with the problem of extending IFCs from Buildings to Bridges, an Alignment for Roads, and for Roads and Railways in general, and to move IFCs from uncoordinated flat space with (0,0) in the corner, to a GIS and 12d environment with world coordinates and projections.

Beware that some groups talk BIM but then insist on data being supplied in an unpublished, encrypted proprietary format. In Australia this is often Revit, Navisworks, DWG or DGN.

This is diametrically opposed to the International Open BIM concept but apart from pointing that out to your client, you are caught between a rock and a hard place.

However for those users caught in the encrypted proprietary format trap, we are working to help solve your problems. For an overview of where we are currently at, please see the information in the next section 33.2 The 12d Approach to BIM.

Continue to 33.2 The 12d Approach to BIM or return to 33 BIM.
33.2 The 12d Approach to BIM

12d Solutions is actively involved in, and supporting, the International effort on IFCs.

12d Solutions is:

(a) a founding member of the Open BIM Alliance which supports the transferring of BIM data using the ISO Standard for IFCs.

(b) working with buildingSMART (the International Group looking after IFCs) on how non-Building data should be transferred using IFCs. See http://www.buildingsmart-tech.org.

(c) working with buildingSMART on how IFCs can be extended to Alignments, Roads and Railways.

(d) working on the Precinct Information Model project, part of the CRC for Low Carbon Living.

This project is looking at the problem of extending BIM from a few building on a site, to a larger area and including roads, drainage, sewerage etc.

For more information on 12d Model and IFCs, see 8.2.19 IFC Output

For those users caught in the encrypted proprietary format trap, although we do not have access to the formats, 12d Solutions will continue to look for ways to make that data accessible to our users.

To this end, the approaches we are pursuing with our users to write out BIM type data from 12d Model are:

(a) Writing Out Fully Structured IFCs

Using IFCs correctly means that the data to be output must have a fully defined hierarchical structure (known as the Spatial Structure).

This is the approach of the 12d Model IFC Writer. See 8.2.19 IFC Output.

(b) Writing Out Unstructured IFCs

The IFC format could also be used in an informal way as a method of transferring data where there is no concern for the spatial structure but just after the object shapes.

12d is currently working on an alternate IFC Writer to do this.

(c) Writing out OBJ and STL Files

Drainage and sewer strings, super strings with round or rectangular sections, extrusions and trimeshes can be written out as OBJ files (see 8.2.17 Export OBJ) or STL files (8.2.18 Export STL).

(d) Writing out Polyface Mesh in DWG

Drainage and sewer strings, super strings with round or rectangular sections, extrusions and trimeshes can be written out to DWG files as Polyface Meshes. See 8.2.7 Output DWG/DFX/DXB Files.

(e) Revit Routines to Read in 12d Model Data.

EXDS have developed routines that run from within Revit to read in 12d Model data in 12d.XML format See www.EXDS.com.au.

The approaches we are using to bring data into 12d Model are:

(a) Reading in OBJs

OBJ files can be read into 12d Model as trimeshes. See 8.1.18 Wavefront OBJ Input

(b) Reading in Polyface Mesh in DWG
Polyface mesh in a DWG file can be read into 12d Model as trimeshes. See 8.1.10 DWG/DXF Input.

(c) Getting Revit Data into 12d Model

Although the Revit database itself is unreadable, Revit can write data out in the Autodesk fbx format and there is an option in 12d Model to read in an fbx file trimeshes. See 8.1.11 FBX Input.

Also if data can be written out from Revit as Polyface Meshes to a DWG file then again that can be read in into 12d Model as trimeshes. See 8.1.10 DWG/DXF Input.

Continue to 33.3 The UK Government and BIM or return to 33 BIM.
33.3 The UK Government and BIM

In 2011, the UK Government released the Government Construction Strategy which was the framework for a range of work streams, all of which have the ultimate aim of reducing the cost of government construction projects by 15-20% (https://www.gov.uk/government/publications/government-construction-strategy).

One problems was identified in Section 2.30:

2.30 A lack of compatible systems, standards and protocols, and the differing requirements of clients and lead designers, have inhibited widespread adoption of a technology which has the capacity to ensure that all team members are working from the same data, and that:

- the implications of alternative design proposals can be evaluated with comparative ease;
- projects are modelled in three dimensions (eliminating coordination errors and subsequent expensive change);
- design data can be fed direct to machine tools, creating a link between design and manufacture and eliminating unnecessary intermediaries; and
- there is a proper basis for asset management subsequent to construction.

and the remedy, BIM, was mandated in Section 2.31:

2.31 The Cabinet Office will coordinate Government’s drive to the development of standards enabling all members of the supply chain to work collaboratively through Building Information Modelling (BIM). This will be a phased process working closely with industry groups, in order to allow time for industry to prepare for the development of new standards and for training

The Strategy also included an Action Plan with a timetable, and Section 7 was for Building Information Modelling (BIM):

7(i)Objective: To introduce a progressive programme of mandated use of fully collaborative Building Information Modelling for Government projects by 2016.

From the Government Construction Strategy: One Year On and Action Plan Update it reported for BIM:

A reciprocal Memorandum of Agreement has been reached with buildingSMART US to develop a national BIM standard with the principles of interoperability. This will be key to future delivery of Level 3 “Open & Shared” BIM.

Continue to 33.4 Common Terms in BIM or return to 33 BIM.
33.4 Common Terms in BIM

Here is a list of some need-to-know BIM terms and their definitions taken from the NBS website http://www.thenbs.com.

NBS is part of RIBA Enterprises Ltd, which is wholly owned by the Royal Institute of British Architects (RIBA) and was contracted by the UK Government to build the National BIM Library.

1. 4D, 5D, 6D
First there was 2D CAD, then 3D CAD – now there are extra dimensions to refer to the linking of the BIM model with time-, cost- and schedule-related information (although the precise order hasn’t to date been agreed across the whole industry).

2. Asset Information Model (AIM), Building Information Model (BIM)
Not only is there the ‘Building’ information model, but the ‘Asset’ information model – which is the name given to the same model post-construction, i.e. supplemented with the data needed to assist in the running of the completed asset. Note that ‘asset’ can also refer to civil engineering and infrastructure work.

3. Common Data Environment (CDE)
This is a central information repository that can be accessed by all stakeholders in a project. Whilst all the data within the CDE can be accessed freely, ownership is still retained by the originator.

The scope and requirements for a CDE are defined in PAS 1192-2 (see 8. PAS 1192).

4. Level 0 BIM, Level 1 BIM, Level 2 BIM, Level 3 BIM
The move to ‘full’ collaborative working via distinct and recognisable milestones, in the form of ‘levels’. These have been defined within a range from 0 to 3, and, whilst there is some debate about the exact meaning of each level, the broad concept is:

**Level 0** – no collaboration.
2D CAD drafting only. Output and distribution is via paper or electronic prints, or a mixture of both.

**Level 1** – a mixture of 3D CAD for concept work, and 2D for drafting of statutory approval documentation and Production Information.
CAD standards are managed to BS 1192:2007, and electronic sharing of data is carried out from a common data environment (CDE), often managed by the contractor.

There is no collaboration between different disciplines – each publishes and maintains its own data.

**Level 2** – collaborative working – all parties use their own 3D CAD models.
Design information is shared through a common file format, which enables any organisation to be able to combine that data with their own in order to carry out interrogative checks on it.

Hence any CAD software that each party used must be capable of exporting to a common file format.

This is the method of working that has been set as a minimum target by the UK government for all public-sector work, by 2016.

**Level 3** – integrated working between all disciplines by using a single, shared project model which is held in a common data environment.
All parties can access and modify that same model, removing the final layer of risk for conflicting information. This is known as ‘Open BIM’ (see 7. Open BIM), and the UK government’s target date for public-sector working is 2018, although the precise requirements have yet to be determined.

Note that the definition of BIM maturity Level 2 was originally developed as part of the UK Government strategy in 2011. It is also defined in PAS 1192-2, with reference to best practice and the adoption tools and standards.

It is also worth noting, though, PAS 1192-2 acknowledges that, given the early stages of adoption of managed methods of working in BIM at the time the PAS was drafted, it can be expected that Level 2 practices will continue to evolve, and that the scope of information sharing and exchange will vary from project to project.

Therefore, PAS 1192-2 anticipates that the definition of Level 2 BIM will continue to evolve around the core principles of the shared use of individually authored models in a CDE.

5. Construction Operations Building Information Exchange (COBie)

COBie is a data schema which is delivered in a spreadsheet data format, and contains a ‘subset’ of the information in the building model (all except graphical data, and hence a subset of IFC (see 6. Industry Foundation Class (IFC)), for FM handover. It was originally devised by the US Army Engineering Corps.

Over the course of a project, data can be added to it from a range of sources (besides CAD programs), relating to brief, design, construction, operation, refurbishment or demolition, as the case may be.

The UK Government’s Level 2 - mandated requirement is for COBie-compliant information exchange. BS 1192-4 documents best practice for the implementation of COBie.

6. Industry Foundation Class (IFC)

IFC is an object-based format, to enable exchange of information between different software. Developed by buildingSMART, a global alliance specialising in open standards for BIM, IFC is an official standard, BS ISO 16739, and contains geometric as well as other data.

7. Open BIM

An open-source approach to collaborative design, realisation and operation of buildings, based on open standards and work flows.

Open BIM is an initiative of several leading software vendors using the buildingSMART Data Model, which incorporates data to ISO 16739 (via the IFC file format), terms to ISO 12006-3 (using the International Framework for Dictionaries, which maps different technical terms that have the same meaning) and process to ISO 29481-1 (the Information Delivery Manual).

8. PAS 1192

The PAS 1192 framework sets out the requirements for the level of model detail (the graphical content), model information (non-graphical content, such as specification data), model definition (its meaning) and model information exchanges:

(a) PAS 1192-2 deals with the construction (CAPEX) phase, and specifies the requirements for Level 2 maturity; sets out the framework, roles & responsibilities for collaborative BIM working; builds on the existing standard of BS 1192, and expands the scope of the Common Data Environment (see 3. Common Data Environment (CDE)).

(b) PAS 1192-3 deals with the operational (OPEX) phase, focussing on use & maintenance of the Asset Information Model, for Facilities Management.

(c) BS 1192-4 documents best practice for the implementation of COBie.
(d) PAS 1192-5 is currently under development, and will cover security of data.

Continue to 33.5 What is Wrong with Local Coordinates? or return to 33 BIM.
33.5 What is Wrong with Local Coordinates?

What we mean by Local Coordinates is the placing of (0,0) somewhere on the site, with a
direction for the x or y axis, NOT a cartographic projection with (0,0) defined on the site.

There is nothing wrong with using a Local Coordinate system as long as you are aware of the
restrictions and consequences. As Einstein said for General Relativity "space is locally flat".

So as long as you are working on a small site (say under 5 kilometres long) and everyone is able
to reliably measure back to your (0,0) and use your definition of angle of the coordinate axes,
then there should be no major problems.

But if you are working on a large project, or trying to combine data from a variety of sources, or
want to coordinate work with a GPS, then you need to know more about how and why there are
problems with Local Coordinates.

One of the problems is that the earth is not flat.

See

- 33.5.1 An Exact Position for Everything on the Earth
- 33.5.2 Map (Cartographic) Projections - Eastings and Northings
- 33.5.3 Why Isn't MGA Used on a Small Building Site?
33.5.1 An Exact Position for Everything on the Earth

To give everything on earth a unique coordinates that fit in with GNSS systems (GPS, GLONASS, BeiDou and Galileo), a reference ellipsoid has been defined with:

(a) (0,0,0) at the Mass centre of the earth (geocentre), a semi major axis of 6,378,137 m, and an inverse flattening of 298.257222101. This is known as GRS80.

This is because satellites orbit around the mass centre of the earth.

(b) Longitude is an angular quantity measured from the Greenwich meridian.

(c) Latitude is an angular quantity measured from the equatorial plane, to the plane defined by the point position and the plumb line to the ellipsoid surface.

(d) Ellipsoid height is the height above the reference ellipsoid.

Using a GNSS system, the Geodetic coordinates of (Latitude, Longitude, Ellipsoid height) can be directly obtained for any position on earth that can see the satellites.

Note: Heights in Australia are not usually quoted as Ellipsoid heights h but instead in AHD (Australian Height Datum) H which is defined in terms of Means Sea Level. The difference between the ellipsoid height and the AHD is known as the N (AHD Value).

\[
\text{AHD (Geoid height)} = \text{Ellipsoid height} - N \ (\text{AHD Value})
\]

Continue to 33.5.2 Map (Cartographic) Projections - Eastings and Northings or return to 33.5 What is Wrong with Local Coordinates? or 33 BIM.
33.5.2 Map (Cartographic) Projections - Eastings and Northerings

Although Geodetic coordinate of Latitude and Longitude give unique coordinates for a point, they are not very appropriate for drawing up civil engineering projects. They are usually represented on a map by mathematically "projecting" them on to a surface, which can be laid flat.

A Map or Cartographic Projection is a transformation of the latitudes and longitudes of locations on the surface of an ellipsoid into locations on a plane. The projection coordinates are usually referred to as Eastings (x) and Northerings (y).

The important thing is that the Cartographic projection can be reversed. That is, has an inverse. So the Cartographic projection

(a) maps a (Latitude, Longitude) to a (Easting, Northing)

and

(b) the inverse projection maps an (Easting, Northing) to a (Latitude, Longitude).

Consequently if you have the (Easting, Northing) then can calculate the equivalent (Latitude, Longitude) and vice versa.

The most commonly used Cartographic projection for civil works is the Transverse Mercator projection.

In mathematical speak, Transverse Mercator projections are conformal projections and preserve angles locally, implying that they map infinitesimal circles of constant size anywhere on the Earth to infinitesimal circles of varying sizes on the map. In contrast, mappings that are not conformal distort most such small circles into ellipses of distortion. An important consequence of conformality is that relative angles at each point of the map are correct, and the local scale (although varying throughout the map) in every direction around any one point is constant.

Transverse Mercator projections are commonly used for road projects by the Road Authorities in each State of Australia. They are also used for the Meridional Circuits in New Zealand.

The Transverse Mercator projection is also used as the basis of the UTM (Universal Transverse Mercator). The UTM is not a single map projection but divides the Earth into sixty zones, each a six-degree band of longitude, and uses a Transverse Mercator projection.

In Australia, MGA coordinates (Map Grid of Australia) are based on the UTM using the ellipsoid GRS80 previously defined.

So an MGA coordinate (Easting, Northing) has a unique (Latitude, Longitude).

And a reading from a GNSS device (commonly known as GPS) uniquely converts to a MGA coordinate, and conversely a MGA coordinate converts to (Latitude, Longitude) for use in a GPS without knowing anything about a local coordinate system.

Continue to 33.5.3 Why Isn’t MGA Used on a Small Building Site? or return to 33.5 What is Wrong with Local Coordinates? or 33 BIM.
33.5.3 Why Isn’t MGA Used on a Small Building Site?

It is very easy to gloss over one very important point about Transverse Mercator projections as used in MGA.

Transverse Mercator projections are conformal projections and although they preserve angles, they do not preserve distances.

So a small circle will transform to a small circle but the radius will vary depending on where you are in an MGA zone.

The amount of the distortion is known as a scale factor and it varies from point to point. Over a small distance the scale factor is almost a constant but that constant value is rarely 1.

What that means in practise is if you draw everything up in MGA coordinates, the actual distance between two points in NOT the standard square root distance between the two points. This means that on a plan in MGA coordinates, you can’t simply use a ruler to measure he distance between two points. You need to allow for the scale factor. Over a small distance the scale factor will be a constant (for example 0.9996) but over a large distance you need to need to do the correct Geodetic calculations.

This also means that in a standard drafting system, the usual distance between two points that is used in conventional drafting dimensioning options, will not give the correct value.

For those working in a local coordinate project you may have noticed the scale factor effect when you have identified two points a good distance apart and you also have their MGA coordinates. If you measure between the points in your local coordinate system and then calculate the square root distance between the two MGA points using the actual MGA coordinates then you won’t get the same number.

This is probably why most projects defined in local coordinates only give the MGA coordinates for one point and a rotation of the axes.

The result of all this is that if you only have a small building site then you can obtain fairly accurate MGA coordinates by applying a 2D Helmert transformation to the local coordinates. That is, a translation, a rotation or the axis and a constant multiplication factor (which could be the Point Scale Factor of the given MGA point).

However, as the size of the project increases, the larger errors will be in the MGA coordinates for points further away from the origin.

Similarly if you apply a translation, rotating and scale to convert data given in MGA coordinates (say from a GIS system or the State Road Authority) to local coordinates, then there will be errors the further away from the "best fitted" point.

Note
If you are not a surveyor you will probably not be aware that in 12d Model, you can specify the Cartographic projection that the coordinates are in and can then obtain the (Latitude, Longitude) for selected points, measure between points and get the square-root distance and also the ellipsoid distance between the points.

Return to 33.5 What is Wrong with Local Coordinates? or 33 BIM.
The 12d Archive file format (called 12d ascii in Version 10 and earlier) is a text file definition from 12d Solutions which is used for reading and writing out string data from 12d Model. 12d Archive files normally end in ‘.12da’ and are often referred to as 12da files.

Unlike the earlier 12d Ascii files in Version 9, from Version 10 onwards the 12d Archive file is a Unicode file.

This document is for the 12d Archive file format used in 12d Model Version 11.

For General Comments about 12da, see 34.1 General Comments about a 12da File

For the 12da definitions:

- Attributes 34.2 Attributes
- Commands 34.3 Commands
- Each string type 34.4 12da Definition for each String Type
- Tin 34.3.7 Tin
- Super Tin 34.3.8 Super Tin

For documentation on the 12d XML file format, see 35 12d XML File Format.
34.1 General Comments about a 12da File

**Unicode** - 12d Archive file is a Unicode file.

```//
```
Anything written on a line after `//` is ignored. This is used to place comments in the file.

**Blank lines**
Unless they are part of a text string, blank lines are ignored.

**Spaces**
Unless enclosed in quotes (""), more than one consecutive space or tab is treated as one space. Except when it is the delimiter after a `//`, an end of line (<enter>) is also considered a space.

**Spaces and special characters in text strings**
Any text string that includes spaces and any characters other than a to z, A to Z or 0 to 9 (alphanumeric), must be enclosed in double quotes. In text strings, double quotes " and backslash \ must be preceded by a \. For example, " and \ define a " and a \ respectively in a text string.

**Names of models, tins, styles, colours and attributes**
Models, tins, styles (linestyles), colours and attributes can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters) and space. Leading and trailing spaces are ignored. The names can be up to 255 characters in length. If the name includes spaces, the name must be enclosed in double quotes ("").

The names for models, tins, styles, colours or attributes can not be blank.

The names for models, tins, styles and colours can contain upper and lower alpha characters which are stored, but the set of model names, tin names, style names, colour names or attribute names for an object must be unique when case is ignored. For example, the model name "Fred" will be stored as "Fred" but "FRED" is considered to be the same model name as "Fred".

**String names**
String names can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters), space, decimal point (.), plus (+), minus (-), comma (,), open and closed round brackets and equals (=). Leading and trailing spaces are ignored. String names can be up to 255 characters in length. If the string name includes anything other than alphanumeric characters, then the name must be enclosed in double quotes (""").

String names can contain upper and lower alpha characters which are retained but case is ignored when selecting by string name. That is, the string name Fred will be stored as Fred but FRED is not considered to be a different string name.

String names do not have to be unique and can be blank.

Continue to the next section 34.2 Attributes or return to 34 12d Archive File Format.
34.2 Attributes

Many 12d Model objects (models and elements such as individual strings and tins) can have an unlimited number of named attributes of type integer (numbers), real and text.

The attributes for an object are given in an attributes block which consists of the keyword attributes followed by the definitions of the individual attributes enclosed in start and end curly braces { and }. That is, an attributes_block is:

```
attributes {
  attribute_1
  attribute_2
  ...
  attribute_n
}
```

where the attribute definitions for the individual attributes attribute_i consists of:

```
  attribute_type attribute_name attribute_value
```

where

- attribute_type is integer, real or text
- attribute_name is the unique attribute name for the object.

If the attribute name includes spaces then the text of the name must be enclosed in double quote character ("")

and

- attribute_value is the appropriate value of the integer, real or a text.

Within an object, the attribute names are case sensitive and must be unique. That is, for attribute names, upper and lower case alphabet characters are considered to be different characters.

If the text for a text attribute includes spaces then the text must be enclosed in double quote characters ("."). If the text is blank, it is given as "".

An example of an attribute block defining four attributes named "pole id", "street", "pole height" and "pole wires" is:

```
attributes {
  text "pole id" "QMR-37"
  text "street" "477 Boundary St"
  real "pole height" 5.25
  integer "pole wires" 3
}
```

Continue to the next section 34.3 Commands or return to 34.12d Archive File Format.
34.3 Commands

Commands consist of a keyword followed by a space and then a value (a keyword and its value is often referred to as a keyword pair). A value must always exist.

```
keyword    value       // a keyword pair
```

There can be more than one command keyword pair per line as long as each keyword pair is separated by a space. In fact, the keyword can be on one line and the value on the next line.

Although the names of commands are only shown in lower case in these notes, commands are case insensitive and all combinations of case are recognised as the same command. That is model, MODEL and Model are all recognised as the command model.

For the definition of the commands in the 12da file see:

34.3.1 Model
34.3.2 Colour
34.3.3 Style
34.3.4 Breakline
34.3.5 Null
34.3.6 String
34.3.7 Tin
34.3.8 Super Tin

Or return to 34 12d Archive File Format.
34.3.1 Model

There are two formats for the model command:

(a) model command when there are no attributes for the model

```
model  model_name
```

All elements (strings, tins, plot frames etc) following until the next model keyword are placed in the model `model_name`. This can be overridden for an element by a model command inside the element definition.

The default model name used for elements when no model name has been specified is `data`.

(b) model command when there are model attributes

If the model includes attributes, the following form of the model command must be used.

```
model {
  name  model_name
  attributes_block
}
```

where the `attributes_block` is defined in 34.2 Attributes.

For example:

```
model {
  name  "telegraph poles"
  attributes {
    text  "pole id"       "QMR-37"
    text  "street"        "477 Boundary St"
    real "pole height"    5.25
    integer "pole wires"   3
  }
}
```

Continue to the next section 34.3.2 Colour or return to 34.3 Commands or 34 12d Archive File Format.
34.3.2 Colour

The format of the `colour` command is:

```
colour  colour_name
```

When reading a 12da file, there is a `current colour`, which has the default value of `red`, and when a `colour` command is read, the `current colour` is set to `colour_name`.

When strings are read in a 12da file, they are given the `current colour`.
This can be overridden for a string by a `string colour command` inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.3 Style or return to 34.3 Commands or 34 12d Archive File Format.

34.3.3 Style

The format of the `style` command is:

```
style  linestyle_name
```

When reading a 12da file, there is a `current linestyle`, which has the default value of `1`, and when a `style` command is read, the `current linestyle` is set to `linestyle_name`.

When strings are read in a 12da file, they are given the `current linestyle`.
This can be overridden for a string by a `string style command` inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.4 Breakline or return to 34.3 Commands or 34 12d Archive File Format.

34.3.4 Breakline

The format of the `breakline` command is:

```
breakline  breakline_type
```

where `breakline_type` is `point` or `line`.

When reading a 12da file, there is a `current breakline type`, which has the default value of `point`, and when a `breakline` command is read, the `current breakline type` is set to `breakline_type`.

When strings are read in a 12da file, they are given the `current breakline type`.
This can be overridden for a string by a `string breakline command` inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.5 Null or return to 34.3 Commands or 34 12d Archive File Format.
34.3.5 Null

The format of the null command is:

```
null   null_value
```

When reading a 12da file, there is a current null value, which has the default value of -999, and when a null command is read, the current null value is set to null_value.

When strings are read in a 12da file and the string has z-values equal to null_value, then the z-value is replaced by the 12d Model null value.

This can be overridden for a string by a null_value command inside the string command defining that string. For the definition of the string command, see 34.3.6 String.

Continue to the next section 34.3.6 String or return to 34.3 Commands or 34 12d Archive File Format.
34.3.6 String

The format of the string command is:

```
string  string_type  {  
  attributes_block
  string_command_1
  string_command_2
  ...
  string_command_n
}
```

The *string_type* is compulsory and must be followed by all the string information enclosed in curly braces { and }.

So if a *string type*, or possibly information inside the string is not recognised, the 12da reader has a chance of being able to jump over the string by looking for the end curly brace }.

Inside the braces are *string commands* as keyword pairs defining information for the string.

There can be more than one *string command* keyword per line as long as each keyword pair is separated by a space. In fact, the *keyword* can be on one line and the *value* on the next line.

Any unrecognised *string commands* are ignored.

The *string command keyword pairs* include *model*, *colour*, *style* and *breakline*, which are all *optional* inside the string definition. However if any of them exist inside a string definition, then the *string command keyword* overrides the current value for *model*, *colour*, *style* or *breakline commands* but the override is only for that particular string.

Not all string types can have an *attributes_block*.

For some string types (e.g. super string) there is more data required than just the *string command* keyword pairs.

This extra data is contained is blocks consisting of a *keyword* followed by the required information enclosed in the curly braces { and }. For example attributes for all *string types* and (x,y,z) data for a super string.

For all string types, if there is not enough recognised information to define the string, the string is ignored.

For the definition for each *string type* and the allowed *string commands* and extra data that is required for that *string type*, see 34.4 12da Definition for each String Type.

**Note:** if the string does not have any attributes then the *attributes_block* can be left out entirely (see 34.2 Attributes for the definition of *attributes_block*).

Continue to the next section 34.3.7 Tin or return to 34.3 Commands or 34 12d Archive File Format.
34.3.7 Tin

Tins (triangulated irregular networks) and Super Tins can be written out and read in from a 12da.

```
tin {
    name  tin_name  // MANDATORY name of the tin when created in 12d Model
    time_created text  // optional - time tin first created
    time_updated text  // optional - time tin last modified

    // Attributes Block:

    // The attributes style, faces, null_length, null_angle, null_combined_value
    // and null_combined_angle are special attributes that has extra information used by
    // 12d Model to create the tin. These special attributes should not be deleted.
    //
    // The attributes in this block and the Attributes block itself are optional.
    // When a tin is read into 12d Model from a 12da file, the style is used
    // as the Tin style.

    attributes {
        text "style" text  // name of line style for the tin
        integer "faces" 0/1  // 0 non triangle data, 1 triangle data
        real "null_length" value  // values for null by angle/length
        real "null_angle" value  // angle in radians
        real "null_combined_length" value  // angle in radians
        real "null_combined_angle" value  // angle in radians
    }
    // any other attributes
}
```

```
// Points Block

// Co-ordinates of the points at the vertices of the triangles
// The points are implicitly numbered by the order in the list (starting at point 1).
//
// The Points Block is MANDATORY

points {
    x-value  y-value  z-value  // point 1
    ""    ""    ""  // point 2
}
```

```
// Triangles Block

// Each triangle is given as a triplet of the point numbers that make up
// the triangle vertices (the point numbers are the implicit position of the points
// given in the Points Block.
// The order of the triangles is unimportant
//
// The Triangles Block is MANDATORY
```
triangles {  // points making up each triangle
    T1-1    T1-2    T1-3  // point numbers of the 3 vertices of first triangle.
    T2-1    T2-2    T3-3  // point numbers of the 3 vertices of second triangle.
}                        // end of triangles block

// Base Colour
// The tin has a base colour that is the default colour for all triangles

colour tin_base_colour     // optional - base colour of the tin

// Colours Block
// Triangles can be given colours other than the base colour by including
// a colours block. The colour for each triangle in then individually given
// (-1 means base colour). The order is the same as the order of the triangles in
// the Triangles Block.
// If all the triangles are the base colour, then simply omit the Colours Block

colours {  // colour for each triangle given in triangle order
    C1    C2    C3
    C4    C5    C6    C7  // colour "-1" means use the base tin colour.
}              // end of colours block

// Input Block
// More information about how the tin was created by 12d Model.
// None of this information is needed when reading a tin into 12d Model.
// This block can be omitted

input {  // data for reconstructing tin from strings
    preserve_strings true/false  // if true, preserve breaklines etc.
    remove_bubbles true/false
    weed_tin true/false
    triangle_data true/false
    sort_tin true/false
    cell_method true/false

    models {  // name of the first model making up the tin
        "model_name_1"
        "model_name_2"  // name of the second model making up the tin
    }                        // end of models block
}                              // end of input block
}                                 // end of tin 12a definition
Continue to the next section 34.3.8 Super Tin or return to 34.3 Commands or 34.12d Archive File Format.
34.3.8 Super Tin

*Super Tins*, which consists of a number of tins (triangulated irregular networks), can be written out and read in from a 12da.

```plaintext
super_tin {
    name  tin_name     // MANDATORY name of the super tin

    time_created text   // optional - time super tin first created
    time_updated text    // optional - time super tin last modified

    // Attributes Block:
    // This is mainly information used by 12d Model to create the super tin.
    // The attributes in this block and the Attributes block itself are optional.
    // When a super tin is read into 12d Model from a 12da file, the style is used
    // as the Super Tin style.

    attributes {
        text "style" text    // name of line style for the tin
        // any other attributes
    }                        // end of attributes block

    // Super Tin Colour
    // The super tin has a base colour

    colour tin_base_colour     // optional - base colour of the super tin

    // Tins Block
    // This is the list of tins that make up the super tin.
    // This block is MANDATORY

    tins {
        "tin_name_1"           // name of the first tin making up the super tin
        "tin_name_2"           // name of the second tin making up the super tin
        "  " "  
    }
}
```

Note that the tins that make up the super tin must exist in 12d Model for the super tin to be fully defined.

Continue to the next section 34.4 12da Definition for each String Type or return to 34.3 Commands or 34 12d Archive File Format.
34.4 12da Definition for each String Type

For the 12da definition of each string type, see:
- 34.4.1 Arc String
- 34.4.2 Circle String
- 34.4.3 Drainage String
- 34.4.4 Face String
- 34.4.5 Feature String
- 34.4.6 Interface String

    colour colour_name style style_name
    breakline point or line
    data { // keyword
        x-value y-value z-value mode
        " " " " // mode = -1 cut
        " " " " // 0 surface
        " " " " // 1 fill
    }
}
```

Continue to the next section 34.4.7 Plot Frame String or return to 34.4.12da Definition for each String Type or 34.4.12d Archive File Format.
### 34.4.7 Plot Frame String

Plot frames can be written out and read in from a 12da file.

```plaintext
string plot_frame {
    name frame_name
    title_file filename
    border 0 or 1
    viewport 0 or 1
    user_title_file 0 or 1
    title_1 text
    title_2 text
    plot_file filename
    text_size mm
    sheet_code text
    width value
    height value
    scale value
    rotation value
    xorigin value
    yorigin value
    left_margin mm
    right_margin mm
    top_margin mm
    bottom_margin mm
    plotter text
    colour colour
    textstyle textstyle_name
}
```

Continue to the next section 34.4.8 Super String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.
34.4.8 Super String

Because the super string is so versatile, its 12da format looks complicated but it is very logical and actually quite simple.

In its most primitive form, the super string is simply a set of (x,y) values as in a 2d string, or (x,y,z) values as in a 3d string, or (x,y,z,radius,bulge_flag) as for a polyline string or even lines, arcs and transitions (spirals and non-spiral transitions).

Additional blocks of information can extend the definition of the super string. For example, text, pipe diameters and visibility.

Some of the properties of the super string extend what were constant properties for the entire string in other string types. For example, breakline type for the string extends to tinability of vertices and segments. One colour for the string extends to individual colours for each segment.

Other properties such as vertex id’s (point numbers), visibility and culvert data are entirely new.

For user attributes, the super string still has the standard user attributes defined for the entire string, but user attributes for each vertex and segment are also supported.

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a super string, being closed is a property of the string and no extra vertex is needed. That is, the first and the last vertices are not the same for a closed super string and the super string knows there is an additional segment from the last vertex back to the first vertex.

Hence in the 12da format, there is a closed flag for the super string:

```
closed  true  or  false
```

where true can be 1 or T or t or Y or y (or words starting with T, t, Y or y))
and false is 0 or F or f or N or n (or words starting with F, f, N or n).

Thus if a string has $n$ vertices, then an open string has $n-1$ segments joining the vertices and a closed string has $n$ segments since there is an additional segment from the last to the first vertex.

With the additional data for vertices and segments in the super string, the data is in vertex or segment order. So for a string with $n$ vertices, there must be $n$ bits of vertex data. For segments, if the string is open then there only needs to be $n-1$ bits of segment data but for closed strings, there must be $n$ bits of data. For an open string, $n$ bits of segment data can be specified and the $nth$ bit will be read in and stored. If the string is then closed, the $nth$ bit of data will be used for the extra segment.
The full 12da definition of the super string is:

```plaintext
string super {
  chainage start_chainage
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  closed true or false
  interval {
    chord_arc value       // chord-to-arc tolerance for curves
    distance value        // chainage interval to break the geometry up
  }

  block of info {
  }
  block of info {
  }
  block of info {
  }
}
```

The blocks of info can be broken up into four types.

(a) blocks defining the position of the vertices in z, y and z

`data_2d` or `data_3d`
(b) blocks defining the geometry of the segments
   *radius_data* and *major_data* or *geometry_data*

(c) a superseded block defining vertices and segment geometry
   *data*

(d) extra information for the vertices and/or segments
   pipe diameters - *diameter_value* or *diameter_data*
   culvert dimensions - *culvert_value* or *culvert_data*
   pipe/culvert justification - *justify*
   colour - *colour* or *colour_data*
   vertex ids (point numbers) at each vertex- *point_data*
   tinability - *breakline* or *vertex_tinability_data* and *segment_tinability_data*
   visibility - *vertex_visible_data* and *segment_visible_data*
   vertex text and annotation - *vertex_text_data* and *vertex_annotation_data*
   segment text and annotation - *segment_text_data* and *segment_annotation_data*
   symbols at vertices - *symbol_value* or *symbol_data*
   vertex attributes - *vertex_attribute_data*
   segment attributes - *segment_attribute_data*
   extrudes
   image data
   holes

The definition for the blocks of each type now follows.

(a) Blocks Defining the Position of the Vertices

For (x, y) Values with a Constant z

If there is only (x,y) values at each vertex (like a 2d string):

```plaintext
data_2d { // keyword
  x-value  y-value
  "      
  "      
}
```

and if there is a non-null constant z for the string

```plaintext
z  value
```

For (x,y,z) Values

If there is (x,y,z) values at each vertex (like a 3d string):

```plaintext
data_3d { // keyword
  x-value  y-value  z-value
  "      "      "
  "      "      "
}
```

(b) Blocks Defining the Geometry of the Segments

Straights and Arcs Only for the Segments

If data_2d or data_3d was used, it is possible to add radius and bulge_flag data:

```plaintext
radius_data { // keyword
  radius for first segment
  radius for second segment
}
radius for last segment

major_data { // keyword
  bulge flag for first segment
  bulge flag for second segment
  ...
  bulge flag for last segment
}

Straights, Arcs and Transitions (Spiral and non-Spiral Transitions) for the Segments

If data_2d or data_3d was used, it is possible to specify if the segments are straight, arcs or transitions using a geometry_data block.

geometry_data {
  segment_info_1 { // information on the first segment
  }
  segment_info_2 { // information on the second segment
  }
  " "
  " "
  segment_info_n-1 { // the last segment if it is open
    information on the (n-1) segment
  }
  segment_info_n { // the last segment if it is closed
    information on the n-th segment
  }
}

where the segment_info blocks are from the following:

(a) Straight

No parameters are needed for defining a straight segment. The straight block is simply:

straight { // no parameters are needed for a straight
}

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices.

We use positive and negative radius, and a flag major which can be set to 1 (on) or off (0) to differentiate between the four possibilities.
So the arc block is:

```plaintext
arc {
  radius  value  // radius of the arc (+ve is above the line connecting the vertices)
  major   0 or 1  // 0 is the smaller arc, 1 the larger arc).
}
```

(c) Spiral - this covers both spiral and non-spiral transitions

There can be a partial transition between adjacent vertices. The partial transition is defined by the parameters:

- \( l_1 \): length of the full transition up to the start vertex
- \( r_1 \): radius of the transition at the start vertex
- \( a_1 \): angle in decimal degrees of the tangent to the transition at the start vertex
- \( l_2 \): length of the full transition up to the end vertex
- \( r_2 \): radius at the end vertex
- \( a_2 \): angle in decimal degrees of the tangent to the transition at the end vertex

Since a radius cannot be zero, a radius of infinity is denoted by zero.

The transition is said to be a leading transition if the absolute value of the radius is increasing along the direction of the transition (the transition will tighten). Otherwise it is a trailing transition.

If a leading transition is a full transition then \( r_1 = 0 \) and \( l_1 = 0 \). Similarly if a trailing transition is a full transition then \( r_2 = 0 \) and \( l_2 = 0 \).

For a partial transition, if the coordinates of the start of the full transition are needed then they can be calculated from \( l_1, r_1, a_1, l_2, r_2, a_2 \) and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii’s are positive then a leading transition will curl to the right (and will be above the line joining the start and end vertices).
The parameters for the *spiral* block are:

```plaintext
spiral {
  type value // type can be clothoid, cubic parabola, westrail-cubic,
               // cubic spiral, natural clothoid, blossom,
               // blossom, sinusoidal, cosinusoidal
  leading 1 or 0 // 1 denotes a leading transition, 0 a trailing transition
  l1 value // length of the full transition at start vertex
  r1 value // radius at the start vertex
  a1 value // angle in decimal degrees of the tangent to the transition
               // at the start vertex
  l2 value // length of the full transition at end vertex
  r2 value // radius at end vertex
  a2 value // angle in decimal degrees of the tangent to the transition
               // at the end vertex
}
```

Notes

1. The *spiral* block covers both spiral and non-spiral transitions.
2. The transitions/spirals supported by 12d Model are:

- **Clothoid** - spiral approximation used by Australian road authorities and Queensland Rail.
- **Cubic parabola** – special transition curve used by NSW railways. Not a spiral.
- **Westrail cubic** – spiral approximating used by WA railways.
- **Cubic spiral** – low level spiral approximation. Only ever used in surveying textbooks.
- **Natural Clothoid** – the proper Euler spiral. Not used by any authority.
**Bloss** – special transition used by Deutsche Bahn. Not a spiral.  
**Sinusoidal** - special transition. Not a spiral.  
**Cosinusoidal** - special transition. Not a spiral.

(c) Block Defining the Vertices and Segments
For compatibility with the polyline, the *data* block gives the \((x,y,z,\text{radius},\text{bulge})\) values at each vertex of the string and so defines both the vertices and the geometry of the segments in the one block.

\[
data \{ \hspace{1cm} \text{// keyword} \\
x\text{-value} & y\text{-value} & z\text{-value} & \text{radius} & \text{bulge} \\
\% \% \% \% \\
\%
\}
\]

(d) Other Blocks

Pipe Diameters
There can be one pipe diameter value for the entire super string or the pipe diameter varies for each segment of the super string.

\[
diameter\text{\_value} \hspace{0.5cm} \text{value} \\
\text{or} \\
diameter\text{\_data} \{ \hspace{1cm} \text{// keyword} \\
\text{pipe diameter for first segment} \\
\text{pipe diameter for second segment} \\
\cdots \\
\text{pipe diameter for last segment} \\
\}
\]

Culvert Dimensions
There can be one culvert width and height for the entire super string or the culvert width and height vary for each segment of the super string.

\[
culvert\text{\_value} \{ \\
\text{width value} \\
\text{height value} \\
\}
\text{or} \\
culvert\text{\_data} \{ \text{properties} \{ \hspace{1cm} \text{// width and height for first segment} \\
\text{width value} \\
\text{height value} \\
\}
\text{properties} \{ \hspace{1cm} \text{// width and height for second segment} \\
\text{width value} \\
\text{height value} \\
\}
\cdots \\
\text{properties} \{ \hspace{1cm} \text{// width and height for last segment} \\
\text{width value} \\
\text{height value} \\
\}
\}
\]

Justification for Pipe or Culverts
There can be only one justification for the pipe or culvert for the entire super string.
justify justification // bottom or invert
// top or obvert
// centre (default)

Colour
There can be one colour for the entire super string which is given by the `colour` command at
the beginning of the string definitions (before the blocks of information) or the colour varies for
each segment of the super string and is specified in a `colour_data` block.

```
colour_data {  // keyword
    colour for first segment
    colour for second segment
    ...
    colour for last segment
}
```

Vertex Id’s (Point Numbers)
Each vertex can have a vertex id (point number). This is not the order number of the vertex in the
string but is a separate id which is usually different for every vertex in every string. The vertex id
can be alphanumeric.

```
point_data {  // keyword
    vertex id or first vertex  // alphanumeric
    vertex id for second vertex
    ...
    vertex id for last vertex
}
```

Tinability
For a `super string`, the concept of breakline has been extended to a property called `tinable` which
can be set independently for each vertex and each segment of the super string.

If a vertex is tinable, then the vertex is used in triangulations. If the vertex is not tinable, then the
vertex is ignored when triangulating.

If a segment is tinable, then the segment is used as a side of a triangle during triangulation. This
may not be possible if there are crossing tinable segments.

```
vertex_tinable_data {  // keyword
    tinable flag for first vertex  // 1 for tinable
    tinable flag for second vertex  // 0 for not tinable
    ...
    tinable flag for last vertex
}
```

```
segment_tinable_data {  // keyword
    tinable flag for first segment  // 1 for tinable
    tinable flag for second segment  // 0 for not tinable
    ...
    tinable flag for last segment
}
```

Note that even if a segment is set to tinable, is can only be used if both its end vertices are also
tinable.

Visibility
For a super string, the concept of visibility and invisibility for vertices and segments has been introduced.

```plaintext
vertex_visible_data {
    visibility flag for first vertex // 1 for visible
    visibility flag for second vertex // 0 for invisible
    ...
    visibility flag for last vertex
}

segment_visible_data {
    visibility flag for first segment // 1 for visible
    visibility flag for second segment // 0 for invisible
    ...
    visibility flag for last segment
}
```

**Vertex Text and Vertex Annotation**

There can be the same piece of text for every vertex in the super string or a different text for each vertex of the super string. How the text is drawn is specified by vertex annotation values. Note that in vertex annotations, all vertices must be either worldsize or all vertices papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all vertices.

```plaintext
vertex_text_value
    text
or
vertex_text_data {
    text for first vertex // text string, enclose
    text for second vertex // by " " if there are any
    ...
    text for last vertex
}

vertex_annotate_value {
    angle value offset value raise value
    textstyle textstyle_name slant degrees xfactor value
    worldsize value or papersize value or screensize value
    justify "top|middle|bottom-left|centre|right"
    colour colour_name
}
or
vertex_annotate_data {
    properties {
        angle value offset value raise value
        textstyle textstyle_name slant degrees xfactor value
        worldsize value or papersize value or screensize value
        justify "top|middle|bottom-left|centre|right"
        colour colour_name
    }
    properties {
        text properties second vertex
    }
    properties {
        ...
    }
    properties {
        text properties for last vertex
    }
}
```

**Segment Text and Segment Annotation**
There can be the same piece of text for every segment in the super string or a different text for each segment of the super string. How the text is drawn is specified by segment annotation values. Note that in segment annotations, all segments must be either worldsize or all segments papersize. That is, worldsize and papersize can not be mixed - the first one found is used for all segments. However, vertex text and segment text do not both have to be papersize or worldsize.

```
segment_text_value
  text
or
segment_text_data {
  text for first segment
  // text string, enclose
  text for second segment
  // by " " if there are any
  ...
  // spaces in the text string
  text for last segment
}
```

```
segment_annotate_value {
  angle value offset value raise value
  textstyle textstyle slant degrees xfactor value
  worldsize value or papersize value or screensize value
  justify "top|middle|bottom-left|centre|right"
  colour colour_name
}
or
segment_annotate_data {
  properties {
    angle value offset value raise value
    textstyle textstyle slant degrees xfactor value
    worldsize value or papersize value or screensize value
    justify "top|middle|bottom-left|centre|right"
    colour colour_name
  }
  properties { text properties second segment }
  properties { ...
  }
  properties { text properties for last segment }
}
```

**Symbols**

There can be the same symbol (defined as a linestyle) for every vertex in the super string or a different symbol for each vertex of the super string. If a symbol does not have a colour, then it uses the string colour or the segment colour.

```
symbol_value {
  // keyword
  style linestyle_name colour colour_name size value
  rotation value    // in dms
  offset value    raise value
}
or
symbol_data {
  // keyword
  properties {
    style linestyle_name colour colour_name size value
    style linestyle colour colour size value
    rotation value    // in dms
    offset value    raise value
  }
  properties { symbol and properties for second vertex }
```
properties { ... }
properties { symbol and properties for last vertex }
}

Vertex Attributes
Each vertex can have one or more user defined named attributes.

```plaintext
vertex_attribute_data {
    attributes {
        attribute_type  attribute_name  attribute_value
        attribute_type  attribute_name  attribute_value
        ...
        attribute_type  attribute_name  attribute_value
    }
    attributes { named attributes for second vertex }
    attributes { ...
    }
    attributes { named attributes for last vertex }
}
```

Segment Attributes
Each segment can have one or more user defined named attributes.

```plaintext
segment_attribute_data {
    attributes {
        attribute_type  attribute_name  attribute_value
        attribute_type  attribute_name  attribute_value
        ...
        attribute_type  attribute_name  attribute_value
    }
    attributes { named attributes for second segment }
    attributes { ...
    }
    attributes { named attributes for last segment }
}
```

Continue to the next section 34.4.9 Super Alignment String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.
34.4.9 Super Alignment String

In an alignment string, only the intersection point method (IP’s) could be used to construct the horizontal and vertical geometry. The IP definition is actually a constructive definition and the tangents points and segments between the tangent points (lines, arcs, transitions etc.) are calculated from the IP definition. For an alignment string, only the IP definitions are included in the 12da file.

For a super alignment, the horizontal and vertical geometry are also defined separately and with construction definitions but the construction definition can be much more complex than just IP’s. For example, an arc could be defined as being tangential to two offset elements, or constrained to go through a given point.

If the horizontal construction methods are consistent then the horizontal geometry can be solved, and the horizontal geometry expressed in terms of consecutive segments (lines, arcs, transitions) that are easily understood and drawn.

Similarly if the vertical construction methods are consistent then the vertical geometry can be solved, and the vertical geometry expressed in terms of consecutive segments (lines, arcs, parabolas) that are easily understood and drawn.

Unlike the alignment, the super alignment stores both the construction methods (the parts) and the resulting vertices and segments (lines, arcs, transitions etc.) that make up the horizontal and vertical geometry (the data).

For many applications such as uploading to survey data collectors or machine control devices, only the horizontal data and the vertical data are required, not the construction methods (i.e. the horizontal and vertical parts). When reading the 12da of a super alignment, only the horizontal and vertical data needs to be read in and the constructive methods (the horizontal and vertical parts) can be skipped over.

Vertices and Segments Forming the Horizontal Data for a Super Alignment
Notes

1. Just using the horizontal and vertical data is valid as long as the super alignment geometry is consistent (and solves) and the horizontal and vertical parts can be created. There are flags in the 12da of the super alignment to say that the horizontal and vertical geometry is consistent and solves.

2. Segments meeting at a common vertex do not have to be tangential although for most road and rail applications, they should be.

The full 12da definition of the super alignment is:

```c
string super_alignment {
    //
    name                string_name
    chainage            start_chainage
    colour              colour_name
    style               style_name
    breakline           point or line
    closed              true or false
    spiral_type         transition_type
    // the spiral_types are clothoid,
    // cubic parabola, westrail-cubic,
    cubic spiral,
    // natural clothoid, blossom, sinusoidal
    and
    // cosinusoidal. Note that some
    spiral_type's
    // are non-spiral transitions
    valid_horizontal    true or false
    valid_vertical      true or false
    // if true then the horizontal geometry
    // is consistent and solves
    // if true then the horizontal geometry
    // is consistent and solves
    block of info { }
    block of info { }
    block of info { }
} // end of super alignment
```

where the block of info can be one of more of:

- attributes, horizontal_parts, horizontal_data, vertical_parts, vertical_data.

The attributes block has been described in the earlier section 34.2 Attributes.

The structure of the blocks horizontal_parts, horizontal_data which define the horizontal geometry, and vertical_parts and vertical_data which define the vertical geometry will now be described in more detail.

For information on horizontal geometry, go to Horizontal Geometry.

For information on vertical geometry, go to Vertical Geometry.
Horizontal Geometry

The horizontal geometry is described by two blocks - the `horizontal_parts` block and the `horizontal_data` block.

The `horizontal_parts` block contains the methods to construct the horizontal geometry such as float (fillet) an arc of a certain radius between two given lines or create a transition (spiral or non-spiral transition) between a line and an arc.

If the horizontal construction methods are consistent, then they can be solved to form a string made up of lines, arcs and transitions. The `horizontal_data` block is simply a list of the vertices and segments (lines, arcs etc.) that make up the solved geometry.

If the geometry in the `horizontal_parts` can be solved and produces a valid `horizontal_data` block, then the flag `valid_horizontal` in the super_alignment block is set to `true`.

```plaintext
valid_horizontal true or false  // true if the horizontal geometry can be solved and
// hence create a valid horizontal_data

horizontal_parts {                  // methods for creating the horizontal geometry
...;
}

horizontal_data {                     // the horizontal segments that make up the solved
  geometry
...;
}
```

For information on `horizontal_parts`, go to the section `Horizontal_parts` and `horizontal_data` `Horizontal_data`

Horizontal_parts

The `horizontal_parts` block describes the methods used to construct the horizontal geometry of the super alignment. The parts that make up the horizontal geometry are defined in chainage order from the start to the end of the super alignment.

```plaintext
horizontal_parts {  // methods for creating the horizontal geometry
  blocks defining the sequential parts
  making up the horizontal geometry
}
```

Apart from the special case of parts defined by horizontal intersection points and their accompanying transitions and arcs, the other parts in the `horizontal_parts` block are not documented.

Horizontal_parts for defined by IP Method Only

For a horizontal intersection point (HIP) with no transitions or arc defined at that HIP, the part is defined by:

```plaintext
ip {
  id value  // part id - a number that is unique for each horizontal and vertical part,
  x value  // and the value of part id is a multiple of 100
  y value  // x co-ordinate of the horizontal intersection point
}
```

For a horizontal intersection point (HIP) with an arc but no transitions defined at that HIP, the part is defined by
arc {
  id  value  // part id - a number that is unique for each horizontal and vertical part,
          // and the value of part id is a multiple of 100
  r   value  // radius of the arc at the HIP
  x   value  // x co-ordinate of the HIP
  y   value  // y co-ordinate of the HIP
}

For a horizontal intersection point (HIP) with an arc and transitions defined at that HIP, the part is defined by

spiral {
  id  value  // part id - a number that is unique for each horizontal and vertical part,
           // and the value of part id is a multiple of 100
  r   value  // radius of the arc at the HIP
  l1  value  // length of the leading transition at the HIP
  l2  value  // length of the trailing transition at the HIP
  x   value  // x co-ordinate of the HIP
  y   value  // y co-ordinate of the HIP
}

Note that the transition used in the spiral block is given by spiral_type in the super_alignment block.

Hence a super alignment with horizontal geometry defined by IP methods only would consist of a horizontal_parts section with only the above ip, arc and spiral blocks in it.

horizontal_parts {
  ip_spiral_arc {
    values  // values defining the ip_spiral_arc block
   "
    values
  }
  ....
  ip_spiral_arc {
    values  // values defining the ip_spiral_arc block
   "
    values
  }
}

For example,
### Horizontal data

The `horizontal_data` block contains the solved horizontal geometry of the super alignment. The solved horizontal geometry is made up of a series of \( (x,y) \) vertices given in a `data_2d` block followed by a `geometry_data` block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, an arc, a transition (e.g. a spiral) or a partial transition.

If the horizontal geometry has \( n \) vertices, then there will be \((n-1)\) segments for an open super alignment or \( n \) segments if the super alignment is closed.

The format of the `horizontal_data` block is:

```
horizontal_data {
  name ""
  chainage
  breakline line or point
  colour
  style linestyle
  closed 0 or 1 // 0 if the string is open, 1 if it is closed
}
```
interval {
  chord_arc value  // chord-to-arc tolerance for curves
  distance value   // chainage interval to break the geometry up
}

data_2d {
  x1-value y1-value  // co-ordinates of the first vertex
  x2-value y2-value  // co-ordinates of the second vertex
  "    "
  xn-value yn-value  // co-ordinates of the n-th vertex
}

geometry_data {
  segment_info_1 {
    information on the first segment
  }
  segment_info_2 {
    information on the second segment
  }
  "    "
  segment_info_n-1 {
    information on the (n-1) segment
  }
  segment_info_n {
    information on the n-th segment
  }
}

where the segment_info blocks are from the following:

(a) Straight

No parameters are needed for defining a straight segment. The straight block is simply:

straight {
  // no parameters are needed for a straight
}

(b) Arc

There are four possibilities for an arc of a given radius placed between two vertices. We use positive and negative radius, and a flag major which can be set to 1 (on) or off (0) to differentiate between the four possibilities.
So the arc block is:

```
arc {
    radius value // radius of the arc (+ve is above the line connecting the vertices)
    major 0 or 1 // 0 is the smaller arc, 1 the larger arc.
}
```

(c) Spiral - this covers both spiral and non-spiral transitions

There can be a partial transition between adjacent vertices. The partial transition is defined by the parameters

- \( l_1 \) length of the full transition up to the start vertex
- \( r_1 \) radius of the transition at the start vertex
- \( a_1 \) angle in decimal degrees of the tangent to the transition at the start vertex
- \( l_2 \) length of the full transition up to the end vertex
- \( r_2 \) radius at the end vertex
- \( a_2 \) angle in decimal degrees of the tangent to the transition at the end vertex

Since a radius cannot be zero, a radius of infinity is denoted by zero.

The transition is said to be a leading transition if the absolute value of the radius is increasing along the direction of the transition (the transition will tighten). Otherwise it is a trailing transition.

If a leading transition is a full transition then \( r_1 = 0 \) and \( l_1 = 0 \). Similarly if a trailing transition is a full transition then \( r_2 = 0 \) and \( l_2 = 0 \).

For a partial transition, if the coordinates of the start of the full transition are needed then they can be calculated from \( l_1, r_1, a_1, l_2, r_2, a_2 \) and the co-ordinates of the start and end vertices.

Note that the radii can be positive or negative. If the radii's are positive then a leading transition will curl to the right (and will be above the line joining the start and end vertices).

The parameters for the spiral block are:

```
spiral {
    type transition_type // any of the transitions supported in 12d
    leading 1 or 0 // 1 denotes a leading transition, 0 a trailing transition
    l1 value // length of the full transition at start vertex
    r1 value // radius at the start vertex
    a1 value // angle in decimal degrees of the tangent to the transition at start vertex
    l2 value // length of the full transition at end vertex
    r2 value // radius at the end vertex
    a2 value // angle in decimal degrees of the tangent to the transition at end vertex
}
```
r2 value // radius at end vertex
a2 value // angle in decimal degrees of the tangent to the transition
// at the end vertex

Notes
1. The **spiral** block covers both spiral and non-spiral transitions.
2. The transitions/spirals supported by **12d Model** are:

```
Select Choice

- clothoid
- cubic parabola
- westrail cubic spir
- cubic spiral
- natural clothoid
- bloss
- sinusoidal
```

**Clothoid** - spiral approximation used by Australian road authorities and Queensland Rail.

**Cubic parabola** – special transition curve used by NSW railways. Not a spiral.

**Westrail cubic** – spiral approximating used by WA railways.

**Cubic spiral** – low level spiral approximation. Only ever used in surveying textbooks.

**Natural Clothoid** – the proper Euler spiral. Not used by any authority.

**Bloss** – special transition used by Deutsche Bahn. Not a spiral.

**Sinusoidal** - special transition. Not a spiral.

**Cosinusoidal** - special transition. Not a spiral.
Vertical Geometry

The vertical geometry is described by two blocks - the vertical_parts block and the vertical_data block.

The vertical_parts block contains the methods to construct the vertical geometry such as float (fit) a parabola of a certain length between two given lines.

If the vertical construction methods are consistent, then they can be solved to form a string made up of lines, parabolas and arcs. The vertical_data block is simply a list of the vertices and segments (lines, parabolas and arcs) that make up the solved geometry.

If the geometry in the vertical_parts can be solved and produces a valid vertical_data block, then the flag valid_vertical in the super_alignment block is set to true.

```plaintext
valid_vertical  true or false /// true if the vertical geometry can be solved and // hence create a valid vertical_data
vertical_parts { // methods for creating the vertical geometry
    ....
}
vertical_data { // the vertical geometry
    ....
}
```

For information on vertical_parts, go to the section Vertical_parts Vertical_data

Vertical_parts

The vertical_parts block describes the methods used to construct the vertical geometry of the super alignment. The parts that make up the vertical geometry are defined in chainage order from the start to the end of the super alignment.

```plaintext
vertical_parts { // methods for creating the vertical geometry
    blocks defining the sequential parts
    making up the vertical geometry
}
```

Apart from the special case of parts defined by vertical intersection points and their accompanying parabolas and arcs, the other parts in the vertical_parts block are undocumented.

Vertical_parts for defined by IP Method Only

For a vertical intersection point (VIP) with no parabola or arc defined at that VIP, the part is defined by:

```plaintext
ip {
    id  value  // part id - a number that is unique for each horizontal and vertical part,
    x   value  // and the value of part id is a multiple of 100
    y   value  // chainage co-ordinate of the VIP
}
```

For a vertical intersection point (VIP) with a parabola defined by a k value at that VIP, the part is defined by

```plaintext
kvalue {
    id  value  // part id - a number that is unique for each horizontal and vertical part
}
```
tical part,  
    // and the value of part id is a multiple of 100
    k value  // k-value of the parabola at the VIP
    x value  // chainage co-ordinate of the VIP
    y value  // height co-ordinate of the VIP
  }

For a vertical intersection point (VIP) with a parabola defined by length at that VIP, the part is
defined by

  length {
    id value  // part id - a number that is unique for each horizontal and vertical part,
    // and the value of part id is a multiple of 100
    l value  // length of the parabola at the VIP
    x value  // chainage co-ordinate of the VIP
    y value  // height co-ordinate of the VIP
  }

For a vertical intersection point (VIP) with a parabola defined by an effective radius at that VIP,
the part is defined by

  radius {
    id value  // part id - a number that is unique for each horizontal and vertical part,
    // and the value of part id is a multiple of 100
    r value  // effective radius of the parabola at the VIP
    x value  // chainage co-ordinate of the VIP
    y value  // height co-ordinate of the VIP
  }

For a vertical intersection point (VIP) with an asymmetric parabola defined by the start and end
lengths at that VIP, the part is defined by

  length {
    id value  // part id - a number that is unique for each horizontal and vertical part,
    // and the value of part id is a multiple of 100
    l1 value  // start length of the asymmetric parabola at the VIP
    l2 value  // end length of the asymmetric parabola at the VIP
    x value  // chainage co-ordinate of the VIP
    y value  // height co-ordinate of the VIP
  }

For a vertical intersection point (VIP) with an arc defined by a radius at that VIP, the part is
defined by

  arc {
    id value  // part id - a number that is unique for each horizontal and vertical part,
    // and the value of part id is a multiple of 100
    r value  // radius of the arc at the VIP
    x value  // chainage co-ordinate of the VIP
    y value  // height co-ordinate of the VIP
  }

Hence a super alignment with vertical geometry defined by IP methods only would consist of a
vertical_parts section with only the above ip, parabola and arc blocks in it.
vertical_parts {
  ip_parabola_arc {
    values // values defining the ip_parabola_arc
    block
      "
      values
    }
    ....
    ip_parabola_arc {
      values // values defining the ip_parabola_arc
      block
        "
        values
      }
  }
}

For example,
The \textit{vertical\_data} block contains the solved vertical geometry of the super alignment.

The solved vertical geometry is made up of a series of (chainage, height) vertices given in a \textit{data\_2d} block followed by a \textit{geometry\_data} block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, a parabola or an arc.

If the vertical geometry has \(n\) vertices, then there will be \((n-1)\) segments for an open super alignment or \(n\) segments if the super alignment is closed.

The format of the \textit{vertical\_data} block is:

\begin{verbatim}
vertical\_data { 

\end{verbatim}
name ""
chainage value
breakline line or point
colour colour
style linestyle
closed 0 or 1 // 0 if the string is open, 1 if it is closed
interval {
  chord_arc value // chord-to-arc tolerance for curves
  distance value // chainage interval to break the geometry up
}
data_2d {
  ch1-value ht1-value // co-ordinates of the first vertex
  ch2-value ht2-value // co-ordinates of the second vertex
  " "
  chn-value htn-value // co-ordinates of the n-th vertex
}
geometry_data {
  segment_info_1 {
    information on the first segment
  }
  segment_info_2 {
    information on the second segment
  }" "
  " "
  segment_info_n-1 { // the last segment if it is open
    information on the (n-1) segment
  }
  segment_info_n { // the last segment if it is closed
    information on the n-th segment
  }
}

where the segment_info blocks are from the following:

(a) Straight
No parameters are needed for defining a straight segment. The straight block is simply:

    straight { // no parameters are needed for a straight
}

(b) Arc
Since vertical geometry can’t go backwards in chainage value, the majors arcs can not be used and hence there are only possibilities for an arc of a given radius placed between two vertices.

We use positive and negative radius to differentiate between the four possibilities.

So the arc block is:

    arc {
      radius value // radius of the arc (+ve is above the line connecting vertices)
      major value // this is ignored since only minor arcs are used
    }
Parabola

There can be a parabola between adjacent vertices. The parabola is defined by giving the coordinates of the vertical intersection point for the parabola:

- **chainage**: chainage of the VIP of the parabola
- **height**: height of the VIP of the parabola

The parameters for the *parabola* block are:

```plaintext
parabola {
  chainage value // chainage of the VIP of the parabola
  height value // height of the VIP of the parabola
}
```

Continue to the next section [34.4.10 Text String](#) or return to [34.4 12da Definition for each String Type](#) or [34.12d Archive File Format](#).
34.4.10 Text String

string text {
   x value  y value  z value
   model model_name  name string_name  colour colour_name
   text  text_value
   angle value  offset value  raise value
   textstyle textstyle_name  slant degrees  xfactor value
   worldsize value  or papersize value  or screensize value
   justify "top|middle|bottom-left|centre|right"
}

The string types in the following sections have been superceded.

Continue to the next section 34.4.11 2d String or return to 34.4 12da Definition for each String Type or 34.12d Archive File Format.
34.4.11 2d String

The 2d string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```plaintext
string 2d {
  z  value  chainage  start_chainage
  model  model_name  name  string_name
  colour  colour_name  style  style_name
  breakline  point or line
  data {  // keyword
    x-value  y-value
    "    "
  }
}
```

Continue to the next section 34.4.12 3d String or return to 34.4 12da Definition for each String Type or 34.12d Archive File Format.
34.4.12 3d String

The 3d string has been superceded and has been replaced by the super string (see \texttt{34.4.8 Super String}).

```c
string 3d {
    chainage \textit{start\_chainage}
    model \textit{model\_name} name \textit{string\_name}
    colour \textit{colour\_name} style \textit{style\_name}
    breakline point or line
    data { // keyword
        x-value y-value z-value
        " " " \\
        " " "
    }
}
```

Continue to the next section \texttt{34.4.13 4d String} or return to \texttt{34.4 12da Definition for each String Type} or \texttt{34.12d Archive File Format}.
34.4.13 4d String

The 4d string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```plaintext
string 4d {
    angle value  offset value  raise value
    worldsize value  or  papersize value  or  screensize value
    chainage start_chainage
    model model_name  name string_name
    colour colour_name  style style_name
    breakline point or line
    textstyle text  slant degrees  xfactor value
    justify "top|middle|bottom-left|centre|right"
    data {       // keyword
        x-value  y-value  z-value  text       // text can not be blank
            " "       " "       " "       // use "" for no text.
    }
}
```

Continue to the next section 34.4.14 Pipe String or return to 34.4 12da Definition for each String Type or 34.12d Archive File Format.
34.4.14 Pipe String

The pipe string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

```plaintext
string pipe {
  diameter value  chainage start_chainage
  model  model_name  name  string_name
  colour  colour_name  style  style_name
  breakline  point or line
  data { // keyword
    x-value  y-value  z-value
      "      "      "
      "      "      "
  }
}
```

Continue to the next section 34.4.15 Polyline String or return to 34.4 12da Definition for each String Type or 34.12d Archive File Format.
34.4.15 Polyline String

The polyline string has been superceded and has been replaced by the super string (see 34.4.8 Super String).

The definition of a closed string has been refined for polyline and super strings. For other string types, closing a string simply meant having the first vertex the same as the last vertex. Hence the vertex was duplicated.

For a polyline string, being closed is a property of the string and no extra vertex is needed - the first and the last vertices are not the same and the polyline string knows there is an additional segment from the last vertex back to the first vertex.

In the 12da format, there is a new closed flag for the polyline string:

```
closed true or false
```

where true can be 1 or T or t or Y or y (or words starting with T, t, Y or y))
and false is 0 or F or f or N or n (or words starting with F, f, N or n).

```
string polyline {
  model model_name name string_name
  colour colour_name style style_name
  breakline point or line
  closed true or false

  data { // keyword
    x-value y-value z-value radius bulge_flag
    " " " "
  }
}
```

Continue to the next section 34.4.16 Alignment String or return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.
34.4.16 Alignment String

The alignment string has been superceded and has been replaced by the super alignment (see 34.4.9 Super Alignment String).

In an alignment string the horizontal and vertical geometry are given separately and both can only be defined by the intersection point method (IP’s).

For the horizontal geometry, the \((x,y)\) position of the horizontal intersection points (HIPS) are given in the order that they appear in the string, plus the circular radius and left and right transition lengths on each HIP.

Hence a horizontal intersection point is given by either

\[
\begin{align*}
\text{x-value} &\quad \text{y-value} &\quad \text{radius} &\quad \text{// circular curve, no transition} \\
\text{x-value} \quad \text{y-value} &\quad \text{radius} \quad \text{spil1} \quad \text{left-transition-length} \quad \text{spil2} \quad \text{right-transition-length}
\end{align*}
\]

\(\text{radius, left-transition-length, right-transition-length}\) can be zero (meaning they don't exist).

For the vertical geometry, the \((\text{chainage, height})\) position of the vertical intersection points (VIPs) are given in increasing chainage order, plus either the radius of the circular arc or the length of the parabolic curve on each VIP.

Hence for a vertical intersection point is given by either

\[
\begin{align*}
\text{ch_value} &\quad \text{z-value} &\quad \text{length} &\quad \text{parabola} \\
\text{ch_value} \quad \text{z-value} &\quad \text{radius} &\quad \text{circle}
\end{align*}
\]

where

the word \text{parabola} is optional. \text{length} and \text{radius} can be zero, meaning that the parabola or arc doesn't exist.

\[
\begin{align*}
\text{string alignment} &\quad \{
\text{model model_name} \quad \text{name string_name} \\
\text{colour colour_name} \quad \text{style style_name} \\
\text{chainage start\_chainage} \quad \text{interval value} \\
\text{draw\_mode value} &\quad \text{// 1 to draw crosses at HIPs and VIPs, 0 don’t draw} \\
\text{spiral\_type text} &\quad \text{// spiral\_type covers both spiral and non-spiral transitions.} \\
&\quad \text{// For an alignment string, the supported transition types} \\
&\quad \text{// are clothoid, cubic parabola, westrail-cubic, cubic spiral} \\
&\quad \text{// More transition are supported in the super alignment} \\
&\quad \text{//}
\}

\text{hipdata} \quad \{
\text{x-value y-value} \quad \text{radius} &\quad \text{// or} \\
\text{x-value y-value} &\quad \text{radius} \quad \text{spil1} \quad \text{left-transition-length} \quad \text{spil2} \quad \text{right-transition-length}
\}

\text{vipdata} \quad \{
\text{ch_value z-value} \quad \text{parabolic-length} &\quad \text{// or} \\
\text{ch_value z-value} \quad \text{parabolic-length} &\quad \text{parabola} \quad \text{// or} \\
\text{ch_value z-value} &\quad \text{radius} &\quad \text{circle}
\}
\]

Continue to the next section 34.4.17 Pipeline String or return to 34.4 12da Definition for each String Type or 34.1 12d Archive File Format.
34.4.17 Pipeline String

The pipeline string has been superceded and has been replaced by the super alignment (see 34.4.9 Super Alignment String).

This is the same as an alignment string except that it has the additional keywords

- **diameter**, which gives the diameter of the pipeline in world units
- **length** of the typical pipe making up the pipeline (used for deflections).

```plaintext
string pipeline {
    model model_name  name string_name
    colour colour_name  style style_name
    diameter diameter  length pipe-length
    chainage start_chainage  interval value
    spiral_type text  // spiral_type covers both spiral and non-spiral transitions
                        // supported by 12d. For an alignment string, the
                        // supported transition types are clothoid, cubic parabola,
                        // westrail-cubic, cubic spiral. Other transition types
                        // are supported in the super alignment
    hipdata {
        x-value y-value radius  // some hips must exist and precede vips
        x-value y-value radius  spill1  left-transition-length  spill2  right-transition-length
    }
    vipdata {  // vips optional
        ch-value z-value parabolic-length
        ch-value z-value parabolic-length  parabola  // or
        ch-value z-value radius  circle
    }
}
```

Return to 34.4 12da Definition for each String Type or 34 12d Archive File Format.
35 12d XML File Format

*Extensible Markup Language (XML)* is a markup language that defines a set of rules for encoding documents in a format which is both human-readable and machine-readable. It is defined by the World Wide Web Consortium’s (W3C) XML Specifications which are free open standards.

The 12d XML file format is a text file definition from 12d Solutions which is used for reading and writing out string data from *12d Model*. 12d XML files normally end in `.12dxml`.

The 12d XML file is a Unicode file.

This document is for the 12d XML file format used in *12d Model* Version 11.

For general comments see:

- 35.1 General Information about XML
- 35.2 General Information about a 12d XML File

For the 12d XML definitions see:

- 35.4 Attributes
- 35.5 Model
- 35.6 Elements Contained in Models which includes
  - 35.6.1 Tin
  - 35.6.2 Super Tin
  - 35.6.5 Arc String
  - 35.6.6 Circle String
  - 35.6.7 Drainage String
  - 35.6.8 Feature String
  - 35.6.9 Plot Frame String
  - 35.6.10 Super String
  - 35.6.11 Super Alignment String
  - 35.6.12 Text String
  - 35.6.13 Trimesh

For documentation on the 12d Archive (12da) file format, see 34 12d Archive File Format.
35.1 General Information about XML

(Unicode) Character
By definition, an XML document is a string of characters. Almost every legal Unicode character may appear in an XML document.

Markup and Content
The characters making up an XML document are divided into markup and content, which may be distinguished by the application of simple syntactic rules.

Generally, strings that constitute markup either begin with the character < and end with a >, or they begin with the character & and end with a ;.

Strings of characters that are not markup are content.

However, in a CDATA section, the delimiters <![CDATA[ and ]]> are classified as markup, while the text between them is classified as content. In addition, whitespace before and after the outermost element is classified as markup.

Characters "<", ">", and "&"
The characters "<", ">", and "&" are key syntax markers and may never appear in content outside a CDATA section. They need to be represented by special escape sequences:

- &lt represents "<"
- &gt represents ">"
- &amp represents "&"

Tag
An XML tag is a markup construct that begins with < and ends with >.
Tags come in three flavours:
(a) start-tags - for example: <section>
(b) end-tags - for example: </section>
(c) empty-element tags - for example: <line-break />

XML Element
A logical document component which either begins with a start-tag and ends with a matching end-tag or consists only of an empty-element tag.
The characters between the start- and end-tags, if any, are the element’s content, and may contain markup, including other elements, which are called child elements.

An example of an element is <Greeting>Hello, world.</Greeting>. Another is <line-break />.

Note: Because elements are 12d Model items that are in a model, in the documentation of 12d XML we will refrain from using element for the element in XML. Instead we will use the words keyword block to refer to special XML Elements in 12d XML.

Empty XML Elements <keyword/>
When an XML element has no content it is called an empty element.
For example <name> </name>
There is special shorthand for empty elements:
<keyword/> is shorthand for <keyword></keyword>

XML Attribute
A markup construct consisting of a name/value pair that exists within a start-tag or empty-element tag. In the example (below) the element *img* has two attributes, *src* and *alt*:

```xml
<img src="madonna.jpg" alt='Foligno Madonna, by Raphael'/>
```

Another example would be

```xml
<step number="3">Connect A to B.</step>
```

where the name of the attribute is "number" and the value is "3".

An XML attribute can only have a single value and each attribute can appear at most once on each element.

**Note:** Because attributes are fundamental *12d Model* items, in the documentation of 12d XML the word attribute will refer to *12d Model* attributes.

The words **XML attribute** will always be used when there is need to refer to an XML attribute.

### XML declaration

XML documents may begin by declaring some information about themselves, as in the following example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
```

### Escaping

XML provides escape facilities for including characters which are problematic to include directly. For example:

There are five predefined entities:

- **&lt;** represents "<"
- **&gt;** represents ">
- **&amp;** represents "&"
- **&apos;** represents '
- **&quot;** represents "
- **&#xa;** represents a new line.

### XML Comments

Comments may appear anywhere in a document outside other markup. Comments cannot appear before the XML declaration.

Comments start with "<!--" and end with "-->".

For compatibility with SGML, the string "--" (double-hyphen) is not allowed inside comments; this means comments cannot be nested.

The ampersand has no special significance within comments, so entity and character references are not recognized as such, and there is no way to represent characters outside the character set of the document encoding.

An example of a valid comment: "<!--no need to escape <code> & such in comments-->

Continue to the next section 35.2 General Information about a 12d XML File or return to 35 12d XML File Format.
35.2 General Information about a 12d XML File

Unicode

12d XML file is a Unicode file.

Blank lines

Unless they are part of a string of characters making up text, blank lines are ignored.

Names of models, tins, styles, colours and attributes

Models, tins, styles (linestyles), colours and attributes can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters) and space. Leading and trailing spaces are ignored. The names can be up to 255 characters in length.

The names for models, tins, styles, colours or attributes can not be blank.

The names for models, tins, styles and colours can contain upper and lower alpha characters which are stored, but the set of model names, tin names, style names, colour names or attribute names for an object must be unique when case is ignored. For example, the model name "Fred" will be stored as "Fred" but "FRED" is considered to be the same model name as "Fred".

String names

String names can include the characters a to z, A to Z, 0 to 9 (alphanumeric characters), space, decimal point (.), plus (+), minus (-), comma (,), open and closed round brackets and equals (=).

Leading and trailing spaces are ignored.

String names do not have to be unique and can be blank.

String names can contain upper and lower alpha characters which are retained but case is ignored when selecting by string name. That is, the string name Fred will be stored as Fred but FRED is not considered to be a different string name.

Keywords Blocks

There are many regularly used blocks of information in 12d XML that are identified and documented by keywords.

The keyword and its block consist of a starting <keyword>, followed by the information in the keyword block, and ending in </keyword>

That is

<keyword> information in the keyword block </keyword>

Continue to the next section 35.3 Regularly Used Keyword Blocks or return to 35 12d XML File Format.
35.3 Regularly Used Keyword Blocks

In the documentation of 12d XML the term **keyword block** refers to a `<keyword>` followed by various information then a `</keyword>`. For the definition of some of the regularly used keyword blocks used in the 12d XML see:

- 35.3.1 Name
- 35.3.2 Colour
- 35.3.3 Line Style
- 35.3.4 Chainage
- 35.3.5 Weight
- 35.3.6 Interval
- 35.3.7 Time Created
- 35.3.8 Time Updated
- 35.3.9 Breakline
- 35.3.10 Null

Or return to 35 12d XML File Format.

### 35.3.1 Name

The format of the name keyword block is:

```
<name>name_text</name>
```

where **name_text** is a string of characters.

What characters can be in the name depends on where the name is used. See [Names of models, tins, styles, colours and attributes](#) and [String names](#).

Continue to the next section 35.3.2 Colour or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

### 35.3.2 Colour

The format of the colour keyword block is:

```
<colour>colour_name</colour>
```

where **colour_name** is a string of characters that is to be the name of a colour or the colour number.

When reading a 12d XML file, there is a current colour, which has the default value of red, and when a colour command is read, the current colour is set to colour_name.

When strings are read in a 12d XML file, they are given the current colour.

This can be overridden for a string by a string colour command inside the string command defining that string. For the definition of the string commands, see 35.6.3 String Header Block.

Continue to the next section 35.3.3 Line Style or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.
35.3.3 Line Style

The format of the **line style** keyword block is:

```xml
<style>line_style_name</style>
```

where `line_style_name` is the name of a line style. It is a string of characters.

When reading a 12d XML file, there is a **current linestyle**, which has the default value of 1, and when a **style** command is read, the **current linestyle** is set to `linestyle_name`.

When strings are read in a 12d XML file, they are given the **current linestyle**. This can be overridden for a string by a **string style command** inside the string command defining that string. For the definition of the string command, see Section 35.6.3 String Header Block.

Continue to the next section 35.3.4 Chainage or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.4 Chainage

The format of the **chainage** keyword block is:

```xml
<chainage>chainage_real</chainage>
```

where `chainage_real` is a real value.

Continue to the next section 35.3.5 Weight or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.5 Weight

The format of the **weight** keyword block is:

```xml
<weight>weight_real</weight>
```

where `weight_real` is a real value.

Continue to the next section 35.3.6 Interval or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

35.3.6 Interval

For all elements other than the super string, the format of the **interval** keyword block is:

```xml
<interval>interval_real</interval>
```

where `interval_real` is a real value.

For a super string, the format of the **interval** keyword block is:

```xml
<interval>
    <chord_arc>chord_arc_real</chord_arc>
    <distance>distance_real</distance>
</interval>
```

where `chord_arc_real` and `distance_real` are real values.

Continue to the next section 35.3.7 Time Created or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.
35.3.7 Time Created

The format of the `time_created` keyword block is:

\[
\text{<time_created>time_text</time_created>}
\]

where `time_text` is a string of characters in the W3C time format.

\[
\text{DD-MMM-YYYYThh:mm:ssZ}
\]

and

- `dd` in the day of the month
- `MMM` in the first three letters of the month
- `YYYY` in the year
- `hh` in the hour in the 24-hour clock
- `mm` in the number of minutes
- `ss` in the number of seconds

For example, 28-Apr-2015T06:42:45Z

Continue to the next section 35.3.8 Time Updated or return to 35.3 Regularly Used Keyword Blocks or 35.12d XML File Format.

35.3.8 Time Updated

The format of the `time_updated` keyword block is:

\[
\text{<time_updated>time_text</time_updated>}
\]

where `time_text` is a string of characters in the W3C time format.

\[
\text{DD-MMM-YYYYThh:mm:ssZ}
\]

and

- `dd` in the day of the month
- `MMM` in the first three letters of the month
- `YYYY` in the year
- `hh` in the hour in the 24-hour clock
- `mm` in the number of minutes
- `ss` in the number of seconds

For example, 28-Apr-2015T06:42:45Z

Continue to the next section 35.3.9 Breakline or return to 35.3 Regularly Used Keyword Blocks or 35.12d XML File Format.

35.3.9 Breakline

The format of the `breakline` keyword block is:

\[
\text{<breakline>breakline_type_text </breakline>}
\]

where `breakline_type_text` is text and can only have the values `point` or `line`.

When reading a 12d XML file, there is a current `breakline` type, which has the default value of `point`, and when a `breakline` command is read, the current `breakline` type is set to `breakline_type_text`.
When strings are read in a 12d XML file, they are given the current breakline type. This can be overridden for a string by a string breakline command inside the string command defining that string. For the definition of the string command, see 35.6.3 String Header Block.

Continue to the next section 35.3.10 Null or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

### 35.3.10 Null

**NOT CERTAIN ABOUT NULL ??**

The format of the null command is:

```
null null_value
```

When reading a 12d XML file, there is a current null value, which has the default value of -999, and when a null command is read, the current null value is set to null_value.

When strings are read in a 12d XML file and the string has z-values equal to null_value, then the z-value is replaced by the 12d Model null value.

This can be overridden for a string by a null_value command inside the string command defining that string. For the definition of the string command, see 35.6.3 String Header Block.

Continue to the next section 35.3.11 Radius or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

Continue to the next section 35.4 Attributes or return to 35 12d XML File Format.

### 35.3.11 Radius

The format of the radius keyword block is:

```
<radius>
  radius_real
</radius>
```

where radius_real is a real value.

Continue to the next section 35.3.12 data_2d or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.

### 35.3.12 data_2d

For some strings, there is a constant z for the entire string, or even no z value at all. For such strings only the (x,y) coordinates are required for each vertex and no space is taken up by redundant z values. Vertex data with no z-values is written out in a data_2d block.

The definition of a data_2d block is:

```
<data_2d>
  <p>x_value_1  y_value_1</p>
  <p>x_value_2  y_value_2</p>
  ...
  <p>x_value_n  y_value_n</p>
</data_2d>
```

where (x_value_i, y_value_i) are the 2D coordinates of the i’th vertex.

Continue to the next section 35.3.13 data_3d or return to 35.3 Regularly Used Keyword Blocks or 35 12d XML File Format.
35.3.13 data_3d

For most string, the z value can vary for each vertex along the string and so the (x,y,z) values are required for each vertex. This vertex data is written out as a data_3d block.

The definition of a data_3d block is:

```xml
<data_3d>
  <p>x_value_1  y_value_1  z_value_1</p>
  <p>x_value_2  y_value_2  z_value_2</p>
  ...
  <p>x_value_n  y_value_n  z_value_n</p>
</data_3d>
```

where (x_value_i, y_value_i, z_value_i) are the 3D coordinates of the i'th vertex.

For example, for a string of 5 vertices

```xml
<data_3d>
  <p>42578.27649249 37366.79821468 null</p>
  <p>42523.36402317 37252.26649295 null</p>
  <p>42575.1386371 37043.59910954 null</p>
  <p>42826.16706828 37026.34090489 null</p>
  <p>42766.49603263 37412.54781911 61.53707464</p>
</data_3d>
```

35.3.14 radius_data and major_data

If there are only straight and arc segments for the string, then for either data_2d or data_3d, it is possible to add a radius and major/minor arc flag for each segment of the string using the radius_data and major_data blocks respectively.

The order of the entries in the radius_data and major_data blocks must match the order of the segments in the string (which is also the order in the data_2d or data_3d block).

So there is exactly one entry for each segment.

**Note:** If there are n vertices in the super string, then there are (n-1) segments for a open string (not closed) and n segments for a closed string.

For each segment there are five possibilities for an arc going between the vertices and these are specified by using positive, zero or negative values for the radius, and 1 or 0 for the major flag.

1. Straight segment - radius = 0. Major flag can be 1 or 0.
2. Positive radius and major flag 0
   The arc is above the straight line joining the two vertices but the arc is the smaller of the two possibilities (minor arc).
3. Positive radius and major flag 1
   The arc is above the straight line joining the two vertices but the arc is the larger of the two possibilities (major arc).
4. Negative radius and major flag 0
   The arc is below the straight line joining the two vertices but the arc is the smaller of the two possibilities (minor arc).
5. Negative radius and major flag 1
   The arc is below the straight line joining the two vertices but the arc is the larger of the two possibilities (major arc).
The *radius_data* block is

```xml
<radius_data>
    radius_for_segment_1
    radius_for_segment_2
    ...
    radius_for_segment_m
</radius_data>
```

where

- `radius_for_segment_i` is the radius for the i’th segment and can be positive, zero or negative, and
- \( m = n-1 \) for an open string or \( m = n \) for a closed string.

If the *radius_block* is missing then the radius is taken to be 0 and all the segments are straight lines.

The *major_data* block is

```xml
<major_data>
    major_flag_for_segment_1
    major_flag_for_segment_2
    ...
    major_flag_for_segment_m
</major_data>
```

where

- `major_flag_for_segment_i` for the i’th segment is 1 or t if the arc is a major arc, and 0 or f if it is a minor arc, and
- \( m = n-1 \) for an open string or \( m = n \) for a closed string.

If the *major_block* is missing then the major flag is taken to be 0 and any segments with arcs are always the minor arcs.

For example, for a closed string of five vertices

```xml
<radius_data>
    100 -300 0 0 0
</radius_data>
<major_data>
    f f f f f
```
35.3.15 Available Transition Types

The transition that are available are

where

- **clothoid**, (or **spiral**) is the spiral approximation used by Australian road authorities and Queensland Rail
- **cubic parabola** (or **state wide rail nsw**) is a special transition curve used by NSW Railways. It is not a spiral.
- **westrail cubic** spiral (or **westrail-cubic**) is a spiral approximation used by WA railways.
- **cubic spiral** (or **spiral**) is a low level spiral approximation. Mainly only used in surveying textbooks.
- **natural clothoid** (or landxml spiral or clothoid landxml) is the full Euler spiral. Not used by any Authority in Australia or New Zealand.
- **bloss** is a Bloss curve.
- **sinusoidal** is a sinusoidal curve.
- **cosinusoidal** is a cosinusoidal curve.
35.4 Attributes

Many 12d Model objects (models and elements such as individual strings and tins) can have an unlimited number of named attributes of type integer (numbers), real and text. Super strings and drainage strings can also have attributes on each vertex and segment.

The attributes for an object are given in an attributes block which consists of the keyword attributes followed by the definitions of the individual attributes enclosed in start and end curly braces { and }. That is, an attributes block is

```
<attributes>
  attribute_1
  attribute_2
  ...
  attribute_n
</attributes>
```

where the attribute definitions for the individual attributes attribute_i consists of

```
<attribute_type>
  <name> attribute_name </name> <value> attribute_value </value>
</attribute_type>
```

where

- attribute_type is integer, real or text
- attribute_name is the unique attribute name for the object.
- attribute_value is the appropriate value of the integer, real or a text.

OR

where attribute_type is group

```
<group>
  <name> group_name </name> attributes_block
</group>
```

where

- group_name is the unique name of the group at this level
- attributes_block is another attributes_block.

Note that the definition of <group> includes an attributes_block which can contain another <group> so the definition is recursive.

Hence you can have a hierarchy or tree of attributes going down to any level.

Within an object, the attribute names are case sensitive and must be unique. That is, for attribute names, upper and lower case alphabet characters are considered to be different characters.

An example of an attributes block defining four attributes named "pole id", "street", "pole height" and "pole wires" is:

```
<attributes>
  <text> <name>pole id</name> <value>QMR-37</value> </text>
  <text> <name>street</name> <value>477 Boundary St</value> </text>
</attributes>
```
<real> <name>pole wires</name> <value>3</value> </text>
</attributes>

Continue to the next section 35.5 Model or return to 35 12d XML File Format.
35.5 Model

Within a 12d Model project, information is collected in units called MODELS. The items that can be stored in a model are called elements and elements include strings, tins, super tins, grid tins, trimeshes and plot frames.

Each model has a unique user-defined text name, model_name, of up to two hundred alphanumeric characters and spaces.

The format for the model keyword block is:

```xml
<model>
  <name>model_name</name>
  attribute_block
  time_created_block
  time_updated_block
  <children>
    element_data_1
    ...  
    element_data_n
  </children>
</model>
```

where:

- model_name is a string of characters for the model name. For the characters allowed, see
- attribute_block is option. For attributes_block see 35.4 Attributes.
- time_created_block is optional. See 35.3.7 Time Created.
- time_updated_block is optional. See 35.3.8 Time Updated.
- element_data_i is an element stored in the model. See 35.6 Elements Contained in Models.

The children block is optional and is mainly there so that in an xml editor, the element_data_i items can be collapsed into the children section.

An example of a model with no elements and no children block:

```xml
<model>
  <name>telegraph poles</name>
  <attributes>
    <text> <name>pole id</name> <value>QMR-37</value> </text>
    <text> <name>street</name> <value>477 Boundary St</value> </text>
    <real> <name>pole wires</name> <value>3</value> </real>
  </attributes>
</model>
```

Continue to the next section 35.6 Elements Contained in Models or return to 35 12d XML File Format.
35.6 Elements Contained in Models

See

35.6.1 Tin
35.6.2 Super Tin
35.6.5 Arc String
35.6.6 Circle String
35.6.7 Drainage String
35.6.8 Feature String
35.6.9 Plot Frame String
35.6.10 Super String
35.6.11 Super Alignment String
35.6.12 Text String
35.6.1 Tin

A tin (triangulated irregular networks) is an element that may, or may not, be in a model. Each tin has a text name, \textit{tin\_name}, of up to two hundred alphanumeric characters and spaces and the names of each tin and super tin in the project must be unique.

The format for the \textit{tin} element is:

\begin{verbatim}
<tin>
  <name>tin\_name</name>
  attribute\_block
  time\_created\_block
  time\_updated\_block
  colour\_block
  points\_block
  triangles\_block
  colours\_block
  input\_block
</tin>
\end{verbatim}

where

\textit{tin\_name}

is a string of characters for the tin name and can't be blank. This must be unique in a project.

For the characters that can make up a tin\_name, see \underline{Names of models, tins, styles, colours and attributes}.

\textit{time\_created\_block}

is the time the tin was originally created, This is optional. For the syntax see \underline{35.3.7 Time Created}.

\textit{time\_updated\_block}

is the last time the tin was last modified, This is optional. For the syntax see \underline{35.3.7 Time Created}.

\textit{colour\_block}

this colour number is the primary (base) colour for all the triangles in the tin. A triangle in the tin will have this colour unless it is overridden by a \textit{colours\_block}. For the syntax of colour\_block, see \underline{35.3.2 Colour}.

\textit{attribute\_block} is optional: For the syntax of an \textit{attributes\_block} see \underline{35.4 Attributes}.

The attributes in this block and the attributes\_block itself are optional.

The attributes \textit{Style}, \textit{Weed}, \textit{Faces}, \textit{Boundary\_String}, \textit{null\_length}, \textit{null\_angle}, \textit{null\_combined\_length} and \textit{null\_combined\_angle} are special attributes that have extra information used by \underline{12d Model} to create the tin. These special attributes should not be deleted.

The format of the special attributes inside the \langle\textit{attributes}\rangle \ldots \langle/\textit{attributes}\rangle is:

\begin{verbatim}
<text> <name>Style</name> <value>style\_name</value> </text>
<integer> <name>Weed</name> <value>weed\_value</value> </integer>
<integer> <name>Faces</name> <value>faces\_value</value> </integer>
<text> <name>Boundary\_String</name> <value>full\_string\_name</value> </text>
<real> <name>null\_length</name> <value>null\_len\_val</value> </real>
<real> <name>null\_angle</name> <value>null\_angle\_rad</value> </real>
<real> <name>null\_combined\_length</name> <value>null\_com\_ln</value> </real>
\end{verbatim}
<real> <name>null_combined_angle</name><value>null_com_rad</value></real>

where

- **style_name** is the style for the tin
- **weed_value** is 0 or 1
- **faces_value** is 0 if the data is not from triangles, 1 if the data is from triangles
- **full_string_name** is the name of a polygon for nulling outside. This is optional.
- **null_len_val** is value for nulling by angle
- **null_angle_rad** is in radians value for nulling by angle
- **null_com_ln** is for nulling by combined angle and length
- **null_com_rad** is in radians for nulling by combined angle and length

**points_block**

This gives the coordinates of the points that will be vertices of the triangles in the tin. The points are implicitly numbered by the order in the list (starting at point 1). The Points Block is MANDATORY.

```xml
<points>
  <p>x_value_1  y_value_1  z_value_1</p>
  <p>x_value_2  y_value_2  z_value_2</p>
  ...
  <p>x_value_m  y_value_m  z_value_m</p>
</points>
```

where (x_value_j, y_value_j, z_value_j) are the coordinates of the j'th point.

**triangles_block**

This gives the triangles that make up the tin.

Each triangle is given as a triplet of the point numbers in the Points block that are the triangle vertices. The order of the triangles is unimportant. The Triangles Block is MANDATORY.

```xml
<triangles>
  <t>t1_pt_1  t1_pt_2  t1_pt_3</t>
  <t>t2_pt_1  t2_pt_2  t2_pt_3</t>
  ...
  <t>tn_pt_1  tn_pt_2  tn_pt_3</t>
</triangles>
```

where tk_pt_1  tk_pt_2  tk_pt_3 are point numbers from the points_block of the three vertices of the k'th triangle.

**colours_block**

Triangles can be given colours other than the base colour by including a Colours Block. The colour for each triangle in then individually given where -1 means use the base colour. The order of the entries in the colours block must match the order of the triangles in the Triangles Block. So there is exactly one entry for each triangle.

If all the triangles are the base colour, then the Colours Block is omitted.

```xml
<colours>
</colours>
```
where \( c_k \) is the colour number of the \( k \)'th triangle in the \( \text{triangles}_\text{block} \).
\( c_k \) equals -1 when there is no special colour set and the triangle is drawn in the base colour.

**input_block**

The **input_block** gives more information about how the tin was created by 12d Model.

None of this information is needed when reading a tin into 12d Model and the **input_ block** can be omitted.

\[
\begin{align*}
\text{<input>}
\text{<preserve_strings> \ pres_str_textLogical </preserve_strings>}
\text{<remove_bubbles> \ rem_bub_textLogical </remove_bubbles>}
\text{<weed_tin> \ weed_tin_textLogical </weed_tin>}
\text{<triangle_data> \ triangle_data_textLogical </triangle_data>}
\text{<sort_tin> \ sort_tin_textLogical </sort_tin>}
\text{<cell_method> \ cell_method_textLogical </cell_method>}
\text{<models>}
\text{ \ \ \ \ model_name_1}
\text{ \ \ \ \ model_name_2}
\text{ \ \ \ \ ...}
\text{ \ \ \ \ model_name_p}
\text{</models>}
\text{<input>}
\end{align*}
\]

where

\( \text{pres_str_textLogical, rem_bub_textLogical, weed_tin_textLogical, triangle_data_textLogical, sort_tin_textLogical and cell_method_textLogical} \) are text and can only have the values true or false.

\( <\text{models}> \text{...} <\text{models}> \) is the list of models in the tin where
\( \text{model_name}_i \) is the name of the \( i \)'th model making up the tin.

Continue to the next section **35.6.2 Super Tin** or return to **35.3 Regularly Used Keyword Blocks** or **35 12d XML File Format**.
35.6.2 Super Tin

A Super Tins consists of a number of tins (triangulated irregular networks).

Each super tin has text name, tin_name, of up to two hundred alphanumeric characters and spaces and the names of each tin and super tin in the project must be unique.

The format for the super_tin element is:

```xml
<super_tin>
  <name>tin_name</name>
  attribute_block
  time_created_block
  time_updated_block
  colour_block
  exact_block
  tins_block
</super_tin>
```

where

- **tin_name**
  
  is a string of characters for the super tin name and can’t be blank. This must be unique in a project.

  For the characters that can make up a tin_name, see [Names of models, tins, styles, colours and attributes](#).

- **time_created_block**
  
  is the time the super tin was originally created, This is optional. For the syntax see [35.3.7 Time Created](#).

- **time_updated_block**
  
  is the last time the super tin was last modified, This is optional. For the syntax see [35.3.7 Time Created](#).

- **colour_block**
  
  this colour number is the primary (base) colour for the super tin. For the syntax of colour_block, see [35.3.2 Colour](#).

- **attribute_block** is optional: For the syntax of an attributes_block see [35.4 Attributes](#).

  The attributes in this block and the attributes_block itself are optional.

  The attribute **Style** is a special attribute that is used by 12d Model to create the super tin. This special attribute should not be deleted.

  The format of the **Style** attribute inside the <attributes> ... </attributes> is:

  ```xml
  <text> <name>Style</name> <value>style_name</value> </text>
  ```

  where

  - **style_name** is the style for the super tin

- **exact_block**

  ```xml
  <exact> exact_text_logical </exact>
  ```

  where

  - **exact_text_logical** is text and can only have the value true or false.
**tins_block**

This gives the tins that make up the super tin within the keyword block **tins**.

```xml
<tins>
  tin_info_1
  tin_info_2
  ...
  tin_info_p
</tins>
```

where

there are p tins in the super tin and **tin_info_i** is information about the i’th tin. The information about a tin is contained in a **tin** block.

```xml
<tin>
  <name>tin_name_i</name>
  <active>active_text_logical</active>
  <mode>mode_text_logical</mode>
</tin>
```

where

**tin_name_i** is the name of the i’th tin making up the super tin.

**active_text_logical** and **mode_text_logical** are text and can only have the value **true** or **false**.

For example

```xml
<super_tin>
  <name>super tin</name>
  <colour>green</colour>
  <attributes>
    <text> <name>Style</name> <value>1</value> </text>
  </attributes>
  <time_created>28-Apr-2015 06:42:45</time_created>
  <time_updated>28-Apr-2015 06:42:45</time_updated>
  <exact>true</exact>
  <tins>
    <tin>
      <name>DESIGN ALL</name>
      <active>true</active>
      <mode>replace</mode>
    </tin>
    <tin>
      <name>HILL</name>
      <active>true</active>
      <mode>replace</mode>
    </tin>
  </tins>
</super_tin>
```

Note that the tins that make up the super tin must exist in **12d Model** for the super tin to be fully defined.

Continue to the next section **35.6.3 String Header Block** or return to **35.3 Regularly Used Keyword Blocks** or **35.12d XML File Format**.
35.6.3 String Header Block

Strings are special types of elements that reside in a model. Strings have common header information and this will be documented in this one spot as a *string_header_block*.

The format for the string_header_block is:

```
string_name_block
chainage_block
colour_block
style_block
weight_block
interval_block
time_created_block
time_updated_block
attribute_block
```

where

- **string_name_block**
  - The format of the *string_name_block* is:
    
    `<name> string_name_text </name>
    
    where
    
    *string_name_text* is a string of allowable characters that is the name of the string. For the characters that can make up a string_name, see *String names*. Any leading and trailing spaces will be removed in the string name.

- **chainage_block**
  - is the start chainage of the string. This is optional. For the syntax see *35.3.4 Chainage*.

- **colour_block**
  - the colour name is the primary colour for the string. For the syntax of colour_block, see *35.3.2 Colour*.

- **style_block**
  - is the line style of the string. This is optional. For the syntax of style_block see *35.3.3 Line Style*.

- **weight_block**
  - is the weight (thickness) of the string. This is optional. For the syntax of weight_block see *35.3.5 Weight*.

- **interval_block**
  - the chainage interval to temporarily introduce extra vertices into the string when the string is in a triangulation to form a tin. For the syntax of interval_block, see *35.3.6 Interval*.

- **time_created_block**
  - is the time the super tin was originally created. This is optional. For the syntax of time_created_block see *35.3.7 Time Created*. 

An example of a string name is:

```
<string>
  design 100.0
</string>
```
time_updated_block

is the last time the super tin was last modified. This is optional. For the syntax of

time_updated_block see 35.3.8 Time Updated.

attribute_block

The string attributes are in this block. For the syntax of an attributes_block see 35.4 Attributes.
The attributes_block is optional.

For example

```
<string_arc>
  <name>arc</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>yellow</colour>
  <style>1</style>
  <weight>2</weight>
  <time_created>28-Apr-2015 07:46:57</time_created>
  <time_updated>28-Apr-2015 07:46:57</time_updated>
  <interval>10</interval>
  <centre>1067.40263766 530.14953857 0</centre>
  <radius>226.6814323</radius>
  <chord_arc>0.1</chord_arc>
  <start>867.42825529 423.40349345 0</start>
  <end>1118.02452861 751.10631241 0</end>
</string_arc>
```

Continue to the next section 35.6.4 Text Information or return to 35.6 Elements Contained in Models or 35.12d XML File Format.
35.6.4 Text Information

See

35.6.4.1 Vertex Annotation Information
35.6.4.2 Segment Annotation Information

35.6.4.1 Vertex Annotation Information

The vertex_annotation_information is

\[ \begin{align*}
&\text{<worldsize> world_size_real </worldsize>} \\
&\text{<textstyle> textstyle_name </textstyle>} \\
&\text{<angle> angle_dec_deg_real </angle>} \\
&\text{<x_factor> x_factor_real </x_factor>} \\
&\text{<slant> slant_dec_deg_real </slant>} \\
&\text{<offset> offset_real </offset>} \\
&\text{<raise> raise_real </raise>} \\
&\text{<text_colour> text_colour_name </text_colour>} \\
&\text{<justify> text_justification_text </justify>}
\end{align*} \]

where

- \text{world_size_real} is the size of the text in world units.
- \text{textstyle_name} is the name of the textstyle for the text.
- \text{angle_dec_deg_real} is the angle of the text. The value is in decimal degrees and is measured in a counter clockwise direction from the positive x-axis.
- \text{x_factor_real} is the factor to apply to the width of the text.
- \text{slant_dec_deg_real} is the angle the text is slanted from the vertical. The value is in decimal degrees and is measured in a clockwise direction from the positive y-axis.
- \text{offset_real} is distance to offset the text from the text vertex.
- \text{raise_real} is the perpendicular distance the text is off the direction line of the text.
- \text{text_colour_name} is the colour of the text. This should be the same as the colour in the string_header_block. For the syntax of colour_block, see 35.3.2 Colour.
- \text{text_justification_text} is the text giving the justification point of the text.
35.6.4.2 Segment Annotation Information

The segment_annotation_information is

```
<worldsize> world_size_real </worldsize>
<textstyle> textstyle_name </textstyle>
<angle> angle_dec_deg_real </angle>
<x_factor> x_factor_real </x_factor>
<slant> slant_dec_deg_real </slant>
<offset> offset_real </offset>
<raise> raise_real </raise>
<text_colour> text_colour_name </text_colour>
<justify> text_justification_text </justify>
```

where

- `world_size_real` is the size of the text in world units.
- `textstyle_name` is the name of the textstyle for the text.
- `angle_dec_deg_real` is the angle of the text. The value is in decimal degrees and is measured in a counter clockwise direction from the segment.
- `x_factor_real` is the factor to apply to the width of the text.
- `slant_dec_deg_real` is the angle the text is slanted from the vertical. The value is in decimal degrees and is measured in a clockwise direction from the positive y-axis.
- `offset_real` is distance to offset the text from the centre of the segment.
- `raise_real` is the perpendicular distance the text is off the direction line of the text.
- `text_colour_name` is the colour of the text. This should be the same as the colour in the string_header_block. For the syntax of colour_block, see 35.3.2 Colour.
- `text_justification_text` is the text giving the justification point of the text.
35.6.5 Arc String

The format for the `string_arc` element is:

```xml
<string_arc>
    string_header_block
    centre_block
    radius_block
    chord_arc_block
    start_block
    end_block
</string_arc>
```

where

- **string_header_block**
  - the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

- **centre_block**
  - The format of the `centre_block` is:
    ```xml
    <centre>
        x_centre_real  y_centre_real  z_centre_real
    </centre>
    ```
  - where
    
    ```plaintext
    (x_centre_real, y_centre_real, z_centre_real) is the centre of the arc.
    ```

- **radius_block**
  - the radius of the arc. For the syntax of radius_block, see 35.3.9 Breakline.
  - A positive radius means that the arc goes from the start point in a clockwise direction (goes to the right) and a negative radius means that the arc goes in a counter clockwise direction (goes to the left).

- **chord_arc_block**
  - The format of the `chord_arc_block` is:
    ```xml
    <chord_arc>
        chord_arc_real
    </chord_arc>
    ```
  - where
    
    ```plaintext
    chord_arc_real is a real number and is the chord to arc tolerance to use to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.
    ```

- **start_block**
  - The format of the `start_block` is:
    ```xml
    <start>
        x_start_real  y_start_real  z_start_real
    </start>
    ```
  - where
    
    ```plaintext
    (x_start_real, y_start_real, z_start_real) is the start coordinate of the arc.
    ```

- **end_block**
  - The format of the `end_block` is:
    ```xml
    <end>
        x_end_real  y_end_real  z_end_real
    </end>
    ```
  - where
    
    ```plaintext
    (x_end_real, y_end_real, z_end_real) is the end coordinate of the arc.
    ```

For example
<string_arc>
    <name>arc</name>
    <chainage>0</chainage>
    <breakline>line</breakline>
    <colour>yellow</colour>
    <style>1</style>
    <weight>2</weight>
    <time_created>28-Apr-2015 07:46:57</time_created>
    <time_updated>28-Apr-2015 07:46:57</time_updated>
    <interval>10</interval>
    <centre>1067.40263766 530.14953857 0</centre>
    <radius>226.6814323</radius>
    <chord_arc>0.1</chord_arc>
    <start>867.42825529 423.40349345 0</start>
    <end>1118.02452861 751.10631241 0</end>
</string_arc>

Continue to the next section 35.6.6 Circle String or return to 35.6.3 String Header Block or 35 12d XML File Format.
35.6.6 Circle String

The format for the `string_circle` element is:

```xml
<string_circle>
  string_header_block
  centre_block
  radius_block
  chord_arc_block
</string_circle>
```

where

- **string_header_block**
  - the common header block for each string. for the contents and the syntax, see Section 35.6.3 String Header Block.

- **centre_block**
  - The format of the `centre_block` is:
    ```xml
    <centre>
      x_centre_real  y_centre_real  z_centre_real
    </centre>
    ```
  - where
    
    \((x_{\text{centre\_real}}, y_{\text{centre\_real}}, z_{\text{centre\_real}})\) is the centre of the circle.

- **radius_block**
  - the radius of the circle. For the syntax of radius_block, see Section 35.3.9 Breakline.
  - A positive radius means that the circle goes in a clockwise direction (goes to the right) and a negative radius means that the circle goes in a counter clockwise direction (goes to the left).

- **chord_arc_block**
  - The format of the `chord_arc_block` is:
    ```xml
    <chord_arc>
      chord_arc_real
    </chord_arc>
    ```
  - where
    
    `chord_arc_real` is a real number and is the chord to arc tolerance to use to temporarily insert vertices into the circle when the circle is included in a triangulation to form a tin.

For example

```xml
<string_circle>
  <name>circle</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>yellow</colour>

Continue to the next section 35.6.7 Drainage String or return to 35.6.3 String Header Block or 35.12d XML File Format.
35.6.7 Drainage String

The full 12dXML definition of the drainage string is:

```xml
<string_drainage>
  string_header_block
  outfall_block
  flow_direction_block
  use_pit_con_points_block
  drainage_sewer_block
  data_3d_block
  radius_data_block
  major_data_block
  pit_records
  pipe_records
</string_drainage>
```

where

- **string_header_block**
  - the common header block for each string. For the contents and the syntax, see 35.6.3 String Header Block.
  - There are also some special attributes in the string attributes in the String Header Block that provide extra information for the drainage string.

- **outfall_block**
  - `<outfall> outfall_real </outfall>`
  - where `outfall_real` is the z-value of the outfall (the low end of the string).

- **flow_direction_block**
  - `<flow_direction> flow_direction_flag </flow_direction>`
  - where `flow_direction_flag` is 1 if the flow is the same as the string direction, or 0 if the flow is opposite to the string direction.

- **use_pit_con_points_block**
  - `<user_pit_con_points> use_pit_connection_points_logical_text </user_pit_con_points>`
  - where `use_pit_connection_points_logical_text` is true if pit connection points are used, or false if pit connection points are not being used and hence the pipes go to the centre of the pits.

- **drainage_sewer_block**
  - `<drainage_sewer> drainage_sewer_choice_text </drainage_sewer>`
  - where `drainage_sewer_choice_text` is drainage (storm water) if it is for drainage and sewer if it is for sewer (foul water).

- **data_3d_block, radius_data_block and major_data_block**
  - The drainage string has an underlying string that is used to define locations of the pits and the geometry for the pipes. The underlying string can have straight and arc segments.
  - The vertex data for the underlying string is given in a data_3d block, and if there are any arcs, then these are specified in radius_data and major_data blocks. See 35.3.13 data_3d and 35.3.14 radius_data and major_data.
Chapter 35  12d XML File Format

pit_records
In plan the pits sit on the underlying string and there is one pit record for each pit. The pits
do not have to be on a vertex of the underlying string.

There is one pit block for each pit in the string and they are in the order that they occur
along the string.

The information for each pit is:

<pit>
  <name> pit_name_text </name>
  <type> pit_type_text </type>
  <chainage> pit_chainage_real </chainage>
  <ip> pit_ip_text </ip>
  <ratio> pit_ratio_real </ratio>
  <x> pit_x_real </x>
  <y> pit_y_real </y>
  <z> pit_z_real </z>
  <road_chainage> pit_road_chainage_real </road_chainage>
  <diameter> pit_diameter_real </diameter>
  <width> pit_width_real </width>
  <sump_level> pit_sump_level_real </sump_level>
  <floating_sump> pit_floating_sump_flag </floating_sump>
  <thickness> pit_thickness_real </thickness>
  <thickness_bottom> pit_thickness_bottom_real </thickness_bottom>
  <thickness_back> pit_thickness_back_real </thickness_back>
  <thickness_left> pit_thickness_left_real </thickness_left>
  <thickness_right> pit_thickness_right_real </thickness_right>
  <con_point_mode> pit_con_points_mode_text </con_point_mode>
  <floating> pit_floating_logical_text </floating>
  <hgl> pit_hgl_real </hgl>
</pit>

where

pipe_records
In plan the pipes sit on the underlying string and the plan geometry is based on the
underlying string. Each pipe goes between two adjacent pits.

There is one pipe block for each pipe in the string and they are in the order that they occur
along the string.

<pipe>
  <name> pipe_name_text </name>
  <type> pipe_type_text </type>
  <colour> pipe_colour_text </colour>
  <diameter> pipe_diameter_real </diameter>
</pipe>
string drainage {

Continue to the next section 35.6.8 Feature String or return to 35.6.3 String Header Block or 35.12d XML File Format.
35.6.8 Feature String

The full 12dXML definition of the drainage string is:

```xml
<string_feature>
  string_header_block
  <radius>feature_radius_real</radius>
  <centre>x_centre_real y_centre_real z_centre_real</centre>
</string_feature>
```

where

- **string_header_block**
  - the common header block for each string, for the contents and the syntax, see *35.6.3 String Header Block*.
  - There are also some special attributes in the string attributes in the String Header Block that provide extra information for the drainage string.

- **feature_radius_real** is the radius of the feature string.

- **(xcentre_real, y_centre_real, z_centre_real)** is the centre of the feature string.

For example

```xml
<string_feature>
  <name>Line 1</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>cyan</colour>
  <style>1</style>
  <time_created>2015-05-19T08:06:01Z</time_created>
  <time_updated>2015-05-19T08:06:01Z</time_updated>
  <centre>42200.06055 37384.05873 null</centre>
  <radius>20</radius>
</string_feature>
```

Continue to the next section *35.6.9 Plot Frame String* or return to *35.6.3 String Header Block* or *35.12d XML File Format*.
35.6.9 Plot Frame String

The format for the `string_plot_frame` element is:

```xml
<string_plot_frame>
  info_block
  time_created_block
  time_updated_block
  sheet_details_block
  title_block_block
  origin_block
  scale_block
  rotation_block
  plotter_details_block
</string_plot_frame>
```

where

**info_block**

The format of the `info_block` is:

```xml
<info>
  <name> plot_frame_name_text </name>
  <colour> plot_frame_name_colour_text </colour>
  <plot_file> plot_file_name_text </plot_file>
</info>
```

where

- `plot_frame_name_text` is a string of allowable characters that is the name of the plot file string. For the characters that can make up a string_name, see [String names](#).
- `plot_frame_name_colour_text` is the colour of the plot frame. For the syntax of colour_block, see [35.3.2 Colour](#).
- `plot_file_name_text` is the name of file that the plot frame will plot to.

**time_created_block**

is the time the plot frame was originally created, This is optional. For the syntax of the time_created_block see [35.3.7 Time Created](#).

**time_updated_block**

is the last time the plot frame was last modified, This is optional. For the syntax of the time_updated_block see [35.3.8 Time Updated](#).

**sheet_details_block**

The format of the `sheet_details_block` is:

```xml
<sheet_details>
  <sheet_code> sheet_code_text </sheet_code>
  <width> sheet_width_real </width>
  <height> sheet_height_real </height>
  <left_margin> sheet_left_margin_real </left_margin>
  <right_margin> sheet_right_margin_real </right_margin>
  <top_margin> sheet_top_margin_real </top_margin>
</sheet_details>
```
<bottom_margin> sheet_bottom_margin_real </bottom_margin>
<border> sheet_border_text_logical </border>
<viewport> sheet_viewport_text_logical </viewport>
</sheet_details>

where

sheet_code_text is the name of the sheet. This can be blank.

sheet_width_real, sheet_height_real, sheet_left_margin_real, sheet_right_margin_real,
sheet_top_margin_real, sheet_bottom_margin_real are all real values and give the size and
margins for the sheet that the plot frame will plot. The units for all of them is millimetres.

plot_frame_border_text_logical and plot_frame_viewport_text_logical are text and can only
have the value true or false.

origin_block

The format of the origin_block is:

<origin> x_real y_real z_real </origin>

where

(x_real, y_real, z_real) is the coordinates of the origin of the plot frame.

scale_block

The format of the scale_block is:

<scale> scale_real </scale>

where

scale_real is the 1: scale for the plots created by the plot frame.

rotation_block

The format of the rotation_block is:

<rotation> rotation_dec_deg_real </rotation>

where

rotation_dec_deg_real is rotation of the plot frame. The value is in decimal degrees and is
measured in a counter clockwise direction from the positive x-axis.

plotter_details_block

The format of the plotter_details_block is:

<plotter_details>

<title_1> title_1_text </title_1>
<title_2> title_2_text </title_2>
<use_title_file> title_file_text_logical </use_title_file>
<title_file> title_file_name_text </title_file>
<text_size> title_text_size_real_mm </text_size>
<textstyle> title_text_style </textstyle>

</plotter_details>

where

title_1_text and title_2_text are two lines of text for the title block. They can be blank.

use_title_file_text_logical is text and can only have the value true or false.

title_file is the path name of the file to use as a title block file. This can be blank.

title_text_size_real_mm is the size of the text in the title block. The units are millimetres.
For example

```xml
<string_plot_frame>
  <info>
    <name>Plot frame</name>
    <colour>green</colour>
    <plot_file>plot</plot_file>
  </info>
  <sheet_details>
    <sheet_code>A0</sheet_code>
    <width>1189</width>
    <height>841</height>
    <left_margin>5</left_margin>
    <right_margin>10</right_margin>
    <bottom_margin>5</bottom_margin>
    <top_margin>10</top_margin>
    <border>true</border>
    <viewport>true</viewport>
  </sheet_details>
  <title_block>
    <title_1>Title 1</title_1>
    <title_2>Title 2</title_2>
    <use_title_file>true</use_title_file>
    <title_file>A0 title.tbf</title_file>
    <text_size>5</text_size>
    <textstyle>1</textstyle>
  </title_block>
  <origin>695.2353 1464.6248</origin>
  <scale>100</scale>
  <rotation>45</rotation>
  <plotter_details>
    <id>9</id>
    <type>model</type>
  </plotter_details>
  <time_created>29-Apr-2015 01:11:52</time_created>
  <time_updated>29-Apr-2015 01:11:52</time_updated>
</string_plot_frame>
```

Continue to the next section 35.6.10 Super String or return to 35.6.3 String Header Block or 35
12d XML File Format.
35.6.10 Super String

Because the super string is so versatile, its 12d XML format looks complicated but it is very logical and actually quite simple.

In its most primitive form, the super string is simply a set of (x,y) values as in a 2d string, or (x,y,z) values as in a 3d string.

Additional blocks of information can extend the definition of the super string and only need to be included if they exist. For example, segment arcs or transitions, vertex ids, vertex and segment text, round pipe diameters or box pipes widths and heights and tinability.

Some of the properties of the super string can be constant for the entire string or can vary for each vertex and/or segment. For example, there can be one colour for the entire string or individual colours for each segment.

For user attributes, the super string not only has the standard user attributes defined for the entire string (string attributes), but also can have user attributes for each vertex (vertex attributes) and for each segment (segment attributes).

Being closed or not is another property of the super string and if the super string is closed then the super string knows there is an additional segment going from the last vertex back to the first vertex. This means that there is no duplication of the first and last vertex needed.

Thus if a super string has \( n \) vertices, then an open super string has \( n-1 \) segments joining the vertices and a closed super string has \( n \) segments since there is an additional segment from the last to the first vertex.

With the additional data for vertices and/or segments in the super string, the data is in vertex or segment order.

So for a string with \( n \) vertices, there must be \( n \) bits of vertex data.
For segments, if the string is open then there only needs to be \( n-1 \) bits of segment data but for closed strings, there must be \( n \) bits of data.

For an open string, \( n \) bits of segment data can be specified and the \( n \)th bit will be read in and stored. If the string is then closed, the \( n \)th bit of data will be used for the extra segment.

**Important Note**
For a super string, the arcs, transitions and offset transitions are that shape in plan.
Hence an arc with a z-value at each end is actually a **helix** and **NOT** part of a three dimensional circle.

Transitions and offset transitions are helixes with a constantly changing radius.
The 12dXML definition of the super string is:

```
<string_super>
  string_header_block
  closed_block
  interval_block
  blocks_of_info_1
  blocks_of_info_2
  ...
  blocks_of_info_n
</string_super>
```

where

- **string_header_block**
  - the common header block for each string. For the contents and the syntax, see 35.6.3 String Header Block.

- **closed_block**
  - `<closed>` closed_text_logical `<closed>`
    - where `closed_text_logical` is true if the super string is closed and false if the super string is open.

- **interval_block**
The interval_block for a super string has a distance (a chainage interval) and a chord_to_arc_real

where

the distance to temporarily introduce extra vertices into the string at the given chainage
distance when the string is in a triangulation to form a tin.

chord_arc_real is a real number and is the chord to arc tolerance to use on any arcs in the
super string to temporarily insert vertices into the arc when the arc is included in a
triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

blocks_of_info
The blocks of info can be broken up into four types.

(a) blocks defining the position of the vertices in z, y and z

Each vertex must have at least an (x,y) value but there may be one z-value for the entire
string and (x,y) at each vertex (data_2d), or an (x,y,z) for each vertex (data_3d).

See 35.6.10.1 Defining the Coordinates of the Vertices

(b) blocks defining the geometry of the segments

Segments can be straights, arcs, transitions or offset transitions.

radius_data and major_data or geometry_data.

See 35.6.10.2 Geometry of the Horizontal Segments

(c) extra information for the vertices and/or segments such as colour, attributes, vertex ids,
symbols tinability etc.

The definition for the blocks of each type now follows.

35.6.10.1 Defining the Coordinates of the Vertices
35.6.10.2 Geometry of the Horizontal Segments
35.6.10.3 Colour
35.6.10.4 String, Vertex and Segment Attributes
35.6.10.5 Vertex Id’s (Point Id’s)
35.6.10.6 Symbols at Vertices
35.6.10.7 Tinability
35.6.10.8 Round or Box (Culvert) Pipes
35.6.10.9 Vertex Text and Vertex Annotation
35.6.10.10 Segment Text and Segment Annotation
35.6.10.1 Defining the Coordinates of the Vertices

See

35.6.10.1.1 One Z or No Z for the String
35.6.10.1.2 Varying Z Values along the String

35.6.10.1.1 One Z or No Z for the String

If there is a non-null constant z value for the entire string then the z value is given by a z block:

<z> z_value </z>

where z_value is the constant z value for the entire string.

And when there is a constant z, or no z, for the string, then only the (x,y) coordinates are required for each vertex and these are given in a data_2d block. See 35.3.12 data_2d

35.6.10.1.2 Varying Z Values along the String

If the z value can vary for different vertices along the string then the (x,y,z) values must be given for each vertex and the data is then written out as a data_3d block. See 35.3.13 data_3d.
35.6.10.2 Geometry of the Horizontal Segments

If the segments are straight lines only then that is the default and no further information is required.

If the segments are only straight lines and arcs, then the radius_data and major_data blocks are used to define a radius and bulge_flag data for each segment of the super string. See 35.6.10.2.1 Only Straights and Arcs for Segments.

If any of the segments are transitions or offset transitions then geometry_data must be used for each segment. geometry_data can represent a straight, arc, transition or offset transition. See 35.6.10.2.2 Straights, Arcs and Transitions for Segments.

35.6.10.2.1 Only Straights and Arcs for Segments

If there are only straight and arc segments for the string, then for either data_2d or data_3d, it is possible to add a radius and major/minor arc flag for each segment of the super string using the radius_data and major_data blocks respectively. See 35.3.14 radius_data and major_data.

35.6.10.2.2 Straights, Arcs and Transitions for Segments

When some of the segments are transitions or offset transitions, then the geometry_data block must be used to give the geometry for each segments.

Either a data_2d or data_3d block defines the coordinates for the vertices and the geometry_data block defines for each segment whether the segment is a straight, an arc or a transition or offset transition.

The definition of the geometry_data block is

```
<geometry_data>
    info_for_segment_1_block
    info_for_segment_2_block
    ...
    info_for_segment_m_block
</geometry_data>
```

where

```
info_for_segment_i_block
```

is the information defining the i'th segment as either a straight, an arc or an offset transition (offset transition or transition), and

m = n-1 for an open string or m = n for a closed string.

For the definition of info_for_segment_i_block see:

35.6.10.2.2.1 Straight
35.6.10.2.2.2 Arc
35.6.10.2.2.3 Offset Transitions
35.6.10.2.2.1 Straight
No parameters are needed for defining a straight segment. The \textit{straight} block is simply:
\begin{verbatim}
<straight> </straight>
\end{verbatim}
or simply
\begin{verbatim}
<straight/>
\end{verbatim}

35.6.10.2.2.2 Arc
There are four possibilities for an arc of a given radius placed between two vertices. We use \textit{positive} and \textit{negative} radius, and a flag \textit{major} which can be set to 1 (on) or off (0) to differentiate between the four possibilities.

\begin{center}
\begin{tikzpicture}
\node at (0,0) {Arcs with same radius but with major on or off};
\node at (-2,0) {Arcs with +ve radius};
\node at (2,0) {Arcs with -ve radius};
\node at (0,-2) {start vertex};
\node at (0,2) {end vertex};
\draw [-] (0,0) circle (2cm);
\draw [-] (-2,0) arc (180:0:2cm);
\draw [-] (2,0) arc (0:180:2cm);
\draw [-] (0,0) circle (1cm);
\draw [-] (-1,0) arc (180:0:1cm);
\draw [-] (1,0) arc (0:180:1cm);
\end{tikzpicture}
\end{center}

The \textit{arc} block is:
\begin{verbatim}
<arc>
  <radius> radius_for_segment </radius>
  <major> major_flag_for_segment </major>
</arc>
\end{verbatim}
where
\begin{itemize}
\item \textit{radius_for_segment} is the radius for the segment and
\item \textit{major_flag_for_segment} is 1 if the arc is a major arc and 0 if it is a minor arc.
\end{itemize}
35.6.10.2.2.3 Offset Transitions

An offset transition is a fixed perpendicular offset (offset_real) of a base transition where the base transition is a Euler spiral (or a certain approximation to it) or some other specially defined curve. The base transition has a start point where the absolute radius of the curve is infinity and then has a continuously decreasing absolute radius as you continue along the curve (this may be in a forward or reverse direction).

The base transition is defined by giving its starting point (xorigin, yorigin) where the radius is infinity and the angle of the tangential line at the start point is angle_decimal_degrees_real and the fact that the radius radius_real occurs at a given curve length length_real along the base transition.

The offset transition is a fixed offset (offset_real) from the base transition and goes from a start point that is specified by giving the length on the base transition where the start point drops perpendicularly onto the base transition (start_length_real) and to the end point that is specified by length on the base transition where the end point drops perpendicularly onto the base transition (end_length_real). The offset can be positive or negative.

If you are travelling along the curve in a forward direction (increasing chainage) then the base transition is said to be a leading transition if the absolute radius decreases as you go along the curve, and a trailing transition if the absolute radius decreases.

The end radius can be positive or negative.

If you are travelling along the curve in a forward direction then for a leading transition, if the end radius is positive then the curve curls to the right, and for a negative end radius, the curve curls to the left.

The curve block covers both spiral and non-spiral transitions with a zero or non zero offset. The curve block is:

```xml
<curve>
  <curve_type> curve_type_text </curve_type>
  <leading> leading_logical_text </leading>
</curve>
```
<xorigin> xorigin_real</xorigin>
<yorigin> yorigin_real</yorigin>
<radius> radius_real</radius>
<length> length_real</length>
<start> start_length_real</start>
<end> end_length_real</end>
<angle> angle_decimal_degrees_real</angle>
<offset> offset_real</offset>
<mvalue> mvalue_real</mvalue>
</curve>

where

curve_type_text is the type of base transition.

For more information on the choices, see 35.3.15 Available Transition Types.

leading_logical_text is true if it is a leading base transition or false if it is a trailing base transition.

(xorigin, yorigin) is the origin of the base transition. That is, where the radius is infinity.

radius_real is the radius at the end of the base transition. The radius is positive if the curve goes to the right when travelling in decreasing absolute radius.

length_real is the curve length and the end of the base transition and the radius is radius_real.

start_length_real is the curve length on the base transition where the start of the offset transition drops perpendicularly onto the base transition.

delimiters

delimiters

delimiters

end_length_real is the curve length on the base transition where the end of the offset transition drops perpendicularly onto the base transition.

angle_decimal_degrees_real is the angle of the tangent of the base transition at the origin of the base transition. It is measured in decimal degrees in a counter clockwise direction from the positive x-axis.

offset_real is the perpendicular offset distance of the transition from the base transition. For a leading transition, a positive value offsets the base transition to the right and a negative value offsets it to the left as you travel in a forward direction.

mvalue_real - if the transition is a cubic parabola then mvalue_real is the mvalue for the cubic parabola, otherwise, mvalue_real is zero.

For example, for a string with four segments

<geometry_data>
<arc>
  <radius>-222.77841769</radius>
  <major>0</major>
</arc>
<curve>
  <type>clothoid</type>
  <leading>false</leading>
  <xorigin>114.78632204</xorigin>
  <yorigin>22.22840069</yorigin>
  <radius>222.77841769</radius>
  <length>194.18990415</length>
  <start>50.95749554</start>
  <end>194.18990415</end>
  <angle>174.01773651</angle>
  <offset>0</offset>
  <mvalue>0</mvalue>
</curve>
<arc>
  <radius>-848.96871636</radius>
  <major>0</major>
</arc>
<straight/>
</geometry_data>
35.6.10.3 Colour

There can be one colour for the entire super string which is given by the \texttt{<colour>} keyword block in the \texttt{string_header_block}, or the colour varies for each segment of the super string and is then specified in a \texttt{<colour_data>} block.

The order of the entries in the \texttt{<colour_data>} block must match the order of the segments in the super string. So there is exactly one entry for each segment.

If all the segment are the string colour, then simply omit the \texttt{<colour_data>} block.

For a super string with \textit{n} vertices

\[
\begin{align*}
\texttt{<colour_data>} \\
\texttt{colour_text_for_segment_1} \\
\texttt{colour_text_for_segment_2} \\
\texttt{...} \\
\texttt{colour_text_segment_m} \\
\texttt{</colour_data>}
\end{align*}
\]

where

\texttt{colour_text_segment_i} is the colour name or colour number for the \textit{i}th segment OR is \texttt{no_colour} when no special colour has been set for the segment and the string colour is then used for that segment. If the name includes spaces then it must be enclosed in \texttt{"}, and

\textit{m = n-1} for an open string or \textit{m = n} for a closed string.

For example for a string with four segments

\[
\begin{align*}
\texttt{<colour_data>} \\
\texttt{"off yellow" magenta no_colour no_colour} \\
\texttt{</colour_data>} \\
\texttt{<leading>false</leading>}
\end{align*}
\]
35.6.10.4 String, Vertex and Segment Attributes

The super string can have attributes for the entire string (string attributes) but can also have attributes for each vertex (vertex attributes) and attributes for each segment (segment attributes).

See

35.6.10.4.1 String Attributes
35.6.10.4.2 Vertex Attributes
35.6.10.4.3 Segment Attributes

35.6.10.4.1 String Attributes

There can be attributes for the entire string. They are part of the String Header Block and are described in 35.6.3 String Header Block.

For example

```xml
<string_super>
  <name>Line 1</name>
  <chainage>0</chainage>
  <breakline>line</breakline>
  <colour>cyan</colour>
  <style>1</style>
  <attributes>
    <text>
      <name>Street</name>
      <value>Weemala Road</value>
    </text>
  </attributes>
  <time_created>2015-05-11T09:08:06Z</time_created>
  <time_updated>2015-05-11T11:59:29Z</time_updated>
</string_super>
```

...
35.6.10.4.2 Vertex Attributes

Each vertex can have one or more user defined attributes.

For a super string with n vertices

```xml
<vertex_attribute_data>
  vertex_attributes_for_vertex_1_block
  vertex_attributes_for_vertex_2_block
  ...
  vertex_attributes_for_vertex_n_block
</vertex_attribute_data>
```

where

`vertex_attributes_for_vertex_j_block` is the attribute_block for vertex j. The attribute_block is defined in 35.4 Attributes.

For example, for a string with four vertices

```xml
<vertex_attribute_data>
  <attributes>
    <real>
      <name>Flow</name>
      <value>27.4</value>
    </real>
  </attributes>
  <attributes/>
  <attributes/>
  <attributes/>
</vertex_attribute_data>
```
35.6.10.4.3 Segment Attributes

Each segment can have one or more user defined attributes.

For a super string with \( n \) vertices

\[
\text{<segment_attribute_data>}
\begin{align*}
&\text{segment_attributes_for_segment}_1\text{_block} \\
&\text{segment_attributes_for_segment}_2\text{_block} \\
&\quad \ldots \\
&\text{segment_attributes_for_segment}_m\text{_block}
\end{align*}
\]

\[
\text{</segment_attribute_data>}
\]

where \( \text{segment_attributes_for_segment}_j\text{_block} \) is an attribute_block for segment \( j \). The attribute_block is defined in 35.4 Attributes, and \( m = n-1 \) for an open string or \( m = n \) for a closed string.

For example, for an open string with four vertices

\[
\text{<segment_attribute_data>}
\begin{align*}
&\text{<attributes>} \\
&\quad \text{<real>} \\
&\quad \quad \text{<name>Material</name>} \\
&\quad \quad \text{<value>clay</value>} \\
&\quad \text{</real>} \\
&\text{</attributes>} \\
&\text{<attributes/>} \\
&\text{<attributes/>} \\
&\text{<attributes/>} \\
&\text{</segment_attribute_data>}
\end{align*}
\]
35.6.10.5 Vertex Id’s (Point Id’s)

Each vertex can have a vertex id (point id).
This is not the number position of the vertex in the string but is a separate id which is usually different for every vertex in every string.
The **vertex id** can be alphanumeric and include spaces.
The definition is:
For a super string with \( n \) vertices

\[
\begin{align*}
\text{point_data} & \\
& point\_id\_text\_for\_vertex\_1 \\
& point\_id\_text\_for\_vertex\_2 \\
& \ldots \\
& point\_id\_text\_for\_vertex\_n \\
\end{align*}
\]

where

- \( point\_id\_text\_for\_vertex\_i \) is the point id of the \( i \)th vertex.
- \( m = n-1 \) for an open string or \( m = n \) for a closed string.

\( point\_id\_text\_for\_vertex\_i \) is the actual text enclosed in ", even if the text does not include spaces. If the point id has not been set for a vertex, the value should be included as "".

For example "Point 1" or "Point2" or "".
If the **point_data** block does not exist then there are no Vertex Ids.

For example, for a string with 4 vertices

\[
\begin{align*}
\text{point_data} & \\
& "Point 1" "Point2" "" ""
\end{align*}
\]
35.6.10.6 Symbols at Vertices

There can be no symbols at all, or the same symbol for every vertex in the using the symbol_value block or the symbol varies for each vertex of the super string using the symbol_data block.

If a symbol does not have a colour, or there is no colour in the symbol definition, then it uses the string colour.

The definitions are:

```
<symbol_value>
  symbol_properties_block
</symbol_value>
```

where

**symbol_properties_block** is the description for the symbol to be used at every vertex of the super string, and

OR

For a super string with \( n \) vertices

```
<symbol_data>
  symbol_properties_for_vertex_1_block
  symbol_properties_for_vertex_2_block
  ...
  symbol_properties_for_vertex_\( n \)_block
</symbol_data>
```

where

**symbol_properties_for_vertex_\( i \)_block** is the description for the symbol at vertex \( i \).

The format of **symbol_properties_block** and **symbol_properties_for_vertex_\( i \)_block** is:

```
<properties>
  <style> symbol_name_text </style>
  <colour> symbol_colour_name_text </colour>
  <size> symbol_size_real </size>
  <rotation> angle_dec_deg_real </rotation>
  <offset_x> symbol_offset_x_real </offset_y>
  <offset_y> symbol_offset_y_real </offset_y>
</properties>
```

where

**symbol_name_text** is the name of the symbol.

**symbol_colour_name** is the colour of the symbol is there is no colours in the symbol definition. If the **colour** block is missing and there is no colours in the symbol definition then the string colour is used. For the syntax of the **colour** block, see 35.3.2 Colour.

**symbol_size_real** is the size of the symbol in the units of the symbol.

**angle_dec_deg_real** is the angle of the symbol. The value is in decimal degrees and is measured in a counter clockwise direction from the positive x-axis.

**offset_x_real** is x distance to offset the symbol from the super string vertex.
offset_y_real is the y distance to offset the symbol from the super string.

The position of the symbol justification point is defined by the offset_x and offset_y from the vertex.

Position of super string vertex

Symbol at a Vertex
35.6.10.7 Tinability

Tinability

For a super string, the concept of breakline has been extended to a property called tinable which can be set independently for each vertex and each segment of the super string.

If a vertex is tinable, then the vertex is used in triangulations. If the vertex is not tinable, then the vertex is ignored when triangulating.

If a segment is tinable, then the segment is used as a side of a triangle during triangulation. This may not be possible if there are crossing tinable segments.

Vertex tinability is given by the vertex_tinable_data block where for a string of n vertices,

```xml
<vertex_tinable_data>
  tinable_flag_for_vertex_1
  tinable_flag_for_vertex_2
  ...
  tinable_flag_for_vertex_n
</vertex_tinable_data>
```

where

`tunable_flag_for_vertex_i` for the i'th vertex is 1 or t if the vertex is tinable, or 0 or f if the vertex is not tinable.

Segment tinability is given by the segment_tinable_data block where

```xml
<segment_tinable_data>
  tinable_flag_for_segment_1
  tinable_flag_for_segment_2
  ...
  tinable_flag_for_segment_m
</segment_tinable_data>
```

where

`tunable_flag_for_segment_i` for the i'th segment is 1 or t if the segment is tinable, or 0 or f if the segment is not tinable, and

m = n-1 for an open string or m = n for a closed string.

For example, for a open string with four vertices

```xml
<vertex_tinable_data>
  t
  t
  f
  t
</vertex_tinable_data>
<segment_tinable_data>
  f
  t
</segment_tinable_data>
```

Note that even if a segment is set to tinable, it can only be used in a triangulation if both its end vertices are also tinable.
35.6.10.8 Round or Box (Culvert) Pipes

All the super string segments can be round or all box (culvert). That is, some can’t be round and others box.

There is also a justification that applies to all round pipes or box pipes in the string.

See

35.6.10.8.1 Pipe Diameters
35.6.10.8.2 Culvert Dimensions
35.6.10.8.3 Justification for Round or Culvert Pipes

35.6.10.8.1 Pipe Diameters

There can be one pipe diameter value for the entire super string using the pipe_value block or the pipe diameter varies for each segment of the super string using the pipe_data block.

The definitions are:

\[
\text{<pipe_value> pipe_diameter_real </pipe_value>}
\]

where pipe_diameter_real is the diameter for every segment of the string.

OR

For a super string with \( n \) vertices

\[
\text{<pipe_data>}
\]

\[
\text{<properties>}
\]

\[
\text{<diameter> pipe_diameter_for_segment_1 </diameter>}
\]

\[
\text{<properties>}
\]

\[
\text{<diameter> pipe_diameter_for_segment_2 </diameter>}
\]

\[
\text{...}
\]

\[
\text{<properties>}
\]

\[
\text{<diameter> pipe_diameter_for_segment_m </diameter>}
\]

\[
\text{</properties>}
\]

\[
\text{</pipe_data>}
\]

where

pipe_diameter_for_segment_i is the pipe diameter for the i'th segment, and

\( m = n-1 \) for an open string or \( m = n \) for a closed string.

35.6.10.8.2 Culvert Dimensions

There can be one culvert width and height for the entire super string using the culvert_value block or the culvert width and height vary for each segment of the super string using the culvert_data block.

The definitions are:

\[
\text{<culvert_value>}
\]

\[
\text{<width> pipe_width_real </width>}
\]
where \textit{pipe\_width\_real} is the width and \textit{pipe\_height\_real} is the height for every segment of the string.

OR

For a super string with \textit{n} vertices

\begin{verbatim}
<culvert_data>
  <properties>
    <width> pipe_width_for_segment_1 </width>
    <height> pipe_height_for_segment_1 </height>
  </properties>
  ... 
  <properties>
    <width> pipe_width_for_segment_m </width>
    <height> pipe_height_for_segment_m </height>
  </properties>
</culvert_data>
\end{verbatim}

where

\textit{pipe\_width\_for\_segment\_i} is the width and \textit{pipe\_height\_for\_segment\_i} is the height for the \textit{i}'th segment and

\textbf{m} = \textit{n}-1 for an open string or \textbf{m} = \textit{n} for a closed string.

35.6.10.8.3 Justification for Round or Culvert Pipes

There can be only one justification for all the round or culvert pipe segments in the super string. The definition is:

\begin{verbatim}
<justify> pipe\_justification\_text </justify>
\end{verbatim}

where

\textit{pipe\_justification\_text} is the justification for the entire pipe and can have the values \textbf{centre}, \textbf{top}, \textbf{obvert}, \textbf{bottom} or \textbf{invert}.

If the \textbf{justify} block is missing then the round pipe or culvert pipe is \textbf{centre} justified.
35.6.10.9 Vertex Text and Vertex Annotation

See

35.6.10.9.1 Vertex Text
35.6.10.9.2 Vertex Annotation

35.6.10.9.1 Vertex Text

There can be not text at each vertex, the same piece of text for every vertex in the super string or a different text for each vertex of the super string.

Note: How the vertex text is drawn is specified by the vertex annotation. See 35.6.10.9.2 Vertex Annotation.

If there is a constant text value for each vertex in the string, then the text value is given by a vertex_text_value block:

<vertex_text_value> text_value_text </vertex_text_value>

where text_value_text is the constant text value for each vertex in the string.

For example, for a string of 5 vertices

<vertex_text_value>Constant text</vertex_text_value>

If there is a different text value for each vertex in the string, then the value of the text for each vertex is given in a vertex_text_data block.

<vertex_text_data>
  <p> text_value_for_vertex_1 </p>
  <p> text_value_for_vertex_2 </p>
  ...
  <p> text_value_for_vertex_n </p>
</vertex_text_data>

where text_value_for_vertex_i is the vertex text for the i’th vertex.

For example, for a string of four vertices

<vertex_text_data>
  <p>First vertex</p>
  <p>Second vertex</p>
  <p>/p>
  </vertex_text_data>
35.6.10.9.2 Vertex Annotation

How the vertex text is drawn at each vertex is specified by the vertex annotation. There can be no vertex annotations at all, or the same vertex annotation is used for every vertex in the string using the `vertex_annotation_value` block, or the vertex annotation varies for each vertex of the super string using the `vertex_annotation_data` block.

Note that in vertex annotations, the size of the text for all vertices must be either world size or all paper size or all screen size. That is, world size, paper size and screen size can not be mixed. The first one found is used for all vertices.

The definitions are:

```
<vertex_annotate_value>
    vertex_annotation_information
</vertex_annotate_value>
```

where

`vertex_annotation_information` is the annotation to be used for drawing the text at every vertex of the super string. For the definition of `vertex_annotation_information` see 35.6.4.1 Vertex Annotation Information.

OR

For a super string with n vertices

```
<vertex_annotation_data>
    annotation_for_vertex_1_block
    annotation_for_vertex_2_block
    ...
    annotation_for_vertex_n_block
</vertex_annotation_data>
```

where

`annotation_for_vertex_i_block` is the description for the vertex annotation for vertex i.

The format of the `annotation_for_vertex_i_block` is:

```
<properties>
    vertex_annotation_information
</properties>
```

where

`vertex_annotation_information` is the annotation for drawing the text at the vertex. For the definition of `vertex_annotation_information` see 35.6.4.1 Vertex Annotation Information.
35.6.10.10 Segment Text and Segment Annotation

See

35.6.10.10.1 Segment Text
35.6.10.10.2 Segment Annotation

35.6.10.10.1 Segment Text

There can be no text on each segment, the same piece of text for every segment in the super string or a different text for each segment of the super string.

Note: How the segment text is drawn is specified by the segment annotation. See 35.6.10.10.2 Segment Annotation.

If there is a constant text value for each segment in the string, then the text value is given by a segment_text_value block:

   <segment_text_value> text_value_text </segment_text_value>

where text_value_text is the constant text value for each segment in the string.

For example, for a string of 5 vertices

   <segment_text_value>Constant text</segment_text_value>

If there is a different text value for each segment in the string, then the value of the text for each segment is given in a segment_text_data block.

   <segment_text_data>
   <p>text_value_for_segment_1</p>
   <p>text_value_for_segment_2</p>
   ...
   <p>text_value_for_segment_m</p>
   </segment_text_data>

where

   text_value_for_segment_i is the segment text for the i'th segment, and
   m = n-1 for an open string or m = n for a closed string.

For example, for a string of four segments

   <segment_text_data>
   <p>First segment</p>
   <p>Second Segment Two lines</p>
   <p>seg3</p>
   <p/>
   </segment_text_data>
35.6.10.10.2 Segment Annotation

How the segment text is drawn at each segment is specified by the segment annotation. There can be no segment annotations at all, or the same segment annotation is used for every segment in the string using the `segment_annotation_value` block, or the segment annotation varies for each segment of the super string using the `segment_annotation_data` block.

Note that in segment annotations, the size of the text for all segments must be either world size or all paper size or all screen size. That is, world size, paper size and screen size can not be mixed. The first one found is used for all segments.

The definitions are:

```xml
<segment_annotate_value>
    segment_annotation_information
</segment_annotate_value>
```

where

`segment_annotation_information` is the annotation to be used for drawing the text at every segment of the super string. For the definition of `segment_annotation_information` see 35.6.4.2 Segment Annotation Information.

OR

For a super string with n vertices

```xml
<segment_annotation_data>
    annotation_for_segment_1_block
    annotation_for_segment_2_block
    ...
    annotation_for_segment_m_block
</segment_annotation_data>
```

where

`annotation_for_segment_i_block` is the description for the annotation at segment i, and.

m = n-1 for an open string or m = n for a closed string.

The format of the `annotation_for_segment_i_block` is:

```xml
<properties>
    segment_annotation_information
</properties>
```

where

`segment_annotation_information` is the annotation for drawing the text at the segment. For the definition of `segment_annotation_information` see 35.6.4.2 Segment Annotation Information.

Continue to the next section 35.6.11 Super Alignment String or return to 35.6 Elements Contained in Models or 35.12d XML File Format.
35.6.11 Super Alignment String

The 12d XML for the Super Alignment String has not yet been documented.

In an alignment string, only the intersection point method (IP's) could be used to construct the horizontal and vertical geometry. The IP definition is actually a constructive definition and the tangents points and segments between the tangent points (lines, arcs, transitions etc.) are calculated from the IP definition. For an alignment string, only the IP definitions are included in the 12d XML file.

For a super alignment, the horizontal and vertical geometry are also defined separately and with construction methods but the construction definition can be much more complex than just IP's. For example, an arc could be defined as being tangential to two offset elements, or constrained to go through a given point.

If the horizontal construction methods are consistent then the horizontal geometry can be solved, and the horizontal geometry expressed in terms of consecutive segments (lines, arcs, transitions) that are easily understood and drawn.

Similarly if the vertical construction methods are consistent then the vertical geometry can be solved, and the vertical geometry expressed in terms of consecutive segments (lines, arcs, parabolas) that are easily understood and drawn.

For the super alignment both the construction methods (the parts) and the resulting vertices and segments (lines, arcs, transitions etc.) that make up the horizontal and vertical geometry (the data) are written out to the 12d XML file.

For most applications such as uploading to survey data collectors or machine control devices, only the horizontal data and the vertical data are required, not the construction methods (i.e. the horizontal and vertical parts). So when reading the 12d XML of a super alignment, only the horizontal and vertical data needs to be read in and the constructive methods (the horizontal and vertical parts) can be skipped over.

Consequently only the horizontal data and the vertical data is full documented for the super alignment.

Notes

1. Just using the horizontal and vertical data is valid as long as the super alignment geometry is consistent (and solves) and the horizontal and vertical parts can be created. There are flags in the 12d XML of the super alignment to say that the horizontal and vertical geometry is consistent and solves.

2. Segments meeting at a common vertex do not have to be tangential although for most road and rail centre lines, they should be.

3. When 12d Model reads in a 12d XML file and there is only horizontal_parts and no horizontal_data then if possible, 12d Model generates the horizontal_data from the horizontal parts. This is very useful if you are creating a 12d XML file for a super alignment string that only uses HIP methods as it is fairly simple to create the horizontal_parts for such a string and that is fully documented in 35.6.11.2 Horizontal Parts When Geometry is Defined by IP Method Only.

4. When 12d Model reads in a 12d XML file and there is only vertical_parts and no vertical_data then if possible, 12d Model generates the vertical_data from the vertical parts. This is very useful if you are creating a 12d XML file for a super alignment string that only uses VIP methods as it is fairly simple to create the vertical_parts for such a string and that is fully documented in 35.6.11.5 Vertical_parts When VG is Defined by IP Method Only.
The 12d XML definition of the super alignment string is:

```
<string_super_alignment>
  string_header_block
drawables_block
spiral_type_block
closed_block
valid_horizontal_block
valid_vertical_block
synch_vertical_block
label_style_block
horizontal_parts_block
horizontal_data_block
vertical_parts_block
vertical_data_block
geometry_modifiers_block
</string_super_alignment>
```

where

- **string_header_block**
  - the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block.

- **drawables_block**
  - the drawables block contains information on how the super alignment is labelled.
  - This block is not documented.

- **spiral_type_block**
  - `<spiral_type> transition_type_text </spiral_type>`
  - where transition_type_text is the default transition type use in the super alignment and is one of

<table>
<thead>
<tr>
<th>Select Choice</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>clothoid</td>
<td></td>
</tr>
<tr>
<td>cubic parabola</td>
<td></td>
</tr>
<tr>
<td>westrail cubic spiral</td>
<td></td>
</tr>
<tr>
<td>cubic spiral</td>
<td></td>
</tr>
<tr>
<td>natural clothoid</td>
<td></td>
</tr>
<tr>
<td>bloss</td>
<td></td>
</tr>
<tr>
<td>sinusoidal</td>
<td></td>
</tr>
<tr>
<td>cosinusoidal</td>
<td></td>
</tr>
</tbody>
</table>

  For more information on the choices, see 35.3.15 Available Transition Types.

- **closed_block**
  - `<closed> closed_text_logical </closed>`
  - where closed_text_logical is true if the super alignment string is closed and false if the super alignment string is open.

- **valid_horizontal_block**
where valid_horizontal_text_logical is true if the super alignment string horizontal geometry solves and false if the horizontal geometry does not solve.

If the horizontal geometry does not solve then the horizontal_data may be rubbish.

valid_vertical_block

where valid_vertical_text_logical is true if the super alignment string vertical geometry solves and false if the vertical geometry does not solve.

If the vertical geometry does not solve then the vertical_data may be rubbish.

synch_vertical_block

where synch_vertical_text_logical is true if the super alignment vertical geometry is to be synchronized to the horizontal geometry whenever the horizontal geometry is modified.

This is an internal 12d Model flag.

label_style_block

where label_style_text is the name of the super alignment label style used for drawing the super alignment.

horizontal_parts_block

the horizontal_parts block contains the methods to construct the super alignment horizontal geometry. For example float (fillet) an arc of a certain radius between two given lines or create a transition (spiral or non-spiral transition) between a line and an arc.

The parts that make up the horizontal geometry are defined in chainage order from the start to the end of the super alignment.

If the horizontal construction methods are consistent, then they can be solved to form a plan string made up of lines, arcs and transitions and this is given in the horizontal_data block.

Because the construction methods can be very complex, the horizontal_parts block will only be documented for the case where all the horizontal parts are horizontal intersection points (HIPs) with an arc and leading and trailing transitions. See 35.6.11.2 Horizontal_Parts When Geometry is Defined by IP Method Only.

horizontal_data_block

the horizontal_data block contains the segments that define the horizontal geometry.

The horizontal_data block needs to be read in.

For the description of the horizontal_data block, see 35.6.11.1 Horizontal Data Block.

vertical_parts_block

the vertical_parts block contains the methods to construct the super alignment vertical geometry. For example float (fillet) an arc of a certain radius between two given lines.

The parts that make up the vertical geometry are defined in chainage order from the start to the end of the super alignment.

If the vertical construction methods are consistent, then they can be solved to form a string in (chainage, offset) space made up of lines, arcs and parabolas and this is given in the vertical_data block.

Because the construction methods can be very complex, the vertical_parts block will only be documented for the case where all the vertical parts are vertical intersection points (VIPs) with an arc or a parabola on the VIP. See 35.6.11.5 Vertical_parts When VG is Defined by IP Method Only.
**vertical_data_block**

the vertical_data block contains the segments that define the vertical geometry.

The vertical_data block needs to be read in.

For the description of the vertical_data block, see 35.6.11.3 Vertical Data Block.

**geometry_modifiers_block**

the geometry_modifiers_parts block contains extra construction information for the super alignment.

This block is not documented.
35.6.11.1 Horizontal Data Block

The *horizontal_data* block contains the *solved* horizontal geometry of the super alignment.

The *solved horizontal geometry* is made up of a series of (x,y) vertices given in a *data_2d* block followed by a *geometry_data* block specifying the geometry of the segments between adjacent vertices. Each segment can be a straight line, an arc, a transition or an offset transition.

If the solved horizontal geometry has *n* vertices, then there will be *n-1 segments* for an *open* super alignment or *n segments* if the super alignment is *closed*.

```
<horizontal_data>
  string_header_block
  closed_block
  interval_block
  data_2d_block
  geometry_data_block
  blocks_of_info_1
  blocks_of_info_2
  ...
```
blocks_of_info_n
</horizontal_data>

where

**string_header_block**

the common header block for each string, for the contents and the syntax, see 35.6.3 String Header Block. This provides information such as colour for the horizontal data.

**interval_block**

The interval_block for a super string has a distance (a chainage interval) and a chord_to_arc_real

where

the **distance** to temporarily introduce extra vertices into the string at the given chainage distance when the string is in a triangulation to form a tin.

**chord_arc_real** is a real number and is the chord to arc tolerance to use on any arcs in the horizontal data to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

**data_2d_block**

the data_2d block defines the (x,y) value of the vertices that makes up the horizontal data.

For the definition of the data_2d block, see 35.3.12 data_2d.

**geometry_data_block**

the segments of the horizontal data can be straights, arcs, transitions or offset transitions.

For the definition of the geometry_data block, see 35.6.10.2 Geometry of the Horizontal Segments

**blocks_of_info**

extra information for the vertices and/or segments such as colour, attributes, vertex text, vertex uids etc are defined in the same way as for super strings.
35.6.11.2 Horizontal Parts When Geometry is Defined by IP Method Only

When the horizontal geometry is defined by IP methods only, then the horizontal_parts is fairly straightforward.

When 12d Model reads in a 12d XML file and there is no horizontal_data section, then 12d Model will calculate the horizontal_parts. So you are writing a 12d XML with only IP methods for the horizontal geometry then simply leave out the horizontal_data section and 12d Model will calculate it for you.

For a horizontal geometry is defined by IP methods only, the horizontal_parts definition is:

```
<horizontal_data>
  info_for_HIP_1_block
  info_for_HIP_2_block
  ...
  info_for_HIP_n_block
</horizontal_data>
```

where info_for_HIP_i_block is the information about the successive HIPs in the super alignment and is one of:

(a) A horizontal intersection point (HIP) with no arc. This is defined by:

```
<ip>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <x> x_ip_coordinate_real </x>
  <y> y_ip_coordinate_real </y>
</ip>
```

where

- part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.
- time_created_block is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.
- time_updated_block is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.
- x_ip_coordinate_real is the x coordinates of the HIP.
- y_ip_coordinate_real is the y coordinates of the HIP.

(b) A horizontal intersection point (HIP) with an arc of a given radius at the HIP. This is defined by:

```
<arc>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <r> arc_radius_real </r>
</arc>
```
Chapter 35  12d XML File Format

Elements Contained in Models

<x> x_ip_coordinate_real </x>
<y> y_ip_coordinate_real </y>
</arc>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block
is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block
is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

arc_radius_real is the radius of the arc on the HIP.

x_ip_coordinate_real is the x coordinate of the HIP.

y_ip_coordinate_real is the y coordinate of the HIP.

(c) A horizontal intersection point (HIP) with an arc of a given length at the HIP
This is defined by:

<length>
   <id> part_id_integer </id>
   time_created_block
   time_updated_block
   <l> arc_length_real </l>
   <x> x_ip_coordinate_real </x>
   <y> y_ip_coordinate_real </y>
</length>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block
is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block
is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

arc_length_real is the length of the arc on the HIP.

x_ip_coordinate_real is the x coordinate of the HIP.

y_ip_coordinate_real is the y coordinate of the HIP.

(d) A horizontal intersection point (HIP) with an arc and transitions
This is defined by:

<spiral>
   <id> part_id_integer </id>

...
time_created_block
time_updated_block
transition_type_block
  <r> arc_radius_real </r>
  <l1> leading_transition_length_real </l1>
  <l2> trailing_transition_length_real </l2>
  <x> x_ip_coordinate_real </x>
  <y> y_ip_coordinate_real </y>
</spiral>

where

*part_id_integer* is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

*time_created_block* is the time the super tin was originally created, This is optional. For the syntax see [35.3.7 Time Created](#).

*time_updated_block* is the last time the super tin was last modified, This is optional. For the syntax see [35.3.7 Time Created](#).

*transition_type_block*

  <transition_type> transition_type_text </transition_type>

where *transition_type_text* is the default transition type use in the super alignment and is one of

<table>
<thead>
<tr>
<th>Choice</th>
</tr>
</thead>
<tbody>
<tr>
<td>clothoid</td>
</tr>
<tr>
<td>cubic parabola</td>
</tr>
<tr>
<td>westrail</td>
</tr>
<tr>
<td>cubic spiral</td>
</tr>
<tr>
<td>natural clothoid</td>
</tr>
<tr>
<td>blossom</td>
</tr>
<tr>
<td>sinusoidal</td>
</tr>
<tr>
<td>cosinusoidal</td>
</tr>
</tbody>
</table>

This block is optional and if it is missing then the *default transition type* for the super alignment is used.

For more information on the choices, see [35.3.15 Available Transition Types](#).

*arc_radius_real* is the radius of the arc on the HIP.

*leading_transition_length_real* is the length of the leading transition on the HIP.

*trailing_transition_length_real* is the length of the trailing transition on the HIP.

*x_ip_coordinate_real* is the x coordinate of the HIP.

*y_ip_coordinate_real* is the y coordinate of the HIP.

**Notes**

1. A <length> block with *arc_length_real* equal to zero, or a <spiral> block with the *arc_radius_real, leading_transition_length_real* and *trailing_transition_length_real* all zero,
will also represent a HIP with no arcs or transitions on it.:  

```xml
<length>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <l> 0 </l>
  <x> x_ip_coordinate_real </x>
  <y> y_ip_coordinate_real </y>
</length>

OR

<spiral>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  transition_type_block
  <r> 0 </r>
  <l1> 0 </l1>
  <l2> 0 </l2>
  <x> x_ip_coordinate_real </x>
  <y> y_ip_coordinate_real </y>
</spiral>
```

2. If the HIP is the first HIP or the last HIP then no arc or transitions will be drawn even if the relevant parameters are non zero.

As an example of horizontal_parts with only HIP methods:
<horizontal_parts>
  <ip>
    <id>100</id>
    <x>42606.66161172</x>
    <y>37239.28824481</y>
  </ip>
  <ip>
    <id>200</id>
    <x>43134.36832349</x>
    <y>37330.26705997</y>
  </ip>
  <spiral>
    <id>300</id>
    <r>50</r>
    <l1>30</l1>
    <l2>40</l2>
    <x>43336.6595</x>
    <y>37469.2563</y>
  </spiral>
  <arc>
    <id>400</id>
    <r>75</r>
    <x>43481.15324268</x>
    <y>37331.6431906</y>
  </arc>
  <ip>
    <id>500</id>
    <x>43627.02308964</x>
    <y>37544.94343852</y>
  </ip>
</horizontal_parts>

Plan View of Super Alignment

Super Alignment Being Edited

Horizontal Parts with IP Methods Only
35.6.11.3 Vertical Data Block

The vertical_data block contains the solved vertical geometry of the super alignment.

The solved vertical geometry is made up of a series of (chainage,height) vertices given in a data_2d block followed by a geometry_data block specifying the geometry of the segments between adjacent vertices. The segment can be a straight line, a parabola or an arc.

Note that the chainage is the chainage of the horizontal geometry defined in the horizontal_data block (see 35.6.11.1 Horizontal Data Block).

If the vertical geometry has n vertices, then there will be n-1 segments for an open super alignment or n segments if the super alignment is closed.

The format of the vertical_data block is the same as for the segments in a horizontal_data block except that the data is (chainage, height) rather than (x,y) and there is no transitions but a parabola instead.

The definition of the vertical_data block is:

```xml
<vertical_data>
  string_header_block
  closed_block
  interval_block
data_2d_block
  geometry_data_block
  blocks_of_info_1
  blocks_of_info_2
  ...
  blocks_of_info_n
</vertical_data>
```

where

string_header_block

the common header block for each string. for the contents and the syntax, see 35.6.3 String Header Block. This provides information such as colour for the vertical data.

interval_block

The interval_block for a super string has a distance (a chainage interval) and a chord_to_arc_real

where

the distance to temporarily introduce extra vertices into the string at the given chainage distance when the string is in a triangulation to form a tin.

chord_arc_real is a real number and is the chord to arc tolerance to use on any arcs in the vertical data to temporarily insert vertices into the arc when the arc is included in a triangulation to form a tin.

For the syntax of interval_block, see 35.3.6 Interval.

data_2d_block

the data_2d block defines the (chainage,height) value of the vertices that makes up the vertical data.

For the definition of the data_2d block, see 35.3.12 data_2d where x is chainage and y is height.

geometry_data_block
the segments of the vertical data can be straights, arcs or parabolas. 
For the definition of the geometry_data block, see 35.6.11.4 Geometry of the Vertical Segments.

blocks_of_info
extra information for the vertices and/or segments such as colour, attributes, vertex text, vertex uids etc are defined in the same way as for super strings.
35.6.11.4 Geometry of the Vertical Segments

If the segments are straight lines only then that is the default and no further information is required.

If the segments are only straight lines and arcs, then the radius_data and major_data blocks are used to define a radius and bulge_flag data for each segment of the super string. See 35.6.11.4.1 Only Straights and Arcs for Segments.

If any of the segments are parabolas then geometry_data must be used for each segment. geometry_data can represent a straight, arc, transition or offset transition. See 35.6.11.4.2 Straights, Arcs and Parabolas for Segments.

35.6.11.4.1 Only Straights and Arcs for Segments

If there are only straight and arc segments for the string, then for the data_2d it is possible to add a radius and major/minor arc flag for each segment of the super string using the radius_data and major_data blocks respectively. See 35.3.14 radius_data and major_data.

35.6.11.4.2 Straights, Arcs and Parabolas for Segments

When some of the segments are parabolas then the geometry_data block must be used to give the geometry for each segments.

When the vertical_data has n vertices, then the definition of the geometry_data block is

```
<geometry_data>
  info_for_segment_1_block
  info_for_segment_2_block
  ...
  info_for_segment_m_block
</geometry_data>
```

where

```
info_for_segment_i_block
```

is the information defining the i'th segment as either a straight, an arc or a parabola and m = n-1 for an open string or m = n for a closed string.

For the definition of info_for_segment_i_block see:

- 35.6.11.4.2.1 Straight
- 35.6.11.4.2.2 Arc
- 35.6.11.4.2.3 Parabola
35.6.11.4.2.1 Straight
No parameters are needed for defining a straight segment. The *straight* block is simply:

```
<straight> </straight>
```
or simply

```
<straight/>
```

35.6.11.4.2.2 Arc
Since vertical geometry can’t go backwards in chainage value, the majors arcs can not be used and hence there are only possibilities for an arc of a given radius placed between two vertices.

We use *positive* and *negative* radius to differentiate between the four possibilities.

![Arc with +ve radius](image)

The *arc* block is:

```
<arc>
  <radius> radius_for_segment </radius>
  <major> major_flag_for_segment </major>
</arc>
```

where

*radius_for_segment* is the radius for the segment where positive is above the line connecting the vertices.

*major_flag_for_segment* is ignored because only minor arcs are allowed.
35.6.11.4.2.3 Parabola

There can be a parabola between adjacent vertices. The parabola is defined by giving the coordinates of the vertical intersection point for the parabola

chainage  chainage of the VIP of the parabola
height  height of the VIP of the parabola

The parabola block is:

```
<parabola>
  <chainage> vip_chainage_real </chainage>
  <height>  vip_height_real </height>
</parabola>
```

where

vip_chainage_real is the chainage of the VIP of the parabola
vip_height_real is the height of the VIP of the parabola
35.6.11.5 Vertical_parts When VG is Defined by IP Method Only

When the vertical geometry is defined by IP methods only, then the `vertical_parts` is fairly straightforward.

When **12d Model** reads in a 12d XML file and there is no `vertical_data` section, then **12d Model** will calculate the `vertical_parts`. So if you are writing a 12d XML with only VIP methods for the vertical geometry then simply leave out the `vertical_data` section and **12d Model** will calculate it for you.

For a vertical geometry is defined by VIP methods only, the `vertical_parts` definition is:

```
<vertical_data>
  info_for_VIP_1_block
  info_for_VIP_2_block
  ...
  info_for_VIP_n_block
</vertical_data>
```

where `info_for_VIP_i_block` is the information about the successive VIPs in the super alignment and is one of:

(a) A vertical intersection point (VIP) with no arc or parabola.
   
   This is defined by:
   
   ```xml
   <ip>
     <id> part_id_integer </id>
     time_created_block
     time_updated_block
     <x> chainage_ip_coordinate_real </x>
     <y> height_ip_coordinate_real </y>
   </ip>
   ```
   
   where
   
   `part_id_integer` is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.
   
   `time_created_block` is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.
   
   `time_updated_block` is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.
   
   `chainage_ip_coordinate_real` is the chainage of the VIP.
   
   `height_ip_coordinate_real` is the height of the VIP.
   
   (b) A vertical intersection point (VIP) with an parabola of a given chainage length at the VIP.
   
   This is defined by:
   
   ```xml
   <length>
     <id> part_id_integer </id>
     time_created_block
     time_updated_block
     <l> parabola_chainage_length_real </l>
   </length>
   ```
<x> chainage_ip_coordinate_real </x>
<y> height_ip_coordinate_real </y>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block
is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block
is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_chainage_length_real is the chainage length of the parabola on the VIP.
chainage_ip_coordinate_real is the chainage of the VIP.
height_ip_coordinate_real is the height of the VIP.

(c) A vertical intersection point (VIP) with an parabola of a given k value at the VIP
This is defined by:

<kvalue>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <k> parabola_k_value_real </k>
  <x> chainage_ip_coordinate_real </x>
  <y> height_ip_coordinate_real </y>
</kvalue>

where

part_id_integer is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

time_created_block
is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

time_updated_block
is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

parabola_k_value_real is the k value of the parabola on the VIP.
chainage_ip_coordinate_real is the chainage of the VIP.
height_ip_coordinate_real is the height of the VIP.

(d) A vertical intersection point (VIP) with an parabola of a given effective radius value at the VIP
This is defined by:

<radius>
  <id> part_id_integer </id>

"
Elements Contained in Models

- **time_created_block**
- **time_updated_block**

  `<r> parabola_effective_radius_value_real </r>`

  `<x> chainage_ip_coordinate_real </x>`

  `<y> height_ip_coordinate_real </y>`

  </kvalue>

  where

  - **part_id_integer** is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

  - **time_created_block**

    is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

  - **time_updated_block**

    is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

  - **parabola_effective_radius_value_real** is the effective radius of the parabola on the VIP.

  - **chainage_ip_coordinate_real** is the chainage of the VIP.

  - **height_ip_coordinate_real** is the height of the VIP.

(e) A vertical intersection point (VIP) with an arc of a given radius at the VIP.

  This is defined by:

  `<arc>`

  `<id> part_id_integer </id>`

  `<r> time_created_block </r>`

  `<r> time_updated_block </r>`

  `<r> arc_radius_real </r>`

  `<x> chainage_ip_coordinate_real </x>`

  `<y> height_ip_coordinate_real </y>`

  </arc>

  where

  - **part_id_integer** is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.

  - **time_created_block**

    is the time the super tin was originally created, This is optional. For the syntax see 35.3.7 Time Created.

  - **time_updated_block**

    is the last time the super tin was last modified, This is optional. For the syntax see 35.3.7 Time Created.

  - **arc_radius_real** is the radius of the arc on the VIP.

  - **chainage_ip_coordinate_real** is the chainage of the VIP.

  - **height_ip_coordinate_real** is the height of the VIP.

(f) A vertical intersection point (VIP) with an asymmetric parabola defined by the start and end
chainage lengths at that VIP
This is defined by:

```xml
<asymmetric>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <l1> parabola_start_chainage_length_real </l1>
  <l2> parabola_end_chainage_length_real </l2>
  <x> chainage_ip_coordinate_real </x>
  <y> height_ip_coordinate_real </y>
</asymmetric>
```

where

- `part_id_integer` is a number that is unique for each horizontal and vertical part and the value is a multiple of 100.
- `time_created_block` is the time the super tin was originally created. This is optional. For the syntax see 35.3.7 Time Created.
- `time_updated_block` is the last time the super tin was last modified. This is optional. For the syntax see 35.3.7 Time Created.
- `parabola_start_chainage_length_real` is the start chainage length of the asymmetric parabola on the VIP.
- `parabola_end_chainage_length_real` is the end chainage length of the asymmetric parabola on the VIP.
- `chainage_ip_coordinate_real` is the chainage of the VIP.
- `height_ip_coordinate_real` is the height of the VIP.

**Notes**

1. A `<length>` block with `arc_length_real` equal to zero, or a `<spiral>` block with the `arc_radius_real`, `leading_transition_length_real` and `trailing_transition_length_real` all zero, will also represent a HIP with no arcs or transitions on it.

```xml
<length>
  <id> part_id_integer </id>
  time_created_block
  time_updated_block
  <l> 0 </l>
  <x> x_ip_coordinate_real </x>
  <y> y_ip_coordinate_real </y>
</length>
```

OR

2. If the VIP is the first VIP or the last VIP then no parabola or arc will be drawn even if the relevant parameters are non zero.
As an example of **vertical_parts** with only VIP methods:

```
<vertical_parts>
  <ip>
    <id> 600 </id>
    <x>-50.8459652 <x>
    <y> 59.79764161 <y>
  </ip>
  <kvalue>
    <id> 700 </id>
    <k> 1.25 <k>
    <x> 38.4627 <x>
    <y> 179.2126 <y>
  </kvalue>
  <length>
    <id> 800 </id>
    <l> 50 <l>
    <x> 172.61694837 <x>
    <y> 154.72967932 <y>
  </length>
  <asymmetric>
    <id> 900 </id>
    <l1> 25 <l1>
    <l2> 75 <l2>
    <x> 270.0182 <x>
    <y> 208.1493 <y>
  </asymmetric>
  <arc>
    <id> 1000 </id>
    <r> 1000 <r>
    <x> 424.2402 <x>
    <y> 196.5637 <y>
  </arc>
  <radius>
    <id> 1100 </id>
    <r> 200 <r>
    <x> 201.5302 <x>

35.6.12 Text String

The format for the `string_text` element is:

```xml
<string_text>
    string_header_block
    point_block
    vertex_text_value_block
    vertex_annotate_value_block
</string_text>
```

where

**string_header_block**

the common header block for each string. for the contents and the syntax, see [35.6.3 String Header Block](#).

**point_block**

The format of the `point_block` is:

```xml
<point>
    x_real  y_real  z_real
</point>
```

where

`(x_real,y_real,z_real)` is the vertex of the text.

**vertex_text_value_block**

The text for the text string.

The format of the `vertex_text_value_block` is:

```xml
<vertex_text_value>
    characters_of_the_text
</vertex_text_value>
```

where

`characters_of_the_text` is the characters of the text with the except of some character that are special characters and are replace by something else.

For example `&` in the text is replaced `&amp` and a new line is given by `&\#xa;`. See [Characters "<", "]" and "]" and Escaping](#).

**vertex_annotate_block**

These are the setting for displaying text at a vertex.

The format of the `vertex_annotate_block` is:

```xml
<vertex_text_value>
    vertex_annotation_information
</vertex_text_value>
```

where

`vertex_annotation_information` is the annotation to be used for drawing the text. For the definition of `vertex_annotation_information` see [35.6.4.1 Vertex Annotation Information](#).

For example

```xml
<string_text>
    <name>text</name>
    <chainage>0</chainage>
    <breakline>line</breakline>
    <colour>yellow</colour>
    <style>1</style>
    <time_created>28-Apr-2015 07:48:35</time_created>
    <time_updated>28-Apr-2015 07:49:33</time_updated>
</string_text>
```
Elements Contained in Models

Continue to the next section 35.6.13 Trimesh or return to 35.6 Elements Contained in Models or 35 12d XML File Format.
35.6.13 Trimesh

A trimesh is a special type of primitive_3 object. A trimesh is made up of 3D triangles and can be described by giving the list of $m$ vertices in the trimesh and the three vertices that make up each of the $n$ triangular faces.

The 12d XML definition of a trimesh is:

```xml
<primitive_3d>
  string_header_block
  trimesh_3d_block
</primitive_3d>
```

where

- `string_header_block` is the common header block for each string. For the contents and the syntax, see 35.6.3 String Header Block.

The `colour` in the `string_header_block` is the base colour for the trimesh.

- `trimesh_block` gives the vertices of the trimesh and then the faces of the trimesh in terms of the vertex numbers.

```xml
<trimesh_3d>
  <vertices>
    <v> x_value_1  y_value_1  z_value_1 </v>
    <v> x_value_2  y_value_2  z_value_2 </v>
    ...
    <v> x_value_n  y_value_n  z_value_n </v>
  </vertices>
  <faces>
    <f> face_1_vertex_1  face_1_vertex_2  face_1_vertex_3 </f>
    <f> face_2_vertex_1  face_2_vertex_2  face_2_vertex_3 </f>
    ...
    <f> face_m_vertex_1  face_m_vertex_2  face_m_vertex_3 </f>
  </faces>
</trimesh_3d>
```

where

- $n$ is the number of vertices and $(x\_value_i, y\_value_i, z\_value_i)$ are the 3D coordinates of the $i$th vertex
- $m$ is the number of faces in the trimesh and $face_j\_vertex_1$, $face_j\_vertex_2$, $face_j\_vertex_3$ are the number of the vertices in the `vertex` block for the $j$th face.

36 12d Survey Guide

The information contained in this appendix outlines the general options, terminology, definitions and methods used by 12d Model for the purpose of the input, reduction and output of survey information. It is a general guide, with the appendices following relating to specific instruments and the interactions with 12d Model.

See
- Guide to Survey Reduction in 12d Model
- Guide to Survey Coding in 12d Model

- The 12d Field File Format
- Batch Typed Entry

Please continue to the next section 36.1 Guide to Survey Reduction in 12d Model.

36.1 Guide to Survey Reduction in 12d Model

The 12d Model survey options are used to reduce electronically recorded survey information and produce 12d Model strings, a process called survey reduction.

In the most general case, there are three steps involved:

1. 12d Model downloads raw data from a data collector and stores it on the computer.

2. The raw data file is converted to a standard 12d Model raw field file format, normally with extension of ".fld". For simplicity, the standard 12d Model raw field file is called the "12d field file".

3. The 12d field file is read into a 12d Model Survey Reduction function (12d Survey function) and reduced. If errors occur, the field data for 12d Survey function can be interactively and/or graphically edited. The reduction produces 12d Model super strings in one or many 12d Model models.

In some circumstances, not all steps are necessary. For example, Step 1 is not necessary when the raw data file is already on the computer (and hence doesn't need downloading).

This often occurs when data collectors have PCMCIA cards and PCMCIA card readers on the computer. Another example is when the raw data file has already been downloaded to the computer using another package such as HyperTerminal. Or maybe the raw data file has already been downloaded in a previous 12d Model session.

Steps 1 and 2 are not necessary when the data is already in the form of a 12d field file. This occurs when other software packages, such as TP Setout, can produce a 12d field file. Or the 12d field file was created in a previous 12d Model session, maybe even on a different computer.
A data flow diagram for the survey reduction process is:

A: Downloading raw data from data collector
   - Download and convert to 12d field file

B: Already have raw file on the computer
   - Convert to 12d field file

C: Already have 12d field file on the computer
   - No conversion required

Data Flow for Survey Reduction

Please continue to the next section 36.2 Guide to Survey Coding in 12d Model.
36.2 Guide to Survey Coding in 12d Model

At first the whole process may seem confusing because there are a multitude of methods of setting up coding in the field. Why isn’t there just one way of doing things?

Firstly, each brand of survey instrument has a totally different format for recording information. Unfortunately there is no industry standard. In fact, different instruments from the same survey instrument manufacturer can have different formats for recording data.

Secondly, many of our customers were already familiar with another survey package and if possible, wished to continue field coding in the same way. Where possible, 12d Model has tried to accommodate this wish. Since 12d Model has replaced a number of survey packages, this led to yet more possible configurations.

12d Model has also been developing its own preferred method of field coding for each instrument. It is not compulsory to use the 12d method but of course it is the only way of taking advantage of features that are not available in other coding systems. For example, defining and using field templates and recording user-defined attributes on points and segments.

So to make help guide you through survey coding section:

(a) There are field coding concepts used in 12d Model that are common to all instruments. For example, feature codes and string numbers, offset, close strings etc.
   These are described in 36.3 Field Coding

(b) There are template field coding concepts used in 12d Model that are common to all instruments. These are described in 36.4 Field Templates

(c) There are shape field coding concepts used in 12d Model that are common to all instruments. These are described in 36.5 Shape field coding

(d) There are traverse field coding concepts used in 12d Model that are common to all instruments. These are described in 36.6 Traverse coding

(e) For leica instruments, the coding methods are different from most other types. These are described in 36.7 Field Coding for Leica Instruments

(f) For non-leica instruments, the concepts used in coding are similar for each type. These are described in 36.8 Field Coding for Non Leica Instruments
36.3 Field Coding

EDM equipment is used to make readings of points in the field. However, rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information.

Unfortunately, there is no industry standard for this extra coding and it is software specific. In 12d Model, the extra information is included in one or both of

- a feature code and string number
- extra commands called field codes

How the feature codes, string number and field codes are added in the field depends on the data collector being used and the coding convention set up by the user in 12d Model.

For example, some surveyors like to enter the feature code before the string number, others like to enter the feature code after the string number. Other surveyors don’t use string numbers at all but prefer to use a New String command to start new strings (mainly ex SDR Map users).

In 12d Model, a particular field coding convention is defined by the user and stored with a unique name as a data collector definition in the file survey.4d. New data collector definitions can be created and existing ones modified using the Survey Data Collectors section of Project=>Browse.

12d Model converts all the raw data files from the different survey instruments and data recorders with different coding conventions, into the one 12d Model standard field file format before being loaded into a 12d Model Survey Reduction function and reduced. The 12d Model standard field file will simply be referred to as the 12d field file or just the field file.

The use of many of the commands allowed in the 12d field file will now be described. The complete definition of all the 12d field file commands will be described later.

The coding methodology for specific data recorders will be described in separate Sections.

Please continue to the next section 36.3.1 Stringing in the Field.
36.3.1 Stringing in the Field

In the coding convention, it is possible to specify that

(a) feature codes and string numbers are used
or
(b) just feature codes.

Case (a) feature codes and string numbers

If feature codes and string numbers are entered with measurements in the field, a coding methodology is used so that strings are automatically created during the reduction process. To allow this stringing, the feature code and string number are interpreted in the following manner:

During reduction, 12d Model connects measurement points with the same feature code and string number in the order they are measured in. That is, the feature code and string number determines which points are joined together to form the vertices of a super string. At the end of the reduction, the string number is dropped and just the feature code remains as the name for the super string.

Hence the feature code and string number combination allows any number of different super strings with the same name (feature code) to be produced.

If the string number is zero, then the point-line type of the super string is set to point. If the string number is non-zero, the point-line type of the super string is set to line.

Finally, during reduction, the feature code can be used as the key to a Map File to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes and string numbers can be intertwined. That is, not all the points in one super string need to be measured before the points in a different super string.

Hence at the end of the reduction, 12d Model super strings are created for each unique feature code and string number combination in the input data.

Note - if the string number is blank, the string number defaults to 0

Case (b) just feature codes

If just feature codes are used then a New String command is used to start a new super string rather than giving a new string number.

During reduction, 12d Model connects measurement points with the same feature code in the order they are measured in until a New String command is found. That is, just the feature code determines which points are joined together to form a super string and the New String command defines when a new super string begins.

At the end of the reduction, the feature code remains as the name for the super string.

Also during reduction, the feature code can be used as the key to a Map File to specify the name, model, colour, point-line type, linestyle, tinability and other details for the super string.

Note that the measurements of points with different feature codes can be intertwined. That is, not all the points in one super string need to be measured before the points in a different super string.

An Example of Coding to String Points Together

Two super strings are to be created, one joining points a and c, the other joining points b and d.
Points may be measured and assigned feature codes and string numbers as follows:

<table>
<thead>
<tr>
<th>Measurement to point</th>
<th>Feature code</th>
<th>String Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>123</td>
<td>01</td>
</tr>
<tr>
<td>b</td>
<td>ABC</td>
<td>01</td>
</tr>
<tr>
<td>c</td>
<td>123</td>
<td>01</td>
</tr>
<tr>
<td>d</td>
<td>ABC</td>
<td>01</td>
</tr>
</tbody>
</table>

Alternatively, the points could have been measured in the order a, c, b, d as long as the correct feature codes and string numbers were entered.

<table>
<thead>
<tr>
<th>Measurement to point</th>
<th>Feature code</th>
<th>String Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>123</td>
<td>01</td>
</tr>
<tr>
<td>c</td>
<td>123</td>
<td>01</td>
</tr>
<tr>
<td>b</td>
<td>ABC</td>
<td>01</td>
</tr>
<tr>
<td>d</td>
<td>ABC</td>
<td>01</td>
</tr>
</tbody>
</table>

Because the string numbers are non-zero, the default point-line type for both super strings is line.

Please continue to the next section 36.3.2 Offsets.
36.3.2 Offsets

It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the coordinates of the required point.

The three offsets that are allowed in the 12d field file are:

**Height** - The height offset adjusts the height of a non-null point. A positive offset adds to the height and a negative offset reduces the height.

**Radial** - The radial offset adjusts the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station and a negative offset is toward the station.

**Tangential** - The tangential offset adjusts the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A positive offset is to the right (looking from the station to the point) and a negative offset is to the left.

Please continue to the next section **36.3.3 Start New String**.
36.3.3 Start New String

A new string is automatically started whenever a different string number is used. However there is also a **start new string** command which begins a new super string even if the string number is the same as the string number for previous points.

The *New String* command is particularly useful for correcting the field error of forgetting to change the string number.

Please continue to the next section 36.3.4 Close String.
36.3.4 Close String

The close string command closes a super string by joining the first and last points of the super string. If a super string is already closed, then the close has no effect. The string closed command can be given at the recording of any point of the string, and the entire string is closed.

Please continue to the next section 36.3.5 Rectangle.
36.3.5 Rectangle

The rectangle command acts on last three points of a string and adds a new point after the last point to form a parallelogram (squashed rectangle). The string is then closed.

The height of the added point is set to null.

```
point 1

point 2

point 3

construct point 4 to form a parallelogram. Its height is null.
```

Form Rectangle

Please continue to the next section 36.3.6 Rectangle by 2 Points.
36.3.6 Rectangle by 2 Points

The rectangle by 2 pts command acts on last two points of a string and adds two new points at a given offset after the last point to form a rectangle. The string is then closed.

The height of the added points are set to null.

Form Rectangle By 2 Points

Points 3 and 4 constructed from a given offset relative to the reference line from 1 to 2. (Positive)

Please continue to the next section 36.3.7 Feature.
36.3.7 Feature

A feature string is a circle with a z-value at the centre but only null values on the circumference of the circle.

The feature commands creates a feature string with the picked up point as its centre and the radius/diameter being set by the feature command.

If a feature string is given a world line style, then the style is centred on the centre point of the feature string and scaled up to the radius of the feature string.

If a feature string is given a screen or paper line style, then the style is wrapped around the circumference of the feature string.

Feature String

Please continue to the next section 36.3.8 Joining Strings.
36.3.8 Joining Strings

There are three commands for joining two strings together.

**Join last points of strings** - the last point of the first string is joined to the last point of the second string. The direction of the final string is along the forward direction of the first string, across to the end of the second string and then in the reversed direction of the second string.

**Join first to last points of strings** - the first point of the first string is joined to the last point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.

**Join first points of strings** - the first point of the first string is joined to the first point of the second string. The direction of the final string is in the reverse direction of the first string, across to the start of the second string and then in the forward direction of the second string.

Please continue to the next section 36.3.9 Arcs Through Points.
36.3.9 Arcs Through Points

There are a number of commands to fit arcs through sequences of three or more points. Note that this is an arc in plan, with different z-values at each of the three points. The z-values are linearly interpolated around the arc between the points.

Hence it is a helix and not a circle in the plane containing the three points. Note that an 3d-arc in a plane not parallel to the x-y plane does not project onto an arc in the x-y plane.

There are arc commands to

(a) fit an arc through the next three points
(b) fit an arc through the previous three points.
(c) fit arcs to sets of three points until stopped.

The first two cases need no explanation but in the final case, a arc is fitted to the first three points, and then another arc to points 3, 4 and 5 and then an arc through 5,6 and 7 and so on. If at any stage there is only one point left, then no arc can be fitted and a straight line is drawn to the final point.

Please continue to the next section 36.4 Field Templates.
36.4 Field Templates

If a series of points are being picked up along the one string then the feature code and string number only need to be entered once since the default is for a measurement to use the last feature code and string number if no new ones are given.

However it is often much more efficient to pick up one point from a number of strings before moving onto the next point of each string (this is called a cross section pick up).

For example when picking up a road, it would be preferable to pick up the points for a section across the road and then move onto the next section rather than picking up all of one string at a time.

In the diagram below, this means picking up one point from each of the strings LV, LS, LK, CL, RK, RS, RV and then moving onto the next cross section rather than picking up all of LV and then all of LS and so on.

Normally if each measurement is from a different string, then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, 12d Model uses field templates.

Basically, a 12d Model field template consists of defining a sequence of feature codes and string numbers pairs for the field template. The field template can be given a unique name or have no name at all.

When a field template is used, measurements are taken without entering a feature code and string number and the feature code and string number for the measurement come from the field template definition.
For example, a field template could be defined as the sequence:

LV 01, LS 01, LK 01, CL 01, RK 01, RS 01, RV 01

When the field template is used, measurements are taken without giving a feature code or string number and the measurements will be sequentially given the codes LV 01, LS 01, LK 01 etc.

To define a 12d Model field template, there is a command to start recording the field template.

The feature codes and string numbers for the next series of measurements until the stop recording command is given, are stored as the field template. There are also commands to insert and delete a point in the template when it is being used for picking up points.

When a field template is used, the feature code and string number from the field template can be used:

(a) in the same order as the codes are defined in the field template (forward direction).
(b) in the opposite order to how the codes are defined in the field template (reverse direction).
(c) in an alternating same and opposite order that the codes are defined in field template (zig-zag)

These three modes of usage of a field template will be described in the following sections.

Please continue to the next section 36.4.1 Forward Direction.
36.4.1 Forward Direction

If the field template is used in the *forward* direction, then the feature codes and string numbers are used in the same order that they were defined to be in the field template. Once the end of the field template is reached, the feature codes and string numbers re-start at the beginning of the field template.

Please continue to the next section **36.4.2 Reverse Direction**.
36.4.2 Reverse Direction

If the field template is used in the reverse direction, then the feature codes and string numbers are used in the reverse order to what they were defined to be in the field template. That is, the feature codes and string numbers start at the end of the field template definition and are used in the reverse order. Once the beginning of the field template is reached, the feature codes and string numbers re-start at the end of the field template and are used in the reverse order.

Please continue to the next section 36.4.3 Zig-Zag.
36.4.3 Zig-Zag

When picking up a road in sections, it is often quickest to pick up the first section going from one side of the road to the other side, and then move onto to the next section point on the other side of the road and pick up points coming back across the road. Hence the points for the second section are in the reverse order to those in the first section. This process is known as zig-zagging.

This situation can be covered in two ways. A field template could be defined containing all the points for two sections and the field template used in the forward (or reverse) direction. For example, the field template to be used in the forward mode could be defined as:

LV 01, LS 01, LK 01, CL 01, RK 01, RS 01, RV 01, RV 01, RS 01, RK 01, CL 01, LK 01, LS 01, LV 01

However, in 12d Model it is only necessary to define the one section

LV 01, LS 01, LK 01, CL 01, RK 01, RS 01, RV 01, RV 01

and when the field template is used, it is specified that it is being used as a zig-zag field template starting on either the zig (the forward direction of the field template) or the zag (the reverse direction of the field template).

Once a zig is completed, 12d Model automatically uses the reverse order of the field template and hence produces a zag. Similar, once a zag is completed, 12d Model uses the forward order of the field template and produces a zig.

Thus a zag automatically follows a zig and a zig follows a zag.

Hence if a field template is used in the zig-zag mode, it can be used as either:

(a) a zig-zag field template starting on the zig
(b) a zig-zag field template starting on the zag.

Please continue to the next section 36.4.4 Skipping Field Template Points.
36.4.4 Skipping Field Template Points

When picking up points using a field template, 12d Model allows for one or more points to be skipped. By default, the points on the strings on either side of the skipped points will then be joined together.

By combining skipping points and start new string commands, points can be skipped and new strings started on the other side of the skipped points.

Please continue to the next section 36.4.5 Insert Template Points or Insert Multiple Codes.
36.4.5 Insert Template Points or Insert Multiple Codes

When picking up points using a field template, 12d Model allows for one or more points to be inserted. The inserted points change the template from that point onwards so that extra strings can be picked up as they arise.

If the insert point command is given after the last point of a template, a flag can be applied to specify which template pick-up the inserted point is to be added to. That is, add it to the last series of points or the next series. This flag is called the "insert special" flag.

If ticked on in the insert panel, or if the flag given in the offset code is 1, the point will be added to the current series of points in the template being picked up.

In the case shown below where SH 01 is inserted, the insert special flag should be set to on so that the next picked up point will be on the current template. The insert would have been made after the last LV 01 observation in the last pick-up direction. The following pick-up will use the redefined template definition.

**Note** - in the example below, it is a zig-zag template so SH 01 is then used again straight away as the first point of the pickup when coming from left to right.

With the Insert, rather than insert new template points, it is also possible to give multiple codes to existing points in the template so that more than one code can be assigned to the one pick-up point (insert multiple codes).

In the case shown below, an insert was made on the next pick-up direction after the LV 01 observation. The multiple code tick box or flag was set on so that the last picked up point will be assigned the extra code specified, in this case DR 01. The template will be applied to all subsequent measurements so that the observed LV 01 string will also be coded DR 01.

---

**Inserting Points in a ZigZag Template**

An **Insert with Multiple code** turned on so no new point is inserted into the template but instead the current template point is multiple coded with the given Feature code DR and String number 01.

An **Insert with Multiple code** turned off. A new point is added into the template with the given Feature code SH and String number 01.

---

Please continue to the next section 36.4.6 Delete Template Points.
36.4.6 Delete Template Points

When picking up points using a field template, 12d Model allows for one or more points to be deleted. The deleted points change the template from the next specified number of points inclusive of the current point. i.e. They are removed from the template.

If a template delete command was given after the LS 01 string in the next pick-up direction, and the number of specified points were 3, the template will be altered such that the next observed string will be RS 01.
36.5 Shape field coding

If an object of a standard section is to be picked up such as a length of kerb, a shape can be defined and extruded/paralleled along a single pick-up string related to that shape.

For example, a kerb shape can be defined by observing all points on a typical section of the kerb and assigning a shape name. Then when picking up the length of kerb, only one reference string to the shape (defined when recording the shape) has to be picked up e.g. lip of kerb. On reduction, 12d can extrude or parallel the shape such that the strings/shape of the kerb are produced for the entire kerb pick-up.

Normally if each measurement is from a different string e.g back of kerb, lip kerb etc., then the feature code and string number would need to be re-entered with each measurement which is a very time consuming process. To simplify the coding for section pick up, 12d Model uses shape field coding.

Basically, a 12d Model shape consists of observing a number of points on a given section of an object. The shape can be given a unique name or have no name at all.

For example, a shape can be defined by observations shown in order above

1- being the reference point, 2- 7 being the shape points. In this case, the 1st point of the shape pick-up coincides with the reference point.

To define a 12d Model shape, there is a command to start and end the recording of the shape. The feature codes and string numbers for the next series of measurements until the stop recording command is given, are stored in the final shape.

As the shape is defined, other field codes can be used in conjunction such as offset. In this example an observation may be made at 5 for the position of 6 using a vertical offset. Similarly for point 7 using the observation at a point near point 2. In addition, points 6 and 7 can be made non-tinable so that formation of a tin is constrained to the surface of the kerb.

The next step is to pick up the entire length of the kerb at the reference string position using the same feature code and string number used for the reference string in the shape pick-up. In this example the lip of kerb.

Once completed, the shape can be extruded or paralleled using the extrude or parallel com-
mands. The parallel command will create a number of strings according to the number of points on the shape. The extrude will create a super string with a shape defined like a pipe string.
36.6 Traverse coding

If a traverse is undertaken as part of a survey, a traverse code and string number can be coded so that 12d can extract the traverse information. The specific traverse code can be supplied in the survey reduction panel under the traverse tab. An example is shown below:

In this case, the feature code of TL will be searched in the field file on reduction, so that a traverse string can be extracted. The user is required to nominate the foresight measurement with the TL code in this example. If they also include the TL code in a backsight to a previously defined traverse leg, a reciprocal calculation will be made. It uses the pair of observations (Foresight and Backsight observations of the same line e.g. Foresight 1001 to 1002 and backsight from 1002 to 1001). This reciprocal calculation takes the mean of the distance and vertical angles eliminating the effects of refraction.

A number of separate but interrelated traverses can be extracted using differing string numbers in the field.

The traverse code also allows for adjustments to be made between known stations. This adjustment maybe be chosen in the reduction panel. This field is optional.
36.7 Field Coding for Leica Instruments

For Leica instruments, the Leica GSI format breaks lines of data into fixed length ‘words’ and cannot use the same encoding method as the other instruments. The 12d Model coding system for the Leica TPS instruments is covered in the section 37.1 12d and Leica TPS Instruments.
36.8 Field Coding for Non Leica Instruments

EDM equipment is used to make readings of points in the field.

Rather than just collecting points, it is usually desirable to add extra information by coding the readings in a way that can be interpreted during the data reduction process and produce more valuable information. Unfortunately, this extra coding is non-standard and software specific.

In 12d Model, all the raw data files from different data collectors are converted into the one standard field file format (the 12d Model field file) before being loaded into a 12d Model Survey Reduction function and reduced. Hence the method for coding information in the data collector in the field needs to be well defined so that it can be sensibly converted into a 12d Model field file (the section 36.10 The 12d Field File Format contains the complete description of the 12d field file).

When a measurement is taken, most data collectors (Sokkia, Geodimeter, Topcon, Nikon etc.) allow the user to enter text which is then output with the measurement data. Depending on the data collector, the total number of characters of text may be strictly limited and may also be restricted to only one line of text. In 12d Model, a coding system has evolved so the text can be interpreted in a meaningful way.
36.8.1 Blocks and the Block (Command) Delimiter

To allow the one line of text to hold a variety of different information, the line of text is broken up into smaller blocks and each block is processed separately.

The character (or characters) used as the block separator is called the command delimiter or block delimiter.

Obviously the command delimiter can not appear in any of the commands inside a block.

What is used for the command delimiter is user defined in the data collector definition and is found on the Delimiters tab of the Survey.4d Create/Edit panel in the section 36.9 Data Collector Definitions.

The default command delimiter is * and this will be used in the examples in this appendix.

Hence using the command delimiter, the text line is broken into separate blocks for processing.

For example, the text string

EB01*XA.road

breaks into the separate blocks.

EB01
XA.road

A block can be either a control code block or a feature code block.

A control code block is any block that start with a valid control code.

Valid control codes are simply the one or more characters of text designated in the Delimiters, Features, Templating, Pipes/Culverts, Not Tinable and Strings tabs in the Survey.4d Create/Edit panel for the selected data collector definition.

If no control code appears at the start of the block, then the block is taken to be a feature code.
For example, for the *Sokkia Feature String* data collector definition which is installed with *12d Model*, the valid control codes are: *, dot (.), space, +, BS, CHK, X, C, R, S, E, ST,XA, XB, XC, XD, XE, XF, NH, XP, XL, XN, I, O and A.

Any block starting with any of above control codes is a *control code block*. Blocks that aren’t control code blocks are *feature code blocks*.

Blocks can include *comments* and how a comment is specified is given in the next section 36.8.2.
Comments in a Block.
The feature code block is discussed in the section 36.8.3 Feature Code Blocks.
The explanation of each control code is given in the section 36.8.4 Control Code Blocks.
Please continue to the next section 36.8.2 Comments in a Block.
36.8.2 Comments in a Block

Comments are supported in a block. There is a Comment delimiter and all characters after the comment delimiter to the end of the block are treated as a comment.

Comments are attached to the measurement point as text.

Hence the measurement will create a vertex on a super string and the comment will create text at that vertex of the super string.

The default for the Comment delimiter is / and it is defined by the Comment field on the Delimiters tab of the Survey 4d Create/Edit panel.

For example, if * is the command (block) delimiter and / is the comment delimiter, then in

EB01/first point of a template*XA.road

there are two blocks EB01/first point of a template and XA.road

and the text "first point of a template" in the first block is a comment and will be added to the super string as vertex text.

Another common character to use as a comment delimiter is a space (' '). For example, if * is the command delimiter and space is the comment delimiter, then in

EB01 first point of a template*XA.road

"first point of a template" is a comment.

The comment delimiter for the Sokkia Feature String data collector is a space

Please continue to the next section 36.8.3 Feature Code Blocks.
36.8.3 Feature Code Blocks

**Feature Code, String Number and String Delimiter**

In a feature code block, the *feature codes* and *string numbers* are given so that strings are automatically created during the reduction process.

The *feature code* and *string number* appear at the start of the feature code block and can be entered in a variety of ways.

Some surveyors like to enter the *string number* before the *feature code* and other surveyors prefer to enter the *string number after the feature code*. Some surveyors prefer to use *no string numbers* at all (SDRmap users) and use a *new string control code* to start a new string.

All three methods are supported in 12d. The setting is made on the *String number position* field on the *Feature Coding* tab of the Survey.4d Create/Edit panel. The default is 'before feature code'.

If string numbers are going to be used (either *before feature code* or *after feature code*) then there are rules for determining what is the feature code and what is the string number. Note that the *string number* is always *numeric* and can be any length.

Firstly, the *feature code* and *string numbers* can be separated by an *optional String* delimiter given by the *String* field on the *Delimiters* tab of the Survey.4d Create/Edit panel. The default character for the *string delimiter* is `+`.

For example, `20+110KVA` is interpreted as string number '20' and feature code '110KVA' if the string number comes before the feature code.
If a **string delimiter is not used**, then there are **some restrictions** on the feature code so that the feature code and string number can be split apart. Note that the **string number** is always **numeric** and can be any length.

If a string delimiter is not used, then either

(a) **the feature code** must be purely **alpha** and then the feature code can be of any length.

or

(b) **the feature code** is purely numeric. Then the feature code must the **fixed length** given by the **Numeric feature coding field** on the **Feature Coding** tab of the **Survey.4d Create/Edit panel**. If the **Numeric feature coding field** is not set and the feature code is numeric, then the whole thing is interpreted as a feature code with a string number of 0.

If a **feature code** is a **mixture of alpha and numeric**, then a **string delimiter must be used** to separate the feature code from the string number. Once a string delimiter is used, feature code can be any length.

**Tinability as Part of the String Number**

For compatibility with other software coding schemes, the tinability of a point can be included as part of the string number. This is **not normally recommended** since 12d has more flexible methods of defining tinability.

The field **Tinability position** on the **Feature Coding** tab of the **Survey.4d Create/Edit panel** controls whether it is used or not. The default is ‘no tinability’ as part of the string number.

If tinability is used as part of the string number, then it consists of either a **0** or a **1**.

If **Tinability position** is set to **before string**, the first character of the **string number** is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.

If **Tinability position** is set to **after string**, the last character of the **string number** is stripped off and taken as the tinability flag. A value of 1 means the point is tinable and 0 is non-tinable.
Offset Codes

It is not always possible to measure a point directly but it may be possible to measure a point nearby and then measure an offset to adjust the measured point by and so produce the co-ordinates of the required point. The three offsets that are allowed in 12d Model are height, radial and tangential. See the Section 36.3.2 Offsets for more information.

The three offsets height, radial and tangential have the codes H, R and T respectively.

The offset codes come after the feature code-string number combination and are separated by the Offset code delimiter whose default value is a decimal point (.) and is defined by the Offset code field on the Delimiters tab of the Survey 4d Create/Edit panel.

After the offset code delimiter, the offset code is given as either H, R or T and then a real value for the offset (with no spaces in between). The offset can be positive or negative with the sign only being recorded if negative. A second and third offset code (H, R or T) can follow the first but no offset code delimiter is used for the second or third offset codes. The offset code delimiter is only used to separate the field code-point number from the offset codes.

In the example 20+110KVA.H2.1T0.5 there is a horizontal offset of 2.1 and a tangential offset of 0.5.

Multiply Coded Points

It is possible to have more than one Feature code block and this will create a multiply coded point.

For example, if the command delimiter is *, then EB01*PP would have the two feature code blocks 'EB01' and 'PP'.

Please continue to the next section 36.8.4 Control Code Blocks.
36.8.4 Control Code Blocks

Control Codes on the Delimiters tab

Extra Coding
This code is only for the instruments supporting the Sokkia SDR format.

The default for the extra coding control code is X and it is defined by the Extra coding field on the Delimiters tab of the Survey 4d Create/Edit panel.

For some instruments, extra lines of information can be entered after a measurement. For example on a Sokkia by using the note (13NM) to add more information to the previous measurement line (07).

The extra coding control code is used to append this additional information to the information on the measurement line. Hence it is then possible to have extra blocks of information on the line (or lines) following the measurement line.

The block containing the extra coding control code must be the last block on the measurement line.

For example,

EB01/first point of a template*XA.road*X
/ this is some extra info that happens to be a comment

is the same as

EB01/first point of a template*XA.road*/ this is some extra info that happens to be a comment

Note that there must be a feature code block on the measurement line otherwise a point will be created with no name.

Backsight
The default for the backsight control code is BS and it is defined by the Backsight field on the Delimiters tab of the Survey 4d Create/Edit panel.

The rest of the block after the backsight control code is the name of the station that the backsight was to, or the point number that the backsight was to.

For example, if BS is the backsight control code

BSPSM3

would designate a backsight to the station PSM3.
If only the backsight control code exists, the point number from the reading is taken as the point number for the backsight. This may be data collector dependent.

**Warning** for feature codes starting with the *backsight* control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the backsight control code because they would be interpreted as backsight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the backsight control code, a string number (which may be zero for a point string) **must** be used otherwise the feature code will be interpreted as a backsight measurement and no measurement point would be created.

**Foresight**

There is no default for the *foresight* control code. It is defined by the Foresight field on the Delimiters tab of the Survey.4d Create/Edit panel.

The rest of the block after the *foresight* control code is the name of the station that the foresight was to, or the point number that the foresight was to.

For example, if *FS* is the backsight control code

FSPSM3

would designate a backsight to the station PSM3.

If only the foresight control code exists, the point number from the reading is taken as the point number for the foresight. This may be data collector dependent.

**Warning** for feature codes starting with the *foresight* control code if the Allow point numbers as stations flag is *not set* on the Advanced tab of the Survey.4d Create/Edit panel.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the foresight control code because they would be interpreted as foresight measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) must be used otherwise the feature code will be interpreted as a foresight measurement.

If the Allow point numbers as stations flag is set on, then a point number used as a foresight will create a measurement point for that point number.

**Check Measurement**

The default for the *check measurement* control code is **CHK** and it is defined by the Check measurement field on the Delimiters tab of the Survey.4d Create/Edit panel.

The rest of the block after the *check measurement control code* is the name of the station that
the check measurement was to, or the point number that the check measurement was to.

For example, if CHK is the check measurement control code

\[ \text{CHKPSM3} \]

would designate a check measurement to the station PSM3.

If only the check measurement control code exists, the point number from the reading is taken as the point number that the check measurement is made to. This may be data collector dependent.

**Warning** for feature codes starting with the check measurement control code.

If the feature codes comes before the string number, then feature codes for ordinary measurements **can not** start with the check measurement control code because they would be interpreted as check measurements and no measurement point would be created.

If the feature codes comes after the string number, then whenever a feature codes for ordinary measurements is used that starts with the check measurement control code, a string number (which may be zero for a point string) **must** be used otherwise the feature code will be interpreted as a check measurement and no measurement point would be created.

**Control Codes on the Strings tab**

### Strings tab on the Survey.4d Create/Edit Panel

<table>
<thead>
<tr>
<th>Non Visible</th>
<th>Strings</th>
<th>Others</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close</td>
<td>C</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rectangle</td>
<td>R</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Rectangle by 2 pts</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Start arc fitting</td>
<td>S</td>
<td></td>
<td></td>
</tr>
<tr>
<td>End arc fitting</td>
<td>E</td>
<td></td>
<td></td>
</tr>
<tr>
<td>New string</td>
<td>ST</td>
<td></td>
<td></td>
</tr>
<tr>
<td>End string</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Close String**

The default for the close string control code is **C** and it is defined by the Close field on the Strings tab of the Survey.4d Create/Edit panel.

The close string control code closes the string that the measurement is a point of.

See the Section **36.3.4 Close String** for more information on closing a string.

**Rectangle**

The default for the rectangle control code is **R** and it is defined by the Rectangle field on the Strings tab of the Survey.4d Create/Edit panel.

The rectangle control code uses the current point and the previous two points in the same string (three points total) and creates a new point to form a parallelogram.

See the Section **36.3.5 Rectangle** for more information on forming a rectangle.

**Rectangle by 2 Pts**

A rectangle_2 control code can be defined by the Rectangle by 2 pts field on the Strings tab of the Survey.4d Create/Edit panel.

The rectangle_2 control code uses the current point, last point and an offset. The rectangle is
defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.
If a negative offset value is given, two points will be created to the left of the reference side.
If no Description is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.
If the feature code and string number exist, then a search is made for the last occurrence of two points with the same feature code and string number. If found, then these points are used to define the reference side of the rectangle.

If the point number exists, then a search is made for the last occurrence of two points with the same feature code and string number as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.
Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.
See the Section 36.3.6 Rectangle by 2 Points for more information on forming a rectangle by 2 points.

Start Arc Fitting
The default for the start arc fitting control code is S and it is defined by the Start arc fitting field on the Strings tab of the Survey.4d Create/Edit panel.
The start arc fitting control code starts arc fitting with the current point.
See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

End Arc Fitting
The default for the end arc fitting control code is E and it is defined by the End arc fitting field on the Strings tab of the Survey.4d Create/Edit panel.
The end arc fitting control code ends arc fitting at the current point. That is, the current point is included in the arc fitting but it is the last point used in the arc fitting.
See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

New String
The default for the new string control code is ST and it is defined by the New string field on the Strings tab of the Survey.4d Create/Edit panel.
The new string control code starts a new string with the current point even if the feature code and string number haven’t changed.
See the Section 36.3.3 Start New String for more information on starting a new string.

End String
The end string control code ends the current string even if the feature code and string number haven’t changed for the next point.

Control Codes on the Features tab
Feature by Radius

There is no default for the feature by radius control code. It is defined by the by radius field on the Features tab of the Survey.4d Create/Edit panel.

The feature by radius control code denotes that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.

See the Section 36.3.7 Feature for more information on feature strings.

Feature by Diameter

There is no default for the feature by diameter control code. It is defined by the by diameter field on the Features tab of the Survey.4d Create/Edit panel.

The feature by diameter control code denotes that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.

See the Section 36.3.7 Feature for more information on feature strings.

Control Codes on the Pipes/Culverts tab

Invert Point for Pipe or Culvert

The default for the invert level control code is I and it is defined by the Invert field on the Pipe/Culverts tab of the Survey.4d Create/Edit panel.

The invert level control code denotes that the point is an invert level (bottom).

The invert commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Obvert Point for Pipe or Culvert

The default for the obvert level control code is O and it is defined by the Obvert field on the Pipe/Culverts tab of the Survey.4d Create/Edit panel.
The obvert level control code denotes that point is an obvert level (top). The obvert command can also define the diameter of a pipe or width and height of a culvert. For example, O.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. O.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Centre Point for Pipe or Culvert
The default for the centre level control code is A and it is defined by the Centre field on the Pipe/Culverts tab of the Survey.4d Create/Edit panel.

The centre level control code denotes that point is an centre level (axial).

The centre command can also define the diameter of a pipe or width and height of a culvert. For example, A.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. A.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Control Codes on the Non Tinable tab

<table>
<thead>
<tr>
<th>Control Code</th>
<th>Non Tinable tab on the Survey.4d Create/Edit Panel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove height</td>
<td>NH</td>
</tr>
<tr>
<td>Point</td>
<td>XP</td>
</tr>
<tr>
<td>Previous segment</td>
<td>XL</td>
</tr>
<tr>
<td>Next segment</td>
<td>XN</td>
</tr>
</tbody>
</table>

Remove Height
The control code to set the height of the current point to null.

The default for the remove height from point control code is NH and it is defined by the Remove height field on the Non-Tinable tab of the Survey.4d Create/Edit panel.

Point
The default for the make point non-tinable control code is XP and it is defined by the Point field on the Non-Tinable tab of the Survey.4d Create/Edit panel.

The make point non-tinable control code makes the current point non-tinable. That is, the point is not used in tins (triangulations).

Previous Segment
The default for the make previous segment non-tinable control code is XL and it is defined by the Previous segment field on the Non-Tinable tab of the Survey.4d Create/Edit panel.

The make previous segment non-tinable control code makes the previous segment non-tinable. That is, the segment that the current point is the end of is non-tinable and hence not used as a breakline in tins (triangulations).

Next Segment
The default for the make next segment non-tinable control code is XN and it is defined by the Next segment field on the Non-Tinable tab of the Survey.4d Create/Edit panel.
The *make next segment non-tinable* control code makes the next segment point non-tinable. That is, the segment that the current point is the start of is non-tinable and hence not used as a breakline in tins (triangulations).

**Control Codes on the Templating tab**

<table>
<thead>
<tr>
<th>Control Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record</td>
<td>Denotes the first point of a new field template definition. The field template definition continues until the next stop recording a field template control code or a start using a field template control code.</td>
</tr>
<tr>
<td>Start</td>
<td>Denotes that a field template is being used. This point takes the feature code and string number from the field template. If it is a named field template, then the control code is followed by the offset code delimiter and then the name of the field template.</td>
</tr>
<tr>
<td>End</td>
<td></td>
</tr>
<tr>
<td>Pause</td>
<td></td>
</tr>
<tr>
<td>Pause after</td>
<td></td>
</tr>
<tr>
<td>Continue</td>
<td></td>
</tr>
<tr>
<td>Skip</td>
<td></td>
</tr>
<tr>
<td>Insert</td>
<td></td>
</tr>
<tr>
<td>Delete</td>
<td></td>
</tr>
</tbody>
</table>

**Record**

The control code to denote that this is the first point of a new field template definition. The field template definition continues until the next stop recording a field template control code or a start using a field template control code.

If the field template is to have a name, then the start recording control code is followed by the offset code delimiter and then the name for the field template. If no name is given, then the field template defines the default field template.

For example, if XA starts recording for the default template, XA.road starts recording the field template called road.

The default for the start recording a field template control code is XA and it is defined by the Record field on the Templating tab on the Survey.4d Create/Edit panel.

See the Section 36.4 Field Templates for more information on field templates.

**Start**

The control code to denote that a field template is being used. This point takes the feature code and string number from the field template. If it is a named field template, then the control code is followed by the offset code delimiter and then the name of the field template.

The field template can also be used as a forward template, a reverse template or as a zig-zag template starting on either a zig or on a zag. The denote using the field template as a forward template, add the offset code delimiter and for. To denote using the field template as a reverse template, add the offset code delimiter and rev. To denote zig-zag mode starting on a zig, add the offset code delimiter and zig. To denote zig-zag mode starting on a zag, add the offset code delimiter and zag.

If anything other than ‘for’, ‘rev’ or ‘zag’ is given, the field template is used as a zig-zag template starting on a zig.

For example, if XB starts using the default template, XB.road.zag starts using the field template
called road as a zig-zag field template starting on a zag.

The default for the start using a template control code is **XB** and it is defined by the Start field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**End**

The control code to end the use of the current field template after the current point. That is, the current point uses the field template but subsequent measurements don’t.

The default for the stop using a template control code is **XC** and it is defined by the End field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**Pause**

The control code to pause using the current field template. The current point does not use the field template.

The default for the pause using a template control code is **XD** and it is defined by the Pause field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**Pause after**

The control code to pause using the current field template and the current point does not use the field template.

There is no default for the pause after control code and it is defined by the Pause after field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**Continue**

The control code to continue the use of a paused field template. The current point uses the field template.

The default for the continuing using a field template control code is **XE** and it is defined by the Continue field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**Skip**

The control code to skip point one or more points of the field template. The current point uses the next point after the skipped points from field template.

If more than one point is to be skipped then the control code is followed by the *offset code* delimiter and then number of points to be skipped.

For example, if **XF** is the skip points control code, **XF.2** skips two points. Note that just **XF** skips one point and the ‘.1’ is not required.

The default for the skipping field template points control code is **XF** and it is defined by the Skip field on the Templating tab of the Survey.4d Create/Edit panel.

See the Section [36.4 Field Templates](#) for more information on field templates.

**Insert**

A default control code to insert a point in the field template can be added to this field. The point in inserted after the last point.
See the Section 36.4 Field Templates for more information on field templates.

**Delete**

A default control code to delete a point in the field template can be added to this field. A number of points can be nominated for deletion.

See the Section 36.4 Field Templates for more information on field templates.
36.8.5 Feature coding for traverse extraction
(Non- Leica instruments)

In the example shown above, three distinct traverses were observed. The main traverse between stations 900 and 901 were given a feature code of TL and a string number of 1 (TL1). A typical observation description follows:

Setup on station 900. A foresight measurement was taken from 900 to 1001. A typical feature code may be:
TL1 FS1001. Where the block delimiter is a space (" ") breaking the feature code up into TL1 and FS1001. This tells the reduction that the observation was a traverse because it has a feature code of TL as specified in the traverse tab of the reduction panel. The foresight control code may be FS, telling the reduction that the observation is a foresight observation to a named point

Setup on station 1001. A backsight to station 900 was observed. A typical feature code may be:
TL1 BS900. Where BS is the backsight control code

A foresight to 1002 may be coded as:
TL1 FS1002.

And so forth.

The observation to station 1013 may be made at the same time as when observing to station 1007 from the setup station 1006. Simply changing the string number to 2 for the observation to 1013 will ensure that it is treated as a different traverse, i.e. TL2 FS1013.

The second traverse between stations 1006 and 902 were given a feature code of TL and a string number of 2 whilst the traverse between stations 1010 and 903 were given a feature code of TL and a string number of 3.

The feature code/ string number needs to be present for at least the foresight or measured leg of each of the traverse legs. If they are also present for the backsight, then foresight/backsight pairs will be grouped together and reciprocal calculations done for that leg.
36.9 Data Collector Definitions

Unfortunately, each brand of data collector has its own method of communicating with a computer and a software package.

To allow for a variety of data collectors, **12d Model** lets the user create and edit data collector definitions which are simply user defined sets of data collector parameters stored under user specified names.

The set of data collector definitions are stored in a file but are created and edited using the **12d Model** panel **Survey.4d Create/Edit**.

The **Survey.4d Create/Edit panel** is accessed via **Project => Management =>Tree**.

First select **Project => Management =>Tree** and then click on the + beside the Project name to expand the list of available information for the project. Then click on the + beside **Survey data collectors** to see the list of existing 12d data collector definitions.

Double click LB on **Create data collector** to create a new data collector definition, or double click LB on an existing data collector definition to examine and/or modify it.

The **Survey.4d Create/Edit** panel will then appear.
The fields and buttons used in this panel have the following functions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Type</th>
<th>Defaults</th>
<th>Pop-Up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collector</td>
<td>input name of the data collector to create/edit.</td>
<td>available</td>
<td>data</td>
<td>collectors</td>
</tr>
<tr>
<td>Defaults</td>
<td>button set all the panel fields to default values.</td>
<td></td>
<td>values</td>
<td></td>
</tr>
<tr>
<td>Clear</td>
<td>button clear the values in the panel fields in all the tabs.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Set</td>
<td>button set the values in the panel fields for the given data collector for this session of 12d Model.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Save</td>
<td>button store the data collector definitions to the survey.4d file.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For descriptions of each of the tabs on the panel, go to:
- *Translation*  [Translation tab](#)
- *Feature coding* [Feature Coding tab](#)
- *Delimiters* [Delimiters tab](#)
- *Download* [Download tab](#)

Translation tab

Instrument input  
Geodimeter, Leica  
Nikon DR1, Nikon AP700, Sokkia 20/33  
Topcon GT700, Topcon FC5

Raw file extension input  
file ending to use for the raw file when it is downloaded.

Macro tick box  
if tick, then the Translator pop-up list only shows **12d Model** macros.  
If not ticked, then the Translator pop-up list only shows programs.
Data Collector Definitions

Translator input list of translators in library
name of the macro/program to translate the raw survey file into the 12d field file format.

Vertical circle input zenith zenith, nadir
define the vertical circle zero.

Feature Coding tab

**String number position** input before before feature code
no string number after feature code
defines if the string number is before or after the feature code or is not used at all (no string number).
When 'no string number' then the New string command is used to start new strings with the same feature code.

**Tinability position** input no tinability before string
no tinability after string
defines the position or absence, of the tinability flag. This should only be used for compatibility with data coded for other systems such as CivilCAD. 12d has more flexible methods of defining tinability.

**Numeric feature coding** integer
if 'no string number' is given for String number position then Number feature coding is ignored.
If a number is given, then the feature code must be numeric and the given number is the length of the feature code (that is, the number of digits in the feature code).
If no number is given, then feature codes are alphabetical characters only except when a String code is used to separate the feature code and string number.
Delimiters tab

Command  
input *  
defines the separator between the feature code/string number and op code commands. The delimiter characters can not be used in any other part of the command line.

Comment  
input /  
defines the separator for comments. Note that this can be a space.

Offset code  
input dot ( .)  
defines the beginning of the offset code block. If the offset code block exists, it must come immediately after the Feature code/string number/itenability block. The offset code used R for radial, T for tangential, H for height.

String  
input +  
separates the feature code from the string number. Used when the feature code includes numbers. For example 110KVA+20  would be a feature code of 110KVA and a string number of 20.

Backsight  
input BS  
if the feature code is this control code then the measurement is to a backsight and not a point.

Foresight  
input  
if the feature code is this control code then the measurement is to a foresight and not a point.

Check measurement  
input CHK  
if the feature code is this control code then the measurement is a check measurement and not a point.

Extra coding  
input X  
denotes that the information following is appended to the previous information for the measurement. This allows extra coding than may be allowed for on the measurement line. Mainly for Sokkia using the note (13NM) to add more information to the previous measurement line (07).
A feature code block must be on the measurement line or a measurement with no name will be created. Also a command block can’t be split between two lines.

</tr>
</tbody>
</table>

**Advanced tab**
Comment raw files
tick box
if tick, include the data from the raw survey file as comments in the 12d field file.

Report header
tick box
if tick, include some header information as comments in the 12d field file.

Allow bad line lengths
tick box
if tick, ignore the fact that the length of the line from the data collector is incorrect. This may lead to other errors so it should be used sparingly.

Verbose
tick box
if tick, then extra information is written to the Output window.

Allow point numbers as stations
tick box
if tick, the point numbers for previous measurements can be used as stations for instrument setups, backsights, foresights and check measurements.

Note

When 12d Model starts up, it checks to see if an environment variable called DATA_COLLECTORS_4D exists and if it does, then the file it points to is used to provide the definitions for the data collectors.

If the environment variable is not set, then 12d Model searches for a file called survey.4d (this was data_collectors_definitions in V3.0) in the standard 12d Model search sequence for set up files.

Upload tab
Data Collector Definitions

**Port**
- Input
- COM1 to COM4
- Port on the computer to use to communicate with the data collector for uploads.

**Baud rate**
- Input
- 9600
- 110, 300 ... 256000
- Baud rate to use for the computer port.

**Data bits**
- Input
- 7
- 5, 6, 7, 8
- Number of data bits to use.

**Stop bits**
- Input
- 1
- 0, 1, 1.5, 2
- Number of stop bits to use.

**Parity**
- Input
- None
- None, even, odd, mark, space
- Parity to use.

**DTR/DSR, RTS/CTS, XON/XOFF, ACK/NAK**
- Tick boxes
- Flow control settings.

**Extension**
- Input
- Ending of the file that will be uploaded. For example, typing in `.sdr` means the file to upload ends in ".sdr"

**CR/LF ?**
- Input
- CR, LF, CR LF, None
- End of line characters - characters needed by the data recorder to denote the end of a line of data being uploaded to the data recorder.

**Delay 1**
- Input
- The time between sending lines of data to the data recorder.
Process input
for some data recorders after a data line is sent, a text string needs to be sent to the data recorder to make it process the data line (e.g. GRE3 used a P).

Delay 2 input
the time between sending the process string and sending the next data line.

Ignore comms errors tick box
if tick, ignore any communication errors whilst uploading to the data recorder.

Instrument tab

Measurement/code order input after measurement code before measurement code after measurement

For Leica only where the feature code/string number record is separate to the measurement record. For all other data recorders the feature code block is in the same record as the measurement.
If ‘code before measurement’, then the feature code/ string number record for a measurement is entered before taking the measurement.
If ‘code after measurement’, then the feature code/ string number record for a measurement is entered after taking the measurement.

Sokkia 08KI as GPS points tick box
if tick, when converting reading an Sokkia SDR file, the "08KI" records are treated as points and no directly entered station co-ordinates.

V4 Columns tab
The V4 columns tab is for compatibility with 12d Model V4 field files which were of fixed column widths.

**Feature code start/end**  
input 1/6  
the start and end column position for the feature code in the field file record.

**String number start/end**  
input 7/9  
the start and end column position for the string number in the field file record.

**Point name/Attribute/Point number start/end**  
input 22/30, 10/16, 17/20  
the start and end column position for the point name/Attribute/Point number in the field file record.

**Total length**  
input  
the total length of line expected.

** Templating tab**

For information on field templating, see [36.4 Field Templates](#).
Record  input  XA  text  characters to denote the start of recording a field template. For example XA starts recording for the default template, XA.road starts recording the field template called road. See 55 Start recording a field template.

Start  input  XB  text  characters to denote the start of using a field template. For example XB starts using the blank field template, XB.road starts using the field template called 'road'. XB.road.zig starts using ‘road’ a zig-zag field template and begins as a zag. See 51 Start using an existing field template.

End  input  XC  text  characters to denote stop using the current field template. See 52 Finish using a field template or finish recording a field template.

Pause  input  XD  text  characters to denote temporarily stop using the current field template to take other measurements. The current point does not use the field template. See 53 Pause using the current field template.

Pause after  input  XD  text  characters to denote temporarily stop using the current field template to take other measurements. The current point does use the field template. See 51 Start using an existing field template.

Continue  input  XE  text  characters to denote continuing to use the current field template after a pause. See 54 Continue the current field template.

Skip  input  XF  text  characters to denote that template points are to be skipped. For example XF means skip one field template point, XF.3 means skip three field template points. See 56 Skipping picking up points when using a field template.
Insert

input  XI  text
characters to denote that template points are to be inserted. For example XI.FE01 means insert a template point of FE01 into the template after the last measured template point. See 58 Insert points when using a field template - after the measurement of last point.

Delete

input  XQ  text
characters to denote that template points are to be deleted. For example XQ.3 means delete the next 3 pts from the template after the last measured template point. See 57 Delete points on a field template - after the measurement of last point.

Shapes tab

For information on shapes, see 36.5 Shape field coding.

Record

input  text
characters to denote the start of recording a shape. For example if RS was used, the code RS starts recording for the default shape, RS.shape_name defines the recording of a shape of name shape_name. See 83 Start recording a shape - before the measurement.

End

input  text
characters to denote stop using the current shape. See 84 Finish using a shape definition or finish recording a shape - after the measurement.

Parallel

input  text
characters to denote the application of a shape by parallelling to the shape reference string. The code may be LK01*PS.shape_name
Where the Parallel command is PS, the shape reference string is LK01 and the shape name = shape_name. See 85 Shape parallel.
Extrude input text characters to denote the application of a shape by extrusion to the shape reference string. The code may be LK01*ES.shape_name. Where the Extrusion command is ES, the shape reference string is LK01 and the shape name = shape_name. See 86 Shape extrude.

Pipes/Culverts tab

Invert input text characters to denote that the measurement was the an invert level. See 80 Pipe invert point (bottom of the pipe).

Obvert input text characters to denote that the measurement was the an obvert level. See 82 Pipe obvert point (top of the pipe).

Centre input text characters to denote that the measurement was the a centreline (axial) level. See 81 Pipe axial point (centre of the pipe).

Note that these commands can also denote the diameter of a pipe or width and height of a culvert. For example, I.3 denotes the measurement was an invert level and it was a pipe of diameter 0.3 units. I.3x.4 denotes the measurement was an invert level and it was a box culvert of width 0.3 and height 0.4 units.

Non Tinnable tab
Remove height
characters to denote that the measurement has a null height. See 30 Remove height from a point - that is make it a null height.

Point
characters to denote that the measurement is a non-tinable point. See 40 Make a point non-tinable.

Previous segment
characters to denote that the next segment of the current string is non-tinable. See 38 Make the previous segment non-tinable.

Next segment
characters to denote that the previous segment of the current string is non-tinable. See 39 Make the next segment non-tinable.

Non visible tab
Point
characters to denote that the measurement is a non-visible point. That is, the point is not visible and is not included in a triangulation. See \texttt{109 Make a point invisible - after the measurement}.

Previous segment
characters to denote that the measurement is the end of a non-visible segment. That is, the previous segment is not used as a breakline in a triangulation and it is not visible. See \texttt{107 Make the previous segment invisible - after the measurement}.

Next segment
characters to denote that the measurement is the start of a non-visible segment. That is, the next segment is not used as a breakline in a triangulation and is not visible. See \texttt{108 Make the next segment invisible - after the measurement for the first point of the segment}.

<td>72 Add real user defined attribute to the current point.</td>
</tr>
</tbody>
</table>
Text  
characters to denote that the next text is to be taken as a user defined text attribute of the current
text
vertex. See 73 Add text user defined attribute to the current point.

Measure  

Previous segment tab (Attributes)

Integer  
characters to denote that the next text is to be taken as a user defined integer attribute of the previous
integer
text
segment. See 77 Add integer user defined attribute to the previous segment.

Real  
characters to denote that the next text is to be taken as a user defined real attribute of the previous
real
text
segment. See 78 Add real user defined attribute for the previous segment.

Text  
characters to denote that the next text is to be taken as a user defined text attribute of the previous
text
segment. See 79 Add text user defined attribute to the previous segment.

Measure  

Next segment tab (Attributes)

Integer  
characters to denote that the next text is to be taken as a user defined integer attribute of the next
integer
text
segment. See 74 Add integer user defined attribute to the next segment.

Real  
characters to denote that the next text is to be taken as a user defined real attribute of the next segment.
real
text
See 75 Add real user defined attribute to the next segment.

Text  
characters to denote that the next text is to be taken as a user defined text attribute of the next segment.
text
See 76 Add text user defined attribute to the next segment.

Measure  

Strings tab

For information on the string commands, see 36.3 Field Coding.
Close characters to denote that the string is closed. That is the current measurement is joined to the first point of the string. See 20 Close string.

Rectangle characters to denote that the string is a rectangle. That is the current measurement and the previous two points of the string are three points of a parallelogram and the fourth point is automatically created (and given a null height). See 45 Make a parallelogram from the last three measurement points.

Rectangle by 2 pts characters to denote that the string is a rectangle. That is the previous two points of the string define one side and an offset defines the opposite side. Positive being to the right. The created points are given null height. See 37 Rectangle by two points.

Start arc fitting characters to denote the start of arc fitting. See 61 Start of arc through sets of three points until end of string, or a 62 occurs.

End arc fitting characters to denote the end of arc fitting. See 62 End the arcs begun by a 61 command.

New string characters to denote that the current measurement is the start of a new string, even if the string number has not changed. See 47 Start a new string using the same feature code and string number.

End string characters to denote that the current measurement is at the end of a string, even if the string number has not changed on the next measurement. See 48 End a string.
Others tab

*Under development.*

![Survey 4d Create/Edit window](image)

Features tab

*For information on Feature string, see 36.3.7 Feature.*
**By radius**

Characters to denote that the feature has a given radius. For example, if RA was used then TRE*RA2 would denote a feature code TRE with a radius of 2 units.

There can be more than one set of characters that define ‘By radius’. The sets are entered into the By radius field separated by a space. For example

RA RAD RD

would specify that RA and RAD and RD can be used to denote that the feature is defined by radius.

**By diameter**

Characters to denote that the feature has a given diameter. For example, if DI was used then TRE*DI2 would denote a feature code TRE with a diameter of 2 units.

There can be more than one set of characters that define ‘By diameter’. The sets are entered into the By diameter field separated by a space. For example

DI DIA DR

would specify that DI and DIA and DR can be used to denote that the feature is defined by diameter.
36.10 The 12d Field File Format

The detailed definition of the standardised 12d Field File will now be given. This is the file that all raw files are converted to before reduction in 12d Model.

A few definitions will be given, followed by the complete description of the 12d Field File.

The raw data files from different data collectors are all converted to the 12d field file format. The 12d field file is text and has a name ending in .fld

Each line in the 12d field file is called a record and consists of an operation code (or op code for short) followed by zero or more tabs and pieces of information.

(a) zero fields

What actually follows the fixed header depends on the op code.

Hence the 12d field file record is:

<table>
<thead>
<tr>
<th>op code</th>
<th>tab</th>
<th>value</th>
<th>...</th>
<th>tab</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>02</td>
<td></td>
<td>abcS</td>
<td></td>
<td></td>
<td>fred</td>
</tr>
</tbody>
</table>

A number of conventions and definitions will be now given, followed by the complete description of the 12d Field File.

Important Note

Op codes are not the same as field codes. Field codes are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

Please continue to the next section 36.10.1 Point Description.
36.10.1 Point Description

The feature codes and string numbers are entered by the surveyor whilst surveying in the field and the point numbers are usually automatically created by the surveying instrument but may sometimes be entered into the instrument by the surveyor.

Other information can also be entered by the surveyor using field codes and associated information. How each field code and associated information is entered in the field depends on the data recorder and the coding convention being used. This is set up in the Data Collector definitions in 12d Model.

The data file from the instrument or data collector (raw file) is first converted in 12d Model to the 12d field file ready for loading into a 12d Model Survey Reduction function for reduction.

In most lines of the 12d field file, a feature code, string number, point number, point name and point text are given and are stored next to each other separated by tabs.

The feature code and string number have already been described.

The point number is the EDM tacheometry measurement point number which is not normally entered by the user but is written in the raw data file by the data collector. This is stored as the point number for the vertex of the super string.

The point name is used to store the name of a station (see the next section on named measurements) and is supplied by the user with certain op codes. It is also used by some op codes that do not require an actual point name but have other special information that needs to be stored.

The point text is stored as vertex text for that vertex of the super string.

In the 12d field file, the feature code, string number, point number, point name and point text are given in this order and are separated by tabs. Each can be up to sixty-three characters in length. If the item is missing then a tab is still needed so there may be two or more sequential tabs.

For simplicity in describing the 12d field file, the feature code, string number, point number, point name and point text are grouped together and called the point description.

Hence the point description consists of the following pieces of information separated by tabs:

- feature code (string name)
- string number
- point number
- point name
- text

So it is convenient to think of the point description record as five columns of information:

<table>
<thead>
<tr>
<th>feature code</th>
<th>string number</th>
<th>point number</th>
<th>point name</th>
<th>text</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>01</td>
<td>1002</td>
<td>STN 4</td>
<td>freddie</td>
</tr>
</tbody>
</table>

Please continue to the next section 36.10.2 Measurements and Named Measurements.
36.10.2 Measurements and Named Measurements

The 12d field file allows five types of measurements that create points (vertices) in super strings. They are
(a) directly entered co-ordinates measurement
(b) EDM measurement (HA,VA,SD, + point_description.)
(c) EDM measurement VD (HA,HD,VD + point_description.)
(d) EDM measurement HT (HA,HD,HT, + point_description.)
(e) three hair stadia measurement

Each type of measurement creates a new point which is appended to the previous points with the same feature code and string number.

The last such measurement is referred to as the current measurement point or current point and the string it is appended to is the current string.

If a point_name exists in the point_description for any of the three types of measurements, then it is called a named measurement and a one point super string of name point_name is created and mapped using the Map File. The vertex text for the one point super string is the station prefix followed by point_name. The point_name is added to an internal list of named points for searching for co-ordinates.

Please continue to the next section 36.10.3 Existing Station Co-ordinates.
36.10.3 Existing Station Co-ordinates

When setting up a new instrument, measuring to a backsight, doing a check measurement or manually entering a bearing to use as the bearing datum difference, the point_name or point number from the point_description is used to specify a point. The (x,y,z) co-ordinates for point_name are found by searching in the following order:

The difference between point names and point numbers is that point names are usually given by the user and should be a unique identifier for a point whilst for that same physical point a number of measurements (and hence point numbers) may be assigned (usually by the data collector). This may be particularly true of control station measurements where measurements are made to a given point name but each measurement is given a different point number by the data collector. In most instances, a measurement to a point has a point number (from the data collector) and 12d automatically gives it the same point name as it is rare to measure a non-control point more than once (the point name can be over ridden by the user).

The names allow the reduction routine to search for the details of that point (e.g. coordinates) to allow for the reduction of further measurements. The order in which this searching takes place is as follows:

First search the Control model (if it exists):

1. A search is made of the control model for a string whose name is the same as the specified point name. If a string is found, the first point of the string is used for the (x,y,z) co-ordinates.
2. A search is made of the control model for a vertex of a string whose point number is the same as the specified point name. If a vertex is found its (x,y,z) co-ordinates are used.
3. If only a point number was specified, a search is made of the control model for a vertex of a string whose point number is the same as the specified point number. If a vertex is found its (x,y,z) co-ordinates are used.

Next search the already entered directly entered co-ordinates (DEC) in the field file:

4. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose point name is the same as the specified point name. If a DEC is found, its (x,y,z) co-ordinates are used.
5. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose point number is the same as the specified point name. If a DEC is found, its (x,y,z) co-ordinates are used.
6. A search is made of previously entered directly entered co-ordinates in the field file for a directly entered co-ordinate whose point number is the same as the specified point number. If a DEC is found, its (x,y,z) co-ordinates are used.

Next search the previous measurements in the field file:

7. A search is made of previous measurements in the field file for a measurement whose point name is the same as the specified point name. If a measurement is found, its (x,y,z) co-ordinates are used.
8. A search is made of previous measurements in the field file for a measurement whose point number is the same as the specified point name. If a measurement is found, its (x,y,z) co-ordinates are used.
9. A search is made of previous measurements in the field file for a measurement whose point number is the same as the specified point number. If a measurement is found, its (x,y,z) co-ordinates are used.
10. or finally, the user is asked to type in the (x,y,z) co-ordinates in a Survey Data Define Station panel. If a model is specified in the Add to model field of the panel, then a new one point super string is created with the name point_name, and as the vertex text for the point, the Station label prefix field value followed by point_name.

For a summary of the 12d Field File Op Codes, go to the section 36.10.5 Summary of 12d Field File Op Codes.
For the full description of the **12d Field File Op Codes**, go to the section [36.10.4 Full Description of 12d Field File Op Codes](#36.10.4)
36.10.4 Full Description of 12d Field File Op Codes

For a summary of the 12d Field File Op Codes, go to the section 36.10.5 Summary of 12d Field File Op Codes.

The record for each op code allowed in the 12d field file will now be described in detail.

For each op code record, two lines and a paragraph of description are given:

- The first line consists of the op code and a short description of the purpose of the code.
- The second line gives the full syntax of the record for that op code.
- The paragraph gives a detailed description of the op code record.

Optional information is enclosed in the square brackets [ ]

All angles in the 12d field file are given in decimal degrees.

**Important Note**

Op codes are not the same as field codes. Field codes are entered by the surveyor in the field and may lead to one or more op codes being created in the 12d field file.

<table>
<thead>
<tr>
<th>Op Code</th>
<th>Description of Record</th>
</tr>
</thead>
</table>
| 1       | Four 10 character information blocks  
01 block1  block2  block3  block4  
This information is ignored. |
| 2       | Directly entered coordinate measurement  
02 Point_description  X  Y  Z  
A measurement point is created with the feature code and string number from the point_description and given (x, y,z) co-ordinates. No reduction is needed.  
The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.  
If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates. |
| 3       | New instrument point  
03 Point_description  instrument_height  
Setting up an instrument at the point with name given in the point_name section of the point_description. The (x,y,z) co-ordinates for point_name are found by first searching the control model, then the list of previously named point in the reduction, point numbers of previous measurements and finally if point_name is still not found, the user is asked to type in the (x,y,z) co-ordinates. A record is written to the report file. |
| 4       | Measurement to backsight  
04 Point_description  horizontal_circle  vertical_circle  slope_distance  azimuth  
Measurement to a backsight whose name is given in the point_name section of the point_description. If the Display panel for backsights field in the Survey Data Reduce panel is tick, then the Survey Data Bearing Datum Difference panel shows the bearing datum difference and the horizontal distance.
difference. A record is written to the report file. The units for horizontal_circle and vertical_circle are decimal degrees. The azimuth may be specified where no coordinate for the backsight point exists in decimal degrees.

5 New target height
   05 Target_height
   Set a new target height.

6 Check measurement
   06 Point_description  horizontal_circle  vertical_circle  slope_distance
   A check measurement is made to the station given in the point_name section of the point_description. A two point super string (with name point_name) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and the station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file. The units for horizontal_circle and vertical_circle are decimal degrees.

7 Measurement - HA, VA, SD
   07 Point_description  horizontal_circle  vertical_circle  slope_distance
   Measurement made by the instrument. A measurement point is created with the feature code and string number from the point_description. The units for horizontal_circle and vertical_circle are decimal degrees.
   The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.
   If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates.

9 Scale factor for subsequent distances
   09 Scale_factor
   Scale factor to apply to subsequent slope distances.

10 Three hair stadia measurement
   10 Point_description  horizontal_circle  vertical_circle  bottom  middle  top
   Manual measurement. A measurement point is created with the feature code and string number from the point_description. The units for horizontal_circle and vertical_circle are decimal degrees.
   The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.
   If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates.

11 Measurement - HA, HD, Height
   11 Point_description  horizontal_circle  horizontal_distance  height
   Measurement made by the instrument. A measurement point is created with the feature code and string number from the point_description. The unit for horizontal_circle is decimal degrees.
   The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.
   If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix
followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates.

### Measurement - HA, HD, Height difference

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Point_description horizontal_circle horizontal_distance height_difference</td>
</tr>
</tbody>
</table>

Measurement made by the instrument. A measurement point is created with the feature code and string number from the point_description. The unit for horizontal_circle is decimal degrees.

The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.

If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates.

### Vertical circle correction

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>09</td>
<td>Vertical_circle_in_decimal_degrees</td>
</tr>
</tbody>
</table>

The vertical_circle_in_decimal_degrees is subtracted from the vertical circle value in any measurements. The units for vertical_circle_in_decimal_degrees is decimal degrees.

### Multiply coded point

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Point_description</td>
</tr>
</tbody>
</table>

Additional coding for the current measurement point created by op codes 02, 07 or 10. A new measurement point is created at the same position as the current measurement point but with the feature code and string number from the point_description for this op code.

The point_number and text from the point_description are recorded as the point number and text for that vertex of the super string.

If a point_name exists in the point_description, then it is a named measurement and a 4d point string of name point_name is created and mapped using the Map File. The 4d text is the station prefix followed by point_name. The point_name is added to the internal list of named points for searching for co-ordinates.

### Arc through previous three points

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>17</td>
<td>[Point_description]</td>
</tr>
</tbody>
</table>

If no point_description is given, then the current measurement point and the two previous points with the same feature code and string number as the current measurement point, are joined by an arc. If there is less than three such points, no arc is fitted.

If a point_description exists, then either the feature code and string number or the point_number section of the point_description can be used.

If the feature code and string number from the point_description exist, the last three previous measurement points of the same feature code and string number are joined by an arc. If the current measurement point has that feature code and string number, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If Point_number exists, then the feature code and string number are taken from the previous measurement point with that point number. That point and the two measurement points previous to the predefined point of the same feature code and string number, are joined by an arc. If there is less than three points, no arc is fitted.

See 36.3.9 Arcs Through Points

### Circle Feature

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>18</td>
<td>Radius</td>
</tr>
</tbody>
</table>

Creates a feature string with the given radius and centred on the current measurement point.
See 36.3.7 Feature

20 Close string
20 [Point_description]

If no point_description is given, the current string is closed.
If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.
If the feature code and string number from the point_description exist, the last previous string with that feature code and string number is closed.
If the point number from the point_description exists, then the string containing that point number will be closed.
See 36.3.4 Close String

21 Join last points of strings
21 Feature_code string_number_1 string_number_2

In the final reduction, the last point of the string with the given feature_code and string_number_1 is joined to the last point of the string with given feature_code and string_number_2. The created string has the given feature_code (no string number is needed since it is the final phase of reduction when the string numbers are dropped).
See 36.3.8 Joining Strings

22 Join first to last point of strings
22 Feature_code string_number_1 string_number_2

In the final reduction, the first point of the string with the given feature_code and string_number_1 is joined to the last point of the string with given feature_code and string_number_2. The created string has the given feature_code (no string number is needed since it is the final phase of reduction when the string numbers are dropped).
See 36.3.8 Joining Strings

23 Join first points of strings
23 Feature_code string_number_1 string_number_2

In the final reduction, the first point of the string with the given feature code and string_number_1 is joined to the fist point of the string with given feature code and string_number_2. The created string has the given feature code (no string number is needed since it is the final reduction when the string numbers are then dropped).
See 36.3.8 Joining Strings

28 Add text to the string name
28 [Point_description] Text

Text is appended to the string name. For example, if 1.200 is entered, “1.200” is appended to the string name.
If no point_description is given, Text is appended to the string name of the current string.
If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.
If the feature code and string number exist, then the last previous string with that feature code and string number has Text appended to the string name.
If the point number exists, then the string containing that point number has Text appended to the string name.
29 Note or memo
29 Comments
Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

30 Remove height from a point - that is make it a null height
30 [Point_description]
If no point_description is given, the height of the current measurement point is set to null.
If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.
If the feature code and string number exist, then the height of the last point of the previous string with that feature code and string number is set to null.
If the point number exists, then the height of the point with that point number is set to null.

37 Rectangle by two points
37 [Point_description] offset_in_metres
The rectangle is defined by two points (reference side) and a offset.
If a positive offset value is given, two points will be created to the right of the reference side.
If a negative offset value is given, two points will be created to the left of the reference side.
If no point_description is given, the two new points will be joined to the given points in a closed rectangular string, and will have the same feature code as the points given.
If the feature code and string number exist, then a search is made for the last occurrence of two points with the same feature code and string number. If found, then these points are used to define the reference side of the rectangle.
If the point number exists, then a search is made for the last occurrence of two points with the same feature code and string number as the point given by the point number. If found, then these points are used to define the reference side of the rectangle.
Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.
See 36.3.6 Rectangle by 2 Points

38 Make the previous segment non-tinable
38 [Point_description]
If no point_description is given, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.
If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.
If the feature code and string number exist, then the last segment of the previous string with that feature code and string number is set to non-tinable.
If the point number exists, then the segment containing the point with that point number as an end point, is set to non-tinable.

39 Make the next segment non-tinable
39 [Point_description]
If no point_description is given, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.
If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then the segment that is created in the future from the last point of the previous string with that `feature code` and `string number` is set to non-tinable.

If the `point number` exists, then the segment containing the point with that point number as a start point, is set to non-tinable.

40 **Make a point non-tinable**

40 `[Point_description]`

If no `point_description` is given, the current measurement point is set to non-tinable. That is, it will not be included in triangulations.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then the last point of the previous string with that `feature code` and `string number` is set to non-tinable.

If the `point number` exists, then the point with that point number is set to non-tinable.

41 **Add additional text for the current measurement point**

41 `Text`

The given `text` is added to the end of any existing text for the current measurement point. Any spaces from column four onwards will be part of the text.

42 **Add a radial offset**

42 `[Point_description]`  `Radial_offset_in_metres`

The `radial_offset_in_metres` is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If no `point_description` is given, the offset is used to adjust the position of the current measured point.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then the last point of the previous string with that `feature code` and `string number` is adjusted.

If the `point number` exists, then the point with that point number is adjusted.

See 36.3.2 Offsets

43 **Add a tangential offset**

43 `[Point_description]`  `Tangential_offset_in_metres`

The `tangential_offset_in_metres` is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If no `point_description` is given, the offset is used to adjust the position of the current measured point.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then the last point of the previous string with that `feature code` and `string number` is adjusted.

If the `point number` exists, then the point with that point number is adjusted.

See 36.3.2 Offsets
Add a height offset

If the height of the specified point is not null, then the `height_offset_in_metres` adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.

If no `point_description` is given, the offset is used to adjust the position of the current measured point. If a `point_description` exists, then either the feature code and string number or the point number section of the `point_description` can be used.

If the feature code and string number exist, then the last point of the previous string with that feature code and string number is adjusted.

If the point number exists, then the point with that point number is adjusted.

See 36.3.2 Offsets

Make a parallelogram from the last three measurement points

If no `point_description` is given, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If a `point_description` exists, then either the feature code and string number or the point number section of the `point_description` can be used.

If the feature code and string number exist, the last three points with that feature code and string number are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If the point number exists, then the feature code and string number of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

See 36.3.5 Rectangle

Make the string a breakline or not

The `point_description` is used to select a string and the `mode` is used specify if the string is a breakline or not.

If no `point_description` is given, the current string is selected.

If a `point_description` exists, then either the feature code and string number or the point number section of the `point_description` can be used.

If the feature code and string number exist, the last string with that feature code and string number is selected.

If the point number exists, then the string containing the point with that point number is selected.

If no `mode` is given, the selected string is set as a point string (that is, not a breakline).

If `mode` is given, then

- if `mode` is 0, the selected string is set to a point string and hence is not a breakline.
- if `mode` is 1, the selected string is set to a `line` string and is therefore a breakline

Start a new string using the same feature code and string number

If no `point_description` is given, the current string is terminated (without including the current
measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same `feature code` and `string number`.

If the `point number` exists, then the previous string containing the point with that point number is terminated before the point number point, and the point becomes the first point of a new string with the same `feature code` and `string number`.

See 36.3.3 Start New String

48 End a string
48 [Point_description]

If no `Point_description` exists, the current string is terminated (including the current measurement point).

If `Feature_code` and `String_number` exist, then the last point of the previous string with that feature code and string number becomes the last point of that string.

If `Point_number` exists, then the previous string containing the point with that point number is terminated after the point number point

50 Specify the bearing to correct for true north - used as the bearing datum difference
50 `Point_description` `bearing_in_decimal_degrees`

The `bearing_in_decimal_degrees` is used as the bearing datum difference for the current instrument set up. The `point_name` in the `point_description` and the `bearing_in_decimal_degrees` are written to the report file.

51 Start using an existing field template
51 `Template_name` `zig_zag_mode`

Start using the field template `Template_name`. If `Template_name` is blank, the default field template is used.

If `mode` is "for", then the field template is used as a forward template.
"rev", then the field template is used as a reverse template.
"zig", then the field template is used as a zig_zag template and is used in the forward definition direction first (that is starts on a zig).
"zag", then the template is used as a zig_zag template and is used in the reverse direction first (that is, starts on a zag).

If `mode` is blank, or anything other than "for", "rev", or "zag" then the field template is used as a zig-zag template starting on a zig.

See 36.4 Field Templates

52 Finish using a field template or finish recording a field template
52

Stops using the current field template or stops recording a field template.

See 36.4 Field Templates

53 Pause using the current field template
53

Pause using the current field template or defining a field template, until a continue field template (54) or a finish field template (52) code is given.

See 36.4 Field Templates
54 Continue the current field template

Continue using or defining the current field template, which has been stopped by a Pause field template command (53). The Continue command only needs to be given once and applies to all following measurements until another Pause or Finish command is given.

See 36.4 Field Templates

55 Start recording a field template

Start recording a field template with the name Template_name. If Template_name is blank, then it is the default field template that is defined. The feature_code and string_number of the following measurements until a Finish code (52) are stored as the field template. There is no limit to the number of points in a field template.

See 36.4 Field Templates

56 Skipping picking up points when using a field template

Allows the user to skip picking up one or more points from the field template currently being used. The next measurement takes the feature_code and string_number from the next point of the field template definition. If num_skipped_points is missing, then only one point is skipped otherwise num_skipped_points are skipped.

See 36.4.4 Skipping Field Template Points

57 Delete points on a field template - after the measurement of last point

Allows the user to delete one or more points from the field template currently being used. The next measurement takes the feature_code and string_number from the next point of the field template definition.

See 36.4 Field Templates

58 Insert points when using a field template - after the measurement of last point

Inserts points into the field template currently being used, or gives an existing point a multiple code. If the Multiple_code_flag = 1, then the feature_code will be added to the previous defined template point else if Multiple_code_flag = 0 (default), it will be added to the template as a separate point. If the insert is done at the end of a section and the Insert_special_flag = 1 the point will be added to the end of the current template section else it will be at the start of the next section. The next measurement takes the feature_code and string_number from the next point of the field template definition.

See 36.4.5 Insert Template Points or Insert Multiple Codes

60 Arc through next three points

If no point_description is given, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If a point_description exists, then either the feature code and/or string number and/or the point number section of the point_description can be used.

If the feature code or string number from the point_description exist, a search is made for a previously
defined measurement with the same feature code or string number. An arc is inserted through this previous measurement and the next two measured points following this previous measurement with the same feature code and string number, as given in \textit{point\_description}. If the current point has that feature code and string number, then it is the first of the three points. If there is less than three points, no arc fitted.

If the \textit{point number} exists, then the \textit{feature code} and \textit{string number} are taken from the previous measurement point \textbf{with} that point number, and an arc is inserted through that point and the next two measurement points with the same \textit{feature code} and \textit{string number}. If there is less than three points, no arc is fitted.

See \texttt{36.3.9 Arcs Through Points}

\section{61 Start of arc through sets of three points until end of string, or a 62 occurs}

61 \texttt{[Point\_description]}

If no \textit{point\_description} is given, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the first of the points.

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If a \textit{point\_description} exists, then either the \textit{feature code} and \textit{string number} or the \textit{point number} section of the \textit{point\_description} can be used.

If the \textit{feature code} and \textit{string number} exist, a search is made for a previously defined measurement with the same feature code and string number. An arc is inserted through the following measured points with the same feature code and string number as given in \textit{point\_description}. If the current point has that feature code and string number, then it is the first of the points.

If the \textit{point number} exists, then the \textit{feature code} and \textit{string number} are taken from the previous measurement point \textbf{with} that point number, and arcs are inserted through that point and the following measured points with the same \textit{feature code} and \textit{string number}.

See \texttt{36.3.9 Arcs Through Points}

\section{62 End the arcs begun by a 61 command}

62 \texttt{[Point\_description]}

If no \textit{point\_description} is given, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the last of the points used in the arc fitting.

If a \textit{point\_description} exists, then either the \textit{feature code} and \textit{string number} or the \textit{point number} section of the \textit{point\_description} can be used.

If the \textit{feature code} and \textit{string number} from the \textit{point\_description} exist, then the fitting of arcs through the points of the previous string with the same feature code and string number is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If the \textit{point number} from the \textit{point\_description} exists, then the point with that point number is the last point used in the arc fitting.

If 12d \texttt{Model} encounters an \texttt{End Arcs} (62) but no \texttt{Start Arcs through sets of three points} (61) command for the string, then a \texttt{Start Arcs through sets of three points} (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

See \texttt{36.3.9 Arcs Through Points}

There are op codes for adding user defined attributes to:

(a) the current string being measured (i.e. the string containing the current measurement point)
(b) the current measurement point
(c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the next measured point of the same feature code and string number)

or

(d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point of the same feature code and string number).

If there is no name for the attribute (name is just spaces or a tab), then the attribute is unnamed. The attributes are coded in the following way:

68 Add an integer user defined attribute to the current string
    68 Name  Integer
    Add an user defined integer attribute to the current string.

69 Add a real user defined attribute to the current string
    69 Name  Real
    Add a real (floating point) user defined attribute to the current string.

70 Add text user defined attribute to the current string
    70 Name  Text
    Add a text user defined attribute to the current string.

71 Add integer user defined attribute to the current point
    71 Name  Integer
    Add an integer user defined attribute to the current measurement point.

72 Add real user defined attribute to the current point
    72 Name  Real
    Add a real (floating point) user defined attribute to the current measurement point.

73 Add text user defined attribute to the current point
    73 Name  Text
    Add a text user defined attribute to the current measurement point.

74 Add integer user defined attribute to the next segment
    74 Name  Integer
    Add an integer user defined attribute to the next segment from the current measurement point.

75 Add real user defined attribute to the next segment
    75 Name  Real
    Add a real (floating point) user defined attribute to the next segment from the current measurement point.

76 Add text user defined attribute to the next segment
    76 Name  Text
    Add a text user defined attribute to the next segment from the current measurement point.

77 Add integer user defined attribute to the previous segment
    77 Name  Integer
    Add an integer user defined attribute to the previous segment for the current measurement point.
78 Add real user defined attribute for the previous segment
78 Name    Real
Add a real (floating point) user defined attribute to the previous segment for the current measurement point.

79 Add text user defined attribute to the previous segment
79 Name    Text
Add a text user defined attribute to the previous segment for the current measurement point.

In addition, extra codes allow special 12d Model pipe strings to be coded in the field

80 Pipe invert point (bottom of the pipe)
80 [Point_description]
If no point_description is given, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.

If the feature code and string number exist, the last point of the previous string with the same feature code and string number as given in point_description is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If the point number exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

81 Pipe axial point (centre of the pipe)
81 [Point_description]
If no point_description is given, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.

If the feature code and string number exist, the last point of the previous string with the same feature code and string number as given in point_description is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If the point number exists, then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

82 Pipe obvert point (top of the pipe)
82 [Point_description]
If no point_description is given, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If a point_description exists, then either the feature code and string number or the point number section of the point_description can be used.

If the feature code and string number exist, the last point of the previous string with the same feature code and string number as given in point_description is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If the point number exists, then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.
83  **Start recording a shape - before the measurement**

83 [Shape_name]

Start recording a shape with the name *Shape_name*. If *Shape_name* is non-blank, then the default field Shape is defined by the *feature_code* and *string_number* of the following measurements until a *Finish* code (84) are stored as the shape. There is no limit to the number of points in a shape.

See 36.5 *Shape field coding*

84  **Finish using a shape definition or finish recording a shape - after the measurement**

Stops using the current shape or stops recording a shape.

See 36.5 *Shape field coding*

85  **Shape parallel**

85 [Shape_name] [Point_description]

Takes all the points on the defined shape of *Shape_name* and parallels them the entire length of the string. Once paralleled, a number of strings are created.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

See 36.5 *Shape field coding*

86  **Shape extrude**

86 [Shape_name] [Point_description]

Takes the defined shape of *Shape_name* and extrudes it along the entire length of the string. Once extruded, only one strings is created which contains all the shape information.

If *Feature_code* and *String_number* exist, the last string with the same *feature code* and *string number* has the shape applied to the entire length of the string.

If *Point_number* exists, then the string containing that point number has the shape applied to the entire length of the string.

See 36.5 *Shape field coding*

92  **Remove all z-values for a string (i.e. make all z-values null)**

92 [Point_description]

If no *point_description* is given, all z-values for the current string are removed.

If a *point_description* exists, then either the *feature code* and *string number* or the *point number* section of the *point_description* can be used.

If the *feature code* and *string number* exist, the last string with the same *feature code* and *string number* has all its z-values removed.

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The *point-line type* may be overridden by the Map File.

93  **Set the Point-line type**

93 [Point_description]

A *point-line type* can be embedding as a 0 or 1 in the *point name* part of the *point description* field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.
If no `point_description` is given, the point-line type for the current string is set to `line`.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, the point-line type is set for the last previous string with the same `feature code` and `string number`.

If the `point number` exists, then the point-line type is set for the string containing that point number.

The point-line type may be overridden by the Map File.

**94 Use name library file/ Map File for vertex text on the string - name mapping**

94 [Point_description]

If this op code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn’t exist, the map file. If neither exist then the op code is ignored.

if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for all vertices of the string that don’t already have vertex text. As a default, the string is set as a point string.

if the map file is used and the feature code of the string is found in the first column of the map file, then the `string name` field of the map file is used as vertex text for all vertices that don’t already have text. As a default, the string is set as a point string.

If no `point_description` is given, then name mapping is applied to the current string.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, then name mapping is applied to the last previous string with the same `feature code` and `string number`.

If the `point number` from the `point_description` exists, then name mapping is applied to the string containing that point number.

A point-line type can be embedding as a 0 or 1 in the `point name` part of the `point_description` field. A zero value specifies a point string, and a non-zero value specifies a line string. If the field was omitted, a line string is assumed.

The point-line type may be overridden by the mapping file.

**95 Pipe string**

95 [Point_description]  diameter

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using op codes 80, 81 and 82.

If no `point_description` is given, the current string is created as a pipe string with the given diameter.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, the last string with the same `feature code` and `string number` is created as a pipe with the given diameter.

If the `point number` exists, then the string containing that point number is created as a pipe string with the given diameter.

**96 Culvert string**

96 [Point_description]  width  height

Culvert strings are always line strings and are stored with the justification of the majority of the string points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of the culvert using op codes 80, 81 and 82.
If no `point_description` is given, the current string is created as a culvert string with the given width and height.

If a `point_description` exists, then either the `feature code` and `string number` or the `point number` section of the `point_description` can be used.

If the `feature code` and `string number` exist, the last string with the same `feature code` and `string number` is created as a culvert with the given width and height.

If the `point number` exists, then the string containing that point number is created as a culvert string with the given width and height.

99 Terminate processing
99
Stop processing the 12d field file at this line. Useful for debugging errors.

107 Make the previous segment invisible - after the measurement
107 [Point_description]
If no `Point_description` exists, the previous segment containing the current measurement point is set to invisible.

If the `Feature_code` and `String_number` exist, then the last segment of the previous string with that `feature code` and `string number` is set to invisible.

If `Point_number` exists, then the segment containing the point with that point number as an end point, is set to invisible.

108 Make the next segment invisible - after the measurement for the first point of the segment
108 [Point_description]
If no `Point_description` exists, the next segment containing the current measurement point as a starting point is set to invisible.

If the `Feature_code` and `String_number` exist, then the segment that is created in the future from the last point of the previous string with that `feature code` and `string number` is set to invisible.

If `Point_number` exists, then the segment containing the point with that point number as a start point, is set to invisible.

109 Make a point invisible - after the measurement
109 [Point_description]
If no `Point_description` exists, the current measurement point is set to invisible.

If `Feature_code` and `String_number` exist, then the last point of the previous string with that `feature code` and `string number` is set to invisible.

If `Point_number` exists, then the point with that point number is set to invisible.

110 Start buildings face observations - before the measurements
110 [Building_name]
Start recording a field template with the name `Building_name`. If `Building_name` is non-blank, then the default building face is defined. The `feature code` and `string number` of the following measurements until a `Finish` code (111) are stored as the building face. There is no limit to the number of points in a building face.

111 End building face observations
111 [Building_name]
If no `Building_name` exists, the current building face observation set is finished (including the current measurement point).
Notes

1. Arc fitting is applied after the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.

2. The point description has several pieces of information embedded in it and has been described in the previous section. For some op codes, the point name section of the point description is used to hold other information.

For a summary of the 12d Field File Op Codes, go to the section 36.10.5 Summary of 12d Field File Op Codes.

108 Next segment of point invisible
109 Point invisible
110 Building face start recording
111 Building face end recording

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non Leica Instruments.

The '13' record can also be used after a measurement record to add additional information to the preceding blocks using the extra coding control code at the end of the previous line (see Extra Coding in the section 36.8.4 Control Code Blocks.

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

'Line 248 line incorrect length. required length is 58. received length is 50.'

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

For the full description of the 12d Field File Op Codes, go to the section 36.10.4 Full Description of 12d Field File Op Codes
37 12d and Survey Instruments

See

37.1 12d and Leica TPS Instruments
37.2 Sokkia Instruments (SDR Files)
37.3 12d and the Trimble Total Station ACU
37.4 12d and Trimble GPS Controllers
37.5 12d and Geodimeter Instruments
37.6 12d and Topcon Instruments
37.1 12d and Leica TPS Instruments

The Leica GSI data format produced by the Leica TPS is used as a raw data file by 12d Model and is converted into a 12d Field File. The contents of the recorded data can be manipulated by use of the Leica’s recording masks. The setup of which is explained in the section 37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d.

Each line (data block) of the Leica GSI file consists of between 1 and 12 words, with the words containing either 16 (8 characters for data) or 24 (16 characters for data) characters. The two formats will be referred to as the 8 format and 16 format respectively.

Measurement lines in the 8 format start with 11 and code lines start with 41.

For the 16 format, measurement lines start with *11 and code lines start with *41.

For an example of a GSI file in the 8 format, go to the section 37.1.6.7.2 Example of Leica GSI File.

When using a Leica, the Leica screen can be standard or controlled by using a code.hex file on the 1000 series or a Geobasic program or Leica Codelist (.crf file) on the 1100 series.

12d Solutions provide a basic code.hex, Geobasic program and various Codelists (.crf files) on the 12d Model Installation CD in the folder ‘Other_Software\Leica’. These can be customised to your requirements - please contact 12d Solutions for more information.

For an example of a Leica screen with standard set-up, Codelist and Geobasic program, please go to the section 37.1.5 Examples of Leica Screens.

37.1.3 Full Description of Leica Field Codes
37.1.4 Summary of Leica Field Codes
37.1.5 Examples of Leica Screens
37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d
37.1.6.7.2 Example of Leica GSI File

Please continue to the next section 37.1.1 Feature Codes and String Numbers.
37.1.1 Feature Codes and String Numbers

The feature code and string number for a measurement are entered in the Leica by giving the feature code in the first word and the string number as the second word of a code line. The feature codes and string numbers can be alpha or numeric and up to 8 (16) characters long.

For example, the feature code ABC with string number 1 is recorded as:

410003+000000ABC 42....+00000001 for the 8 format

or

*410003+0000000000000ABC 42....+0000000000000001 for the 16 format.

Some surveyors like to define the feature code and string number before they make a measurement. Other surveyors prefer to define the feature code and string number after they make a measurement.

When defining a Data Collector setup, 12d Model allows the user to specify whether the feature code comes before or after a measurement:

code before measurement

The given feature code and string number applies to the next measurement and all subsequent measurements until another feature code and string number is entered.

code after measurement

The given feature code and string number applies to the last measurement and all subsequent measurements until another feature code and string number is entered.

However, for a particular data collector setup, it can be only be defined as one of the two choices. That is you can't change between having feature codes before or after measurements in the one raw file.
Summarising:

Whether feature code definitions come before or after the measurements is defined in the Survey Data Collector definition and is set by the Measurement/Code order field on the Instrument tab of the Survey.4d Create/Edit panel.

For a data collector definition, there is the choice of code before or after the measurement.

Pop-up list of data collector definitions

Please continue to the next section 37.1.2 Leica Field Codes.
37.1.2 Leica Field Codes

12d Model also uses code lines to supply extra information using field codes. All *field codes* are entered as the first word of the code line and to differentiate it from a *feature code*, the *field code* is proceeded by a ".". Depending on the field code, more information may be required and it is entered in words 2 and above in the code line.

Each *field code* will now be described in detail.

For each *field code*, two lines and a paragraph of description are given:

- The first line consists of the *field code* and a short description of the purpose of the code.
- The second line gives the full syntax of the record for that *field code*.
- The paragraph gives a detailed description of the *field code*.

A 12d Model code list containing 12d Model field codes is available for the TPS to help coding in the field.

Field Code Conventions

In the syntax for the *field codes*, optional Words or groups of Words are enclosed in the square brackets `[ ]`.

However, when the Leica TPS creates the Leica GSI format, the data in all Words is right justified and left filled with zeros. Consequently, 12d Model strips leading zeros from all Words before processing the data.

This means that

(a) an *optional Word* still exists in the file but its data field is simply filled with zeros.

(b) any *text* in a Word cannot start with a zero. You would need to start with a space and then a zero.

In the *field code* descriptions, the point just measured is referred to as the current measurement point, the current point or the last measurement point.

The *string* that the current measurement point belongs to is called the current string.

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes

For the full description of the Leica Field Codes, go to the section 37.1.3 Full Description of Leica Field Codes.

For an example of a raw Leica file, please go to the section 37.1.6.7.2 Example of Leica GSI File.
37.1.3 Full Description of Leica Field Codes

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes

</tr>
</tbody>
</table>
|            | During reduction a two point super string (with name Station_name) from the instrument point to the measured point is created in the default model for the check measurement. The instrument point name, the station name and the differences between the measurement point co-ordinates and station co-ordinates are written as text along the super string. The differences between the measurement and the known point is also written to the report file.
.9 Scale factor for subsequent distances

Word 1 .9 Word 2 Scale_factor

Scale factor to apply to subsequent slope distances.

.11 Next measurement is to a named station - before the measurement

Word 1 .11 Word 2 Station_name [Word 3 Feature_code Word 4 String_number Word 5 Target_height]

This field code gives a name to a measurement so that it can be used in other field codes for setting up an instrument on, backsighting to or doing a check measurement to.

The next measurement locates a new instrument station with the name Station_name. A point with vertex text of Station_name is created. The Station_name is added to the internal list of named points for searching for co-ordinates.

If Feature_code exists, the point is given that Feature_code, otherwise the current feature code is used.

For traverse reduction, if the traverse code specified in the reduction panel matches the Feature code given in Word 3, the data will be included in a traverse reduction, string number can also be specified. Also the target height to the foresight can be given in this command.

.14 Feature code and string number - before or after measurement depends on the data collector definition

Word 1 .14 Word 2 Feature_code Word 3 String_number [Word 4 text Word 5 text] ...

A field code for entering the feature code and string number rather than using the standard method of using word 1 and word 2. This is for use with Leica quick codes which must put out a fixed first word. Any additional text is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

This field code is used always before or always after measurements depending on the Measurement/code field on the Instrument tab of the Survey.4d Create/Edit panel for the selected data collector definition.

.15 Vertical circle correction for subsequent measurements - before the measurement

Word 1 .15 Word 2 Vertical_circle_in_decimal_degrees

The vertical_circle_in_decimal_degrees is subtracted from the vertical circle value in any subsequent measurements.

.16 Additional code for point (multiply coded point) - after the measurement

Word 1 .16 Word 2 Feature_code Word 3 String_number [Word 4 Point_name] [Word 5 Point_text]

Additional coding for the current measurement point. A new measurement point is created at the same position as the current measurement point but with the Feature_code and String_number from this field code. The same point number is used as for the current measurement point.

If Point_text exists, it is used as the vertex text for that vertex of the super string.

If Point_name exists, then it is a named measurement and during reduction, a 4d point string of name Point_name is created and mapped using the Map File. The 4d text is the station prefix followed by Point_name. The Point_name is added to the internal list of named points for searching for co-ordinates.

.17 Arc through previous three points - after the measurement of last point of arc

Word 1 .17 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, then the current measurement point and the two previous points with the same feature code and string number as the current measurement point, are joined by an arc. If there is less
than three such points, no arc is fitted.

If the Feature_code and String_number exist, the last three previous three measurement points of the same feature code and string number are joined by an arc. If the current measurement point has that feature code and string number, then it is the third of the three points used. If there is less than three points, no arc is fitted.

If Point_number exists, then the feature code and string number are taken from the previous measurement point with that point number, and that point and the two measurement points previous to the pre-defined point of the same feature code and string number, are joined by an arc. If there is less than three points, no arc is fitted.

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

.18 Circle Feature - after the measurement

Word 1 .18 Word 2 Radius [Word 2 Radius …]

Creates a feature string with the given radius and centred on the current measurement point. If there is more than one radius, then separate feature strings are created each with one of the radii.

.20 Close string - after the measurement

Word 1 .20 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exits, the current string is closed.

If the Feature_code and String_number exist, the last previous string with that feature code and string number is closed.

If Point_number exists, then the string containing that point number is closed.

See the Section 36.3.4 Close String for more information on closing a string.

.21 Join last points of strings

Word 1 .21 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the last point of the string with the given Feature_code and String_number_1 is joined to the last point of the string with given Feature_code and String_number_2. The created string has the given Feature_code (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.22 Join first to last point of strings

Word 1 .22 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the first point of the string with the given Feature_code and String_number_1 is joined to the last point of the string with given Feature_code and String_number_2. The created string has the given Feature_code (no string number is needed since it is the final phase of reduction when the string numbers are dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.23 Join first points of strings

Word 1 .23 Word 2 Feature_code Word 3 String_number_1 Word 4 String_number_2

In the final reduction, the first point of the string with the given Feature_code and String_number_1 is joined to the first point of the string with given Feature_code and String_number_2. The created string has the given Feature_code (no string number is needed since it is the final reduction when the string numbers are then dropped).

See the Section 36.3.8 Joining Strings for more information on joining strings.

.28 Text appended to a string name

Word 1 .28 Word 2 Text [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]
Chapter 37  12d and Survey Instruments

Text is appended to the string name. For example, if 1.200 is entered, “ 1.200” is appended to the string name.

If only Text is given, Text is appended to the string name of the current string.

If the Feature_code and String_number exist, then the last previous string with that feature code and string number has Text appended to the string name.

If Point_number exists, then the string containing that point number has Text appended to the string name.

.29 Note or memo - after the measurement

Word 1    .29    [Word 2    text]     [Word 3    text]     ...

Any text may be entered and will be added to the check measurements model at the position of the current measurement point.

.30 Remove height from a point - that is make it a null height - after the measurement

Word 1    .30    [Word 2    Feature_code    Word 3    String_number]   [Word 4    Point_number]

If only Word 1 exists, the height of the current measurement point is set to null.

If Feature_code and String_number exist, then the height of the last point of the previous string with that feature code and string number is set to null.

If Point_number exists, then the height of the point with that point number is set to null.

.37 Rectangle by two points

Word 1    .37     Word 2    offset_in_metres   [Word 3    Feature_code    Word 4    String_number]   [Word 5    Point_number]

The rectangle is defined by two points (reference side) and a offset.

If a positive offset value is given, two points will be created to the right of the reference side.

If a negative offset value is given, two points will be created to the left of the reference side.

If Feature_code and String_number exist, the last two points with that feature code and string number are used and a fourth points are created to form a rectangle. The height of the two new points are set to null. The string is then closed.

If Point_number exists, then the feature code and string number of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

Two consecutive rectangles are unable to be defined side by side. In other words if the two points given are part of string of greater than two vertices, the command will only work for sets of two points that are exclusively defined. i.e. For a 5 point string, a rectangle can be defined by points 1 and 2, and 4 and 5.

See the Section 36.3.5 Rectangle for more information.

.38 Make the previous segment non-tinable (not a breakline) - after the measurement

Word 1    .38    [Word 2    Feature_code    Word 3    String_number]   [Word 4    Point_number]

If only Word 1 exists, the previous segment containing the current measurement point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the Feature_code and String_number exist, then the last segment of the previous string with that feature code and string number is set to non-tinable.

If Point_number exists, then the segment containing the point with that point number as an end point, is set to non-tinable.

.39 Make the next segment non-tinable (i.e. not a breakline) - after the measurement for the first point of the segment

Word 1    .39    [Word 2    Feature_code    Word 3    String_number]   [Word 4    Point_number]
If only Word 1 exists, the next segment containing the current measurement point as a starting point is set to non-tinable. That is, it will not be treated as a breakline in triangulations.

If the Feature_code and String_number exist, then the segment that is created in the future from the last point of the previous string with that feature code and string number is set to non-tinable.

If Point_number exists, then the segment containing the point with that point number as a start point, is set to non-tinable.

.40 Make a point non-tinable - after the measurement
Word 1 .40 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]
If only Word 1 exists, the current measurement point is set to non-tinable. That is, it will not be included in triangulations.

If Feature_code and String_number exist, then the last point of the previous string with that feature code and string number is set to non-tinable.

If Point_number exists, then the point with that point number is set to non-tinable.

.41 Add additional text to the current measurement point - after the measurement
Word 1 .41 Word 2 text [Word 3 text] ...
The given text is added to the end of any existing vertex text for the current measurement point. Any leading zeros in the text words will be ignored.

.42 Add a radial offset - after the measurement
Word 1 .42 Word 2 Radial_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]
The Radial_offset_in_metres is used to adjust the position of the specified point by a plan distance from the specified points original position, along the plan line joining the current station to the specified point. A positive offset is away from the station, negative is toward the station.

If only Word 1 and 2 exist, the offset is used to adjust the position of the current measured point.

If Feature_code and String_number exist, then the last point of the previous string with that feature code and string number is adjusted.

If Point_number exists, then the point with that point number is adjusted.
See the Section 36.3.2 Offsets for more information on offsets.

.43 Add a tangential offset - after the measurement
Word 1 .43 Word 2 Tangential_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]
The Tangential_offset_in_metres is used to adjust the position of the specified point by a plan distance from the specified points original position, at rights angles to the plan line joining the current station to the specified point. A negative offset is to the left (looking from the station), and positive is to the right (looking from the station).

If only Word 1 and 2 exist, the offset is used to adjust the position of the current measured point.

If Feature_code and String_number exist, then the last point of the previous string with that feature code and string number is adjusted.

If Point_number exists, then the point with that point number is adjusted.
See the Section 36.3.2 Offsets for more information on offsets.

.44 Add a height offset - after the measurement
Word 1 .44 Word 2 Height_offset_in_metres [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]
If the height of the specified point is not null, then the Height_offset_in_metres adjusts the height of the point. A positive offset adds to the height, a negative offset reduces the height.
If only Word 1 and 2 exist, the offset is used to adjust the position of the current measured point.

If Feature_code and String_number exist, then the last point of the previous string with that feature code and string number is adjusted.

If Point_number exists, then the point with that point number is adjusted.

See the Section 36.3.2 Offsets for more information on offsets.

.45 Make a parallelogram from the last three measurement points - after the measurement

Word 1 .45 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current measurement point and the two previous points from the current string are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If Feature_code and String_number exist, the last three points with that feature code and string number are used and a fourth point is created to form a parallelogram (squashed rectangle) and the height of the fourth point is set to null. The string is then closed.

If Point_number exists, then the feature code and string number of the point with that point number are used and processed as above. Note that the point with the point number is not necessarily used.

See the Section 36.3.5 Rectangle for more information on forming a parallelogram.

.46 Make the entire string a breakline or not (tinable or non-tinable)

Word 1 .46 [Word 2 Breakline_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

Word 2: Breakline_type:

If Breakline_type is 0, the selected string is set to a point string and hence is not a breakline (non-tinable).

If Breakline_type is 1, the selected string is set to a line string and is therefore a breakline (tinable).

Words 3, 4, and 5:

If none of Words 3, 4 and 5 exist, the Breakline_type is applied to the current string.

If Feature_code and String_number exist, the Breakline_type is applied to the last string with that feature code and string number.

If Point_number exists, then the Breakline_type is applied to the string containing the point with that point number.

.47 Start a new string using the same feature code and string number - after the measurement of the first point of the new string

Word 1 .47 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current string is terminated (without including the current measurement point) and the current measurement point becomes the first point of a new string with the same feature code and string number.

If Feature_code and String_number exist, then the last point of the previous string with that feature code and string number becomes the first point of a new string with the same feature code and string number.

If Point_number exists, then the previous string containing the point with that point number is terminated before the point number point, and the point becomes the first point of a new string with the same feature code and string number.

.48 End a string

Word 1 .48 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current string is terminated (including the current measurement point).

If Feature_code and String_number exist, then the last point of the previous string with that feature
code and string number becomes the last point of that string. If \textit{Point\_number} exists, then the previous string containing the point with that point number is terminated after the point number point.

.50 \textbf{Specify the bearing to correct for true north - used as the bearing datum difference}  

\textit{Word 1}  .50 \textit{Word 2} \texttt{Bearing\_in\_decimal\_degrees} \ [\textit{Word 3} \texttt{Text}]

The \texttt{Bearing\_in\_decimal\_degrees} is used as the bearing datum difference for the current instrument set up. The \texttt{Text} and the \texttt{Bearing\_in\_decimal\_degrees} are written to the reduction report file.

.51 \textbf{Start using an existing field template - before the measurement}  

\textit{Word 1}  .51 \textit{Word 2} \ [\textit{Template\_name}] \ [\textit{mode}]

Start using the template \texttt{Template\_name}. If \texttt{Template\_name} is blank, the default template is used. If \textit{mode} is "for", then the field template is used as a \texttt{forward} template. If \textit{mode} is "rev", then the field template is used as a \texttt{reverse} template. If \textit{mode} is "zig", then the field template is used as a \texttt{zig\_zag} template and is used in the \texttt{forward} direction first. If \textit{mode} is "zag", then the field template is used as a \texttt{zig\_zag} template and is used in the \texttt{reverse} direction first.

If \textit{mode} is blank, or 0, or anything other than "for", "rev", or "zag", then the field template is used as a \texttt{zig\_zag} field template starting on a zig. See the Section \texttt{36.4 Field Templates} for more information on field templates.

.52 \textbf{Finish using a field template or finish recording a field template - after the measurement}  

\textit{Word 1}  .52

Stops using the current field template or stops recording a field template.

.53 \textbf{Pause using the current field template - after the measurement}  

\textit{Word 1}  .53

Pause using the current field template or defining a field template, until a continue template (54) or a finish field template (52) code is given.

.54 \textbf{Continue the current field template - before the measurement}  

\textit{Word 1}  .54

Continue using the current field template or defining the current field template, which has been stopped by a \texttt{Pause} command (53). The \texttt{Continue} command only needs to be given once and applies to all following measurements until another \texttt{Pause} or \texttt{Finish} command is given.

.55 \textbf{Start recording a field template - before the measurement}  

\textit{Word 1}  .55 \textit{Word 2} \ [\textit{Template\_name}]

Start recording a field template with the name \texttt{Template\_name}. If \texttt{Template\_name} is non-blank, then the default field template is defined. The \textit{feature\_code} and \textit{string\_number} of the following measurements until a \texttt{Finish} code (52) are stored as the field template. There is no limit to the number of points in a field template. See the Section \texttt{36.4 Field Templates} for more information on field templates.

.56 \textbf{Skipping picking up points when using a field template - after the measurement of last point before skipping points}  

\textit{Word 1}  .56 \textit{Word 2} \ [\texttt{num\_skipped\_points}]

Allows the user to skip picking up one or more points from the field template currently being used. The \texttt{next measurement} takes the \textit{feature\_code} and \textit{string\_number} from the next point of the field template definition. If \texttt{num\_skipped\_points} is missing, then only one point is skipped otherwise \texttt{num\_skipped\_points} are skipped.
.57 Delete points on a field template - after the measurement of last point

Word 1 .57 Word 2 [num_points_to_delete]

Allows the user to delete one or more points from the field template currently being used. The next measurement takes the feature code and string number from the next point of the field template definition.

.58 Insert points when using a field template - after the measurement of last point

before inserting points

Word 1 .58 Word 2 Feature_code Word 3 String_number Word 4 Multiple_code_flag Word 5 Insert_special_flag

Allows the user to insert points into the field template currently being used. The next measurement takes the feature code and string number from the next point of the field template definition.

If the Multiple_code_flag = 1, then the feature code will be added to the previous defined template point else if Multiple_code_flag = 0 (default), it will be added to the template as a separate point.

If the insert is done at the end of a section and the Insert_special_flag = 1 the point will be added to the end of the current template section else it will be at the start of the next section.

.60 Start of arc through next three points - after the measurement of the first point of the arc

Word 1 .60 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, an arc is inserted through the current measurement point and the next two measured points with the same feature code and string number as the current measurement point. If there is less than three points, no arc is fitted.

If Feature_code and String_number exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the previous measurement and the next two measured points following this previous measurement with the same feature code and string number. If the current point has that feature code and string number, then it is the first of the three points. If there is less than three points, no arc is fitted.

If Point_number exists, then the feature code and string number are taken from the previous measurement point with that point number, and an arc is inserted through that point and the next two measurement points with the same feature code and string number. If there is less than three points, no arc is fitted.

See the Section 36.3.9 Arcs Through Points for more information on arc fitting.

.61 Start of arc through sets of three points until end of string, or a 62 occurs - after the measurement of the first point of the arc

Word 1 .61 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

The arcs are fitted as follows - the first arc is fitted through points one, two and three, the next arc through points three, four and five etc. If there is less than three points remaining at the end, then no arc is fitted to the end points.

If only Word 1 exists, arcs are inserted through the following sets of measurement points with the same feature code and string number as the current measurement point. The current measurement point is the first of the points.

If the current point has that feature code and string number, then it is the first of the points. If there is less than three points, then no arc is fitted.

If the feature code and string number exist, a search is made for a previously defined measurement with the same feature code or string number. An arc is inserted through the following measured points with the same feature code and string number as given in point_description. If the current point has that feature code and string number, then it is the first of the points.

If Point_number exists, then the feature code and string number are taken from the previous measurement point with that point number, and arcs are inserted through that point and the following measured points with the same feature code and string number.
If **12d Model** encounters a *Start Arcs through sets of three points* but no *End Arcs* command for the string, then an *End Arcs* is assumed at the end of the string.

See the Section [36.3.9 Arcs Through Points](#) for more information on arc fitting.

**.62** End the arcs begun by a 61 command - after the measurement of the last point of the arcs

```
Word 1 .62 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]
```

If only Word 1 exists, then the fitting of arcs through the points of the current string is stopped. The current measurement point is the last of the points used in the arc fitting.

If Feature_code and String_number exist, then the fitting of arcs through the points of the previous string with the same feature code and string number is stopped. If the current measurement point has that feature code and string number, then it is the last point used in the arc fitting.

If Point_number exists, then the point with that point number is the last point used in the arc fitting.

If **12d Model** encounters an *End Arcs* (62) but no *Start Arcs through sets of three points* (61) command for the string, then an *Start Arcs through sets of three points* (61) is assumed to apply at the beginning of the string and hence arc fitting will be applied to the entire string.

See the section [36.3.9 Arcs Through Points](#) for more information on arc fitting.

There are field codes for adding user defined attributes to:

(a) the current string being measured (i.e. the string containing the current measurement point)
(b) the current measurement point
(c) the next segment from the current measurement point (i.e. the segment joining the current measurement point and the next measured point of the same feature code and string number)

or

(d) the previous segment to the current measurement point (i.e. the segment joining the current measurement point to the previous measured point of the same feature code and string number).

The attributes can be named or unnamed and are coded in the following way:

If Word 2 is missing (i.e. all zeros), then the attribute is an un-named attribute and the rest of the Words on the line is the attribute value. The attribute is given the special name "unnamed attribute n" for n=1, 2, ... .

**.68** Add an integer user defined attribute to the current string

```
Word 1 .68 [Word 2 Name] Word 3 Integer
```

Add an user defined integer attribute to the current string.

**.69** Add a real user defined attribute to the current string

```
Word 1 .69 [Word 2 Name] Word 3 Real
```

Add a real (floating point) user defined attribute to the current string.

**.70** Add text user defined attribute to the current string

```
Word 1 .70 [Word 2 Name] Word 3 Text [Word 4 Text] ...
```

Add a text user defined attribute to the current string.

**.71** Add integer user defined attribute to the current point

```
Word 1 .71 [Word 2 Name] Word 3 Integer
```
Add an integer user defined attribute to the current measurement point.

**.72 Add real user defined attribute to the current point**

```
Word 1 .72  [Word 2 Name]  Word 3 Real
```

Add a real (floating point) user defined attribute to the current measurement point.

**.73 Add text user defined attribute to the current point**

```
Word 1 .73  [Word 2 Name]  Word 3 Text  [Word 4 Text] ...
```

Add a text user defined attribute to the current measurement point.

**.74 Add integer user defined attribute to the next segment**

```
Word 1 .74  [Word 2 Name]  Word 3 Integer
```

Add an integer user defined attribute to the next segment from the current measurement point.

**.75 Add real user defined attribute to the next segment**

```
Word 1 .75  [Word 2 Name]  Word 3 Real
```

Add a real (floating point) user defined attribute to the next segment from the current measurement point.

**.76 Add text user defined attribute to the next segment**

```
Word 1 .76  [Word 2 Name]  Word 3 Text  [Word 4 Text] ...
```

Add a text user defined attribute to the next segment from the current measurement point.

**.77 Add integer user defined attribute to the previous segment**

```
Word 1 .77  [Word 2 Name]  Word 3 Integer
```

Add an integer user defined attribute to the previous segment from the current measurement point.

**.78 Add real user defined attribute to the previous segment**

```
Word 1 .78  [Word 2 Name]  Word 3 Real
```

Add a real (floating point) user defined attribute to the previous segment from the current measurement point.

**.79 Add text user defined attribute to the previous segment**

```
Word 1 .79  [Word 2 Name]  Word 3 Text  [Word 4 text] ...
```

Add a text user defined attribute to the previous segment from the current measurement point.

In addition, extra codes allow **12d Model** pipe strings to be coded in the field.

**.80 Pipe invert point (bottom of the pipe) - after the measurement**

```
Word 1 .80  [Word 2 Feature_code  Word 3 String_number]  [Word 4 Point_number]
```

If only Word 1 exists, the current measurement point is on the invert (bottom) of a pipe. This is the default for measurements to points on pipe strings. If the point is not part of a pipe string, it is ignored.

If **Feature_code** and **String_number** exist, the last point of the previous string with the same feature code and string number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

If **Point_number** exists, then the point with that point number is on the invert (bottom) of a pipe. If the point is not part of a pipe string, it is ignored.

**.81 Pipe axial point (centre of the pipe) - after the measurement**

```
Word 1 .81  [Word 2 Feature_code  Word 3 String_number]  [Word 4 Point_number]
```
If only Word 1 exists, the current measurement point is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If Feature_code and String_number exist, the last point of the previous string with the same feature code and string number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

If Point_number exists, then the point with that point number is on the axis (centre) of a pipe. If the point is not part of a pipe string, it is ignored.

**.82 Pipe obvert point (top of the pipe) - after the measurement**

Word 1 .82 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current measurement point is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If Feature_code and String_number exist, the last point of the previous string with the same feature code and string number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

If Point_number exists, then the point with that point number is on the obvert (top) of a pipe. If the point is not part of a pipe string, it is ignored.

**.83 Start recording a shape - before the measurement**

Word 1 .83 [Word 2 Shape_name]

Start recording a shape with the name Shape_name. If Shape_name is non-blank, then the default field Shape is defined by the feature_code and string_number of the following measurements until a Finish code (84) are stored as the shape. There is no limit to the number of points in a shape.

See the Section 36.4 Field Templates for more information on field templates.

**.84 Finish using a shape definition or finish recording a shape - after the measurement**

Word 1 .84

Stops using the current shape or stops recording a shape.

**.85 Shape parallel**

Word 1 .85 Word 2 Shape_name [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If Feature_code and String_number exist, the last string with the same feature code and string number has the shape applied to the entire length of the string.

If Point_number exists, then the string containing that point number has the shape applied to the entire length of the string.

Parallelling the shape will produce separate strings for each point of the shape.

**.86 Shape extrude**

Word 1 .86

Word 1 .85 Word 2 Shape_name [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If Feature_code and String_number exist, the last string with the same feature code and string number has the shape applied to the entire length of the string.

If Point_number exists, then the string containing that point number has the shape applied to the entire length of the string.

Extruding the shape will produce a single string for the shape.
.92 Remove all z-values for a string (i.e. make all z-values null) - after the measurement

Word 1 .92 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 exists, all z-values for the current string are removed.

If Feature_code and String_number exist, the last string with the same feature code and string number has all its z-values removed.

If Point_number exists, then the string containing that point number has all its z-values removed.

If Point_line_type is 0, the selected string is set to a point string.

If Point_line_type is 1, the selected string is set to a line string.

.93 Set the Point-line type - after the measurement

Word 1 .93 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If only Word 1 exists, the current string is created as a point string.

If Feature_code and String_number exist, the last previous string with the same feature code and string number has its point-line type modified.

If the point_number exists, then the string containing that point number has its point-line type modified.

If Point_line_type is 0, the selected string is set to a point string.

If Point_line_type is 1, the selected string is set to a line string.

.94 Use name library/mapping file for vertex text on the string - name mapping - after the measurement

Word 1 .94 [Word 2 Point_line_type] [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

If this field code exists then during reduction, vertex text is creating using either the name library, or if the name library doesn’t exist, the map file. If neither exist then the field code is ignored.

if a name library is used and the feature code of the string is found in the first column of the name library, then the entry from the second column of that row will be used as text for all vertices of the string that don’t already have vertex text. As a default, the string is set as a point string.

if the map file is used and the feature code of the string is found in the first column of the map file, then the string name field of the map file is used as vertex text for all vertices that don’t already have text. As a default, the string is set as a point string.

If only Word 1 exists, then name mapping is applied to the current string.

If Feature_code and String_number exist, then name mapping is applied to the last previous string with the same feature code and string number.

If Point_number exists, then name mapping is applied to the string containing that point number.

If Point_line_type is 0, the selected string is set to a point string.

If Point_line_type is 1, the selected string is set to a line string.

.95 Circular Pipe string - after the measurement

Word 1 .95 Word 2 Diameter [Word 3 Feature_code Word 4 String_number] [Word 5 Point_number]

Pipe strings are always line strings and are stored with the justification of the majority of the string points. Individual pipe points are picked up either top (obvert), centre (axial) or bottom (invert) of the pipe using field codes 80, 81 and 82.

If only Word 1 and 2 exists, the current string is created as a pipe string with the given diameter.

If Feature_code and String_number exist, the last string with the same feature code and string number is created as a pipe with the given diameter.
If Point_number exists, then the string containing that point number is created as a pipe string with the
given diameter.

.96  Box Culvert string - after the measurement  
Word 1 .95 Word 2 Width Word 3 Height [Word 4 Feature_code Word 5 String_number] [Word 6 Point_number]

Culvert strings are always line strings and are stored with the justification of the majority of the string
points. Individual culvert points are picked up either top (obvert), centre (axial) or bottom (invert) of
the culvert using field codes 80, 81 and 82.

If only Word 1, 2 and 3 exist, the current string is created as a culvert string with the given width and
height.

If Feature_code and String_number exist, the last string with the same feature code and string number
is created as a culvert with the given width and height.

If Point_number exists, then the string containing that point number is created as a culvert string with
the given width and height.

.99  Terminate processing  
Word 1 .99

Stop processing the field file at this line. Useful for debugging errors.

.107  Make the previous segment invisible - after the measurement  
Word 1 .107 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the previous segment containing the current measurement point is set to
invisible.

If the Feature_code and String_number exist, then the last segment of the previous string with that
feature code and string number is set to invisible.

If Point_number exists, then the segment containing the point with that point number as an end point, is
set to invisible.

.108  Make the next segment invisible - after the measurement for the first
point of the segment  
Word 1 .108 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the next segment containing the current measurement point as a starting point is
set to invisible.

If the Feature_code and String_number exist, then the segment that is created in the future from the last
point of the previous string with that feature code and string number is set to invisible.

If Point_number exists, then the segment containing the point with that point number as a start point, is
set to invisible.

.109  Make a point invisible - after the measurement  
Word 1 .109 [Word 2 Feature_code Word 3 String_number] [Word 4 Point_number]

If only Word 1 exists, the current measurement point is set to invisible.

If Feature_code and String_number exist, then the last point of the previous string with that feature
code and string number is set to invisible.

If Point_number exists, then the point with that point number is set to invisible.

.110  Start buildings face observations - before the measurements  
Word 1 .110 Word 2 [Building_name]

Start recording a field template with the name Building_name. If Building_name is non-blank, then the
default building face is defined. The feature_code and string_number of the following measurements
until a Finish code (111) are stored as the building face. There is no limit to the number of points in a
building face.

.111 End building face observations
   Word 1 .111 Word 2 [Building_name]

If only Word 1 exists, the current building face observation set is finished (including the current measurement point).

Notes

1. Arc fitting is applied after the Joins are processed. Hence the new joined strings are created and then curve fitting is applied according to the arc codes (start arc, end arc, fit arcs, stop fitting arcs etc.) on any vertex of the string.

For a summary of the Leica Field Codes, go to the section 37.1.4 Summary of Leica Field Codes
### 37.1.4 Summary of Leica Field Codes

Most of the field codes are entered after the measurement is taken and they will have a (AM) after the description. Some of the field codes are entered before the measurement is taken (mainly set up codes) and will have a (BM) after the description.

<table>
<thead>
<tr>

Pipe invert point (bottom of the pipe) (AM)
Pipe axial point (centre of the pipe) (AM)
Pipe obvert point (top of the pipe) (AM)
Start recording a shape - before the measurement
Finish using a shape definition or finish recording a shape - after the measurement
Shape parallel
Shape extrude
Remove all z-values for a string (i.e. make all z-values null) (AM of point of the string)
Set the Point-line type
Use name library file/ mapping file for vertex text on the string - name mapping
Circular pipe string with diameter (AM)
Box culvert string with dimensions (AM)
Terminate processing
Make the previous segment invisible - after the measurement
Make the next segment invisible - after the measurement for the first point of the segment
Make a point invisible - after the measurement
Start buildings face observations - before the measurements
End building face observations

For a full description of the Leica codes, please go to the section 37.1.3 Full Description of Leica Field Codes.
For an example of a raw Leica file, please go to the section 37.1.6.7.2 Example of Leica GSI File.
37.1.5 Examples of Leica Screens

**Standard Screen**

When using a Leica instrument with no code.hex on the 1000 series, or Geobasic program or Codelist (.crf file) on the 1100 series, hitting the *Code* button brings up the standard Leica screen:

![Standard Leica Screen](image)

The information entered in *Code* goes to Word 1 of the line written to the Leica GSI file.

The information in *Info 1* to *Info 8* go to Word 2 to Word 9 respectively of the line written to the GSI file.

As an example, to enter a *directly entered co-ordinate* (the 2 field code),

*"2" is entered in the *Code* field*

*X, Y and Z in Info 1, Info 2 and Info 3 respectively.*

*the feature code (STN) is entered into Info 4*

*the station name "10" is entered into Info 7*
To enter a feature code and string number to be used for measurements, the feature code is entered into the Code field and the string number is entered into Info 1.
Leica Geobasic Program

A Leica Geobasic program gives the programmer full control over the Leica screen.

**WARNING**

Only one Geobasic program can exist on the Leica at any one time. Loading a Geobasic program will over write the existing Geobasic program on the instrument. Make sure you have a backup copy of the existing Geobasic program on your computer before loading a new one onto the instrument.

If you do not have a backup copy of the existing Geobasic program, do not load a new one.

The front screen of the 4D Solutions supplied Geobasic program
Leica Codelist

A Leica Codelist (.crf file) controls what is displayed and validated on the Leica screen and what values are recorded whenever the Code button is selected. For example, when using the 4D Solutions supplied Codelists, a list of defined feature codes and descriptions are displayed.

The Codelist controls what codes are displayed and whenever a code is selected, what information is required for that code. The Codelist also specifies what information is written out to the GSI file for that code.

After hitting the Code button, the list of codes from the Codelist is displayed in alphanumerical order. Because the 12d Model field codes start with a ".", they will appear at the top of the list.

A code can be typed in or the list can be scrolled through using the arrow keys.

The highlighted code is selected by pressing the Leica Enter Key. The menu for the selected code then appears. The line of data is written out to the GSI file when the F1 (REC) button is selected.

---

![The menu after selecting .21 from the 12d Model Codelist](image2)
37.1.6 Setup of Leica 1100 instrument for Detail Pickup and use with 12d

The following relates to the setup of a Leica 1100 series instrument for topographic/detail pickup and use with 12d.

37.1.6.1 Setting up the Instrument

37.1.6.1.1 Copying the CRF file

A number of example .crf files are included on the installation CD. These can be found in the directory Other Software\Leica\. For the purpose of this documentation, we will use the file 12D_DS.CRF which is designed for detail pickup. This file should be copied from the 12d CD to the folder “Code” on the Leica card.

This file contains all of the field codes used in 12d Model along with a sample code listing.

37.1.6.1.2 Set up the display and record masks

Turn on and level instrument

Press F1 to Continue
Press 5 to configure the instrument

Press 1 for instrument configuration
Press 05 for Display and Record mask setup

Display mask:
Press F3 to set up display mask
Type in the description DETAIL SURVEY for the Mask name

Select the following settings:

1st Word……Point Id
2nd Word……Code
3rd Word……Info 1
4th Word……Ref1. Ht.
5th Word……Hz
6th Word……Horiz. Dist
7th Word……East
8th Word……North
9th Word……Elev

Press F1
Record mask:
Press F4 to set up record mask

Type in the description DETAIL SURVEY for the Mask name

Select the following settings:

REC format….GSI16 (16 char)
1st Word……Point Id (11)
2nd Word……Hz (21)
3rd Word……V (22)
4th Word……Slope Dist (31)
5th Word……Ref. Ht. (87)
6th Word……East (81)
7th Word……North (82)
8th Word……Elev (83)

Press F1

Press F1

Press F1 to exit menu
Press F1 to exit menu
37.1.6.1.3 Leica field codes

It is important to know when the code is entered into the instrument as some codes should precede a reading (BM) and some come after (AM). In this manual if a code is related to the current string then it is placed before the reading.

Below is a list of the commonly used codes to be used:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.2</td>
<td>Directly entered coordinates</td>
</tr>
<tr>
<td>.3</td>
<td>New instrument station</td>
</tr>
<tr>
<td>.4</td>
<td>Backsight reading (BM)</td>
</tr>
<tr>
<td>.5</td>
<td>Height of target (BM)</td>
</tr>
<tr>
<td>.6</td>
<td>Check measurement (BM)</td>
</tr>
<tr>
<td>.9</td>
<td>Scale factor (BM)</td>
</tr>
<tr>
<td>.11</td>
<td>Foresight station (BM)</td>
</tr>
<tr>
<td>.14</td>
<td>Feature code and string number (Use for Leica quick codes only)</td>
</tr>
<tr>
<td>.15</td>
<td>Vertical circle correction (d.dddd) (BM)</td>
</tr>
<tr>
<td>.16</td>
<td>Additional code for point (AM)</td>
</tr>
<tr>
<td>.17</td>
<td>Arc thru last 3 points (AM)</td>
</tr>
<tr>
<td>.18</td>
<td>Circle (AM)</td>
</tr>
<tr>
<td>.20</td>
<td>Close string (AM)</td>
</tr>
<tr>
<td>.29</td>
<td>Note (AM)</td>
</tr>
<tr>
<td>.30</td>
<td>Remove height from point (AM)</td>
</tr>
<tr>
<td>.37</td>
<td>Rectangle by two points (AM)</td>
</tr>
<tr>
<td>.38</td>
<td>Make last segment non tinable (AM)</td>
</tr>
<tr>
<td>.39</td>
<td>Make next segment non tinable (AM)</td>
</tr>
<tr>
<td>.40</td>
<td>Make point non tinable (AM)</td>
</tr>
<tr>
<td>.42</td>
<td>Add radial offset (AM)</td>
</tr>
<tr>
<td>.43</td>
<td>Add tangential offset (AM)</td>
</tr>
<tr>
<td>.44</td>
<td>Add height offset (AM)</td>
</tr>
<tr>
<td>.45</td>
<td>Create parallelogram from last three points (AM)</td>
</tr>
<tr>
<td>.47</td>
<td>Start new string with same code and string no. as previous string (AM)</td>
</tr>
<tr>
<td>.48</td>
<td>End string (AM)….Not generally used</td>
</tr>
</tbody>
</table>

Templates

<table>
<thead>

37.1.6.2 Setting up files

The existing station coordinates for a pickup can be entered into the Leica by hand or they can be uploaded using 12d. The 12d upload sequence will be described here.

37.1.6.2.1 Uploading coordinate file

Select option Survey=>Upload=>Create points upload file

![Create Instrument Points Upload File](image)

- Select the instrument **Leica GSI 16**
- Select the model of station points
- Type the start and end point if applicable
- Type in the file name to create
- Select Write file

37.1.6.2.2 Copy the upload file

The file upload file should be copied to the folder "GSI" on the Leica card

37.1.6.2.3 Data file setup

Turn on and level instrument
Press F1 to Continue

Press 2 to select Data job file.

This is the file containing the control points if uploaded or if entered during the survey. Keep the file name separate from the measured data file name.
Select the file to use followed by the F1 key or press F2 to create a new file.

Press F1 to continue.

37.1.6.3 Measured file setup

Select 1 to set up Measured job file. This is the file that will contain the detail survey readings.
Select F2 to create new file

Type in new job name

Press F1 to continue

Press F1 to continue
37.1.6.4 Code list selection

Press 3 to select code list
Select the code list 12D_DS.CRF

Press F1 to continue
37.1.6.5 Station setup

We can use Quick set (See the section 37.1.6.6 Setup using Quick set (QSET)) for the station setup or manually select the Station.

The following notes assume that the data file contains station coordinates. If not the user will have to follow prompts to insert the coordinates.

37.1.6.5.1 Manual setup

Press F5 for set up.
Press F1 to select station

Type in setup station number
Type in the instrument height

Press F5 to read the coordinates from the data file
To view the bearing between the setup station and backsight station select FNC
Press 4 to check orientation

Type in the backsight station number

The Azimuth is displayed
Type in the reflector height of the backsight
Sight to the backsight station and press F4 to set the bearing.

The Bearing is set. Notice that the Azimuth and HZ values are set to the same value. Press F2 to take a distance to the backsight station.
Arrow down to view the distance error

If acceptable press F1 to continue
To save the station information press F3 then F1 to continue
Take Backsight reading:
Type in the start point number of the survey
Type in the reflector height. This can also be done as part of the backsight measurement as shown below.
Select CODE

Type in .4 for backsight code followed by the enter key
Type in backsight station number
Type in traverse code and traverse no. string number if using traverse coding. For more information about traverse coding see the section 36.6 Traverse coding.

Scroll down using the arrow keys to show other parameters

Press F1 to record the code

Point to backsight station and press F1 to take and record reading
37.1.6.6 Setup using Quick set (QSET)

**IMPORTANT NOTE:** If using QSET, you **MUST** take a check reading to your backsight station as described below.

Press F5 for set up

Press F4 for Quick set
Type in setup station number

Type in the backsight station number
Type in instrument height

Type in height of target then Press F2 to take reading to backsight to initialise the QSET function.
Press F4 to continue

Press F3 to record the station setup information.

IMPORTANT NOTE: If using QSET, you MUST take a check reading to your backsight station as described below.
Take Check reading (Mandatory):
Type in reflector height
Select CODE

Type in .6 for check measurement code followed by the enter key
Type in the check station number
Type in the description

Press F1 to record code
Type in the reflector height

Select F1 to take reading
37.1.6.7 Normal readings

Always change the code prior to starting a new feature and ensure the reflector height is correct.

37.1.6.7.1 Select Code

Type in the required code and string number.

Press F1
37.1.6.7.2 Example of Leica GSI File

The following GSI file has been coded with the Feature Code being recorded after the measurement. The Feature code definition is then applied to all subsequent measurements until another measurement with a following Feature Code definition is found.

The data collector definition Leica GSI 12D which is shipped with 12d Model, is an appropriate data collector definition for converting the example GSI file to a 12d Field File ready for processing.

For the data collector definition Leica GSI 12D, the feature code comes after the measurement.

The data collector definition Leica 12D which is shipped with 12d Model is selected using the option Survey=>Setup.
12d and Leica TPS Instruments

Directly entered co-ords for station 10

Instrument set-up on 10 with instrument height of 1.715

Next measurement is backsight to 931

Measurement to backsight - has point number 1765

New target height of 1.338

Measurement FC DHW SN 0 - Pt no 1766

Set feature code DHW string number 0

Set feature code RDG string number 1

Next measurement is backsight to 931

儀器於776米高處測量

Description

Leica GSI File in 8 Format using 12d Model Field Coding and Giving Feature Codes After a Measurement

Close the previous string RDG

has point number 1770

Measurement - FC RDG SN 1

has point number 1769

Measurement - FC RDG SN 1

has point number 1768

Measurement - FC RDG SN 1
37.2 Sokkia Instruments (SDR Files)

This Section deals with interfacing 12d with Sokkia SDR20/33 data formats specifically with the SDR33 electronic field book (Controller). Other controllers and instruments such as the powerset range of total stations also use these formats.

A large number of instruments support the Sokkia SDR data format including (Trimble Total Station ACU), not just those from Sokkia.

For the topic:
1. Field Coding see the section 37.2.1 Coding For SDR Files
2. Sending raw file from controller to 12d 37.2.1.1.1 Downloading SDR File To 12d
3. Converting raw data to field file see the section 37.2.1.1.2 Converting SDR Raw File To Field File
4. Creating Points upload file see the section 37.2.1.1.3 Creating SDR Point Upload File
5. Creating Road upload file see the section 37.2.1.1.4 Creating SDR Roads Upload File
6. Creating Tin upload file see the section 37.3.7 Create Tin Upload File

Also, SDRMap users should also read the section 37.2.1.1 Special Notes for SDRmap Users
37.2.1 Coding For SDR Files

The Sokkia SDR20/33 data formats are used as raw data files by 12d Model and are converted into a 12d Field File before reduction. 12d Model uses the following Sokkia records:

01 Record header - SDR format
02 Station details
03 Target height
07 Back bearing details
08 Position - directly entered co-ordinates
09 Observation - measurement
13 Comment or continuation of blocks
15 RTK station details
16 RTK observation - measurement
57 RTK antenna height

Users can enter text for each measurement (observation 09 record or position 08 record) which is appended to the end of the record and this is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non Leica Instruments.

The ‘13’ record can also be used after a measurement record to add additional information to the preceding blocks using the extra coding control code at the end of the previous line (see Extra Coding in the section 36.8.4 Control Code Blocks).

Strictly speaking the Sokkia SDR20/33 formats use fixed length lines and if the lengths are incorrect, an error message will be written to the Output Window. For example,

‘Line 248 line incorrect length. required length is 58. received length is 50.’

These messages often appear after a raw file has been manually edited because most editors remove space padding at the end of a line.

To ignore such error messages, there is a setting Allow bad line lengths on the Advanced tab of the Survey.4d Create/Edit panel. If this is set for a data collector, then lines of incorrect length will not be rejected.

For non SDRmap users, please proceed to the section 37.2.1.1.1 Downloading SDR File To 12d.

SDRmap users, please continue to the next section 37.2.1.1 Special Notes for SDRmap Users.
37.2.1.1 Special Notes for SDRmap Users

SDRmap does not use String numbers - only Feature codes are used and a New String command to denote the start of a new string.

12d Model supports only using a Feature code by setting the String number position on the Feature Coding tab to no string number.

If no string number is set for the data collector (and so no string numbers are used in the field), then there is no way of telling from the field data whether the string is a point string or a line string (setting the pt-line type for the string).

For the no string number case, the method of defining the point-line type is to:

(a) use a map file during the reduction

and

(b) have a key in the map file to match the feature code and have the pt-line type set for that key. If the feature code does not match any key in the map file, the string defaults to a point string.

and

(c) because by default the pt-string column in the map file is ignored during reduction (the string number usually defines the pt-line type), the Use pt/line mapping tick box in the Survey Data Reduction Function panel must be set to tick to force the pt-line column in the mapping file to be used.

Please continue to the next section 37.2.1.1 Downloading SDR File To 12d.
37.2.1.1 Downloading SDR File To 12d

Raw SDR files can be input to 12d for reduction by two basic methods:

1. Download directly from the instrument
2. Copy the SDR file to the working folder directly from a PCMCIA card or by using a data transfer product such as "HyperTerminal" or "Wincomms". For this method, see the following section 37.2.1.1.2 Converting SDR Raw File To Field File.

An option exists within 12d to download the raw SDR file from the instrument. This option has the added functionality that is reduces the raw propriety format (SDR file) to a 12d field file format at the same time. This conversion requires that the data collector definition be set before the download of the file is commenced.

Select the data collector type

Select option Survey=>Setup
The raw file will be converted to the 12d field file format using the specified translator macro.

Select **Survey=>Download**
Prepare the data collector for download by connecting to appropriate port, selecting file to download etc.

Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters.
Enter a name for the field file.

Press **download**.

The 12d download window is shown.

Prepare the data collector for download by connecting to appropriate port, selecting file to download etc.
From the Data collector main menu select the **FUNC** (function) menu.

Toggle down to the **Communications** menu.

Press **OK** to select menu.
Select the **Options** menu to view the current settings.

Select the **Current view** to **Yes** only. If the POS view were set to **Yes** also, the POS points would be sent also and eventually reduced twice in 12d (once from observations and the other from the POS record). Press **Clear** to leave menu.
Select the **COM** menu to view the current comms settings.

Ensure the comms settings are as per the values set in the 12d download option.

Select **Clear** to leave the menu.
Select the **SEND** menu

Select the file to download

Press **OK** to send
Chapter 37  12d and Survey Instruments

37.2.1.1.2 Converting SDR Raw File To Field File

The file is shown downloading line by line in the 12d download window.

<table>
<thead>
<tr>
<th>Comms</th>
<th>X0</th>
<th>X1</th>
<th>Y0</th>
<th>Y1</th>
<th>Z0</th>
<th>Z1</th>
<th>NS</th>

<td></td>
</tr>
</tbody>
</table>

When the download is finished select the **stop** button and then **finish**

Please continue to the next section 37.2.1.1.2 Converting SDR Raw File To Field File
37.2.1.1.2 Converting SDR Raw File To Field File

If a raw SDR file is copied to the working folder from a PCMCIA card or other means such as transferring it from a third party software package, it must be converted to a 12d field file for reduction inside 12d.

**Select the data collector type**

Select option *Survey=>Setup*

Select the **Data collector** choice icon

Select *Sokkia String Feature*

Select **set** and **finish**

Select option *Survey=>Convert raw*
Any errors will be listed in the Output window. If the Output window is not shown, it can be opened using the option Window=>Output Window

37.2.1.1.3 Creating SDR Point Upload File

Create upload file in 12d

After creating the setout points an upload file can be created for the sdr format

Select option Survey=>Upload=>Create points upload file
Fill in the rest of the screen as per normal

Select Write File

A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc.
Loading file into controller using 12d upload facility

The points upload file can be transferred to the controller for setout using the upload panel.

Connect the controller to the PC
Select option *Survey=>Upload=>Upload*

Ensure that the correct values are set for the comms settings i.e. they match the data collector parameters

Select the upload file by selecting the folder icon and selecting the appropriate file

Prepare the data collector for uploading.
From the communication menu, select the receive button.

Once the data collector is ready, the data can be sent from 12d.
37.2.1.1.3 Creating SDR Point Upload File

Create upload file in 12d

After creating the road alignment an upload file can be created for the SDR33 format

Select option Survey=>Upload=>Create roads upload file

Select Instrument choice icon

Select Sokkia Roading - Alignment Road
A SDR33 file is created ready to send to the instrument directly using the upload facility or by copying the file to PCMCIA cards etc. The steps involved in uploading the file to the controller using the 12d upload facility can be seen in the previous section Loading file into controller using 12d upload facility.

Please continue to the next section 37.2.1.2 Example of Sokkia SDR File

37.2.1.2 Example of Sokkia SDR File

The raw Sokkia SDR file ‘detail1.sdr’ has been coded in accordance with the data collector definition Sokkia String Feature which is shipped with 12d Model.

The data collector Sokkia String Feature is set using the option Survey=>Setup.
Sokkia Instruments (SDR Files)
For the *Sokkia String Feature* data collector definition, the *string number* is given before the *feature code*.

Some of the control codes defined for the *Sokkia String Feature* data collector that are used in the example are:

* is used as the Command (Block) delimiter
space is used as the comment delimiter
*S* and *E* are used to start arc fitting and end arc fitting respectively
*R* is the Rectangle (make a parallelogram) command
the template commands *XA*, *XB*, *XC* and *XD* are used
the invert I and obvert O commands are used,
*XN* for the next segment to be non-tinable (that is, not a breakline).

The listing of the raw file 'Detail1.sdr' is now given, followed by a dump of a *12d Model* view displaying the job. No Map File has been used in the reduction so no line styles appear on the view.
**WARNING** - The raw file 'Detail1.sdr' is in the Survey area of the training data but the file has been manually edited and if read in with the standard Sokkia String Feature data collector, will have bad line lengths and the data ignored. To read the file in, the *Allow bad line lengths* on the **Advanced** tab of the Sokkia String Feature data collector will need to be set before converting the raw file to a 12d field file.

```
<table>
<thead>

</tbody>
</table>
```

need to tick on to read in raw files with invalid line lengths
37.3 12d and the Trimble Total Station ACU

This Section deals with interfacing 12d with the Trimble Total Station ACU unit data formats.

These notes are not meant to take the place of the operations manuals for the Trimble ACU but rather to act as a guide for ensuring the correct file types are used between the two systems.

See the sections:

37.3.1 Coding
37.3.2 Sending Raw file to 12d
37.3.3 Creating and Setting Data Collector Type
37.3.4 Convert Raw File
37.3.5 Creating Point Upload File
37.3.6 Create Roads Upload File
37.3.7 Create Tin Upload File
37.3.1 Coding

On the ACU the user can either manually type in a code for field readings or use a code library to pre-define codes which can then be selected from a list.

To use a code library the user should select the relevant library when creating the job.

If using string numbers the Feature library can be set to **None** and the string number, feature code, field code and delimiters can be manually typed in.

Codes are typed in to the ACU in the **Measure Points** option.
Please continue to the next section 37.3.2 Sending Raw file to 12d
37.3.2 Sending Raw file to 12d

The raw file can be transferred from the ACU as a format similar to the SDR33. This is called the SDR33 DC file format.

Connect the ACU to the PC using TRIMBLE DATA TRANSFER

Select Receive tab then select Add

Select the Job to download using the format SDR33 FORMAT DC FILE
Select **Transfer All** to transfer the file.

Please continue to the next section 37.3.3 Creating and Setting Data Collector Type.
37.3.3 Creating and Setting Data Collector Type

Create new data collector type

We will create a specific name for the Trimble data collector even though it is similar to the SDR33 format.

Select Project=>Browse

Select the Survey data collectors branch

Double click on **Sokkia String Feature**
This loads up the default parameters for the SDR33 format.

Type in the new name **Trimble String Feature**
Select **Set** then **Save**

Select **User directory**
Select **Save** then **Finish**

Select **Finish** back in the previous panel
To set the changes the project has to be restarted by selecting **Project=>Restart**

Select the data collector type
Select option **Survey=>Setup**

Select the **Data collector** choice icon

Double click on **Trimble String Feature**

Select **Set** then **Finish**

Please continue to the next section **37.3.4 Convert Raw File**
37.3.4 Convert Raw File

To convert raw file to field file select option **Survey=>Convert raw**

Select the **Raw file** choice icon
Select the Trimble file (extension should be .sdr)
Pick **Select**
The Field file name will be generated

Any errors can be listed by opening the Output window using option **Window=>Output Window**

```
format = sdr33
Line 7 command not implemented <OSNM>
Line 8 non supported derivation code <02>
Line 14 command not implemented <OSNM>
Line 15 non supported derivation code <02>
```
Close the Error panel

Select **Finish**

The field file can now be reduced in the normal manner

Please continue to the next section 37.3.5 Creating Point Upload File
37.3.5 Creating Point Upload File

Create upload file in 12d

After creating the setout points an upload file has to be created for the Trimble format.

Select option Survey=>Upload=>Create points upload file

Select Instrument choices icon
Select Trimble XYZ

Fill in the rest of the screen as per normal

Select Write File

A standard comma delimited file is created ready to send to the ACU
Loading file into job in ACU

The points upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using TRIMBLE DATA TRANSFER

Select **Send** tab then select **Add**
Select the file to upload using format **Comma delimited coordinate file**
Select **Transfer All** to transfer the file.

To load the file into the current job on the ACU select **Menu=>Files**

Select **Import / Export**
Select **Receive ASCII data**

Select **File format** choice icon then pick **Comma Delimited (*.CSV, *.TXT)**

Select **Receive from** choice icon and pick **Trimble Data**

Select **From file** choice icon and select file
Select the field order for the file as (1) Point number, (2) Easting, (3) Northing, (4) Level and (5) Code

Select the Next page icon

Select Receive
Select **OK** to finish.

The points can be displayed by selecting **Map** and zooming all of the job.

Please continue to the next section [37.3.6 Create Roads Upload File](#).
37.3.6 Create Roads Upload File

Create upload file in 12d

After creating the road alignment an upload file has to be created for the Trimble format.
Select option **Survey=>Upload=>Create roads upload file**

Select **Instrument** choice icon

Select **Trimble Roading**

Select **Select H-Align**

Pick and accept the alignment string

Type in a road name

To include Vertical geometry tick check box

To include Cross sections tick check box

To assume last segment of each section is a batter tick check box then type in default cut and fill grades

Select **Cross section model**

Type in a file name

Select **Write** then **Finish**
Loading file to the ACU

The road upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Send** tab then select **Add**
Select the road file to upload using format **Survey Controller file**
Select **Transfer All** to transfer the file

Once the road file has been copied into the ACU it can be setout using option **Survey=>Stakeout=>Roads**
Please continue to the next section 37.3.7 Create Tin Upload File
37.3.7 Create Tin Upload File

Create upload file in 12d

After creating the triangulation an upload file has to be created for the Trimble format.

Select option **Survey=>Upload=>Create triangle upload file**

Select the **File Type** choice icon and select **Trimble**

Type in Job name

Type in output file name

Select the tin to list

Select the boundary string for the tin

Select **Write** then **Finish**

Select **Yes** to create the file
Loading and using the file in the ACU

The tin upload file can be transferred to the ACU for setout.

Connect the ACU to the PC using **TRIMBLE DATA TRANSFER**

Select **Send** tab then select **Add**
Select the tin file to upload using format **Triangulated Terrain model**
Select **Transfer All** to transfer the file.

Once the tin has been copied into the ACU it can be called up when using the Stakeout option

**Survey=>Stakeout=>DTM**

Select the uploaded tin file to setout
The cut to the tin is calculated and displayed.
37.4 12d and Trimble GPS Controllers

The Trimble Geomatics Office software which comes with most Trimble GPS units can produce a Sokkia SDR file which is used by 12d Model as a raw data file.

However, the Trimble software writes out the (x,y,z) co-ordinates of GPS points as a "08KI" record which is normally treated by 12d Model as directly entered co-ordinates for a Station.

To overcome this problem, there is a flag in the data collector definitions to treat the Sokkia 08KI records as GPS points.

So before converting a Sokkia SDR file from a Trimble GPS unit, define a data collector which has a tick for the field Sokkia 08KI as GPS points on the Instrument tab of the Survey.4d Create/Edit panel.

The code information that is entered on the Trimble in the field is appended the Sokkia 08KI record and is processed as blocks of information as given in the section 36.8 Field Coding for Non Leica Instruments and the appendix 37 12d and Survey Instruments.
37.5 12d and Geodimeter Instruments

This appendix deals with interfacing 12d with Geodimeter files.

See the sections:

37.5.1 12d UDS’s
37.5.2 Using 12d Field Ops Codes on the Geodimeter
37.5.3 Example of Geodimeter File
37.5.1 12d UDS’s

The geodimeter allows the recording of information in a format specified by the user. Data for each label can be prompted for and measurements from the instrument can be registered. The user can assign a certain series of labels to a User Defined Sequence or UDS.

For 12d to reduce files from the geodimeter instruments, the recorded information from the instrument must be in a specific format that 12d can understand. A number of Geodimeter UDS files are supplied on the 12d Model Installation CD in the folder ‘Other_Software\Geodimeter’.

For uploading or direct entry of UDS’s to your particular instrument see your instrument manual.

These UDS’s have been set up so that 12d can convert the raw files from the instrument in a 12d field file. These UDS’s should be installed prior to undertaking surveys that are to be reduced by 12d. The standard UDS that 12d supply is as follows:

- UDS 1 - used within UDS 8 to record 12d field op codes.
- UDS 2 - prompts for additional data for a 12d field op code.
- UDS 5 - job administration at the start of a job
- UDS 6 - station co-ordinates entry
- UDS 7 - station set up - name and instrument height
- UDS 8 - data pick-up

UDS 5 is run at the beginning of the job and it runs UDS 6, which runs UDS 7 which runs UDS 8. UDS 1 can be run as required from within UDS8 to give 12d field file op codes.

### 12d standard UDS’s for pick-up with Geodimeter

<table>

12d and Geodimeter Instruments

Page 7107
The Geodimeter data format is used as a raw data file by 12d Model and is converted into a 12d Field File before reduction by potentially 2 different macros:

1) geodat4d.4do (default) for use with the 12d standard UDS’s.
2) geodat_qmrd.4do (Specialised reduction) for use with Queensland MRD UDS’s.

For the geodat4d.4do macro (default) 12d Model uses the following Geodimeter labels:

- 0= Information
- 1= Attributes
- 2= Station name or named point
- 3= Instrument height
- 4= Blocks
- 5= Point number
- 6= Target (signal) height
- 7= Horizontal angle
- 8= Vertical angle
- 9= Slope distance
- 37= Northing (X) value
- 38= Easting (Y) value
- 39= Height (Z) value
- 51= Date
- 53= Operator
- 90= End of record, flush buffer
- 91= 12d Model field file op code
- 92= Parameters for the previous 12d op code
- 95=

In particular, the Geodimeter PCode label block (4=) is used as the text of blocks that are interpreted according to the descriptions given in the earlier section 36.8 Field Coding for Non-Leica Instruments.

A new conversion macro for V6.0, geodat_qmrd.4do recognises geodimeter Program 22 and Program 32 commands if the following setup/procedures are used:

1. The geodimeter should be set to record program numbers. This is shown by the label 0=Pn in the raw file, where n is the program number and is assigned by the instrument. To set this up on the instrument use MENU 6 1(Switches) and turn Prg_Num on.

2. For 12d to convert raw files using geodimeter programs such as P22 and P32 the data must contain a label 61=n each time an UDS or onboard program is started (Where n is the program number). This allows 12d to be able to determine when one program is finished and another started. Queensland MRD have created their own UDS’s which utilise the 61= label so that it is prompted for within the UDS’s. They have also set up a UDS (UDS 6) which is used to place the label at the commencement of an onboard program such as program 22.

Please continue to the next section 37.5.2 Using 12d Field Ops Codes on the Geodimeter.
37.5.2 Using 12d Field Ops Codes on the Geodimeter

In additional to the commands accessible from the blocks, most of the 12d field file op codes are accessible directly from the Geodimeter.

The label '91=' label is used to specify a 12d field file op code and any following '92=' labels provide any additional information required by the 12d op code.

The 12d field file ops codes apply to the measurement before the op code.

For a complete definition of the 12d Model field file and the 12d Model field file op codes, see the section 36.10 The 12d Field File Format

Please continue to the next section 37.5.3 Example of Geodimeter File.
37.5.3 Example of Geodimeter File

The raw file 'Geodimeter.job' has been coded in accordance with the data collector definition Geodimeter 12D which is shipped with 12d Model. The 12d Model Geodimeter UDS's were used in the field pick-up.

The data collector Geodimeter 12D is set using the option Survey=>Setup

Some of the tabs on the Geodimeter 12D data collection definition as show below. Note that * is used as the Command (Block) delimiter, the string number is given after the feature code, S is used to start arc fitting and R is the Rectangle (make a parallelogram) command.

The listing of the raw file is now given, followed by a dump of a 12d Model view displaying the
job with string names (feature codes) and point numbers toggled on. The raw file 'Geodimeter.job' is in the Survey area of the training data. It can be converted into a 12d field file by using the default conversion macro geodat4d.4do.

Plan View with of the Reduced Geodimeter Data Displayed
with Point Numbers and String Names (Feature Codes) Turned On
The following raw field file has been taken from an QMRD Geodimeter 610 which has the QMRD UDS’s installed. The file can be converted into a 12d field file by using the geodat_qmrd.4do. Note the inclusion of the activity codes (61=) that have been added to the file with the use of the UDS’s. It also shows the use program 22 and the traverse extraction facility. For more information on traverse extraction see the section 36.6 Traverse coding.

38 Geodetics Summary

Various options in 12d Model use geodetic calculations to present and change data. These options use terminology that are common to the field of geodetics, which will be defined here.

Most of the terminology adopted follows definitions given in the Australian GDA Technical Manual which is published by the Intergovernmental Committee on Surveying and Mapping (ICSM). This publication is a valuable reference document and the reader is encouraged to obtain a copy for a full understanding of the topic. The document can be accessed on the internet at the following address http://www.icsm.gov.au/gda/tech.html

38.5 Converting Between AMG, ISG and MGA
38.1 Shape Of The Earth

The determination of the Earth’s shape is a science known as Geodesy. Today, it is widely accepted that the Earth’s shape best approximates an ellipsoid that has been revolved around the Earth’s polar axis. Put another way, the shape is a sphere that has been squashed at the north and south poles. The non-spherical shape is due to gravity.

A number of ellipsoids have been calculated to best approximate the Earth’s shape at local locations and the earth as a whole. The best fit is concerned with matching the Earth’s equipotential gravity field (the Geoid that is best approximated by Mean Sea Level), to a geometric ellipsoid shape. As such, there a wide number of definitions.

Some commonly used ellipsoids are:

1. **GRS80**

<table>
<thead>
<tr>
<th>Ellipsoid</th>
<th>Semi-major axis</th>
<th>Inverse flattening</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRS80</td>
<td>6,378,137.0</td>
<td>298.257222101</td>
</tr>
</tbody>
</table>

From GDA Technical Manual
This ellipsoid is used for Australia's GDA definition (Geocentric Datum of Australia GDA 94) used for MGA (Map Grid of Australia) calculations, New Zealand's NZGD2000 datum as well as other geocentric earth model datums around the world.

### 2. ANS

<table>
<thead>
<tr>
<th>Ellipsoid</th>
<th>Semi-major axis</th>
<th>Inverse flattening</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANS</td>
<td>6,378,160</td>
<td>298.25</td>
</tr>
</tbody>
</table>

This was the ellipsoid used to define the Australian Geodetic datum (AGD 84) used for AMG (Australian Map Grid) calculations and ISG (Integrated Survey Grid) co-ordinates.

### 3. NZ Geodetic 49

<table>
<thead>
<tr>
<th>Ellipsoid</th>
<th>Semi-major axis</th>
<th>Inverse flattening</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZ Geodetic 49</td>
<td>6,378,399.065</td>
<td>297.0</td>
</tr>
</tbody>
</table>

This was the ellipsoid used to define the NZ 1949 Geodetic datum. The semi-major axis given here has been adjusted to compensate for errors in units conversion from links to meters.

Continue to the next section 38.2 Geodetic Coordinates or return to 38 Geodetics Summary.
38.2 Geodetic Coordinates

Once an ellipsoid or **Geodetic Datum** is defined, a position on the earth’s surface can be described in terms of Geodetic coordinates. These coordinates are **Longitude**, **Latitude** and **Ellipsoid height**.

**Longitude** is a angular quantity measured from the Greenwich meridian. It is most commonly described in terms of degrees, minutes, seconds East or west of the Greenwich meridian.

**Latitude** is a angular quantity measured from the equatorial plane, to the plane defined by the point position and the plumb line to the ellipsoid surface. It is most commonly described in terms of degrees, minutes, seconds South or North to the equator.

The **ellipsoid height**, \( h \) is the height above the reference ellipsoid. Most height datums are not based on ellipsoid height but are based on the **geoid**. e.g. AHD in Australia.
As such, levels from GPS observations (which are *ellipsoid* heights) need to be corrected to a *geoidal* or *orthometric height*. To do this, we require the separation or gap distance between the two different surfaces. This separation is known as the *N value*.

The **Ellipsoid height** = Geoid height + N value

or

\[ h = H + N \]

*N* values can be defined in a geoidal model such as *Ausgeoid98* which represents grids of *N* values over all of Australia.

For a given Geodetic coordinate, an N value can be interpolated from the model and applied to the ellipsoid height to give a geoidal height. Similarly, the N value can be used to convert a geoidal height to an ellipsoid height.

Since most geodetic calculations are made on the ellipsoid, the **ellipsoid height** is required for precise calculations.

Continue to the next section *38.3 Map (Cartographic) Projections* or return to *38 Geodetics Summary*. 
38.3 Map (Cartographic) Projections

In order to represent ellipsoid data on a flat surface for mapping, it is necessary to use a projection. A projection enables points on the earth's surface to be mathematically projected onto an imaginary developable surface. This surface can then be developed or "rolled flat". Typically, this surface is a cylinder or cone.

The Transverse Mercator system (TM) projects coordinates onto a cylinder that is tangent to the equator and the entire length of a meridian of Longitude.

12d Model allows a number of projections to be specified including, Universal Transverse Mercator (UTM), Transverse Mercator (TM) and Rectified Skew Orthomorphic (RSO). There are many more available using the General type.

Within 12d Model, a projection can be defined that specifies both the reference ellipsoid and projection type. This then can be used for geodetic calculations.

A projection has various parameters that define it. These are specific to the projection and are clearly defined for major mapping systems. For example MGA94 zone 56 projection is defined as follows:

Continue to the next section 38.4 Terminology or return to 38 Geodetics Summary.
38.4 Terminology

The various geodetic options in 12d Model mostly use standard geodetic terminology as defined in the Australian GDA technical manual. For clarity, they will be defined again here. For some options it is important to note that some terminology used in Australia has quite a differing meaning in other countries.

38.4.11 Line Scale Factor
38.4.12 Combined Point Scale Factor
38.4.13 Azimuth and Convergence
38.4.1 Ellipsoid Distance

The **ellipsoid distance** is the reduced distance along the *surface* of the ellipsoid. Standard survey measurements are reduced to the horizontal but require a correction due to the height above the ellipsoid. This is usually done by a **height scale factor** which takes into account the ellipsoid height at each end of the measured line. i.e.

\[
HeightScaleFactor = 1 - \frac{h_M}{R + h_M}
\]

Where:

- \( h_M \) = Mean terrain height (mean of the two ellipsoid heights at either end of the measured line)
- \( R \) = Radius of the earth in the azimuth of the line.

**Note:** An error of 60 meters in the value of \( h_M \) will introduce an error of 10 ppm in the reduced ellipsoid distance. With the introduction of the Australian Geocentric datums, the N values have increased markedly over Australia. So even if a survey is undertaken at sea level (Geoid height approximately 0.0), the ellipsoid heights may very well be greater than 60 meters. As The Ellipsoid height = Geoid height + N value, N values should be considered when reducing measured distances to these datums.

For older Australian ellipsoids, Mean seal level approximated the surface of the ellipsoid (i.e. N value approximately 0.0), so corrections could use geoidal heights to bring the distances down onto the reference surface.

The ellipsoid distance can be calculated using the calculated height factor:

**Ellipsoid Distance** = Reduced Horizontal Distance \( \times \) height scale factor.

Continue to the next section 38.4.2 **Bearings and Distances - Plane and Grid** or return to 38.4 **Terminology** or 38 **Geodetics Summary**.
38.4.2 Bearings and Distances - Plane and Grid

If you have a point on an ellipsoid and a Transverse Mercator projection (such as UTM), the projection co-ordinates are known as the grid co-ordinates of the point (Easting and Northing).

On an ellipsoid, the straight line joining two points is the Great circle between the two points. If each point along the Great circle is projected onto the grid, the path that is traced out is an arc between the points.

That is, the straight lines on an ellipsoid project onto the TM grid as arcs.

In the diagram below, the Great circle arc through points A and B on the ellipse projects onto the arc shown through Points A and B in grid co-ordinates.

So the straight line joining the two points in the plane is different from the projection of the great circle (straight line on the ellipse) joining the two points on the ellipse.

Continue to the next section 38.4.3 Plane Bearing, Projection Bearing or return to 38.4 Terminology or 38 Geodetics Summary.
38.4.3 Plane Bearing, Projection Bearing

If a straight line is drawn in the plane between two points on a grid, the angle between grid north and this line is equal to the plane bearing.

In other words, if the two point's coordinates are known, standard plane trigonometry can be used to calculate the bearing of the line.

\[
\tan(\text{plane bearing}) = \frac{(E_2 - E_1)}{(N_2 - N_1)}
\]

Projection bearing and plane bearing is used interchangeably in 12d Model.

Continue to the next section 38.4.4 Australian Grid Bearing, Ellipsoid Bearing or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.4 Australian Grid Bearing, Ellipsoid Bearing

In Australia, the grid bearing is the angle between grid north and the tangent to arc at a point on the arc. e.g Point A. The grid bearing at point A is not equal to the reverse grid bearing from point B.

This term is also known as the ellipsoid bearing in some countries.

**Warning:** In some countries, including New Zealand and the US, the term Grid bearing is used for the previously defined term Plane bearing. However, as defined in the Australian GDA technical manual, the definition of Grid bearing is different to that of a plane bearing.

To avoid confusion, we will use the term ellipsoid bearing.

Continue to the next section 38.4.5 Plane Distance or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.5 Plane Distance

The plane distance is the length in the plane of the straight line joining two points on a grid - that is, the standard distance between two points in a plane.

\[
\text{plane distance} = \sqrt{(E_2 - E_1)^2 + (N_2 - N_1)^2}
\]

Continue to the next section 38.4.6 Australian Grid Distance or return to 38.4 Terminology or 38 Geodetics Summary.
38.4.6 Australian Grid Distance

On an ellipsoid, the *straight line* joining two points on the ellipsoid is the Great circle between the two points. The *straight lines* on an ellipsoid project onto the UTM grid as arcs. In the diagram below, the arc shown through points A and B is the projection of the Great circle arc through points A and B on the ellipse.

In Australia, the *grid distance* is the distance on this *arc* from point A to B.

The difference between the plane distance and the grid distance is usually negligible.

**Warning:** In some countries, the term *grid distance* is used for the definition of plane distance here.

Continue to the next section 38.4.7 *Datum* or return to 38.4 *Terminology* or 38 *Geodetics Summary*. 
38.4.7 Datum

Within the Geodetic sections of 12d Model, the term *datum* relates to the reference ellipsoid adopted by countries/organisations for mapping projects.

For example AGD is the Australian Geodetic Datum, using the ANS ellipsoid parameters. GDA refers to the Geodetic Datum of Australia, using the GRS80 ellipsoid as the basis for defining geodetic coordinates.

In New Zealand, the NZGD49 datum refers to the NZ Geodetic 49 ellipsoid. The NZGD2000 datum is the New Zealand geodetic datum which again refers to the GRS80 ellipsoid.

Continue to the next section 38.4.8 Zone or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.8 Zone

The meaning of *zone* is specific to the UTM projection type which is commonly used around the world as a mapping projection. This includes AMG and MGA in Australia.

The Universal Transverse Mercator projection splits the world into 60 zones of 6 degrees of longitude. The zone numbering starts at 180 degrees West, longitude. Each zone has a specific central meridian and range of longitude that defines it. As such, by supplying a zone number, a number of parameters about a projection can be deduced.

For example, Australia is covered by the UTM zones 49 to 56.

Continue to the next section 38.4.9 Arc-to-Chord Correction (\(t-T\) correction) or return to 38.4 Terminology or 38 Geodetics Summary.
38.4.9 Arc-to-Chord Correction (t-T correction)

The *arc-to-chord* correction is the quantity to be added algebraically to an ellipsoid bearing (Australian grid bearing) to obtain a plane bearing.

\[
\text{Plane Bearing} = \text{Ellipsoid Bearing} + \text{Arc-To-Chord Correction}
\]

\[
\text{Plane Bearing} = \text{Australian Grid Bearing} + \text{Arc-To-Chord Correction}
\]

This correction is only really applicable for lines over 10 km but it is included in calculations for completeness. The correction shown in the example below is negative in sign but it can also be positive.

Continue to the next section 38.4.10 Point Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.
38.4.10 Point Scale Factor

The **point scale factor** is the ratio of an infinitesimal plan distance at a point on a grid to a corresponding ellipsoid distance.

It can be used as an approximation to convert (factor) measured ellipsoid distances to plane distances.

Continue to the next section 38.4.11 Line Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.11 Line Scale Factor

The **line scale factor** is the ratio of the plane distance on a grid to a corresponding ellipsoid distance. i.e.

\[
\text{LineScaleFactor} = \frac{\text{PlanDist}}{\text{EllipsoidDist}}
\]

This factor can be used to calculate either the plane or ellipsoid distance given the Line Scale Factor and the other distance. i.e.

**Plane distance = Ellipsoid distance x Line scale factor,**

Similarly,

**Ellipsoid distance = Plane distance / Line scale factor.**

Continue to the next section 38.4.12 Combined Point Scale Factor or return to 38.4 Terminology or 38 Geodetics Summary.

38.4.12 Combined Point Scale Factor

The **combined point scale factor** is the product of the point scale factor and the height scale factor. i.e.

**Combined Scale Factor = Point Scale Factor x Height Scale Factor.**

Continue to the next section 38.4.13 Azimuth and Convergence or return to 38.4 Terminology or 38 Geodetics Summary.
38.4.13 Azimuth and Convergence

**Azimuth** is the horizontal angle measured from an *ellipsoidal meridian clockwise from north* and the great circle between measured points.

It is also known as the *True Azimuth*. In general, this value will be calculated internally in 12d Model.

**Convergence** or *Grid Convergence* is the angular quantity to be added algebraically to an *Azimuth* to obtain an ellipsoid bearing (Australian grid bearing). i.e.

Ellipsoid Bearing = Azimuth + Grid Convergence

Australian Grid Bearing = Azimuth + Grid Convergence

**Warning:** In some countries, the *Grid Convergence* has the opposite sign.

Combining

Ellipsoid Bearing = Azimuth + Grid Convergence

Australian Grid Bearing = Azimuth + Grid Convergence

and

Plane Bearing = Ellipsoid Bearing + Arc-To-Chord Correction

Plane Bearing = Australian Grid Bearing + Arc-To-Chord Correction

produces the equation

**Plane Bearing = Azimuth + Grid Convergence + Arc-To-Chord Correction**

or
Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction
True Azimuth = Plane Bearing - Grid Convergence - Arc-To-Chord Correction

**Warning:** In some countries, the *Grid Convergence* has the opposite sign.

Please continue to the next section [38.5 Converting Between AMG, ISG and MGA](#) or return to [38.4 Terminology](#) or [38 Geodetics Summary](#).
38.5 Converting Between AMG, ISG and MGA

In Australia the ellipsoid used to represent the shape of the earth used to be defined by AGD 84 but it has now has been changed to an ellipsoid that has its centre at the centre of mass of the earth (geocentric - GDA 94). See 38.1 Shape Of The Earth.

This is to fit in with GPS because satellites orbits are centred on the centre of mass.

This means that the Latitude and Longitude of every point has changed.

The use of UTM projections (Universal Transverse Mercator - see 38.3 Map (Cartographic) Projections) and Zones still apply but because the latitude and longitude of each point has change, its Easting and Northing for a UTM zone has also changed.

AMG 84 Zones are the co-ordinates for the UTM Projections defined for six degree zones using the ellipsoid defined by AGD 84.

MGA 94 Zones are the co-ordinates for the UTM Projections defined for six degree zones using ellipsoid define by GDA 94.

Note - ISG 84 Zones are the co-ordinates for the TM Projections defined for two degree zones using the ellipsoid defined by AGD 84.

For converting between the different datums AGD66/84 and GDA94 (i.e. AMG, ISG, Long Lat <-> MGA, Long Lat), use the option

Survey =>Conversions =>AGD66/84 <-> GDA94 (see 17.10.4 AGD66/84 <-> GDA94)

For converting between different AMG Zones (AMG <->AMG) or different MGA Zones (MGA->MGA) use the option

Survey =>Conversions =>Australian conversions. See 17.10.1 Australian Conversions.

For converting between different ISG/AMG Zones (AMG,ISG <->AMG, ISG)
Survey => Conversions => Cartographic. See 17.10.2 Cartographic.

Return to 38 Geodetics Summary.
This appendix contains information about files used for setting up and configuring 12d Model.

See

39.1 Folder Structure Installed by 12d Model
39.2 Files for Setting Up 12d
39.3 Library, User Library, Customer Library
39.4 Environment Variables
39.5 12d Model Options Map
39.6 Monitoring 12d Model Usage
39.7 Running Macros and Chains on Start Up
39.8 Arguments When Starting 12d Model
39.1 Folder Structure Installed by 12d Model

12d Model has Set Up files to define how new projects are created, define colours, linestyles, symbols etc. and control many other aspects of 12d Model.

12d Model comes with defaults for these things but most users wish to customise many of the settings, share them between groups of users across a network etc.

To make customisation easier, all the 12d Model customisation files (called Set Up files) have default names and on installation, are stored in a folder called Set_ups.

To customise 12d Model, users only need to which file to modify for that particular customisation.

When 12d Model 11 is installed on a Windows computer, the major components are installed in the Microsoft preferred installation folder Program Files, in the sub folders 12d\12dmodel\11.00.

That is, the software and associated files are installed in Program Files\12d\12dmodel\11.00.

However, without Administrator privilege, users do no have write access to Program Files.

To allow non-administrator users access to Set Up areas that users can store modified files, 12d Model 11 also installs extra folders in an area that could be accessed by the user. The default folder structure for this area is C:\12d\11.00

So the customisation system allows the use of both the areas Program Files\12d\12dmodel\11.00

and

C:\12d\11.00 for storing Set Up and other files necessary for the tailoring and running of 12d Model.

Please continue to the next section 39.2 Files for Setting Up 12d.
39.2 Files for Setting Up 12d

When 12d Model fires up, it looks for special files (called Setting Up or Setup files) to define many of its features. Hence the Setup files can be used to customize 12d Model for a site, a client or even a user.

When 12d Model creates a new project, or changes to another project, then for each Setting Up file

EITHER

(a) an environment variable for the Setup file exists, and the value of the environment variable is taken as the full path name of the file to be used as that Setup file.

OR if the environment variable does not exist for the Setup file

(b) a file with the default Setup file name is searches for in specially named folders, in a fully defined order.

The search for each Setup file is independent of any other Setup file. That is, for each Setup file, the folders are searched in the specific order until that file is first found and the searching stops for that Setup file. and then the search is begun again for the next Setting Up file.

Consequently the Setup files do not all have to be in the same folder. This greatly increases the tailorability of 12d Model.

The description, default name and any environment variable for each Setup file are given in the sections 39.2.1 Setup Files Only Used for a New Project, 39.2.2 Setup Files Only Used for an Existing Project and 39.2.3 Setup Files Used for New and Existing Projects.

The folders searched for Setup files, and the folder search order, is described in the section 39.2.4 Folders Searched for Setup Files.

See

39.2.1 Setup Files Only Used for a New Project
39.2.2 Setup Files Only Used for an Existing Project
39.2.3 Setup Files Used for New and Existing Projects
39.2.4 Folders Searched for Setup Files
39.2.5 Searching Order for Setup Files
39.2.6 Writing Out Setup Files
39.2.7 Some Special Setup Files
39.2.1 Setup Files Only Used for a New Project

The two Setup files, setups.4d and defaults.4d, are only used when creating a **NEW 12d Model** project, and after the project is created, the information supplied in these two Setup files is **stored within the 12d Model project** and is then modified from within **12d Model** when in that project.

Similarly the file macros.4d is a file of macros or chains (one per line) that are only run when a **new** project is created (**project_macros.4d** is a run when an **existing** project is opened).

defaults.4d

- define the defaults for a **new** project.
- Modified by the **Defaults** panel from the **Projects => Management => Defaults** option.
- Once a project is created, the defaults can be modified inside 12d Model.
- The defaults are then saved with the project.
- The environment variable is **DEFAULTS_4D**.
- For more information go to the section 39.2.7.3 **Defaults File (defaults.4d)**

setups.4d

- define the layout of views on the screen for a **new** project.
- Once a project is created, the view layout can be modified inside **12d Model**.
- The view layout is then saved with the project.
- The environment variable is **SETUPS_FILE_4D**.
- For more information go to the section 39.2.7.1 **Set Ups File (setups.4d)**

macros.4d

- a file of macros and/or chains (one per line) that are run when a **new** project is created (see 5.9 **Running Macros and Chains on Start Up**).
- The environment variable is **RUN_MACROS_FILE_4D**.
39.2.2 Setup Files Only Used for an Existing Project

The file `project_macros.4d` is a file of macros or chains (one per line) that are only run when an existing project is opened. So `project_macros.4d` is modified between accesses to the project then the modified version of the file is used for the project.

`project_macros.4d`

a file of macros (one per line) that are run when an existing project is opened (see 5.9 Running Macros and Chains on Start Up).

The environment variable is `RUN_PROJECT_MACROS_FILE_4D`. 
39.2.3 Setup Files Used for New and Existing Projects

The other Setting Up files are searched for each time a project is created or opened. So if these files are modified between accesses to the project then the modified versions of the files are used for the project.

Some of the Setup files that 12d Model searches for each time a project is opened are:

colours.4d // sets the colour names and red, green, blue mix; also defines the default pens that the colours map to (as displayed in the panel colours to pens). See 39.2.7.2 Colours File (colours.4d).

The environment variable is COLOURS_4D.

digitize.4d // list and defines the digitizers available in 12d Model. See 8.5.7 Digitizer Definitions File.

The environment variable is DIGITIZERS_4D.

ev.4d // contains values for environment variables See 39.4 Environment Variables.

The environment variable is ENVIRONMENT_4D.

fonts.4d // defines the fonts used in text styles. See 40.3 Textstyles and Fonts.

The environment variable is FONTS_4D.

gui.4d // define the fonts and colours used in panels and menus, spacing between items in panels and menus and the maximum pop-up length. See 39.2.7.6 GUI.

The environment variable is GUI_4D.

layout.4d // a file containing the screen layout file information (slx/slf) for placing menus or panels on the screen. The layout file is used every time a project is opened. The layout file can have most menus and panels in it. See 42.2.3 Screen Layout File in the appendix 42 Special File Formats.

The environment variable is LAYOUT_FILE_4D.

linestyl.4d // defines the line styles (linestyles, worldstyles, groupstyles and twoptstyles). See 40.1 Line Styles.

The environment variable is LINESTYLES_4D.

names.4d // a special name mapping file which is used to define for given string names, information such as colours, model etc. This is used in some panels to fill out other panels fields after entering the string names in the panel.

The environment variable is NAME_MAPPINGS_4D.

plotters.4d // defines the plotters that appear in the pop-up for the plotter type panel field. See 43.2 Defining Plotters - Plotters.4d.

The environment variable is PLOTTERS_4D.

pmf.4d // plotter mapping file for defining mapping of 12d Model colours to pens with thicknesses, and the rgb for the pens See 43.3.2.1 Definition of a Plotter Mapping File.

The environment variable is PLOTTER_MAPPING_4D.

sheets.4d // gives sheet sizes and names used in the pop-up for the sheet size panel field. See 39.2.7.4 Sheet Sizes File (sheets.4d)

The environment variable is SHEET_SIZES_4D.

survey.4d // lists and defines the data collectors available in 12d Model See 7.9.3 Survey Data Collectors

The environment variable is DATA_COLLECTORS_4D.

symbols.4d // defines the symbols. See 40.2 Symbols
The environment variable is `SYMBOLS_4D`.

textstyl.4d  // defines the text styles. See 40.3 Textstyles and Fonts.
The environment variable is `TEXTSTYLES_4D`.

textstyle_names.4d  // defines the textstyle favourites
The environment variable is `TEXTSTYLE_MAPPINGS_4D`.

toolbars.4d  // defines the toolbars. See 41.3 User Defined Toolbars.
The environment variable is `TOOLBARS_4D`.

userkeys.4d  // defines the action of function keys. See 41.1 User Defined Function Keys.
The environment variable is `FUNCTION_KEYS_4D`.

usermenu.4d  // defines the user defined walk-right menus for User on 12d Model menus. See 41.2 User Defined Menus.
The environment variable is `USER_OPTIONS_4D`.

xtramenu.4d  // defines the 12d Solutions defined walk-right menus for User on 12d Model menus. See 41.2 User Defined Menus.
The environment variable is `EXTRA_OPTIONS_4D`.

The folders searched for Setting Up files, and the folder search order, is described in the next section 39.2.4 Folders Searched for Setup Files.
39.2.4 Folders Searched for Setup Files

When 12d Model 11 is installed on a Windows computer the major components installed by 12d Solutions are under the Microsoft preferred installation folder Program Files, in the sub folders 12d\12dmodel\11.00. That is Program Files\12d\12dmodel\11.00.

Without Administrator privilege, users do no have access to this area.

Note: these are the folders used for 32-bit 12d Model on a 32-bit Windows and 64-bit 12d Model on a 64-bit Windows. For a 32-bit 12d Model on a 64-bit Windows, the software is installed in Program Files (X86)\12d\12dmodel\11.00

Other information that can be accessed and modified by the user, will be installed in the sub folders C:\12d\11.00 in an area that the user has access to.

The structure of the folders containing Setting Ups files are Set_ups and User. How the various folders are searched for Set Up files will be described in the following sections.

set_ups

The 12d Model installation creates a number of specific folders such as the operating system-cpu specific folder (for example nt.x86 for 32-bit 12d Model on Intel chips and nt.x64 for 64-bit 12d Model on Intel chips), and areas for set up files: namely an o/s-cpu specific set_ups under the o/s-specific folder and a set_ups under Program files\12d\12dmodel\11.00 (or Program files (X86)\12d\12dmodel\11.00 for 32-bit 12d Model on 64-bit Windows).

It is also possible to move the set_ups folder Program files\12d\12dmodel\11.00\set_ups to another location, and even give it another name, by defining an environment variable SET_UPS_4D which gives the path of the moved folder

```
SET_UPS_4D folder // 12d supplied folder of Setting Up files
```
User and Customer_User

Users usually want to customise 12d Model by modify one or more of the Setup files but most users do not have written access to the Program Files folder, and Program files\12d\12dmodel\11.0\set_ups. Also, any files in the set_ups folders may be overwritten by future 12d Model installations.

To overcome these two problem, there are two special folders (reserved for customers) that are searched before set_ups for any Setting Up files.

One folder is only looked for when it has been created by a user and is pointed to by the environment variable CUSTOMER_USER_4D. It has no default name but is whatever name has been set up for it. We will call it as cust_user.

The other folder has the default name user.

The folders cust_user and user should NOT be under Program Files but in 12d\11.0 which the 12d Model installer usually creates in a folder that the 12d Model user has read/write access to. The default folder to contain user and cust_user is C:\12d\11.0

During the 12d Model installation, if user does not exist, an empty user folder is created.

The folder cust_user is not created and if required, must be created by the user and the environment variable CUSTOMER_USER_4D set up to point to it.

To find a Setting Up file, the folder cust_user will be searched for before user, and user is searched for before set_Ups.

Consequently any modified Setting Up files should be placed in cust_user or user and then they will be found before the file of the same name in set_ups (user may contain o/s-cpu specific folders).

When a new 12d Model version is issued (e.g. 11), the contents of cust_user and user from the previous version of 12d Model (e.g. V10) need to be copied over to the new cust_user and user area. This is NOT done automatically during the installation in case there are files that need to be modified for the newer version.

There is also an environment variable USER_4D which can be set to point to another user defined folder which will be searched for Setting Up files before the default user is searched.
This is a common method for having all users on a network share the same Setup files. The common files are placed on a disk drive accessible by all the users and the environment variable USER_4D defined to point to that folder.

**Note** - both user and the folder pointed to by USER_4D can exist.

**Current and Home**

The folder that a project is in (the current folder) and the users home folder are also searched for Setup files.
39.2.5 Searching Order for Setup Files

When 12d Model creates a new project, or changes to another project, it searches folders for the Setup files in a well defined order.

Each Setup file has a default name, and unless there is an environment variable for that specific Setup file defining its exact name and path, folders are searched in a specific order until the file is found. The search is begun afresh for each Setup file so different Setup files may come from different folders.

The fixed search order for any Setup files is

1. check for the appropriate environment variable defining the full path to the specific Setup file.

If the environment variable is not defined, or the file pointed to does not exist, then the folders are searched for in the following order for the specific Setting Up file with its default name (e.g. colours.4d)

2. the projects current folder
3. the users home folder
4. specific cpu folder in CUSTOMER_USER_4D
5. file folder defined by CUSTOMER_USER_4D
6. specific cpu folder in USER_4D e.g. nt.x86 for Intel
7. file folder defined by USER_4D
8. specific cpu folder in User under C:\12d\11.00
9. User under C:\12d\11.00
10. the folder defined by SET_UPS_4D
11. set_ups folder under the specific cpu folder under Program Files\12d\12dmodel\11.0
12. set_ups folder under Program Files\12d\12dmodel\11.00

Once the appropriate Setup file is found, the search is terminated and that, and only that file, is used.

Notes

(a) When an existing project is opened by 12d Model, the Setting Up files setups.4d,
defaults.4d and macros.4d are not used. These files are only used for defining a NEW project.

(b) project_macros.4d is only used when opening an EXISTING project and not a new project.

(c) A Setup file such as colours.4d may exist in one or more of the above folder. However, only the first occurrence of the file found when using the above search order, is used.

Please continue to the next section 39.2.6 Writing Out Setup Files.
39.2.6 Writing Out Setup Files

Most of the Setup files can be created and edited within 12d Model using panels such as Projects => Management => Defaults.

When the Write button is selected on these panels, a Write Setup File panel comes up to specify where the file is to be written out to.

The choices on the panel allow the file to be written out to:

**Found folder** - the folder where the file currently being used by 12d Model resides. This will be unavailable (greyed out) if the user doesn’t have access to the folder.

**Current folder** - the folder where the project currently being used by 12d Model resides. This will be unavailable (greyed out) if the user doesn’t have access to the folder.

**User folder** - the user folder. This will be unavailable (greyed out) if the user doesn’t have access to the folder.

**Other folder** - any folder can be selected.

A project restart is required for the new file to take effect.

If you are having problems writing to the file, click on the Properties button to bring up the Properties panel for the selected file (if it exists) and check the Security for the file.
Please continue to the next section 39.3 Library, User Library, Customer Library.
39.2.7 Some Special Setup Files

See

39.2.7.1 Set Ups File (setups.4d)
39.2.7.2 Colours File (colours.4d)
39.2.7.3 Defaults File (defaults.4d)
39.2.7.4 Sheet Sizes File (sheets.4d)
39.2.7.5 Transitions and Spirals File
39.2.7.1 Set Ups File (setups.4d)

The St Up file, setups.4d, is used to define the initial screen set-ups. It can be used for
- the system font used for text
- the size of the initial window
- the position of the main menu, header menu, function menu, function recalc menu, snaps menu, volumes menu, geometry menu, sewer menu, pipeline menu
- the position of the screen message box, xyz message box
- the position of the save project panel (now redundant)
- the position, size, name and viewing parameters for the initial views

The co-ordinate system used for specifying the position of the left hand top corner of items on the screen is by column and row. For items which include an area of the screen (such as the window and views), a width and depth are also specified.

The column value is measured from the left hand size of the screen and the row value is measured from the top of the screen.

The units for row, column, width and depth are screen pixels.

```
columns      width
rows         depth
```

Note - If any views are defined in the set_up_file, then the position of the screen message box must be also be defined and it must be before the definition of any view.

The format of the commands in the file setups.4d is

```
WINDOW      column_value  row_value  width    depth
// main window
MAIN MENU    column_value  row_value
FUNCTION MENU column_value  row_value
FUNCTION RECALC MENU column_value  row_value
GEOMETRY MENU column_value  row_value
PIPELINE MENU column_value  row_value
SEWER MENU   column_value  row_value
SURVEY MENU  column_value  row_value
VOLUMES MENU column_value  row_value
SNAPS MENU   column_value  row_value
SNAPS BUTTONS HORIZONTAL column_value  row_value
SNAPS BUTTONS VERTICAL column_value  row_value
PROJECT SAVE PANEL column_value  row_value

// Views

PLAN VIEW     column_value  row_value  width    depth  name
```
The following parameters were used for V5.00 but are ignored for V5.0 onward:

SCREEN MESSAGE BOX

XYZ MESSAGE BOX

Continue to the next section 39.2.7.2 Colours File (colours.4d) or return to 39.2.7 Some Special Setup Files.
39.2.7.2 Colours File (colours.4d)

**12d Model** allows the use of up to 10,240 distinct colours for drawing in any view.

The colours are numbered from 0 to 10,239 and the user can define how the colour appears on the screen by giving the red, green and blue intensities (RGB) for each colour, and what name is used throughout the program when referring to a particular colour number.

The *colour names* and RGB mix associated with each colour number, pop up order etc are defined in the file **colours.4d**.

Each line of the file refers to a particular colour number.

There are nine items on each line, each separated by one of more spaces, with an optional comment at the end which is preceded by //.

The items in their order on a colour line are:

1. **red intensity value** - a value between 0 and 255
2. **green intensity value** - a value between 0 and 255
3. **blue intensity value** - a value between 0 and 255
4. **plotter pen number** - 0 or a positive integer
   
   When plotting, the plotter pen number is the default pen number that the colour is mapped to. This may be overridden by a plotter mapping file.

5. **colour name** - the name that can be used instead of the colour number.
   
   The colour name used to describe the colour is given in quotes. Colour names can be alphanumeric with a decimal point, although upper and lower case are considered the same. Each colour must have a unique colour name. If an underscore "_" is used in a colour name in the colours.4d file then a space is inserted in **12d Model**. The colour name must be enclosed within quotes. For example, "dark red".

6. **colour number** - 0 or a positive integer. the actual colour number that the line refers to.
   
   The colour number is the actual colour number that the line refers to and what is actually stored in **12d Model**. A colour numbers can only occur once in the colours.4d file but there can be gaps in the colour numbers.

7. **colour pop-up number**
   
   The colour pop-up number is an integer that can be negative, zero or positive. Colour pop-up numbers can only occur once in the colours.4d file but there can be gaps in the colour pop-up numbers.
   
   The colour pop-up number is used to decide which colours are should in the Colour box. If **Display colours** is set to n in **Project =>Management =>Defaults**, then the colours with the n smallest pop-up numbers are displayed in the Colour box pop-up. So the order that the colours are chosen to appear in the colour pop-up is independent of the colour number.

8. **colour group**

   The colour group is simply text and does not have to be unique. The colour group is enclosed in quotes. For example, "vis".

   The colour group is not currently used in **12d Model** but in the future will be used to give a tree structure to the colours pop-up.

9. **colour legacy name**

   This is another name that the colour number could be known as. This was introduced to allow upward compatibility when going from the colours.4d supplied in v10 to that supplied in v11.

10. // **comment**

    text that is treated as a comment. It must be preceded by //.

The colours.4d file is displayed and modified by using the Edit Colours panel brought up from the
[Edit] item on the Colours pop-up, Select Colour. For more information, go to the section 4.22 Colours.

Continue to the next section 39.2.7.3 Defaults File (defaults.4d) or return to 39.2.7 Some Special Setup Files.
39.2.7.3 Defaults File (defaults.4d)

The `defaults` file, `defaults.4d`, defines the initial default settings used in the 12d Model Default and the Systems Defaults panels.

The `defaults` file can contain:

// general defaults

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT COLOUR</td>
<td>red</td>
</tr>
<tr>
<td>DEFAULT POINT COLOUR</td>
<td>yellow</td>
</tr>
<tr>
<td>DEFAULT TIN COLOUR</td>
<td>brown</td>
</tr>
<tr>
<td>DEFAULT CONTOUR COLOUR</td>
<td>cyan</td>
</tr>
<tr>
<td>DEFAULT CONTOUR INDEX COLOUR</td>
<td>magenta</td>
</tr>
<tr>
<td>DEFAULT TEXT SIZE</td>
<td>8</td>
</tr>
</tbody>
</table>

// view settings

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT CULLING OFF/ON</td>
<td></td>
</tr>
<tr>
<td>DEFAULT CULLING SIZE</td>
<td>1.0</td>
</tr>
<tr>
<td>DEFAULT SECTION VIEW EXAGGERATION</td>
<td>10.0</td>
</tr>
<tr>
<td>DEFAULT PERSPECTIVE VIEW EXAGGERATION</td>
<td>1.0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT FAST TEXT CULL SIZE</td>
<td>4.5</td>
</tr>
<tr>
<td>DEFAULT NONE TEXT CULL SIZE</td>
<td>2.0</td>
</tr>
</tbody>
</table>

// highlighting

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT ANGLE MODE</td>
<td>BEARINGS/DEGREES</td>
</tr>
<tr>
<td>DEFAULT HIGHLIGHT COLOUR</td>
<td>white</td>
</tr>
<tr>
<td>DEFAULT HIGHLIGHT CROSS COLOUR</td>
<td>yellow</td>
</tr>
<tr>
<td>DEFAULT HIGHLIGHT CROSS SIZE</td>
<td>2.0</td>
</tr>
</tbody>
</table>

// drawing points

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT CHORD ARC TOLERANCE</td>
<td>0.1</td>
</tr>
<tr>
<td>DEFAULT POINT CROSS SIZE MMS</td>
<td>2.0</td>
</tr>
<tr>
<td>DEFAULT POINT CROSS SIZE PIXELS</td>
<td>3</td>
</tr>
</tbody>
</table>

// trash model and mode

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT TRASH MODEL</td>
<td>model_name</td>
</tr>
<tr>
<td>DEFAULT TRASH MODE</td>
<td>trash string</td>
</tr>
<tr>
<td></td>
<td>delete string</td>
</tr>
<tr>
<td></td>
<td>keep string</td>
</tr>
</tbody>
</table>

// miscellaneous

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT NAME SETTINGS</td>
<td>file_name</td>
</tr>
</tbody>
</table>

The information panel for each editor can be toggled on/off and the initial state when a new edit operation is begun is given by

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT EDIT INFORMATION</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>

When output report are created, the scripts/programs pointed to by EDITOR_4D and PRINTER_4D will be run depending on the values of the defaults display reports and print reports.

<table>
<thead>
<tr>
<th>Default Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT DISPLAY REPORT FILES</td>
<td>1</td>
</tr>
</tbody>
</table>
Similarly when plots are created, the script/program pointed to by PLOTTER_4D and will be run depending on the value of the default `send plots`

```
DEFAULT PRINT REPORT FILES 1 // run PRINTER_4D
0 // don’t run 

0 // don’t run 
```

Similarly when plots are created, the script/program pointed to by PLOTTER_4D and will be run depending on the value of the default `send plots`.

```
DEFAULT SEND PLOT FILES 1 // run PLOTTER_4D
0 // don’t run 

0 // don’t run 
```

The number of minutes between displays of the `save project` yes-no box is given by

```
DEFAULT SAVE INTERVAL minutes // 0 for never
```

The file defining string colours can have up to 10,240 colours in it however this number is usually inconvenient to display in the standard colour pop-up so there is a setting to set how many colours are displayed from the list.

```
DEFAULT POPUP COLOURS number_of_colours // default 16
```

The precision for displaying real numbers in the information panel and in boxes and panel fields can be set.

```
DEFAULT PRECISION integer // info panel - default 3
DEFAULT BOX PRECISION integer // boxes & panels -default 4
```

The sign for cut areas and volumes can be positive or negative (fill is the opposite) and is given by

```
DEFAULT CUT VOLUME SIGN -1 // negative for cut (default)
1 // positive for cut
```

Text in text string, 4d strings and linestyles may be in pixels and must be given a millimetre size for plotting. Pixel text is multiplied by a factor to convert it to a millimetre size. The pixels to mm plot

```
DEFAULT PIXELS TO MM PLOT FACTOR real // default 1.0
```

Continue to the next section 39.2.7.4 Sheet Sizes File (sheets.4d) or return to 39.2.7 Some Special Setup Files.
39.2.7.4 Sheet Sizes File (sheets.4d)

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named sheets.4d which is in the normal Set Up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D file // file of plotter sheets sizes
```

The layout of the sheet sizes file is

```
// User definition file for sheets sizes in 12d Model
// Heights and widths are in mm.

// sheet name  width  height
A0           1189  841
A1           841   594
A2           594   420
A3           420   297
A4           297   210
B1           1000  707
```

Continue to the next section 39.2.7.5 Transitions and Spirals File or return to 39.2.7 Some Special Setup Files.
39.2.7.5 Transitions and Spirals File

A transition is a means of easing from a straight to a curve (full transition) or from one radius curve to another radius curve (partial transition).

There is often confusion between the words spirals and transition curves come in a variety of formulae and spiral is just one type of transition curve.

See

39.2.7.5.1 Spirals
39.2.7.5.2 Left/Right, Leading/Trailing Transitions
39.2.7.5.3 Transitions/Spirals Supported by 12d Model

39.2.7.5.1 Spirals

A spiral curve (Euler spiral) is a special type of transition where the radius of curvature is proportional to the length along the curve.

That is

\[ \text{Radius of curvature at a point } x \text{ length from start of spiral to that point} = \text{Constant} \]
\[ r_l = K \]

Although the above definition fully defines a spiral (or Euler curve), spiral calculations are difficult by hand and so no authority uses the full definition but uses an approximation to the Euler spiral.

A Euler spiral can be uniquely defined in terms of a start tangent vector, a final radius of curvature (R) and a total spiral length (L).

The equation for this spiral can be given in terms of a local co-ordinate system where the origin is at the start of the spiral and the x-direction (abscissa) is along the tangent vector at the start of the spiral. The y-direction (ordinate) is given as the offset from the x-axis of the point on the spiral.

Formulae for the local co-ordinates of a point on the spiral can then be derived in terms of the distance of the point along the spiral (the spiral length to the point) and the given constants L (the total spiral length) and R (the final radius of curvature of the spiral).

These formulae for the local co-ordinates of a point on the spiral are polynomial series in terms of the spiral length to that point.

For use in calculations, the local co-ordinates can be approximated by restricting the polynomial series for the abscissa and the offset to a fixed number of terms.

So for example, the so called clothoid spiral used by Australian road authorities is defined as using exactly 5 terms for the abscissa (x) polynomial and exactly 4 terms of the offset (y) polynomial.

Note that a spiral is a transition but not all transitions are spirals.

Continue to the next section 39.2.7.5.2 Left/Right, Leading/Trailing Transitions or return to 39.2.7 Some Special Setup Files.
39.2.7.5.2 Left/Right, Leading/Trailing Transitions

The radius of curvature $R$ (or simply the radius) of a transition is allowed to be positive or negative.

To agree convention of going to the left or right when travelling along a road and the sign of the curve radius, the radius of curvature $R$ of a transition is allowed to be positive or negative.

If $R$ is positive, the transition will then curve to the right.

If $R$ is negative, the transition will then curve to the left.

Also depending on the direction of travel along a transition, the absolute radius of curvature will be increasing or decreasing going along the transition.

If the radius is decreasing along the transition, it is called a leading transition.

If the radius is increasing along the transition, it is called a trailing transition.

---

**Leading and Trailing Transitions with Positive Radius**

If the direction of the travel along the string is reversed, the radius of the transitions, and the arc, will be negative and the leading transition become trailing transition and the trailing transition becomes a leading transition.
### Leading and Trailing Transitions with Negative Radius

Continue to the next section 39.2.7.5.3 Transitions/Spirals Supported by 12d Model or return to 39.2.7 Some Special Setup Files.
39.2.7.5.3 Transitions/Spirals Supported by 12d Model

Users must be aware of the exact transition definitions that are to be used in their work.

In Australia, totally different transitions are used by NSW Rail, Queensland Rail and WA Rail.

Luckily all the road authorities in Australia use the same spiral approximation, and that is the same spiral approximation used by Queensland Rail.

So if work is being done in Western Australia or New South Wales, a different transition type is needed in the road alignments from that used in any rail alignments.

The transitions/spirals supported by 12d Model are:

- **Clothoid** - spiral approximation used by Australian road authorities and Queensland Rail.
- **Cubic parabola** – special transition curve used by NSW railways. Not a spiral.
- **Westrail cubic** – spiral approximating used by WA railways.
- **Cubic spiral** – low level spiral approximation. Only ever used in surveying textbooks.
- **Natural Clothoid** – the proper Euler spiral. Not used by any authority.
- **Bloss** – special transition used by Deutsche Bahn. Not a spiral.
- **Sinusoidal** - special transition. Not a spiral.
- **Cosinusoidal** - special transition. Not a spiral.

Return to 39.2.7 Some Special Setup Files.
39.2.7.6 GUI

**Note** - this section is only for versions earlier than V4.0 and is here for historical reasons

The file *gui.4d* defined the colours used for screen objects (the graphical user interface objects), screen fonts, maximum pop-up length, and spacing in the menus and panels.

The *gui.4d* file is read every time a project (new or old) is opened.

### 39.2.7.6.1 GUI Colours

The colours associated with each screen object are given in terms of intensity values of red, green and blue. The intensity values are between 0 and 255, where 0 represents no colour and 255 full colour.

The layout for screen colours in the *gui.4d* file is:

```plaintext
// object RGB values- red green blue
VIEW BACKGROUND COLOUR   0    0     0  // black
VIEW BORDER COLOUR        255  255    0 // yellow
BUTTON HIGHLIGHT COLOUR   255  255    0 // yellow
BUTTON TEXT COLOUR        127  127    127 // grey
BUTTON BACKGROUND COLOUR  60    60    200 // dark blue
MENU BACKGROUND COLOUR    150   90     0 // brown
MENU BORDER COLOUR        255  255    0 // yellow
PANEL BACKGROUND COLOUR   150   90     0 // brown
PANEL BORDER COLOUR       255  255    0 // yellow
FRONT SCREEN LOGO COLOUR  255  255    0 // yellow
FRONT SCREEN TEXT COLOUR  0    255    0 // green
FRONT SCREEN BACKGROUND COLOUR 60   60    200 // dark blue
WINDOW BACKGROUND COLOUR 1  64   128     0 // half green
WINDOW BACKGROUND COLOUR 2  0   128   196 // cyan
```

### 39.2.7.6.2 Maximum Pop-Up Length

The maximum number of items in a pop-up list before splitting into walk-right pop-ups is given by (necessary when using VGA screens on PC’s)

```plaintext
POPUP LENGTH integer //maximum number of items in a pop-up
```

### 39.2.7.6.3 Fonts for Menus and Panels

A font can be defined for use in the menu and panel titles areas and a separate font for the rest of the text in the menus and panels.

The fonts are defined in the *gui.4d* file as:

```plaintext
SYSTEM TITLE FONT font_name // font for titles
SYSTEM FONT font_name // font used elsewhere
```

For X-Windows, the `font_name` is the name of the required font from the font list given by the command `xlsfonts`.

For Windows NT, the `font_name` is made up of the Windows font name plus zero or more parameter values for the font.

The font name and parameter values are given as one text name, `font_name`, by concatenating the font name and values with only a minus separating them.
If the font name consists of more than one word, the font name is enclosed in double quotes (").

Hence for NT, an example of defining fonts is:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Font</td>
<td>font name (less than 32 characters)</td>
</tr>
<tr>
<td>Height</td>
<td>number</td>
</tr>
<tr>
<td>italic</td>
<td></td>
</tr>
<tr>
<td>underline</td>
<td></td>
</tr>
<tr>
<td>strikeout</td>
<td></td>
</tr>
<tr>
<td>Weight</td>
<td>thin extralight light normal medium semibold bold extrabold heavy</td>
</tr>
<tr>
<td>Quality</td>
<td>draft proof</td>
</tr>
<tr>
<td>Pitch</td>
<td>default_pitch fixed_pitch variable_pitch</td>
</tr>
<tr>
<td>Family</td>
<td>decorative modern roman script swiss</td>
</tr>
</tbody>
</table>

**Defaults**

- Height 14
- Weights fw_dontcare (family weight don't care)
- Pitch font default pitch
- Family ff_dontcare (font family don't care)
- Quality default_quality
- italic false
- underline false
- strikeout false

For example:

- Arial-14-bold-italic is the font Arial, of height 14 and bold and italic
- "Courier New"-16-italic is the font Courier New, of height 16 and bold.

Under NT, if the font is not properly defined or doesn't exist, then the system font is used.

Under X-Windows, if the font does not exist, the font fixed is tried. If fixed does not exist, 12d Model will not start up.

### 39.2.7.6.4 Spacing for Borders and Panels

There are parameters to control the amount of space in border, between items etc. for menus and borders. These are normally set by 12D Solutions and should not need to be modified.

- SCREEN TEXT BORDER X pixels
- SCREEN TEXT BORDER Y pixels
- SCREEN TEXT EXTRA X pixels
- SCREEN TEXT EXTRA Y pixels
- EDIT BOX BORDER X pixels
- EDIT BOX BORDER Y pixels
- PANEL BORDER X pixels
- PANEL BORDER Y pixels
- PANEL GAP Y pixels
- VERTICAL BORDER X pixels
- VERTICAL BORDER Y pixels
- VERTICAL GAP Y pixels
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>HORIZONTAL BORDER X</td>
<td>pixels</td>
</tr>
<tr>
<td>HORIZONTAL BORDER Y</td>
<td>pixels</td>
</tr>
<tr>
<td>HORIZONTAL GAP Y</td>
<td>pixels</td>
</tr>
<tr>
<td>INPUT BOX BORDER X</td>
<td>pixels</td>
</tr>
<tr>
<td>INPUT BOX BORDER Y</td>
<td>pixels</td>
</tr>
</tbody>
</table>
39.3 Library, User Library, Customer Library

Apart from Setting Up files which are only accessed when a project is opened or first created, there are two or three special library areas that are searched for files with the appropriate file ending whenever the folder icon at the end of a panel file field is selected. For example, clicking on the folder icon for a Map File panel field would display a list of files ending in .mapfile and .mf.

One folder, Library, is supplied by 12d Solutions Pty Ltd and is installed by 12d Model, and two other folders, User_Lib and Customer_Lib are not touched in an install and only contains files placed there by users.

39.3.1 Library

In a manner similar to the folder set_ups, the location of Library can be modified defining the environment variable

LIB_4D

If the environment variable LIB_4D doesn’t exist, or the folder it points to doesn’t exist, then the folder Library installed by 12d as Program files\12d\12dmodel\11.00\Library is used.

The files of the required ending in library are listed under the [Lib] walk right of pop-ups.

39.3.2 User Library

Because most users do not have write access to Program files\12d\12dmodel\11.00\Library, and the fact that any files in that area may be deleted or overwritten by future 12d Model installations, there is a special user library folder called User_lib where user library files should be placed.

The user library, is also a folder and is pointed to by the environment variable

USER_LIB_4D

or if the environment variable USER_LIB_4D or the folder that it points to doesn’t exist, in a folder called User_lib directly under the user accessible area C:\12d\11.00

The files from the User library are listed under the [User Lib] walk right of the pop-up.

So unlike the files in the folders set_ups or user, files in the 12d supplied area Library and the user file in User_lib, are all displayed.
39.3.3 Customer Library

There is one more folder that is only looked for when it has been created by a user and is pointed to by the environment variable CUSTOMER_LIB_4D. It has no default name but is whatever name the user gave it. For convenience, we will call it Customer_lib.

So the customer library, is also a folder and is pointed to by the environment variable CUSTOMER_LIB_4D

If the environment variable CUSTOMER_LIB_4D or the folder that it points to doesn’t exist, then no Customer Library is used.

The files from the Customer library are listed under the [Customer Lib] walk right of the pop-up.

So unlike the files in the folders set_ups or user, files in the 12d supplied area Library and the users files in User_lib and Customer_lib, are all displayed.

Notes
1. The list of special endings for files is given in the Appendix, Special File Formats.
2. A full list of environment variables is given in the later section 39.4 Environment Variables.

Please continue to the next section 39.4 Environment Variables.
39.4 Environment Variables

When **12d Model** is invoked for a new or existing project, it uses environment variables to tailor the system.

In Windows, environment variables can be set for each User from the Control Panel, but a much easier method to set the environment variables used by **12d Model** is to include them in a special file which is read in each time a project (new or existing) is opened by **12d Model**.

The environment variables that **12d Model** recognises can be broken into two types

(a) mode type where the environment variable is only a flag setting a mode

and

(b) a second type which point to a file, program or folder. For the environment variables of the second type, a default file/program is often searched for if the environment variable is not defined.

The folder search order for the default files for the file group of environment variables is given in the previous sections.

The list of environment variables will be given in alphabetical order but it will be obvious from the documentation which type the environment variable is.
39.4.1 Alphabetical Environment Variables List

For environment variables that simply set a flag or value (the default value is shown in bold), the documentation will be:

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Value</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
</table>

For environment variables that point to a file, program or folder, and their associated default files/programs, the documentation will be:

<table>
<thead>
<tr>
<th>Environment Variable Name</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
</table>

Environmental Variables List

ACAD_SEEDFILES_4D

ACAD_SEEDFILES_4D folder no default
if not blank, the full path name of the folder holding Autocad template files.

ADAC_VERSION_4D

ADAC_VERSION_4D text
the ADAC Schema version, e.g. 4.1.0 or 4.0.0

ALIGNMENT_CORRIDOR_FIXUP_4D

ALIGNMENT_CORRIDOR_FIXUP_4D value 0 or 1 default 1
if not zero, alignment corridor calculations introduced in V8 are used.
If zero, the V7 alignment corridor calculations are used.

ALLOW_ANONYMOUS_FUNCTIONS_4D

ALLOW_ANONYMOUS_FUNCTIONS_4D value 0 or 1
if tick, when a file is read with a File input option, a function is automatically created and named.
This function must exist to allow data to be added to a view after it is read in, to be able to delete all the data read in at a later time, and to re-run the function to reread the data file and replace the data read in last time.

ALLOW_NAMED_POINT_ATTRIBUTES_4D

ALLOW_NAMED_POINT_ATTRIBUTES_4D value 0 or 1

ALLOW_OLD_PLOTTING_4D

ALLOW_OLD_PLOTTING_4D value 0 or 1
If not zero, then a menu Plot =>Old plotting is included which has all the old text ppf options.

ALLOW_SUPER_TINS_EXACT_CALCS_4D

ALLOW_SUPER_TINS_EXACT_CALCS_4D value 0 or 1
Options using tins are split into two categories:
(1) options that require sections through tins
(2) options that require the triangles of the tin
if ticked, this allows super tins to be used in options where triangles are required for calculations.
if not ticked, this prevents super tins to be used in options where triangles are required for calculations.

Note: ticking this option requires super tins to be updated when a tin within the super tin changes, so
there is a time, storage, and memory cost. It was found that some projects only ever required options that used sections (not triangles), so for these type of projects, there is an efficiency gain by turning off this option.

**ALWAYS_VALIDATE_PROJECTDETAILS_4D**

if ALLOW_ANONYMOUS_FUNCTIONS_4D is set to 1, then when a file is read with a File input option, a function is automatically created and named. This function can be used to delete all the data at a later time, to allow the data to be added to a view after it is read in, and to re-run the function to reread in the data file.

**ASK_ON_CHAIN_COMMAND_DELETE_4D**

**AUTHORIZATION_4D**

The authorization file is normally called *nodes.4d*, and is under the folder `c:\12d\model\version_number`. However, the file name and path can be set by the user with the AUTHORIZATION_4D environment variable.

The full path-name of the file is given.

**AUTO_CERTIFY_DONGLE_4D**

if non zero, then when the warning period is active for the CodeMeter Container (dongle) being used by 12d Model, 12d Model will automatically attempt to certify the dongle and if successful, no intervention by the user is required. See 7.6.5.4 Certify CodeMeter.

Note that the computer must have internet access for Certification to take place.

**AUTO_DELETE_WALKRIGHTS_4D**

If not zero, the environment variable AUTO_DELETE_WALKRIGHTS_4D sets the distance in pixels that is used to collapse the cascade of walk-right menus when the cursor moves that distance past the end of the last walk-right menu.

The default value is 32.

**AUTO_HIDE_PANEL_SELECTS_4D**

This mode was introduced so that the panel was not in the way when selecting a string. It is particularly useful on tablets with limited screen area.

**AUTO_MODEL_SYNC_4D**

if auto-model sync is set to on, the server projects for any shared models added to this project are checked to see if they have been modified (checked every SHARE_CHECK_INTERVAL seconds). If any models have been modified, they are re-copied to this project.
AUTO_PAN_SELECT_4D
AUTO_PAN_SELECT_4D value 0 or 1 default 1
if non zero, if you have accepted but not accepted a string and are zoomed in on the strings and type ch value where the position at that chainage is off the view, the view will autopan so that the new selection point (at chainage value) is on the view. This applies for all typed selects.

AUTO_RESET_SELECT_4D
AUTO_RESET_SELECT_4D 0 Don’t use auto-reset reselect
1 Use auto-reset reselect

The reset mechanism for picking has been modified for V5.0 and above. Reset is now done automatically if the cursor is moved a user specified distance (given by AUTO_RESET_TOLERANCE_4D) after a pick (without accepting), and a separate user specified distance (given by AUTO_RESET_DRAG_TOLERANCE_4D) after a directional pick (without accepting).

The default value is 1.

AUTO_RESET_SELECT_DRAG_TOLERANCE_4D
AUTO_RESET_SELECT_DRAG_TOLERANCE_4D value
Reset distance for directional picks.

If AUTO_RESET_SELECT_4D is non zero, then AUTO_RESET_SELECT_DRAG_TOLERANCE_4D is the distance in pixels to move the cursor to reset the picking rejection list for a directional pick.

The default value is 50.

AUTO_RESET_TOLERANCE_4D
AUTO_RESET_TOLERANCE_4D value
Reset distance for non-directional picks.

If AUTO_RESET_SELECT_4D is non zero, then AUTO_RESET_TOLERANCE_4D is the distance in pixels to move the cursor to reset the picking rejection list for a non-directional pick.

The default value is 5.

AUTO_TIN_SYNC_4D
AUTO_TIN_SYNC_4D 0 Don’t auto sync tins default 0
1 Auto sync tins

if auto-tin sync is set to on, the server projects for any shared tins added to this project are checked to see if they have been modified (checked every SHARE_CHECK_INTERVAL seconds). If any tins have been modified, they are re-copied to this project.

AUTOCAD_PATTERNS_4D
AUTOCAD_PATTERNS_4D folder no default
if non blank, the full path name of the AutoCAD patterns file.

BISECTORS_4D
BISECTORS_4D 0 Don’t use bisector section default 0
1 Use bisector section

When applying templates to a horizontal intersection point with a sharp change of direction, (that is, it is not an end point and the HIP has no curve on it and there is a change of direction at the HIP), either two sections can be applied at the HIP point (applied perpendicular to the line on either side of the HIP point) or just a single bisector section applied to the bisector of the change of angle through the HIP.
The default value is 0.

**BOXING_CONTINUE_ON_FAIL_4D**

**BOXING_CONTINUE_ON_FAILURE_4D**

value 0 or 1  
**default** 0

if non zero, the boxing stops if there is an error such as not being able to intersect with a tin. 
If zero, the boxing stops when an error is found.

**BOXING_RULES_COLOUR_4D**

**BOXING_RULES_COLOUR_4D**

colour  
**default** blue

the colour of the text in the Type column in the Boxing Rules panel for all Boxing command other than Comment, Decision, Goto and Labels.

**BOXING_COMMENT_COLOUR_4D**

**BOXING_COMMENT_COLOUR_4D**

colour  
**default** yellow

background colour for the Comment boxing command grid row in the Boxing Rules panel. The text in the grid row is black.

**BOXING_DECISION_GOTO_COLOUR_4D**

**BOXING_DECISION_GOTO_COLOUR_4D**

colour  
**default** mauve

the colour of the text in the Type column for the Decision and Goto commands in the Boxing Rules panel.

**BOXING_LABEL_COLOUR_4D**

**BOXING_LABEL_COLOUR_4D**

colour  
**default** light red

the colour of the text in the Type column for the Label command in the Boxing Rules panel.

**BOXING_REGION_COLOUR_4D**

**BOXING_REGION_COLOUR_4D**

colour

the colour of the text in the row for the Region command in the Boxing Rules panel.

**BOXING_WALL_OFFSET_4D**

**BOXING_WALL_OFFSET_4D**

real  
**default** 0.000001

when boxing automatically creates a vertical wall, this is the offset distance between the top and bottom of the vertical wall.

**CAD_START_IN_MULTI_PICK_4D**

**CAD_START_IN_MULTI_PICK_4D**

tick box

**CHECK_FOR_UPDATES_4D**

**CHECK_FOR_UPDATES_4D**

integer

if non zero, the 12d web site is checked on startup for any newer updates to **12d Model**.
If zero, the 12d web site is not checked.

**CIVILCAD_PATH_4D**

**CIVILCAD_PATH_4D**

folder  
no default

if non blank, the full path name of the folder holding CivilCAD files.

There is no default.

**COLOURS_4D**

**COLOURS_4D**

filename  
**default** colours.4d
file of colour rgb definitions and names. See 39.2.7.2 Colours File (colours.4d).
The default is colours.4d.

CONSTRUCTION_SNAP_MODEL_4D

CONSTRUCTION_SNAP_MODEL_4D model name
If non blank, the model to use for objects created during construction snaps.

CUBED_CHARACTER_4D

CUBED_CHARACTER_4D integer (base 10) default 179
The integer (base 10) value of the character to use as the cubed symbol.

CUSTOMER_LIB_4D

CUSTOMER_LIB_4D folder name no default name
if the environment variable exists and the folder exists, then the folder is available when selecting
a library file (see 39.3 Library, User Library, Customer Library).
There is no default folder name.

CUSTOMER_USER_4D

CUSTOMER_USER_4D folder name no default name
if the environment variable exists and the folder exists, then the folder is part of the search for
locating setup files (see 39.2 Files for Setting Up 12d).
There is no default folder name.

CUT_HEIGHT_ZONE_COLOUR_4D

CUT_HEIGHT_ZONE_COLOUR_4D colour default dark red
the colour of the text in the Type column for the Cut commands involving height, in the Modifiers
section of the Left/Right MTF Modifiers panel.

CUT_WIDTH_ZONE_COLOUR_4D

CUT_WIDTH_ZONE_COLOUR_4D colour default light red
the colour of the text in the Type column for the Cut commands involving width, in the Modifiers
section of the Left/Right MTF Modifiers panel.

CUT_SLOPE_ZONE_COLOUR_4D

CUT_SLOPE_ZONE_COLOUR_4D colour default dark red
the colour of the text in the Type column for the Cut commands involving slope, in the Modifiers
section of the Left/Right MTF Modifiers panel.

CUT_ZONE_COLOUR_4D

CUT_ZONE_COLOUR_4D colour default red
the colour of the text in the Type column for the Cut commands (other than those involving width,
high or slope) in the Modifiers section of the Left/Right MTF Modifiers panel.

DATA_COLLECTOR_4D

DATA_COLLECTOR_4D data collect name
the data collector that is used if no data collector is set for a project.
There is no default.

DATA_COLLECTORS_4D

DATA_COLLECTORS_4D filename default survey.4d
file of definitions of available data collectors
The default is survey.4d.

**DATA_TIPS_4D**

<table>
<thead>
<tr>
<th>DATA_TIPS_4D</th>
<th>0</th>
<th>Don’t show data tips</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>Show data tips</td>
</tr>
</tbody>
</table>

When non zero, data tips are displayed when the cursor moves over vertices in a plan view.
The default value is 0.

**DEBUG_DONGLE_ACCESS_4D**

**DEBUG_DONGLE_ACCESS_4D** positive integer
time between searches for a dongle

**DECISION_ZONE_COLOUR_4D**

**DECISION_ZONE_COLOUR_4D** colour default green
the colour of the text in the Type column for the Decision commands in the Modifiers section of the Left/Right MTF Modifiers panel.

**DEFAULTS_4D**

**DEFAULTS_4D** filename default defaults.4d
file of defaults - only used for new project
The default is defaults.4d. See 39.2.7.3 Defaults File (defaults.4d).

**DEFAULT_PLAN_PLOT_SCALE_4D**

**DEFAULT_PLAN_PLOT_SCALE_4D** value
value is the scale (1:value) for new plan views
If a value is given, then it is used the default scale for any new plan view created in a project.
Note that the scale is used in the plan view for displaying text, linestyles and symbols that have been defined in paper units.

**DEFAULT_RASTER_DPI_4D**

**DEFAULT_RASTER_DPI_4D** real_dots_per_inch
default dots per inch to use for plotting rasters
The default value is 150.0

**DEFAULT_TABLE_WIDTH_4D**

**DEFAULT_TABLE_WIDTH_4D** number_of_characters default 32
Gives the number of characters displayed in tables such as decisionals and mtf editor.
The default value is 32.

**DEFAULT_VIEW_COLOUR_4D**

**DEFAULT_VIEW_COLOUR_4D** colour_number default 0
The default background colour for views.

**DEGREES_CHARACTER_4D**

**DEGREES_CHARACTER_4D** integer (base 10) default 176
The integer (base 10) value of the character to use as the degrees symbol.
DGN_PLOT_SEED_FILE_4D
DGN_PLOT_SEED_FILE_4D filename
if non blank, the full path name of the file to use as a seed file for Microstation plots.

DIAMETER_LARGE_CHARACTER_4D
DIAMETER_LARGE_CHARACTER_4D integer (base 10) default 216
The integer (base 10) value of the character to use as the large diameter symbol.

DIAMETER_SMALL_CHARACTER_4D
DIAMETER_SMALL_CHARACTER_4D integer (base 10) default 248
The integer (base 10) value of the character to use as the small diameter symbol.

DIGITIZERS_4D
DIGITIZERS_4D filename default digitize.4d
file of digitizer definitions
The default is digitize.4d. See 8.5.7 Digitizer Definitions File.

DISABLE_MTF_WARNINGS_4D
DISABLE_MTF_WARNINGS_4D 0 Display the mtf warnings in the text editor
1 Write mtf warnings to the background window
Controls whether the mtf warnings go to a file or to the output window.
If non zero, write mtf warnings to the background window
If zero, display the mtf warnings in the text editor.
The default value is 0.

DONGLE_4D - no longer used

Important Note: this environment variable is not used for 12d Model 11 and above.
Hardlock dongles will not work for 12d Model 11 and above so this environment variable is ignored by these versions of 12d Model.
The environment variable can have a number of parameters to control the use of Hardlock network and stand alone dongles.
(a) DONGLE_4D -local OR -no_local
usually used when there is a network dongle and need to know if any stand alone Hardlock dongle is to be looked for on the computer that the user is on.
if -local, then a stand alone Hardlock dongle is looked for on the computer the user is on.
If -no_local, then no stand alone Hardlock dongle is looked for on the computer the user is on.
For example DONGLE_4D - local or -no local
(b) DONGLE_4D -no network OR -network first OR -network last
need to specify if any network Hardlock network dongle is to be looked for.
if -no network, then no Hardlock network dongle is looked for.
If -network first, then a Hardlock network dongle is looked for before a stand alone local dongle.
If -network last, then a Hardlock network dongle is looked for after looking for a stand alone local dongle.
For example DONGLE_4D -no_network or - network_first or -network_last
(c) DONGLE_4D -login_retries number of retries to find a Hardlock dongle
the number nn of retries to make when searching for a Hardlock dongle and it is not found.
For example  DONGLE_4D -login_retries 3
(d) **DONGLE_4D** -login_wait ss
the number of seconds **ss** to wait between retries to find a network Hardlock dongle.
For example **DONGLE_4D** -login_wait 5

(e) **DONGLE_4D** -no_dongle
if the parameter -no_dongle is found, then no search is made for a Hardlock dongle.
For example **DONGLE_4D** -no_dongle

(f) **DONGLE_4D** -debug
if the parameter -debug is found, then Hardlock dongle debug information is written to the
For example **DONGLE_4D** -debug

See the separate notes on installing a network dongle for more details.

**DONGLE_ORDER_4D** - no longer used

**Important Note:** this environment variable is not used for **12d Model 11** and above.
Hardlock dongles will not work for **12d Model 11** and above so this environment variable is ignored by these versions of **12d Model**.

**DONGLE_ORDER_4D** choice box Hardlock/Wibu, Wibu/Hardlock
the order to search for network dongles.
If **Wibu/Hardlock**, then Wibu networks dongles are searched for before any Hardlock dongles.
If **Hardlock/Wibu**, then Hardlock networks dongles are searched for before any Wibu dongles.
All new dongles are Wibu so most **12d Model** sites now only have Wibu dongles.

**DONGLES_4D**
**DONGLES_4D** full path name to dongles.4d
The dongles file is normally called **dongles.4d** and is searched for as a Set Up file. However, the
file name and path can be set by the user with the **DONGLES_4D** environment variable.
The full path-name of the file is then given.

**DOUBLE_CONFIRM_DELETE_4D**

**DOUBLE_CONFIRM_DELETE_4D** 0 Confirm deletes/cleans without undos once
1 Confirm deletes/cleans without undos twice

Controls whether or not the user is asked once or twice to confirm that deletes and cleans that do not have undos are to be done.
If non zero, the user is asked twice to confirm for deletes and cleans.
If zero, the user is asked once to confirm for deletes and cleans.
The default value is 1.

**DRAFTING_SPLIT_MESSAGE_4D**

**DRAFTING_SPLIT_MESSAGE_4D** 0 Confirm deletes/cleans without undos once
1 Confirm deletes/cleans without undos twice

If non zero, for CAD Dimensions, Leaders and Tables, long messages that are written to the screen message area are broken up into two shorter lines with the first one being displayed. Both the shorter lines have a (m)ore on them to get to the other line. However all the typed commands for the options are still recognised regardless of whether they are visible or not in the split message.
If zero, the messages are not split into two lines.
The default value is 0.
Environment Variables

DRAINAGE_4D
DRAINAGE_4D filename default drainage.4d
file of definitions for the drainage option
The default is drainage.4d.

DRAINAGE_EDIT_GRADE_4D
DRAINAGE_EDIT_GRADE_4D tick box

DRAINAGE_PPF_4D
DRAINAGE_PPF_4D full path name of .ppf file no default
Points to the file used as the default plot parameter file (.ppf) for the panel New Plot Drainage Network.
The path name to the .ppf file can contain $LIB which expands out to the path of the library area.
For example, $LIB/drainage.ppf points to the file drainage.ppf in the area defined by $LIB_4D.

DRAINAGE_FLOW_DIR_4D
DRAINAGE_FLOW_DIR_4D 0 Flow direction is opposite to the string direction
1 Flow direction is the same as string direction
Defines the default flow direction used in the creating a drainage string.
The environment variable DRAINAGE_FLOW_DIR_4D specified whether the default flow direction that appears in the Create Drainage String panel is that the flow direction in the line is in the same direction as the direction of the drainage string (ascending chainage) or that the flow direction in the drainage line is in the opposite direction to the direction of the drainage string (descending chainage).

If non zero, the drainage flow direction is the same as the string direction.
If zero, the drainage flow direction is in the opposite direction to the string direction.
The default value is 0.

DWG_PLOT_SEED_FILE_4D
DWG_PLOT_SEED_FILE_4D filename
if non blank, the full path name of the file to use as a template file for AutoCAD plots.

DWG_PLOT_UNIT_4D
DWG_PLOT_UNIT_4D English OR Metric
if non blank, the units to use for AutoCAD files.

EDIT_BOX_WIDTH_IN_CHARACTERS_4D
EDIT_BOX_WIDTH_IN_CHARACTERS_4D number default 10
if non blank, the number of characters to make the width of an Edit Box on a panel.

EDITOR_4D
EDITOR_4D script/program 10.00\cpu_area\te
the script or program that is fired up when a report is created. It usually points to an editor.
If the parameter display reports in the panel sys default settings (given by the menu option Utilities => Default=>Sys defaults) is set to yes, the editor displays each report as it is created.
The default is 10.00\cpu_area\te.

ENVIRONMENT_4D
ENVIRONMENT_4D full path name of file default env.4d
It is possible to set all the environment variables from a file normally called env.4d. The environment variable file is searched for in the standard Set Up areas (local, USER_4D, user, set_ups) or is set by the environment variable ENVIRONMENT_4D.

The default is env.4d.

The format of the environment variable file is given in the section 39.4.2 Setting Environment Variables.

**EXTRA_OPTIONS_4D**

**EXTRA_OPTIONS_4D** file default xtramenu.4d

If non blank, the full path name of the 12d Solutions supplied file of definitions for some extra menus.

The default is xtramenu.4d. See 41.2 User Defined Menus

**EXTRA_START_END_MTF_4D**

**EXTRA_START_END_MTF_4D** 0 extra start/end on default 1

1 extra start/end on

Used in the Modifiers section of the MTF.

If EXTRA_START_END_MTF_4D =1, then the Extra start and Extra end tick boxes on the MTF panels are ticked.

If EXTRA_START_END_MTF_4D =0, then the Extra start and Extra start tick boxes on the MTF panels are not ticked.

The default value is 1.

**EXTRUSIONS_4D**

**EXTRUSIONS_4D** filename default extrusions.4d

This points to the file which contains the definition of the extrusions in the Extrusions Library. Please see 12.13.6 Extrusions for more information about extrusions.

The default is extrusions.4d.

**FAST_ACCEPT_4D**

**FAST_ACCEPT_4D** 0 don’t set fast accept snap to on for new projects default 0

1 set fast accept snap on for new projects

If non zero, the Fast Accept snap (A snap) is turned on by default for new projects.

If fast accept is turned on, then when an item is picked and there is only one item in the selection list, that item is automatically selected without clicking MB.

**FAST_CONSTRUCTION_SNAPS_4D**

**FAST_CONSTRUCTION_SNAPS_4D** 0 don’t set construction snap to on for new projects default 0

1 set construction snap to on for new projects

If non zero, the Fast Construction snap (K snap) is turned on by default for new projects.

The default value is 0.

**FAST_ZOOM_PAN_4D**

**FAST_ZOOM_PAN_4D**

**FLD_IGNORE_XTRA_WORDS_4D**

**FLD_IGNORE_XTRA_WORDS_4D** 0,1

If non zero, trailing tabs are not considered words in a field file. Mainly for Leica when it is writing a format file which can’t suppress trailing tabs when writing a 12d Field file.

The default value is 0.
FILE_READ_ADD_TO_VIEW_4D

FILE_READ_ADD_TO_VIEW_4D choice box
if anonymous function are set, the data created by the File input option can be added to a view. The choices are:

Do nothing - don’t add the data read in to any view
Add to current view - add the data read in to the current view (the current view is the view that highlighted)
Add to new view - automatically create a new view and add the data read in to that view
Add to named view - add the data read in to the view given by FILE_READ_ADD_TO_VIEW_NAME_4D

FILE_READ_ADD_TO_VIEW_NAME_4D

FILE_READ_ADD_TO_VIEW_NAME_4D text box
name of the view to use if FILE_READ_ADD_TO_VIEW_4D is set to Add to named view. If the view does not exist then it is created.

FILL_HEIGHT_ZONE_COLOUR_4D

FILL_HEIGHT_ZONE_COLOUR_4D colour default dark green
the colour of the text in the Type column for the Fill commands involving height, in the Modifiers section of the Left/Right MTF Modifiers panel.

FILL_SLOPE_ZONE_COLOUR_4D

FILL_SLOPE_ZONE_COLOUR_4D colour default dark green
the colour of the text in the Type column for the Fill commands involving slope, in the Modifiers section of the Left/Right MTF Modifiers panel.

FILL_WIDTH_ZONE_COLOUR_4D

FILL_WIDTH_ZONE_COLOUR_4D colour default light green
the colour of the text in the Type column for the Fill commands involving width, in the Modifiers section of the Left/Right MTF Modifiers panel.

FILL_ZONE_COLOUR_4D

FILL_ZONE_COLOUR_4D colour default green
the colour of the text in the Type column for the Fill commands (other than those involving width, height or slope) in the Modifiers section of the Left/Right MTF Modifiers panel.

FINAL_CUT_SLOPE_ZONE_COLOUR_4D

FINAL_CUT_SLOPE_ZONE_COLOUR_4D colour default black
the colour of the text in the Type column for the Final command for Final Cut slope, in the Modifiers section of the Left/Right MTF Modifiers panel.

FINAL_FILL_SLOPE_ZONE_COLOUR_4D

FINAL_FILL_SLOPE_ZONE_COLOUR_4D colour default black
the colour of the text in the Type column for the Final command for Final Fill slope, in the Modifiers section of the Left/Right MTF Modifiers panel.

FINAL_NO_CUT_SLOPE_ZONE_COLOUR_4D

FINAL_NO_CUT_SLOPE_ZONE_COLOUR_4D colour default black
the colour of the text in the Type column for the Final command for No Cut slope, in the Modifiers section of the MTF Modifiers panel.
FINAL_NO_CUT_FILL_SLOPE_ZONE_COLOUR_4D
   FINAL_NO_CUT_FILL_SLOPE_ZONE_COLOUR_4D colour default dark brown
   the colour of the text in the Type column for the Final commands for No cut/fill, in the Modifiers section of the MTF Modifiers panel.

FINAL_NO_FILL_SLOPE_ZONE_COLOUR_4D
   FINAL_NO_FILL_SLOPE_ZONE_COLOUR_4D colour default black
   the colour of the text in the Type column for the Final command for No Fill slope, in the Modifiers section of the MTF Modifiers panel.

FINAL_WIDTH_ZONE_COLOUR_4D
   FINAL_WIDTH_ZONE_COLOUR_4D colour default light brown
   the colour of the text in the Type column for the Final commands involving width, in the Modifiers section of the MTF Modifiers panel.

FINAL_ZONE_COLOUR_4D
   FINAL_ZONE_COLOUR_4D colour default brown
   the colour of the text in the Type column for the Final commands (other than those involving width or slope) in the Modifiers section of the MTF Modifiers panel.

FIXED_DECISION_ZONE_COLOUR_4D
   FIXED_DECISION_ZONE_COLOUR_4D colour
   the colour of the text in the Type column for the Fixed Decision commands in the Left/Right MTF Modifiers panel.

FIXED_HEIGHT_ZONE_COLOUR_4D
   FIXED_HEIGHT_ZONE_COLOUR_4D colour default dark blue
   the colour of the text in the Type column for the Fixed commands involving height, in the Modifiers section of the Left/Right MTF Modifiers panel.

FIXED_WIDTH_ZONE_COLOUR_4D
   FIXED_WIDTH_ZONE_COLOUR_4D colour default light blue
   the colour of the text in the Type column for the Fixed commands involving width, in the Modifiers section of the Left/Right MTF Modifiers panel.

FIXED_XFALL_ZONE_COLOUR_4D
   FIXED_XFALL_ZONE_COLOUR_4D colour default dark blue
   the colour of the text in the Type column for the Fixed commands involving xfall, in the Modifiers section of the Left/Right MTF Modifiers panel.

FIXED_ZONE_COLOUR_4D
   FIXED_ZONE_COLOUR_4D colour default blue
   the colour of the text in the Type column for the Fixed commands in the Modifiers section of the Left/Right MTF Modifiers panel.

FONTS_4D
   FONTS_4D filename default fonts.4d
   font definitions
   The default is fonts.4d. See 40.3 Textstyles and Fonts

FULL_HYDRAULIC_REPORT_4D
Environment Variables

**FULL_HYDRAULIC_REPORT_4D** 0, 1  default 0

The rational hydraulic report contains hydrology data. If non zero, the hydrology calculations for each catchment set (1 to 3) are written to the hydraulic report.

**FUNCTION_KEYS_4D**

FUNCTION_KEYS_4D  filename  default userkeys.4d

function key definitions

The default is userkeys.4d. See [41.1 User Defined Function Keys](#).

**GENIO_WILDCARD_4D**

GENIO_WILDCARD_4D  text  default *.mos

Sets the ending of the files selected for the pop-up list for the File field in the Read Genio Data panel.

The default value is "*.mos".

**GIS_ARCSDE_PATH_4D**

GIS_ARCSDE_PATH_4D  filename  the full path name to the ArcSDE DLL. This is only required when using the ArcSDE Server.

**GIS_ORACLE_PATH_4D**

GIS_ORACLE_PATH_4D  filename  the full path name to the Oracle DLL. This is only required when using the Oracle Server.

**GUI_4D**

GUI_4D  Standard  default Standard

Non Standard

Defines the mouse button usage within 12d Model. The default value is Standard.

**GUI_COLOURS_4D**

GUI_COLOURS_4D  filename  default gui.4d

file of colour definitions used in the GUI

The default is gui.4d. See [39.2.7.6 GUI](#).

**HARDLOCK_4D**

HARDLOCK_4D 1, 0

if non zero, search for 12d Hardlock dongles.

If zero, don’t search for Hardlock dongles

**HARDWARE_ARCS_4D**

HARDWARE_ARCS_4D 1  Use hardware arcs  default 1

0  Hardware arcs are not used

if non zero, use computer hardware to draw arcs (rather than software).

If zero, draw arcs in software

The default value is 1.

**HEIGHT_MAX_DEFAULT_4D**

HEIGHT_MAX_DEFAULT_4D  integer (world units)  default 0
set the default value to use in Plan Settings panels that have a **Height max (w)** field.

**HELP_4D**

HELP_4D  folder  default 11.00\help

folder containing the 12d Model help files.

The default is **11.00\help**.

**HELP_BUTTONS_4D**

HELP_BUTTONS_4D  0  Disable help buttons on panels

1  Enable help buttons on panels.

If non zero, **Help** buttons are added to panels.

The default value is **0**.

**HIMETRIC_4D**

HIMETRIC_4D  0  Printer resolution of 0.04 mm - for Win 95,98,ME default 0

1  Printer resolution of 0.01 mm - for Win NT, 2000, XP

For Windows 95, 98 and ME, the printer resolution can only be 0.04 mm when covering an A0 sheet.

Under Windows NT, 2000 and XP, no such restriction exists and the full resolution of 0.01 mm can be used so the environment variable HIMETRIC_4D allows access to the higher resolution for Windows NT, 2000 and XP.

The default value is **0**.

See also **WINDOWS_PRINTERS_4D** for enabling access to Windows printers.

**HINGE_OFFSET_ZONE_COLOUR_4D**

HINGE_OFFSET_ZONE_COLOUR_4D  colour

the colour of the text in the Type column for the Hinge Offset commands in the **Hinge Modifiers** panel.

**HINGE_HEIGHT_ZONE_COLOUR_4D**

HINGE_HEIGHT_ZONE_COLOUR_4D  colour

the colour of the text in the Type column for the Hinge Height commands in the **Hinge Modifiers** panel.

**HINGE_POSITION_ZONE_COLOUR_4D**

HINGE_POSITION_ZONE_COLOUR_4D  colour

the colour of the text in the Type column for the Hinge Position commands in the **Hinge Modifiers** panel.

**HLS_IPADDR**

HLS_IPADDR  list of IP addresses and/or computer names

if **non blank**, a list of IP addresses and/or computer names to search for a 12d Hardlock network dongle. The items in the list are separated by commas

If **blank**, search the entire network for a 12d Hardlock network dongle

**HOME_4D**

HOME_4D  folder

three folder levels up from where 12d.exe is

12d Model home folder
INTERPRET_DMS_INPUT_OLD_4D

INTERPRET_DMS_INPUT_OLD_4D $0, 1$
if non zero, the special case of 0.mms is interpreted as mm minutes and s seconds. That is, 0.123 is interpreted as 12 minutes and 3 seconds.
If zero, the special case of 0.mms is interpreted as mm minutes and 10 x s seconds. That is, 0.123 is interpreted as 12 minutes and 30 seconds.

LABEL_PVC_150_PIPES_4D

LABEL_PVC_150_PIPES_4D $0, 1$ default 1
If non zero, the 150 PVC pipes are labelled on the drainage long section.
If zero, the 150 PVC pipes are not labelled on the drainage long section.

LAYOUT_FILE_4D

LAYOUT_FILE_4D filename default layout.4d
a file containing the screen layout file information (slx/slf) for placing menus or panels on the screen. The layout file is used each time a project is opened to place the menus and panels in it on the screen. See 42.2.3 Screen Layout File in the appendix 42 Special File Formats.
The default is layout.4d.

LIB_4D

LIB_4D folder HOME_4D\11.00\library
12D Solutions library folder for input files such as mapping, template and macros (4DML’s).
The default is HOME_4D\11.00\library.

LINESTYLE_BOX_HEIGHT_4D

LINESTYLE_BOX_HEIGHT_4D value
If non blank, the pixel height of the linestyle and symbol scrolling pop-ups.
The default is 512

LINESTYLE_BOX_WIDTH_4D

LINESTYLE_BOX_WIDTH_4D value
If non blank, the pixel width of the linestyle and symbol scrolling pop-ups.
The default is 256

LINESTYLE_DUPLICATE_MODE_4D

LINESTYLE_DUPLICATE_MODE_4D choice box
This environment variable manages what to do if symbols or linestyles with the same name are read from the symbols.4d or linestyle.4d file
Do nothing - accept all instances of symbols/linestyles of the same name
Take first - accept only the first instance of the symbol/linestyle
Take last - accept only the last instance of the symbol/linestyle

LINESTYLES_4D

LINESTYLES_4D filename default linestyl.4d
file of linestyle definitions
The default is linestyl.4d. See 40.1 Line Styles

LIST_POPUPS_4D

LIST_POPUPS_4D 1 Pop-up lists as scrolling lists
0  Pop-up lists as menus (as in versions up to V3.2)

Defines the look of pop-up lists.
If non zero, the popup lists are scrolling lists.
If zero, the pop-ups are menus which turn into walk-right menus when the list is too long.
The default value is 1.

LOOK3D_4D  1  3D look and greenish background  default 1

The default value is 1.

LOG_DIR_4D

LOG_DIR_4D  folder-path-name  default is local folder

An error log file is created each time 12d Model is invoked. The error log name automatically
created by 12d Model and has the form:

log?????.4de

where  ??????  is a hashed number using your login name, process id & the current time.
The  folder  that the error log file is created in is given by the environment variable LOG_DIR_4D.
The full path-name of the folder is given.
If LOG_DIR_4D is not used, 12d Model tries to create the log file in the current folder, the HOME
folder, the TMP folder and the TEMP folder.
If creating an error log file fails in all these areas, 12d Model does not create an error log file.

LONG_SECTION_PPF_4D

LONG_SECTION_PPF_4D  path name to .ppf file  no default

This environment points to the file used as the default plot parameter file (.ppf) for the panel
section  long  plot.
The path name to the .ppf file can contain $LIB which expands out to the path of the library area.
For example, $LIB/long.ppf points to the file long.ppf in the area defined by $LIB_4D.

MACRO_INPUT_MODE_4D

MACRO_INPUT_MODE_4D  0  Don’t put current value into the console  default 0

1  Put current value into console.

Controls whether or not the value passed down in the variable to receive the answer for any
macro prompt, is actually placed into the console panel as the default answer so that it can be
accepted by just typing <enter> into the console panel.
The default value is 0.

MAXIMUM_TRASH_SIZE_4D

MAXIMUM_TRASH_SIZE_4D  positive integer  default 0

the maximum number of Mb that the size of the trash file can be.
If the value is 0, the Trash Bin is  not  limited in size.
The default value is 0.

MIDDLE_DOT_CHARACTER_4D

MIDDLE_DOT_CHARACTER_4D  integer (base 10)  default 183

The integer (base 10) value of the character to use as the squared symbol.

MINI_DUMP_LEVEL_4D

MINI_DUMP_LEVEL_4D  choice box
MODEL_FOR_TIN_PREFIX_4D

MODEL_FOR_TIN_PREFIX_4D pre*pos default is "tin"

This environment variable is used to customize the default model for the tin in the panels for creating triangulations. Text can be defined for prepending and/or appending to tin name to create a default model name from the tin name.

The text for prefixing and postfixing is given in a special form: pre-text*post-text

If pretext only, just give the text. If post text is required, precede it by a ".".

If the environment variable is not set, the default "tin " is used.

MODEL_VIEW_WALKRIGHTS_4D

MODEL_VIEW_WALKRIGHTS_4D 0 Use data source in options
1 Walk-rights for model/view as in up to V3.2

Defines whether the Data source field is used instead of model/view walk-rights used in V3.2.

The default value is 0.

MOVIE_4D

MOVIE_4D executable default xanim

X-Windows only - program for running perspective movie

MS_SEEDFILES_4D

MS_SEEDFILES_4D folder no default

if non blank, the full path name of the folder of Microstation seed files.

MTF_TMP_4D

MTF_TMP_4D anything not defined

If defined, then the temporary files for mtf calculations go to the Windows temp folder. This is to get over a bug in Novell under Windows 95.

MTF_CONSTRUCTION_HINGE_NAME_4D

MTF_CONSTRUCTION_HINGE_NAME_4D text

the default name used to refer to the Hinge string as a link in a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_DESIGN_LAYER_NAME_4D

MTF_DESIGN_LAYER_NAME_4D text

the default name for the design layer in a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_EXTRA_START_END_VAL_4D

MTF_EXTRA_START_END_VAL_4D real value

the default extra start/end value for a new MTF. After a MTF is created, the value can be changed within the MTF, and saved with the MTF.

MTF_NAMED_PART_HIGHLIGHT_TEXT_SIZE_4D

MTF_NAMED_PART_HIGHLIGHT_TEXT_SIZE_4D real value

the size of the text to use when the name of the named part is highlighted.

MTF_SEED_INCLUDE_MTFS_4D

MTF_SEED_INCLUDE_MTFS_4D 0 or 1

if non zero, existing MTF files are included (in addition to files of type .MTF_Seed) in the choices.
of files which can be used as a MTF Seed file.

if zero, only files of type .MTF_Seed are included in the choices of files which can be used as a MTF Seed file.

MTF_SNIPPET_TEMP_FILE_EXTENSION_4D

MTF_SNIPPET_TEMP_FILE_EXTENSION_4D text

if not blank, the standard .tmp_mtf file extension will be replaced with this value.

If blank, the standard .tmp_mtf file extension will be used.

For more information on snippets, see 21.5 Defining and Using Snippets.

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_4D

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_4D 0 or 1

if non zero, the temporary file created after the preprocessing occurs for the snippet is given the same name as the snippet, with the file extension .tmp_mtf

If zero, the MTF name is used. Note: If there is more than one snippet, this file will be overwritten.

For more information on snippets, see 21.5 Defining and Using Snippets.

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_KEEP_4D

MTF_SNIPPET_TEMP_FILE_USE_SNIPPET_NAME_KEEP_4D 0 or 1

if non zero, the temporary files created after the preprocessing occurs for the snippet are left on the hard drive.

If zero, the temporary files are deleted.

NOTE: If the snippet is compiled, the temporary files are always deleted.

For more information on snippets, see 21.5 Defining and Using Snippets.

MULTI_LINE_TEXT_4D

MULTI_LINE_TEXT_4D value 0 or 1 default 0

If non zero, a Text Edit Box is used instead of the Input Box and more than one line of text can be typed into the Text Edit Box.

NAME_MAPPINGS_4D

NAME_MAPPINGS_4D filename default names.4d

A name mapping file can be specified which is used to fill out information such as colour, model etc. for given string names.

The name mapping works in two ways. After typing part or all of a string name,
(a)  if <enter> is entered, the map file is searched for a match in the first column.
    If a match is found, the name, colour, model, style etc. from the other columns in the name mapping file are used to fill out the panel fields.

(b)  if a <tab> is entered, the second column is searched for a list of completions (if a * is found, the first column is used for that check) which are displayed in a pop-up. When an entry is selected from the completion list, the name, colour, model, style etc. from the columns in the name mapping file are used to fill out the panel fields.

(c)  name mapping file is used to fill out the panel fields.

NEVER_SNAP_ITSELF_4D

NEVER_SNAP_ITSELF_4D 1 try to stop a string snapping to itself during editing

0 let a string snap to itself - behaviour in V3.2

Tries to stop a string snapping to itself during editing.
The default value is 1.

NEW_DRAINAGE_PPF_4D
new path name of binary pff file  no default
Points to the file used as the default binary parameter file (.drainppf) for the long section plot produced by the panel Drainage Plot PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library area. For example, $LIB/drainage_long.drainppf points to the file drainage_long.drainppf in the area defined by $LIB_4D.

NEW_DRAINAGE_MELB_PPF_4D
new path name of binary pff file  no default
Points to the file used as the default binary parameter file (.melbppf) for the long section plot produced by the panel Sewer Plot Melbourne Water PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library area. For example, $LIB/melb_water.melbppf points to the file melb_water.melbppf in the area defined by $LIB_4D.

NEW_DRAINAGE_PLAN_PPF_4D
new path name of binary pff file  no default
Points to the file used as the default binary parameter file (.drainplanppf) for the plan annotation produced by the panel Drainage Plan Plot PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library area. For example, $LIB/drainage_plan.drainplanppf points to the file drainage_plan.drainplanppf in the area defined by $LIB_4D.

NEW_LONG_SECTION_PPF_4D
new path name of binary pff file  no default
Points to the file used as the default binary parameter file (.lplotppf) for the long section plot produced by the panel Section Long Plot PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library area. For example, $LIB/long_section.lplotppf points to the file long_section.lplotppf in the area defined by $LIB_4D.

NEW_MTF_EDITOR_AUTOPAN_DEFAULT_4D
new MTFEDITOR_ZOOM BUFFER 4D  0, 1  default 1
if non zero, the default for Autopan is on for the MTF Left/Right MTF Modifiers panel.
if zero, the default for Autopan is off for the MTF Left/Right MTF Modifiers panel.

NEW_MTF_EDITOR_DEFAULT_HEIGHT_4D
real_value
real_value is the height in pixels of the MTF Left/Right MTF Modifiers panel.
The default value is 250

NEW_MTF_EDITOR_DEFAULT_WIDTH_4D
real_value
real_value is the width in pixels of the MTF Left/Right MTF Modifiers panel.
The default value is 750

NEW_MTF_EDITOR_PASTED_MODIFIER_COLOUR_4D
NEW_MTF_EDITOR_PASTED_MODIFIER_COLOUR_4D  colour
when you cut/paste the modifiers, the background colour of the pasted rows will remain that
colour until you edit them, i.e. this option lets you know the pasted rows until you edit them.

NEW_MTF_EDITOR_ZOOM_BUFFER_4D
NEW_MTF_EDITOR_ZOOM_BUFFER_4D  real_value
real_value is a percentage.
if Autopan is on for the Left/Right MTF Modifiers panel, then when a command is clicked on in
the panel and the region to pan into is not displayed on the view, then the extent displayed it the
required amount increased by the real_value percentage.
The default value is 5

NEW_PIPELINE_PPF_4D
NEW_PIPELINE_PPF_4D  full path name of binary pff file  no default
Points to the file used as the default binary pipeline plot parameter file (.pipelineppf) for the long
section plot produced by the panel Pipeline Plot PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library
area. For example, $LIB/pipeline_long_section.pipelineppf points to the file
pipeline_long_section.pipelineppf in the area defined by $LIB_4D.

NEW_PLOT_FRAME_PPF_4D
NEW_PLOT_FRAME_PPF_4D  full path name of binary pff file  no default
Points to the file used as the default binary parameter file (.plotframeppf) for the plan plot
produced by the panel Plot Frame PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library
area. For example, $LIB/plot_frame.plotframeppf points to the file plot_frame.plotframeppf in
the area defined by $LIB_4D.

NEW_STRING_CREATES_4D
NEW_STRING_CREATES_4D

NEW_TOOLBARS_VISIBLE_4D
NEW_TOOLBARS_VISIBLE_4D  1, 0  default
if non zero, when a project starts up, all the toolbars are checked to see if they are listed in the
workspace (visible or invisible) and if the toolbar does not exist, then the toolbar will be
displayed.
This is to allow any new toolbars added to toolbars.4d to be automatically displayed so that the
user knows that it exists.
if zero, then new toolbars are not displayed. That is, only toolbars listed in the workspace (visible
are displayed.

NEW_X_SECTION_PPF_4D
NEW_X_SECTION_PPF_4D  full path name of binary pff file  no default
Points to the file used as the default binary plot parameter file (.xplotppf) for the cross section
plots produced by the panel Section X Plot PPF Editor.
The path name to the binary pff file can contain $LIB which expands out to the path of the library
area. For example, $LIB/cross_section.xplotppf points to the file cross_section.xplotppf in
the area defined by $LIB_4D.

NOP_ZONE_COLOUR_4D
NOP_ZONE_COLOUR_4D  colour
Chapter 39  Setting Up & Configuring 12d

Environment Variables

the colour of the text in the Type column for the commands that aren't in the Fixed, Cut, Fill or Final sections of the modifiers in the Left/Right MTF Modifiers panel, e.g. Interval commands.

NVALUES_4D
NVALUES_4D filename default nvalues.4d
This points to the file which is used as the file of n value definitions. These are described in 7.6.7 N values and the editing of the n values file is documented in 7.6.7.2 Create/Edit N-Values.
The default is nvalues.4d.

OPENGL_CACHE_4D
OPENGL_CACHE_4D value 0 or 1 default 1
If non zero, rasters and textures are cached in the graphics card memory for potential speed ups. More memory in the graphics card allows more caching and usually more performance gains.

OPENGL_CACHE_TINS_4D
OPENGL_CACHE_TINS_4D value 0 or 1 default 0
If non zero, tins are cached in the graphics card memory for potential speed ups. More memory in the graphics card allows more caching and usually more performance gains.

OPENGL_MIPMAP_4D
OPENGL_MIPMAP_4D value 0 or 1
If ticked, the graphics card down samples for rasters when the image is further away. Default value is 1.

OPENGL_MIPMAP_BILLBOARDS_4D
OPENGL_MIPMAP_BILLBOARDS_4D value 0 or 1
If ticked, the graphics card down samples for billboards when the image is further away.

OPENGL_MIPMAP_PLAN.Images_4D
OPENGL_MIPMAP_PLAN.Images_4D value 0 or 1 default 1
If ticked, the graphics card down samples plan images when draped onto a tin.

OPENGL_MIPMAP_PROJECTOR.Images_4D
OPENGL_MIPMAP_PROJECTOR.Images_4D value 0 or 1 default 1
If ticked, the graphics card down samples projector images (a projector is for the "hidden" perspective image data object of a super string).

OPENGL_OFFSET_4D
OPENGL_OFFSET_4D value 0 or 1 default 1
If non zero, the coordinates are localised for OpenGL calls. This is to work around problems with some graphics cards that can’t handle large coordinates.

OPENGL_VIEW_BACKING_STORE_4D
OPENGL_VIEW_BACKING_STORE_4D value 0 or 1
if 1, a backing store is used.
if 0, a backing store is not used.
For Window Vista/Windows 7, the default is 1. Otherwise the default is 0.

ONSCREEN_KEYBOARD_4D
ONSCREEN_KEYBOARD_4D value 0, 1 or 2
if 0, then no onscreen keyboard comes up when you double click in a panel field.
if 1, when you double click in a panel field that takes typed input, then a dockable onscreen keyboard come up for the user to type the data for the panel field into.
if 2, when you double click in a panel field that takes typed input, then a full screen onscreen keyboard come up for the user to type the data for the panel field into.

The default is 0.

ONSCREEN_KEYBOARD_FONT_SIZE_4D

ONSCREEN_KEYBOARD_FONT_SIZE_4D number
if non blank, the pixel size of the font for the onscreen keyboard.
If blank, it defaults to the normal system font size.
The default is the normal system font size.

ONSCREEN_KEYBOARD_LAYOUT_4D

ONSCREEN_KEYBOARD_LAYOUT_4D value 0, or 1
if 0, then when there is an onscreen keyboard, it comes up with a full keyboard.
if 1, then when there is an onscreen keyboard, it comes up with just a numeric keyboard.
The default is 0.

OVERFLOWING_TRASH_MODE_4D

OVERFLOWING_TRASH_MODE_4D choice box default Auto manage
the action to take when the trash bin exceeds the maximum trash bin size.
If Auto manage, the oldest files in the trash bin are deleted until the new item can fit in the trash bin.
if Auto empty, files in the trash bin are deleted.

Note - if a large model or tin is deleted and it is bigger than the maximum trash bin size, the user is alerted and asked to decide if they want the element to go in the trash bin anyway, or if they want to permanently delete it.
The default value is Auto manage.

PAN_MODE_4D

PAN_MODE_4D 0 Use standard pan for pan, pans on views
1 Use pan deltas for pan, pans on views

Sets whether pan or pan delta is used for the pan and pans buttons on views.
The default value is 0.

PATTERNS_4D

PATTERNS_4D filename default patterns.4d
Points to the file used to define the patterns used for super string fills.
The default is patterns.4d.

PDF995_TIME_LIMIT_4D

PDF995_TIME_LIMIT_4D number
the number of seconds to wait for PDF995 to finish producing the current PDF file.

PICK_ONLY_ON_SELECTS_4D

PICK_ONLY_ON_SELECTS_4D

PLAN_TABLE_SETTINGS_4D
Environment Variables

Chapter 39 Setting Up & Configuring 12d

Plan Table Settings 4D 0 Don’t allow setting by model default 0

1 Allow setting by model

Trial only - allow the drawing of z-values, vertices etc. on the plan view to be set by individual models rather than for all models on the view.

The default value is 0.

Plotter 4D

Plotter 4D script/program no default

This environment variable points to a script/program which can be fired up whenever a plot is generated. The name of the plot is given as the first script parameter of the script.

If the parameter Send plots on the ‘System Settings’ tab of the menu option Utilities => Defaults is set to yes, the plotter script is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the script is called separately for each of the plots.

An example of a script to send the plot to port lpt1 for Windows NT would be

```
@echo off
copy %1 lpt1
```

An example for Windows NT which looks for hp files is

```
@echo off
echo.
echo ------------------------------------------------------:

next_file
if "%1" == "" goto done
echo %1 | find /i ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
echo Plotting file %1
shift
goto next_file
:hp_plotter
echo Plotting %1 to HP plotter
shift
goto next_file
:done
echo ------------------------------------------------------:
```

Plotter Mapping 4D

Plotter Mapping 4D filename default pmf.4d

This points to the file which is used as the default plotter mapping file. The format for the plotter mapping file is described in the section 43.3 Mapping 12d Colours to Pens and RGBs in the Appendix 39 Setting Up & Configuring 12d.

The default is pmf.4d.

Plotters 4D

Plotters 4D filename default plotters.4d

This points to the file which contains user defined plotters. The format for the file of user defined plotters is described in the section 43.2 Defining Plotters - Plotters.4d in the Appendix 39 Setting Up & Configuring 12d.

The default is plotters.4d.
Environment Variables

PLOT_SYMBOLS_4D filename default plotsymb.4d
Points to the file used to define the symbols used in long and cross section plots.
The default is plotsymb.4d.

POLYPOLYLINES_4D

POLYPOLYLINES_4D 0 Don’t use speed ups default 2
1 Intermediate speed ups
2 Faster speed ups.

A few experimental techniques are available for speeding up the drawing on the screen.
For some specific things such as fast contours, fast mesh and point crosses, the techniques can result in some redraws being up to three times faster.
The default env.4d shipped with 12d Model has this set to 2.

PREVIEW_VIEW_4D

PREVIEW_VIEW_4D text
if non blank, the name of the view whose image is dumped on exiting the project. The image is used as the project preview.
If blank then the last active view is used.

PRINTER_4D

PRINTER_4D script/program no default
Points to a script or program which can be fired up whenever a report is generated. The name of the report is given as the first parameter of the script.
If the parameter Print reports on the ‘System Settings’ tab on the menu option Utilities => Defaults is set to yes, the printer script is run as each report is created.

PROCESSOR_AFFINITY_4D

PROJECT_DETAILS_4D

PROJECT_DETAILS_4D file name
If non blank, the full path name of the file of project details file to use for new projects.

PROJECT_NAMES_4D

PROJECT_NAMES_4D 0 Use long filenames for internal files default
1 Use short names (8.3 format)
The use of long or short extension names for internal 12d Model files for items such as models, tins, templates etc. is controlled by the environment variable PROJECT_NAMES_4D.
Opening a new project with the short name format, project-name.4dp, will automatically create a short name project (i.e. a project using the short extension names - 3 characters after the .).
The default value is 0.

PROJECTIONS_4D

PROJECTIONS_4D filename default carto.4d
This points to the file which is used as the file of projections. These are described in 7.6.6 Projections and the editing of the projections file is documented in 7.6.6.2 Create/Edit Projection.
The default is carto.4d.

PROMPT_ON_VIEW_CLOSE_4D

PROMPT_ON_VIEW_CLOSE_4D 0, 1
If non zero, when a view is closed/deleted, a prompt asks for a confirmation of deleting/closing. If zero, no confirmation is requested when a view is closed/deleted. The default is 0.

**PURGE_TRASH_DAYS_4D**

`PURGE_TRASH_DAYS_4D number_of_days default 0`

`number_of_days` is a positive integer and is the number of days before the Trash Bin is automatically purged of tins and models.

If `number_of_days` is zero, the Trash Bin is **not** purged.

The default value is 0.

**RECENT_PROJECTS_4D**

`RECENT_PROJECTS_4D positive integer default 20`

The maximum number of accessed projects displayed in the Projects list when **12d Model** starts up.

**REMEMBER_MTF_PANEL_SIZE_4D**

`REMEMBER_MTF_PANEL_SIZE_4D 0 or 1`

If non zero, when a MTF panel is placed on the screen and closed with Finish, its final position and size are recorded and used when the panel is opened again.

**REPORT_HEADER_4D**

`REPORT_HEADER_4D 0 Report files have no header page`

`1 Some header information is used`

`2 A full header page is produced. default 2`

Controls the amount of header information in reports.

For the cases 1 and 2, the header information includes

(a) the 12d Model Project
(b) the name of the user
(c) the organization
(d) the current date
(e) the current report file name

The default value is 2.

**RUN_MACROS_FILE_4D**

`RUN_MACROFILE_4D filename default macros.4d`

if non blank, the full pathname of the file of macros (one per line) that are run when a new project is created.

**Note:** This is only run for new projects. **RUN_PROJECT_MACROS_FILE_4D** is run when opening an existing project.

The default is macros.4d

**RUN_PROJECT_MACROS_FILE_4D**

`RUN_PROJECT_MACROS_FILE_4D filename default project_macros.4d`

if non blank, the full path name of the file of macros (one per line) that are run when an existing project is opened.

**Note:** This is only run when opening existing projects. **RUN_MACROS_FILE_4D** is run when creating a new project.

The default is project_macros.4d
Environment Variables

SDR_DISPLAY_V8_FORMAT_4D

SDR_DISPLAY_V8_FORMAT_4D

SETUPS_FILE_4D

SETUPS_FILE_4D filename default setups.4d

file setting up the initial screen layout for new projects. This is not to be confused with
SET_UPS_4D which is where the standard Set Up files are installed. See SETUPS_FILE_4D.
The default is setups.4d. See 39.2.7.1 Set Ups File (setups.4d).

SET_UPS_4D

SET_UPS_4D folder HOME_4D\11.00\set_ups

directory for storing the standard Set Up files installed by 12D Solutions.
The default is HOME_4D\11.00\set_ups.

SEWER_PPF_4D

SEWER_PPF_4D path name to .ppf file no default

points to the file used as the default plot parameter file (.ppf) for the panel new plot sewer

network.

SHARE_CHECK_INTERVAL_4D

SHARE_CHECK_INTERVAL_4D positive integer default 0

if non zero, the number of seconds between checks to see if any of the shared tins or models
added to the project have been modified.

SHARE_LOCKS_FOLDER_4D

SHARE_LOCKS_FOLDER_4D folder default no folder

if non blank, the full path name of the folder used to keep lock files for shares.
If no folder is given, the locking files are stored inside the project.

SHARE_MAP_FILE_4D

SHARE_MAP_FILE_4D filename default blank

if non blank, the full path name of the map file to be applied to shared models.

SHARED_ELEMENT_COLOUR_4D

SHARED_ELEMENT_COLOUR_4D colour default blue

the colour to use in a list of tins/models for showing shared tins/models. That is, the tins/models
that have been added to the project as shared tins/models are shown in this colour.
Setting the colour to black will disable this feature.

SHARING_CACHE_4D

SHARING_CACHE_4D folder default no folder

if non blank, the full path name of the folder that is used to store the models and tins and tins that
are shared into the project. Each time the project is started, each model and tin that is shared
into the project is checked to see if has changed since the last time it was used in the project,
and if has not changed then the copy in the Sharing Cache Folder is used. This can greatly
improve performance when the models and tins are being shared into your project from across
the network.
If no folder is given, no caching of models or tins is done.

SHARED_ELEMENT_COLOUR_4D
SHARING_ELEMENT_COLOUR_4D  colour  default rgb 255,165,0

the colour to use in a list of tins/models for showing the tins/models in the project that you are allowing to be shared. That is, those tins/models in the project that the user has allowed others to share are shown in this colour.

Setting the colour to black will disable this feature.

SHEET_SIZES_4D

SHEET_SIZES_4D  filename  default sheets.4d

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal Set Up areas, or is pointed to by the environment variable SHEET_SIZES_4D.

The default is sheets.4d. See 39.2.7.4 Sheet Sizes File (sheets.4d).

SHOW_OPTION_EXECUTION_TIME_4D

SHOW_OPTION_EXECUTION_TIME_4D  integer  0

if non zero, the time taken for an option to run is written to the output window.

If zero, the information is not written to the output window.

SHOW_PATHS_4D

SHOW_PATHS_4D  anything

If non blank, then when 12d Model fires up the actual file names defined by any environment variables are written to the output window. This is useful for debugging.

SHOW_PROJECT_DETAILS_4D

SHOW_PROJECT_DETAILS_4D  0, 1  default 1

If non zero, the Edit Project Details panel is displayed when a new project is created.

SHOW_TITLE_VARIABLES_4D

SHOW_TITLE_VARIABLES_4D  0  any $variable not used is left as blank
1  any $variable not used is shown as $variable
2  all $variable’s are plotted with no substitution

This is used for debugging the title block file.

If 0, any $variable not used in the title blank file is left as blank.

If 1, any $variable not used is shown as $variable.

If 2, all $variable are plotted with no substitution.

The default value is 0.

SHOW_VISTA_VIRTUAL_STORE_PATHS_4D

SHOW_VISTA_VIRTUAL_STORE_PATHS_4D  tick box

if ticked, then for Microsoft Vista, when 12d Model fires up, the actual file names defined by any environment variables are written to the output window. This is useful for debugging due to the fact that Vista may put file sin strange places.

SNIPPET_ZONE_COLOUR_4D

SNIPPET_ZONE_COLOUR_4D  colour  default light grey (RGB(155, 140, 150)

the colour of the text in the Type column for the Snippet command in the Modifiers section of the Left/Right MTF Modifiers panel.
SORT_COLOURS_BY_POPUP_NUM_4D

SORT_COLOURS_BY_POPUP_NUM_4D 0,1  default 1

Controls the display order of the colours in the Select Colour popup that you get when you click on a Colour icon.

If SORT_COLOURS_BY_POPUP_NUM_4D is 1, the colours in the Select Colour popup are sorted by the Pop-up Number given for the colours in the Colours.4d file.

If SORT_COLOURS_BY_POPUP_NUM_4D is 0, the colours in the Select Colour popup are sorted alphabetically.

The default value is 1.

SPECIAL_OFFSET_CHAINAGES_4D

SPECIAL_OFFSET_CHAINAGES_4D

SPEED_TABLES_4D

SPEED_TABLES_4D

SQUARE_CHARACTER_4D

SQUARE_CHARACTER_4D integer (base 10)  default 178

The integer (base 10) value of the character to use as the squared symbol.

STATION_PREFIX_4D

STATION_PREFIX_4D text  There is no default.

The default prefix to use in the Survey Data Setup panel or to use if no prefix has been set for the project.

There is no default value.

SUPER_ADVANCED_MODE_4D

SUPER_ADVANCED_MODE_4D

SUPER_ALIGNMENT_STYLE_4D

SUPER_ALIGNMENT_STYLE_4D filename  default astyles.4d

Points to the file used to define the symbology used for super alignments.

The default is astyles.4d.

SUPER_STRINGS_4D

SUPER_STRINGS_4D 1  Use the super string

0  Don’t use the super string.

Controls whether the super string is accessible or not.

The default value is 1.

SYMBOLS_4D

SYMBOLS_4D filename  default symbols.4d

Points to the file used to define the symbols used for super strings.

The default is symbols.4d.

SYSTEM_NAMES_4D

SYSTEM_NAMES_4D 1  Only use the longer names

2  Only use the 8.3 file names

3  Use short names first then look for a long name.

For file name compatibility with DOS 8.3 format, the default names for all Set Up files can be
restricted to just short names (8.3), long names, or short and then long.  The default value is 3.

TRANSFORMATIONS_4D
TRANSFORMATIONS_4D filename default 7params.4d
This points to the file which is used as the file of seven parameter transformations. These are described in 7.6.8 7 Parameters and the editing of the transformations file is documented in 7.6.8.1 Create/Edit 7 Parameters.
The default is 7params.4d.

TEXTSTYLE_MAPPINGS_4D
TEXTSTYLE_MAPPINGS_4D filename default textstyle_names.4d
file of textstyles favourites definitions
The default is textstyle_names.4d

TEXTSTYLES_4D
TEXTSTYLES_4D filename default textstyl.4d
file of textstyles definitions
The default is textstyl.4d. See 40.3 Textstyles and Fonts.

TEXTURE_MAP_4D
TEXTURE_MAP_4D filename default texture_map.4d
This points to the file which defines the tables of texture mappings. These are described in 12.13.4 Texture Map Edit.
The default is texture_map.4d.

TICK_DRAW_CROSS_4D
TICK_DRAW_CROSS_4D 0 Nothing for off
1 Cross for off
The default value is 0.

TIN_VIEWPORT_CLIP_4D
TIN_VIEWPORT_CLIP_4D 0 Drawing tins, fast contours as per V3.1
1 A speed up for drawing tins, fast contours
Use some experimental techniques for speeding up the drawing of tins, fast contours.
The env.4d file shipped with 12d Model has this set to 1.

TOOLBAR_DUPLICATE_MODE_4D
TOOLBAR_DUPLICATE_MODE_4D choice box
This environment variable manages what to do if toolbars with the same name are read from a toolbars.4d file. The choices are

Do nothing - accept all toolbars of the same name
Take first - accept only the first instance of the toolbar
Take last - accept only the last instance of the toolbar

TOOLBARS_4D
TOOLBARS_4D filename default toolbars.4d
file of toolbar definitions and names
The default is toolbars.4d. See 41.3 User Defined Toolbars
Environment Variables

TP_STAKEOUT_PATH_4D

TP_STAKEOUT_PATH_4D folder - no default

If non-blank, the full path name of the folder of TP Stakeout files.

TRIMESH_TO_DWG_MODE_4D

TRIMESH_TO_DWG_MODE_4D - Do not write OR Faces OR Polyface mesh

If **Do not write**, trimeshes are not written out to a DWG file.

If **Faces**, a trimesh is written out to DWG file as individual 3D Faces.

If **Polyface mesh**, a trimesh is written out to a DWG file as a Polyface mesh.

Note that a Polyface mesh has only one colour.

TYPED_UNITS_MODE_4D

TYPED_UNITS_MODE_4D

0 - International units only e.g. f and F are both International feet

1 - USA units only e.g. f and F are both US feet

2 - Mixed e.g. f is International feet and F is US feet

Controls the typed input units for feet - international and/or US

The default value is 0.

UNDO_4D

UNDO_4D

0 - Don't allow undo's

1 - Allow undo/redos - default 1

Undo and Redo is available for most operations from **12d Model V3.1 onwards**. The availability of Undo/Redo facility is controlled by the environment variable:

The default value is 1.

USAGE_LOG_4D

USAGE_LOG_4D folder - no default

When set, log files of the form

<log file folder>/<dongle> <user> <computer> <time stamp> <process ID>.log

will be created in the given folder.

That is, the log files will all be in the one folder.

USAGE_LOGS_4D

USAGE_LOGS_4D folder - no default

When set, log files of the form

<log file folder>/<dongle>/<user>/<computer>/<time stamp> <process ID>.log

will be created in the given folder.

That is, the log files will be in subfolders dongle:<user>:computer.

USE_ALL_USERS_PROFILE_4D

USE_ALL_USERS_PROFILE_4D - 0, 1

If no-zero then the file env.4d and the folders user and user_lib are looked for in **Documents and Setting All Users**.

USE_BACKUPS_4D_FOLDER_4D

USE_BACKUPS_4D_FOLDER_4D - 0, 1 - default 1

If non-zero: in the places where **12d Model** creates a backup file when a new file is created
Environment Variables

Chapter 39 Setting Up & Configuring 12d

(Using the file endings 1, 2, ... for the old file) then the backup file is placed in the folder backups.4d.

Backups are created for options such as env.4d editor, mtf editor, boxing editor, survey.4d editor, whenever the "Write Setup File(s)" is displayed, plus the macro calls Backup_version_file and Restore_version_file.

The backups.4d folder is created in the project working folder (that is, in the folder containing the .project folder).

USE_DENSITY_CHECKS_4D

USE_DENSITY_CHECKS_4D 0 Don’t do density checks
1 Do density checks default 1

If non zero then for a new project, the default for Use density drawing in the Defaults panel is tick.

If zero then for a new project, the default for Use density drawing in the Defaults panel is no tick.

For more information on density drawing, see Use density drawing tick box.

Note: This setting is only applicable to the 250M version of 12d Model.

USE_DISPLAY_MANY_SNAP_4D

USE_DISPLAY_MANY_SNAP_4D

USE_ECW_SERVER_4D

USE_ECW_SERVER_4D

USE_IMAGE_SERVER_4D

USE_IMAGE_SERVER_4D

USE_NAMES_COMMENT_4D

USE_NAMES_COMMENT_4D

USE_NEW_LINESTYLE_LIST_BOX_4D

USE_NEW_LINESTYLE_LIST_BOX_4D value 0, 1

If non zero, the linestyle and symbol pop-up lists are in scrolling boxes so they don’t run over the bottom of the screen. The list of linestyles/symbols is displayed in a tree structure with the Groups as the nodes of the tree.

If zero, the linestyle and symbols lists are one long list with each Groups being an item in the list. The list may get too long to fit on the screen.

The default value is 1.

USE_NEW_SELECT_4D

USE_NEW_SELECT_4D

USE_SUPER_STRINGS_4D

USE_SUPER_STRINGS_4D

USE_TRASH_BIN_4D

USE_TRASH_BIN_4D 0 Don’t use the Trash Bin default 1
1 Use the Trash Bin

The Trash Bin is used to store copies of deleted tins and models, and cleaned models. The items can be retrieved from the Trash Bin. The Trash Bin is automatically purged of contents after PURGE_TRASH_DAYS_4D.
The default value is 1.

**USE_VALIDATION_COLOURS_4D**

**USE_VALIDATION_COLOURS_4D** value 0 or 1 default 1

If 1, when a panel field fails to validate, the panel field is filled with the colour given by

**USER_4D**

**USER_4D** folder HOME_4D\11.00\user

user folder containing Set Up files

The default is HOME_4D\11.00\user.

**USER_LIB_4D**

**USER_LIB_4D** folder HOME_4D\11.00\user_lib

user library folder for input files such as mapping, template and macros (4DML's).

The default is HOME_4D\11.00\user_lib.

**USER_OPTIONS_4D**

**USER_OPTIONS_4D** file default usermenu.4d

To help customise 12d Model, the walk-right menu User on the main 12d Model menu, can be user defined. The text for each button of User, plus the action taken when the button is selected is user specified. Any of the buttons can include further walk-right menus.

The definitions for the menus on User's is given in the file usermenu.4d which is searched for in the standard Set Up areas (local, USER_4D, user, set_ups) or set by the environment variable USER_OPTIONS_4D.

if USER_OPTIONS_4D is blank, usermenu.4d is searched for in the standard search path for User files.

if USER_OPTIONS_4D is not blank, then it is used as the full path name of the user supplied file of definitions for user defined menus.

The default is usermenu.4d. See 41.2 User Defined Menus

**V7_TITLE_BLOCKS_4D**

**V7_TITLE_BLOCKS_4D** value 0 or 1 default 1

if non zero, the title block file is in 12da format.

If zero, the title block is in the pre V7 title block .tf format

**VALIDATION_FAIL_COLOUR_4D**

**VALIDATION_FAIL_COLOUR_4D** text

If not blank, the colour to fill the panel field with when there is a validation error for the field. The text is either a colour name, a colour number or RGB(x,y,z).

This is only used if USE_VALIDATION_COLOURS_4D is non zero (or at least not set to zero since the default is one).

If blank, the default colour is RGB(255,72,72),

**VEHICLE_PATH_4D**

**VEHICLE_PATH_4D** folder no default

The DOS Version of Vpath is no longer supported.

The environment variable VEHICLE_PATH_4D points to the folder where the Dos version of the Vpath executable is located. Note that WINDOWS_VEHICLE_PATH_4D points to the Windows
version.

**VIEW_BITMAP_BUTTONS_4D**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>User text for view buttons</td>
</tr>
<tr>
<td>1</td>
<td>Use icons for view buttons</td>
</tr>
</tbody>
</table>

The default value is 1

**VIEW_BUTTONS_4D**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No view buttons are displayed</td>
</tr>
<tr>
<td>1</td>
<td>The view buttons are displayed</td>
</tr>
</tbody>
</table>

If non zero, then menu items (view buttons) are displayed on the views (as icons or text). If zero, menu items (view buttons) are not displayed on the views.

The default value is 1

**Note**: displaying *view buttons* as icons or text is controlled by **VIEW_BITMAP_BUTTONS_4D**

**WARP_CURSOR_HIDE_4D**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Don’t hide the cursor before moving it</td>
</tr>
<tr>
<td>1</td>
<td>Hides the cursor before moving it</td>
</tr>
</tbody>
</table>

Controls whether the cursor is hidden before moving - only needed on some computers. If non zero, don’t hide the cursor before moving it. If zero, hides the cursor before moving it.

The default value is 0.

**WEB_SEARCH_4D**

**WEB_SEARCH_4D** search engine web address *www.google.com*

web address of the search engine that is fired up from the 12d option

*Help =>12d on the Web =>Search the web.*

**WEED_TOLERANCE_4D**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Don’t weed</td>
</tr>
<tr>
<td>1</td>
<td>Weed tolerance</td>
</tr>
</tbody>
</table>

used in Alignment and Super strings so that when arcs have been chord-to-arc’d, the resulting points are weeded so that no point is closer than the weed tolerance. Is is also used in Apply and Apply MTF so that no cross sections are closer than the weed tolerance.

**WIBU_4D**

**WIBU_4D** 1, 0

if non zero, search for 12d Wibu dongles.

If zero, don’t search for Wibu dongles

**WIBU_DONGLE_4D**

The environment variable can have a number of parameters to control the use of Wibu network and stand alone dongles.

(a) **WIBU_DONGLE_4D** -local OR -no_local

usually used when there is a network dongle and need to know if any stand alone Wibu dongle is to be looked for on the computer that the user is on.

if **local**, then a stand alone Wibu dongle is looked for on the computer the user is on.

If **-no local**, then no stand alone Wibu dongle is looked for on the computer the user is on.

For example  **WIBU_DONGLE_4D** -local or -no local
(b) \texttt{WIBU\_DONGLE\_4D} \texttt{-no\_network OR -network\_first OR -network\_last}

need to specify if any network Wibu network dongle is to be looked for.

if \texttt{-no\_network}, then no Wibu network dongle is looked for.
If \texttt{-network\_first}, then a Wibu network dongle is looked for before a stand alone local dongle.
If \texttt{-network\_last}, then a Wibu network dongle is looked for after looking for a stand alone local dongle.

For example \texttt{WIBU\_DONGLE\_4D} \texttt{-no\_network} or \texttt{-network\_first} or \texttt{-network\_last}

(c) \texttt{WIBU\_DONGLE\_4D} \texttt{-login\_retries number of retries to find a Wibu dongle}

the number \texttt{nn} of retries to make when searching for a Wibu dongle and it is not found.

For example \texttt{WIBU\_DONGLE\_4D} \texttt{-login\_retries 3}

(d) \texttt{WIBU\_DONGLE\_4D} \texttt{-login\_wait ss}

the number of seconds \texttt{ss} to wait between retries to find a network Wibu dongle.

For example \texttt{WIBU\_DONGLE\_4D} \texttt{-login\_wait 5}

(e) \texttt{WIBU\_DONGLE\_4D} \texttt{-no\_dongle}

if the parameter \texttt{-no\_dongle} is found, then no search is made for a Wibu dongle.

For example \texttt{WIBU\_DONGLE\_4D} \texttt{-no\_dongle}

(f) \texttt{WIBU\_DONGLE\_4D} \texttt{-debug}

if the parameter \texttt{-debug} is found, then Wibu dongle debug information is written to the

For example \texttt{WIBU\_DONGLE\_4D} \texttt{-debug}

See the separate notes on installing a network dongle for more details.

\texttt{WIBU\_IPADDR}

\texttt{WIBU\_IPADDR} \hspace{1cm} list of IP addresses and/or computer names

if \texttt{non blank}, a list of IP addresses and/or computer names to search for a 12d Wibu network dongle. The items in the list are separated by commas

If \texttt{blank}, search the entire network for a 12d Wibu network dongle

\texttt{WINDOWS\_PRINT\_MODE\_4D}

\texttt{WINDOWS\_PRINT\_MODE\_4D} \hspace{1cm} value

value is an integer representing "bit mask".

If \texttt{bit 1} set (contributes 1 to value): Windows 2000/XP print dialog means PrintDlgEx otherwise if bit 1 is not set, then PrintDlg.

if \texttt{bit 2} set (contributes 2 to value): Use exclusive access to the printer to force direct printing to the printer (may need Printer admin access)

if \texttt{bit 3} set (contributes 4 to value): Use an intermediate print file so that printing is first done to a file and then that file is submitted to the printer

So the legal values are from 0 to 7

\texttt{WINDOWS\_PRINTER\_SET\_DOCUMENT\_PROPERTIES\_4D}

\texttt{WINDOWS\_PRINTER\_SET\_DOCUMENT\_PROPERTIES\_4D}

\texttt{WINDOWS\_PRINTERS\_4D}

\texttt{WINDOWS\_PRINTERS\_4D} \hspace{1cm} value

0 \hspace{1cm} Don't allow Windows printers
1 \hspace{1cm} Enable Windows printers

The default value is 1.

\texttt{WINDOWS\_VEHICLE\_PATH\_4D}
Chapter 39 Setting Up & Configuring 12d

Environment Variables

WINDOWS_VEHICLE_PATH_4D folder no default
if non blank, the full path name of the folder where the Windows program Vpath is located.

**Note** - Vpath is the Vehicle Turning Path program written by Queensland Department of Transport and Main Roads that is provided free of charge.

**WINTER_4D**

WINTER_4D path name to WINTER program

*12d Model* no longer uses the external Winter program and so this environment variable is no longer used.

Points to the WINTER program for calculation N-values for Australia.

**WINTER_DATA_4D**

WINTER_DATA_4D folder no default
Folder containing the Winter data of N-values for Australia.

**WINTER_USE_NEW_METHOD_4D**

WINTER_USE_NEW_METHOD_4D value 0, 1 default 1
if tick, re-reading the Winter data is avoided and this speeds up the calculation for the Winter interpolations.

**WORKSPACE_FILE_4D**

WORKSPACE_FILE_4D path name
if non blank, the full path name of the workspace file for new projects.

**WRITE_ALL_PLOT_PARAMETERS_4D**

WRITE_ALL_PLOT_PARAMETERS_4D 0 Only write out the plot parameters that are used in the ppf.

WRITE_ALL_PLOT_PARAMETERS_4D 1 Write out all plot parameters to a ppf file
Controls whether all plot parameters are written out to a ppf file or just those that have been used in the ppf file.

The default value is 1.

**X_SECTION_PPF_4D**

X_SECTION_PPF_4D path name to .ppf file no default
points to the file used as the default plot parameter file (.ppf) for the panel section X plot.

The path name to the .ppf file can contain $LIB which expands out to the path of the library area. For example, $LIB/cross.ppf points to the file cross.ppf in the area defined by $LIB_4D.

**ZOOM_ORIGIN_DYNAMIC_4D**

ZOOM_ORIGIN_DYNAMIC_4D 0 The centre of the view is the zoom centre point

ZOOM_ORIGIN_DYNAMIC_4D 1 The point you pick is the zoom centre point
Controls the origin of the dynamic zoom.

If non zero then the point selected in the view to indicate which view to dynamically zoom (and to be the zoom-in, zoom-out definition point) becomes the point to dynamically zoom about. Whilst the dynamic zoom is running, another point can be selected to become the new zoom origin.

The default value is 0.

**ZOOM_PAN_DYNAMIC_4D**

ZOOM_PAN_DYNAMIC_4D 0 Dynamic pan is not the default

ZOOM_PAN_DYNAMIC_4D 1 Dynamic pan is the default for pan
If non zero then **dynamic pan** is the default for the pan options. The middle mouse button (or `d`) is not required to place the pan option in dynamic mode. In fact, it would then toggle it off.

The default value is 0.

**Notes**

(a) If any of the environment variables (pointing to files) are not set, or the file pointed to does not exist, then 12d Model searches for the default files in a number of locations. The search order is given at the beginning of this Appendix.

(b) The eagle pen mapping file, `eagleplt.emf` is also searched for in the same order as the default files.

(c) When an **existing** project is opened by 12d Model, the setups.4d and defaults.4d are not used.

Please continue to the next section **39.4.2 Setting Environment Variables**.
39.4.2 Setting Environment Variables

The simplest method for setting the required environment used in 12d Model is to place them into a file, called the environmental file (default name env.4d).

Environment Variables File

It is possible to define a file which sets the value for one or more environment variables.

The file format consists of one line for each environment variable being set and each line contains the environment variable name, followed by one or more spaces and then the value for the environment variable:

```
environment_variable_name  value
```

The value of any environment variable given in the environment variable file overrides any other definition for that environment variable.

The file used as the environmental variable file is checked for in the following order - as soon as a file is found, the search terminates and that file is used:

1. as a command line argument when 12d Model is fired up. The syntax is
   ```
   12d  -env  path_name
   ```
   where path_name is the full path name of the file
2. pointed to by the environment variable ENVIRONMENT_4D
   ```
   ENVIRONMENT_4D file  // file of environment variables
   ```
   // default env.4d
3. a file called env.4d which is searched for in the standard Set Up areas (local, USER_4D, user, set_ups).

An example of an environment variable file is

```
EDITOR_4D  te  // set the text editor used
SHOW_PATHS_4D  1  // show file names set by environment variables
SHEET_SIZES_4D  c:\standards\shfile
```

Setting Environment Variables not in a File

Environment variables can be set in Windows NT for a user from the Environment tab on the System Properties panel brought up by clicking on the System icon in the Control Panel of Windows.

To bring up the Control Panel, click on Start in the Windows Task bar, walk right on Settings and then click on Control Panel.

Please continue to the next section 39.2.7.1 Set Ups File (setups.4d).
39.5 12d Model Options Map

The 12d Model menu map shows the menu structure for all the sub-menus on the main 12d Model menu and the menus on the views.

The map is designed to be printed out for users who wish to affix it to a wall.

The PDF file of the menu map on the 12d Model Installation CD in the folder Documentation\12d Model menu map

Or in the Updates section of the web site www.12d.com.

Please continue to the next section 39.6 Monitoring 12d Model Usage.
39.6 Monitoring 12d Model Usage

See

39.6.1 Overview of 12d Usage
39.6.2 Generating the .log files
39.6.3 Installing 12d_usage.exe
39.6.4 Running 12d_usage.exe
39.6.5 Consolidating the .log files
39.6.6 Reporting on 12d Model Usage
39.6.1 Overview of 12d Usage

**12d Model** usage can be monitored for single-user and network licenses (or a mix of both), whether installed on a single computer, a local-area network, or a wide-area network across different time zones.

Monitoring the usage is a 3 stage procedure:
1. Generating individual .log files for each **12d Model** session run.
2. Consolidating all the completed .log files into a CSV file.
3. Reporting the usage details, using the CSV file as input.

The 1st stage is achieved by setting an environment variable in your env.4d file(s).
The last 2 stages are achieved by running the supplied program: 12d_usage.exe.

Continue to the next section 39.6.2 Generating the .log files or return to 39.6 Monitoring 12d Model Usage.

39.6.2 Generating the .log files

By setting one of two possible environment variables in the env.4d file(s) used for your **12d Model** sessions, uniquely named .log files can be generated in a specified folder on your network.

For example, by adding the lines:

```
usage_log_4d F:\12d model usage
```

or

```
usage_logs_4d F:\12d model usage
```

to your env.4d file(s), then each time a **12d Model** session is run, a .log file will be created in the "F:\12d model usage" folder. This folder, referred to as the <log file folder>, can be anywhere on your network and can have any name, but it must be created beforehand, and all 12d Model users must have write-access to it.

In the first case, using variable “usage_log_4d”, log files will be generated in the form:

```
<log file folder>\(<dongle> <user> <computer> <time stamp> <process ID>.log)
```

In the second case, using variable “usage_logs_4d”, log files will be generated within sub-folders of the form:

```
<log file folder>\<dongle>\<user>\<computer>\(<time stamp> <process ID>.log)
```

Note that the <time stamp> represents the start time of the **12d Model** session in GMT (also known as UTC or Zulu Time).

It does not matter which variable you decide to use, and you can even use a mix of the variables, if you have more than one env.4d file. However, regardless of which variable you use, it is recommended that the <log file folder> is the same for all **12d Model** users on your network so that all **12d Model** sessions can be easily included in the reports.

The .log file generated in the <log file folder> for each individual **12d Model** session run on your network, contains all the information required about that session. While the session is still running, the log file will be updated at a minimum of every 75 seconds, with the time that the session has been active. At the close of the **12d Model** session, the log file is again updated and is set as “completed”.

Continue to the next section 39.6.3 Installing 12d_usage.exe or return to 39.6 Monitoring 12d Model Usage.
39.6.3 Installing 12d_usage.exe

You can put the 12d_usage.exe program wherever you like on your network. Then, simply create a shortcut to the program on your desktop, making sure the shortcut properties are set as follows:

- **Target:** `<path to program location>\12d_usage.exe`
- **Start in:** `<path to Working Folder>`

The Working Folder is the folder that you run the 12d_usage.exe program from (it does not have to be the same as the location of the 12d_usage.exe file). After running the program for the first time, a file named 12d_usage.defaults will be created in the Working Folder. This file is used to save your settings from the last run of the program and to load your settings for the next run of the program. In addition, you might also wish to use the Working Folder to store your 12d Model Usage report files (although you are free to store them elsewhere).

Continue to the next section 39.6.4 Running 12d_usage.exe or return to 39.6 Monitoring 12d Model Usage.

39.6.4 Running 12d_usage.exe

To run the 12d_usage program, simply double-click on the shortcut icon you created at install time. This will open up a DOS window from where the program’s keyboard-driven menu system can be run.

From the Main menu within the 12d_usage program, your keyboard-driven menu options are:
- **C** Bring up the Consolidate menu
- **R** Bring up the Report menu
- **Q** Exit (quit) the 12d_usage program

Continue to the next section 39.6.5 Consolidating the .log files or return to 39.6 Monitoring 12d Model Usage.
39.6.5 Consolidating the .log files

After a while, you should notice that a lot of .log files are being generated in your specified <log file folder>. To consolidate all these .log files into a single Comma-Separated-Variable (CSV) file, you will need to run the 12d_usage.exe program, and press the “C” key to bring up the Consolidate menu.

From the Consolidate menu, your keyboard-driven menu options are:

F Specify the <log file folder>

O Specify the output CSV file name

T Toggle whether to delete or rename consolidated log files

C Consolidate 12d Model session log files

Q Exit the Consolidate menu and return to the Main menu

When specifying the name of the CSV file you wish to consolidate your log files to (using the “O” key), if you want a .csv file extension (to allow the file to be easily loaded into MS?Excel for your own custom reports, for example), you must include the .csv in the file name. It is recommended that all users of the 12d_usage program consolidate log files to the same CSV file every time. Newly consolidated logs are always appended to an existing CSV file. If there is to be more than one user of the 12d_usage program, it might be a good idea to specify the CSV file to be in the <log file folder> or the Working Folder (or at least, some folder that all 12d_usage users can access).

You also need to specify how to tidy up the log files, after they have been consolidated, so that they are not consolidated more than once. Your options here are to rename or to delete the log files (the “T” key toggles between rename and delete). If you choose to rename them, they will be renamed with a .logc extension. If you choose to delete them, they will be lost forever, and the only record you will have of your consolidated sessions will be contained in the CSV file. As such, you should be very careful not to delete your CSV file.

Pressing the “C” key will then go ahead and consolidate the log files. Note that consolidation will only take place on “completed” log files (or on log files that have not been updated for more than 24 hours - to handle the case of a power failure, for instance).

Continue to the next section 39.6.6 Reporting on 12d Model Usage or return to 39.6 Monitoring 12d Model Usage.
39.6.6 Reporting on 12d Model Usage

After creating or adding to your consolidated CSV file, you can press the “R” key from the Main menu, in order to bring up the Report menu.

From the Report menu, your keyboard-driven menu options are:

I Specify the input CSV file name (generated from the Consolidate menu)
O Specify the output report file name
M Toggle whether to overwrite or append to existing report file
D Add/Remove Dongle constraints
C Add/Remove Computer constraints
U Add/Remove User constraints
F Add/Remove Folder constraints
P Add/Remove Project constraints
E Add/Remove Program constraints
V Add/Remove Version constraints
T Specify Start and End times for report (in Local Time of 12d_usage User*)
S Specify which summary tables you want in the report
R Generate the 12d Model Usage report
Q Exit the Report menu and return to the Main menu

After generating the report (using the “R” key), you will be asked if you want to view the report file. If you answer yes (using the “Y” key), the report file will be opened using Notepad.exe as the default file editor. If you would prefer to use a different file editor, you can specify it by manually editing the 12d_usage.defaults file (see Installing 12d_usage.exe), and replacing the word “notepad” (last line of the file), with the command to start your preferred editor.

*Note: In general, if reporting on 12d Model sessions running on a WAN across different time zones, Local Time of 12d Model User and Local Time of 12d_usage User may be different.

Return to 39.6 Monitoring 12d Model Usage.

Or continue to the non related next section 39.7 Running Macros and Chains on Start Up.
39.7 Running Macros and Chains on Start Up

To allow for tailoring 12d Model when a new project is created or an existing project opened, 12d Model runs user supplied files of macros and/or chains.

For new projects, the default name of the file is macros.4d

This can be changed to a different file by setting the environment variable

RUN_MACROS_FILE_4D file_of_macros_to_run_for_new_projects

For existing projects, the default name of the file is project_macros.4d

This can be changed to a different file by setting the environment variable

RUN_PROJECT_MACROS_FILE_4D file_of_macros_to_run_for_existing_projects

(the environment variables can be set on the Extra A tab of the env.4d editor - see 7.6.3 env.4d)

The files consist of macros and/or chains, one per line, where

- for macros, just the name of the macro is needed on the line
- and for chains, the command run_chain name_of_the_chain is needed on the line.

The macros and chains are run in the order that they occur in the file.

Please continue to the next section 39.8 Arguments When Starting 12d Model.
39.8 Arguments When Starting 12d Model

*12d Model* can be started from an icon, or it can be started from a command line in a batch file by pointing to the *12d Model* executable, *12d.exe*. For example,

```
"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe"
```

fires up the 64-bit *12d.exe*.

**Note** This is what is used in the **Target:** field for a 12d icon. See 5.6 Project Shortcuts.

For a command line and the **Target:** field, new projects can be created and opened, existing projects can be opened, and/or a user specified *env.4d* file used.
39.8.1 Creating a New Project

The command

```
path_to_12d.exe -create full_path_name_to_12d_project_to_create
```

creates a **new** project of the given name, and *12d Model* starts up and opens up the new project. If any of the path names contain spaces, then they must be enclosed in double quotes (").
39.8.2 Opening an Existing Project

If the full pathname to an existing project is given after the `12d.exe` command, **12d Model** starts up and opens the existing project.

```
path_to_12d.exe full_path_name_to_existing_12d_project
```

For example

"C:\Program Files\12d\12dmodel\11.00\int.x86\12d.exe" "C:\12d jobs\airport\airport.project"

If any of the path names contain spaces, then they must be enclosed in double quotes (" ").
39.8.3 Environment Variables Shortcut

If a file of 12d Model environment variables has been set up by the user (see section 39.4 Environment Variables in Appendix 39 Setting Up & Configuring 12d), then instead of setting the environment variable ENVIRONMENT_4D to point to the file or setting it up with the default name, env.4d, the environment file can be passed to 12d.exe using the -env command.

For example

"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe" -env F:\12d\env.4d would fire up the 64-bit 12d.exe using the file of environment variables called F:\12d\env.4d

The command

"C:\Program Files\12d\12dmodel\11.00\nt.x64\12d.exe" -env F:\12d\env.4d
"C:\12d jobs\airport\airport.project"

would fire up the 64-bit 12d.exe using the file of environment variables called F:\12d\env.4d and also automatically open the project "C:\12d jobs\airport\airport.project".

If any of the path names contain spaces, then they must be enclosed in double quotes ("").

To return to the beginning of this appendix, click on 39 Setting Up & Configuring 12d.
40 Linestyles, Symbols, Textstyles & Patterns

This appendix contains information about how linestyles, symbols and text is defined and used in 12d Model.

See
- 40.1 Line Styles
- 40.2 Symbols
- 40.3 Textstyles and Fonts
- 40.4 Patterns
40.1 Line Styles

Users can define their own lines styles to use when drawing 12d Model strings. The definition of linestyles are stored in a file called linestyl.4d. (note that there is no e at the end of linestyl).

Line styles in the file can be created/edited/deleted using the Linestyle Create/Edit/Delete panel which is brought up by double clicking on Create linestyle in the Linestyles expansion of the Project Tree (see 7.9.4 Linestyles) brought up by the Project =>Tree option.

The Linestyle Create/Edit/Delete panel acts as an interactive editor to a text file which contains the linestyle definitions.

The user defined line styles can be broken into three types depending on how many origin points the line style has, plus a group style.

(a) **one origin** line styles - linestyle, paperstyle, worldstyle

These can be repeated along the string (continuous mode) or just be applied at each vertex of the string (vertex mode).

The units for the one origin line style can be in pixels, millimetres or world units and the line styles are given specific names depending on the units. The one origin line styles are called

- **linestyle** if the definition of the one origin style is given in **pixel** units
- **paperstyle** if the definition of the one origin style is given in **paper** units
- **worldstyle** if the definition of the one origin style is given in **world** units

The line styles *linestyle, paperstyle, worldstyle* can be made up of lines, arcs, circles and text.
Chapter 40  Linestyles, Symbols, Textstyles & Patterns

Note - to provide more flexibility, for most applications vertex mode has been replaced by symbols on super strings. Unlike vertex mode, symbols can be independently scaled and rotated.

(b) two origins line style - twoptstyle
The line style that can be is stretched between two adjacent vertices is called a twoptstyle style and has two origins.
Because the size is determined by two vertices which are only in world units, the twoptstyle is always in world units.
The line style twoptstyle can be made up of lines, arcs, circles and text.

(c) three origins line style
The line style that can be is stretched in two directions using three adjacent vertices is called a threeptstyle style and has three origins.
Because the size is determined by three vertices which are only in world units, the threeptstyle is always in world units.
The line style threeptstyle can only be made up of lines.

(d) group line style
The final type of line style is called a groupstyle and is a combined style made up of one or more linestyles, paperstyles, worldstyles or twoptstyles.

Warning
The words line style have been used to cover all the different types linestyle, paperstyle, worldstyle, twoptstyle, threeptstyle or groupstyle but for historical reasons, the word linestyle has also been used for all the different types although it also refers to a particular line style.

For further information about line styles, see
40.1.1 Defining Line Styles
40.1.2 Linestyl_4d
40.1.3 Line Style Definitions

Or return to 40.1 Line Styles
40.1.1 Defining Line Styles

A line style is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.

The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn’t drawn to the point.

The default origin of the line style is defined to be the midpoint of the bounding box surrounding the line style. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are xorigin and yorigin commands to override the default origin of the line style.

If a yorigin is set, then it is used as the y-coordinate of the line style. If the xorigin isn’t given, then the xorigin is the midpoint of the x-extent of the bounding box of the line style.

Similarly, if a xorigin is set, then it is used as the x-coordinate of the line style.

If the yorigin isn’t given, then the yorigin is the midpoint of the y-extent of the bounding box of the line style.

The default length of the line style is the horizontal size of the bounding box.

There is a length commands to override the default length of the line style.

The length must always be positive but it can be larger or smaller than the line styles’s calculated horizontal length.
The origin and the length of the line style are both used in positioning and redrawing the line style.

For continuous mode, the origin of the line style is initially placed at a distance of half of the length of the line style along the first link in the string, and then moved the distance length along the string and redrawn. This is repeated along the string until the end of the string is reached. Hence for continuous mode, the style is continually repeated along the string.

For vertex mode, the origin of the line style is placed at each point of the string and the line style drawn around the origin.

Continue to 40.1.2 Linestyl.4d or return to 40.1 Line Styles.
40.1.2 Linestyl.4d

The definitions for the available linestyles are normally stored in a file called *linestyl.4d* which is read in each time 12d Model opens an existing project or creates a new project. *Linestyl.4d* is searched for in the standard set up paths, or is pointed to by the environment variable

```
LINESTYLES_4D       filename
```

The definition of the line styles will be given in the following section 40.1.3 *Line Style Definitions*.

Continue to 40.1.3 *Line Style Definitions* or return to 40.1 *Line Styles*. 
40.1.3 Line Style Definitions

See

40.1.3.1 Linestyles, Paperstyles and Worldstyles
40.1.3.2 Twoptstyles
40.1.3.3 Threeptstyles
40.1.3.4 Groupstyles
40.1.3.5 Description of the draw_commands for Linestyles

40.1.3.1 Linestyles, Paperstyles and Worldstyles

The line style with one origin is called a

- **linestyle** if the definition of the style is given in pixel units
- **paperstyle** if the definition of the style is given in paper units
- **worldstyle** if the definition of the style is given in world units.

**Aside:**
A line style with two origins is called a **twoptstyle**, and a line style with three origins is called a **threeptstyle**. These behave differently to linestyles, paperstyles and worldstyles and will be documented separately.

The one origin style can be drawn at each point of a string (vertex mode) or redrawn regularly along the lines joining string vertices (continuous mode).

The definition of a **linestyle** of a given name *name* is

```plaintext
linestyle name {
    set_up_commands
    draw_commands
}
```

A **paperstyle** is

```plaintext
paperstyle name {
    set_up_commands
    draw_commands
}
```

and a **worldstyle** is

```plaintext
worldstyle name {
    set_up_commands
    draw_commands
}
```

where the set_up_commands must be before the draw_commands.

The linestyle/paper/worldstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes "".

The line style itself is defined inside the braces where there can be zero or more set_up_commands from the list

- **length** value
- **group** name
- **mode** value
factor value
xorigin value
yorigin value

followed by zero or more draw_commands from the list
move x-value y-value
draw x-value y-value
rmove dx-value dy-value
rdraw dx-value dy-value
colour colour_name
circle radius
arc radius start-angle end-angle
text "text" angle height "justification"
text "text" angle height "justification" "textstyle"
text "text" angle height "justification" "textstyle" xfactor slant offset_width offset_height
repeat num_repeats{ repeat_commands repeat_draw_commands}

The repeat command is a positive integer num_repeats
and zero or more repeat_commands from the list
xpos x-value
ypos y-value
rfactor value

and zero or more repeat_draw_commands where repeat_draw_commands include all the
draw_commands except repeat.

The set_up commands for linestyles, paperstyles and worldstyles will now be described. The
draw_commands will be described after the definition of a groupstyle since they are the same
for linestyles, paperstyles, worldstyles and twoptstyles.

set_up_commands for Linestyles, Paperstyles and Worldstyles

group
The group is used to associate line styles in pop-up menus.
If the group is not defined, the style is placed in a default (blank) group.
If the group name includes imbedded spaces, then it must be enclosed in double quotes "."

mode
mode specifies whether the linestyle, paperstyle or worldstyle is drawn at the individual
vertices on a string (vertex mode) or it is to be redrawn regularly along the lines joining the
vertices on the string (continuous mode).
If the mode is not specified, the mode used for a string depends on the breakline type of the
string and the number of vertices on the string.

<table>
<thead>
<tr>
<th>Breakline Type</th>
<th>Number of Vertices</th>
<th>mode: vertex</th>
<th>mode: continuous</th>
<th>mode: not-given</th>
</tr>
</thead>
<tbody>
<tr>
<td>point</td>
<td>1</td>
<td>vertex</td>
<td>cross</td>
<td>vertex</td>
</tr>
<tr>
<td></td>
<td>&gt;1</td>
<td>vertex</td>
<td>continuous</td>
<td>vertex</td>
</tr>
<tr>
<td>line</td>
<td>1</td>
<td>vertex</td>
<td>cross</td>
<td>vertex</td>
</tr>
<tr>
<td></td>
<td>&gt;1</td>
<td>vertex</td>
<td>continuous</td>
<td>continuous</td>
</tr>
</tbody>
</table>
NOTE: in early versions of 12d Model, mode was known as pointline and had the values point instead of vertex, and line instead of continuous.

**factor**
This command factors up/down the drawing co-ordinates, heights and radii.

**xorigin, yorigin**
The default origin of the line style is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The xorigin and yorigin commands are used to override the default origin of the line style.

**length**
If length is omitted, then length is taken to be the horizontal size of the calculated bounding box of the style.

The length must always be positive but it can be larger or smaller than the line style’s calculated horizontal size.

The origin of the line style and the length are both used in positioning and redrawing the line style.

In vertex mode, the origin of the line style is placed at the string points.

In continuous mode, the origin is initially placed at a distance of half of length along the first line in the string, and then moved the distance length along the string for each redraw.

**Examples**

```plaintext
// Fence1
worldstyle "FENCE1"{
  group SWCS
  factor 20
  move 0 0
  rdraw 1 0
  rmove 0.25 -0.25
  rdraw 0.25 0.50
  rmove 0.25 -0.25
  rdraw 1 0
}
```

Linestyles and Worldstyles
// Drainage

worldstyle drainage {
  group "4d"
  factor 0.1
  colour green
  move 0.0 -2.0 draw 30 -2.0
  move 30 -1.5 draw 15 -1.5
  move 15 -1.0 draw 30 -1.0
  move 30 -0.5 draw 15 -0.5
  move 15 0.0 draw 30 0.0
  move 30 0.5 draw 15 0.5
  move 15 1.0 draw 30 1.0
  move 30 1.5 draw 15 1.5
  move 30 2.0 draw 0 2.0
}

// Floodlight

worldstyle FLOODLIGHT {
  group "Energex"
  mode vertex
  xorigin 0
  yorigin 0
  colour "yellow"
  circle 0.225
  move -.45 0
draw -0.225 0
  move 0.45 0
draw 0.225 0
  move 0 -.45
draw 0 -0.225
  move 0 0.45
draw 0 0.225
  move -.159 0.159
draw -0.318 0.318
  move 0.159 0.159
draw 0.318 0.318
  move 0.159 -0.159
draw 0.318 -0.318
  move -0.159 -0.159
draw -0.318 -0.318
  move 0 0.8
  text "FL" 0 0.5 "centre-middle"
}

Continue to 40.1.3.2 Twoptstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.
40.1.3.2 Twoptstyles

A twoptstyle is a line style which is stretched so that one cycle fits between consecutive vertices on a string (line or arc segments). This is achieved by defining two origins for the twoptstyle and the first and second origins are mapped to the consecutive vertices on the string.

Hence the mapping of the two origins defines the final size of the size in world units.

The twoptstyle can stretch in just the direction along the string, or both along and perpendicular to the direction of the string.

Also the twoptstyle can be drawn for each line/arc on the string, or for every second line/arc of the string.

For a feature/circle string, the first origin is placed at the centre of the feature/circle and the second origin is placed on the circumference of the feature/circle. Hence the size of the twoptstyle is determined by the radius of the feature/circle string.

The definition of a twoptstyle of a given name is

```
twoptstyle name {
  set_up_commands
  draw_commands
}
```

where the set_up_commands must be before the draw_commands.

The twoptstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes “”.

The twoptstyle itself is defined inside the braces where there can be zero or more set_up_commands from the list

- group
- stretch_mode
- cycle_mode
- xorigin1
- yorigin1
- xorigin2
- yorigin2

followed by zero or more draw_commands from the list

- move x-value y-value
- draw x-value y-value
- remove dx-value dy-value
- rdraw dx-value dy-value
- colour colour_name
- circle radius
- arc radius start-angle end-angle
- text "text" angle height justification
- text "text" angle height justification textstyle
- text "text" angle height justification textstyle xfactor slant offset width offset_height
- repeat num_repeats { repeat_commands repeat_draw_commands}

The repeat command is a positive integer num_repeats and zero or more repeat_commands from the list

- xpos x-value
- ypos y-value
- rfactor value
and zero or more repeat_draw_commands where repeat_draw_commands include all the draw_commands except repeat.

The set_up commands for a twoptstyle will now be described. The draw_commands will be described after the definition of a groupstyle since they are the same for linestyles, paperstyles, worldstyles and twoptstyles.

**set_up_commands for Twoptstyles**

**group**

The group is used to associate line styles in pop-up menus.

If the group is not defined, the line style is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes “”.

**stretch_mode**

stretch_mode controls whether the symbol stretches in just the direction along the string, or both along and perpendicular to the direction of the string.

<table>
<thead>
<tr>
<th>stretch_mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>// stretch in one direction only (default)</td>
</tr>
<tr>
<td>2</td>
<td>// stretch in both directions</td>
</tr>
</tbody>
</table>

A twoptstyle stretches between two vertices in one or both directions.

**cycle_mode**

cycle_mode controls whether the symbol is drawn for each line/arc on the string, or for every second line/arc of the string.

<table>
<thead>
<tr>
<th>cycle_mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>// draws on every line/arc (default)</td>
</tr>
<tr>
<td>2</td>
<td>// draws every second line/arc</td>
</tr>
</tbody>
</table>

A twoptstyle draws on each line/arc or every second line/arc

**xorigin1, yorigin1**

The point (xorigin1, yorigin1) is mapped to the first vertex that the twoptstyle is being applied to.

The default first point of origin of the twoptstyle is defined to be the minimum x value and the average of the minimum and maximum y values \((x_{\text{min}},(y_{\text{min}}+y_{\text{max}})/2)\).

The xorigin1 and yorigin1 commands are used to override the default first origin of the twoptstyle.

**xorigin2, yorigin2**

The point (xorigin2, yorigin2) is mapped to the second vertex that the twoptstyle is being applied to.

The default second point of origin of the twoptstyle is defined to be the maximum x value.
and the average of the minimum and maximum y values \((x_{\text{max}}, (y_{\text{min}} + y_{\text{max}})/2)\).

The `xorigin2` and `yorigin2` commands are used to override the default second origin of the `twoptstyle`.

**Examples**

```plaintext
// Gate
twoptstyle GATE {
    group "Two Points"
    stretch_mode 2
    cycle_mode 2
    colour red
    move 100 105
draw 140 95
draw 140 105
draw 100 95
draw 100 105
}

// two point tree
twoptstyle 2PT_TREE {
    group "4d_standards"
    stretch_mode 2
    cycle_mode 2
    xorigin10
    yorigin10
    // xorigin22.5
    // yorigin2 1.25

colour "green"
move 0 0
circle 2.5
move 2.48 0.2
draw 0.5 0
draw 2.48 -0.2
move 2.2 -1.2
draw 1.2 -0.9
draw 1.8 -1.7
move 0.7 -2.4
```

}

Continue to 40.1.3.3 Threepstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.
40.1.3.3 Threeptstyles

A **threeptstyle** is a line style that one cycle fits between groups of three consecutive vertices on a string (line or arc segments). This is achieved by defining **three origins** for the threeptstyle.

The threeptstyle is fitted to three consecutive vertices by stretching the threeptstyle differently in two perpendicular directions.

The **first** and **second origins** are **mapped** to the **first two consecutive vertices** of the groups of three vertices on the string and that defines a stretching in the direction from vertex one to vertex two.

The second stretching is perpendicular to the line joining the first two origins and is in the direction of the third origin. When fitting the threeptstyle to the three points, the threeptstyle is stretched in the direction **perpendicular** by the factor equal to:

\[
\frac{\text{(perpendicular distance of the third point from the line joining the first two vertices)}}{\text{(perpendicular distance of the third origin from the line joining the first two origins)}}.
\]

So the **third origin** is usually **not mapped** to the **third vertex**. But the third origin will be on the line through the third vertex and parallel to the line through the first two vertices.

Hence the mapping of the three origins defines the final size of the size in world units.

**Important Note** - because of the stretching in two independent directions, the threeptstyle can only be made up of straight lines.

The definition of a **threeptstyle** of a given name is

```markdown
threeptstyle  name {
  set_up_commands
  draw_commands
}
```

where the **set_up_commands** **must** be before the **draw_commands**.

The **threeptstyle** must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes ".

The **threeptstyle** itself is defined inside the braces where there can be zero or more **set_up_commands** from the list

- `group` name
- `xorigin1` value
- `yorigin1` value
- `xorigin2` value
- `yorigin2` value
- `xorigin3` value
- `yorigin3` value

followed by zero or more **draw_commands** from the list

- `move` x-value y-value
- `draw` x-value y-value
- `rmove` dx-value dy-value
- `rdraw` dx-value dy-value
- `colour` colour_name
- `repeat` num_repeats{ repeat_commands repeat_draw_commands }

The **repeat** command is a positive integer **num_repeats** and zero or more **repeat_commands** from the list

- `xpos` x-value
and zero or more repeat_draw_commands where repeat_draw_commands include all the
draw_commands except repeat.

The set_up commands for a threeptstyle will now be described. The draw_commands will be
described after the definition of a groupstyle since they are the same for linestyles, paperstyles,
worldstyles and twoptstyles.

set_up_commands for Threeptstyles

group

The group is used to associate line styles in pop-up menus.
If the group is not defined, the line style is placed in a default (blank) group.
If the group name includes imbedded spaces, then it must be enclosed in double quotes ".

xorigin1, yorigin1

The point (xorigin1, yorigin1) is mapped to the first vertex that the threeptstyle is being applied
to.

The default first point of origin of the threeptstyle is defined to be the minimum x value and
the average of the minimum and maximum y values (x_min,(y_min+y_max)/2).

The xorigin1 and yorigin1 commands are used to override the default first origin of the
threeptstyle.

xorigin2, yorigin2

The point (xorigin2, yorigin2) is mapped to the second vertex that the threeptstyle is being
applied to.

The default second point of origin of the threeptstyle is defined to be the maximum x value and
the average of the minimum and maximum y values (x_max,(y_min+y_max)/2).

The xorigin2 and yorigin2 commands are used to override the default second origin of the
threeptstyle.

xorigin3, yorigin3

The point (xorigin3, yorigin3) is mapped to the a point on the line parallel to the line through
the first two vertices and going through the third vertex of the three vertices that the
threeptstyle is being applied to.

The default third point of origin of the threeptstyle is defined to be the maximum x value and
the maximum y value (x_max,y_max).

The xorigin3 and yorigin3 commands are used to override the default third origin of the
threeptstyle.

Examples
A threeptstyle stretches between two vertices in one direction and has a different stretch in the perpendicular direction.

```plaintext
threeptstyle "simple turn arrow" {
    group "3 pts"
    xorigin1 0
    yorigin1 0
    xorigin2 10
    yorigin2 0
    xorigin3 10
    yorigin3 3

    colour cyan
    move 0.0 0.0
    draw 10.0 0.0

    colour magenta
    move 10.0 0.0
    draw 10.0 3.0

    colour yellow
    move 10.0 3.0
    draw 9.0 2.0
    move 10.0 3.0
    draw 11.0 2.0
}
```

Continue to 40.1.3.4 Groupstyles or return to 40.1.3 Line Style Definitions or 40.1 Line Styles.
40.1.3.4 Groupstyles

A **groupstyle** is a combined line style which is made up of one or more **linestyles**, **paperstyles**, **worldstyles** and/or **twoptstyles**.

The definition of a **groupstyle** is simply an optional **group** for the line style to belong to, and a list of linestyle, paperstyles, worldstyle and twoptstyle names which must have already been defined in the file.

```
groupline style name {
    group name
    style_name_1
    style_name_2
    ...
}
```

If the **groupstyle** name contains spaces, then it must be enclosed in double quotes "". For example, ""style 1"".

**Example**

```
// POLE
worldstyle POLE {
    group "Electricity"
    mode vertex
    circle 0.5
}
// FN
worldstyle FN {
    group "Fences"
    length 5
    draw 4 0
    move 4.4 0.6
    draw 4.6 -0.6
}
// PF
}groupstyle "PF" {
    group "Miscellaneous"
    "POLE"
    "FN"
}
```
40.1.3.5 Description of the draw_commands for Linestyles

**move** \[ x-value \quad y-value \]
move the pen from the current pen position to the new position \((x-value, y-value)\).

**draw** \[ x-value \quad y-value \]
draw from the current pen position to the new position \((x-value, y-value)\).

**rmove** \[ dx-value \quad dy-value \]
move relative from the current pen position through the distance \((dx-value, dy-value)\).

**rdraw** \[ dx-value \quad dy-value \]
draw relative from the current pen position through the distance \((dx-value, dy-value)\).

**colour** \[ colour-name \]
change colour (line styles can contain more than one colour).
If colour is not defined, the line style is drawn in the colour of the string that the line style is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes ".

**circle** \[ radius \]
draw a circle of the given radius at the current pen position.
After drawing a circle, the current pen position is left at the centre of the circle.

**arc** \[ radius \quad start-angle \quad end-angle \]
draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.
After drawing an arc, the current pen position is left at the centre of the arc.

**text** \[ text \quad angle \quad height \quad "justification" \]
the characters text are drawn at the current pen position with the given angle, height, justification and possibly textstyle, xfactor, slant, offset_width and offset_height. Angle and slant are given in degrees, minutes and seconds in the ddd.mmssfff format. Slant is between -45 and 45 degrees.
The allowed justifications are
top-left top-centre top-right
middle-left middle-centre middle-right
bottom-left bottom-centre bottom-right
and the value is enclosed inside double quotes (").
After drawing text, the current pen position is left where it was before the text was drawn.

**repeat** \[ num_repeats \{ repeat_commands \quad repeat_draw_commands \} \]
The repeat command allows the set of repeat_draw_commands inside the braces (the repeat-style) to be re-drawn a number of times (num_repeats), and with each redraw, the size of the repeat-style is modified.
In the definition of repeat, there can be zero or more repeat_commands from the list

**xpos** \[ x-value \]
ypos       y-value
rfactor    value

and zero or repeat_draw_commands where repeat_draw_commands include all
draw_commands except repeat.

Unlike style, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is
actually drawn with this origin at the position given by the values of xpos and ypos.
The repeat-style is drawn num_repeats times and on each redraw, the distances, heights and
radii are factored by the amount

\[ \text{repeat_factor} = (1 - i \cdot \text{rfactor}) \]
\[ \text{where } i = 0, 1, ..., \text{num_repeats}-1 \]

If rfactor is not specified, it is given the default value of 1/num_repeats. The factor is then

\[ \text{repeat_factor} = (\text{num_repeats} - i)/\text{num_repeats} \]
\[ \text{where } i = 0, 1, ..., \text{num_repeats}-1 \]

Examples of the Repeat Command
1. To produce circles of radius 10,9,8,...1 about the origin.
   repeat 10 { circle 10}

2. To produce circles of radius 10,9.5,9,...5.5 about the origin
   repeat 10 { rfactor 0.05 circle 10}

More Examples of Line, Paper and World Styles
1. draw a circle of radius 20. The origin of the style is (0,0)
   worldstyle "circle" {
      move 0 0
      circle 20
   }

2. draw a circle of radius 20. The origin of the style is (100,100)
   paperstyle "circle" {
      move 100 100
      circle 20
   }

3. draw a circle of radius 20. The origin of the style is (0,0)
   linestyle "circle" {
      xorigin 0
      yorigin 0
      move 100 100
      circle 20
   }

4. draw a gate symbol as a twoptstyle.
   worldstyle "circle" {
      group "fences"
      stretch_mode 1 // one direction stretch
      cycle_mode 2 // draw every second line
      move 0 0
   }

Line Styles
draw 0 0.1
draw 1 0
draw 1 0.1
draw 0 0
}

5. draw concentric circles of centre (0,0) inside a box

linestyle "dot" { 
xorigin 0
yorigin 0
move -5 -5
draw -5 25
draw 25 25
draw 25 -5
draw -5 -5
repeat 10 {
    move 0 0
    circle 10
}
}

6. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

linestyle "arc" { 
    move 0 0
    arc 10 45 -45
}

7. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

worldstyle "arc 1" { 
    move 0 0
    arc -10 45 -45
}

8. top-left justified text with a circle centred on the actual text position

linestyle "top-left" { 
    group text
    move 0 0
    circle 4
    text "<top left>" 0 10 "top-left"
}

Return to 40.1.3 Line Style Definitions or 40.1 Line Styles.
40.2 Symbols

Users can define their own symbols to draw at vertices of 12d Model strings. The definition of symbols are stored in a file called symbols.4d.

Symbols in the file can be created/edited using the Symbols Create/Edit/Delete panel which is brought up by double clicking on Create symbol in the Symbols expansion of the Project Tree (see 7.9.5 Symbols) brought up by the Project =>Tree option.

The Symbol Create/Edit/Delete panel acts as an interactive editor to a text file which contains the symbol definitions.

The user defined symbols can be applied to each vertex of a string. Each symbol can be made up of lines, arcs, circles and text.

A symbol applied to vertices.

The units for the symbol can be in pixels, millimetres or world units. The symbol is called a

- paperstyle if the definition of the symbol is given in paper units
- worldstyle if the definition of the symbol is given in world units

For further information about Symbols, see
40.2.1 Defining Symbols
40.2.2 Symbol.4d
40.2.3 Symbol Definition

Or return to 40.2 Symbols
40.2.1 Defining Symbols

A symbol is defined in a (x,y) co-ordinate system as a series of moves, drawn, arcs, circles and text commands.

The bounding box of the line style is the smallest rectangle parallel to the (x,y) axis which contains all the moves, draws, circles and arcs of the line style. Note that moves are included in the bounding box even if a line isn’t drawn to the point.

The default origin of the symbol is defined to be the midpoint of the bounding box surrounding the symbol. The bounding box includes the points moved to and drawn to, but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

There are xorigin and yorigin commands to override the default origin of the symbol.

If a yorigin is set, then it is used as the y-coordinate of the symbol. If the xorigin isn’t given, then the xorigin is the midpoint of the x-extent of the bounding box of the symbol.

Similarly, if a xorigin is set, then it is used as the x-coordinate of the symbol. If the yorigin isn’t given, then the yorigin is the midpoint of the y-extent of the bounding box of the symbol.

The default length of the line style is the horizontal size of the bounding box.

There is a length commands to override the default length of the symbol. The length must always be positive but it can be larger or smaller than the symbols calculated horizontal length.

The origin and the length of the symbol are both used in positioning and sizing the symbol.

Continue to 40.2.2 Symbol 4d or return to 40.2 Symbols.
40.2.2 Symbol.4d

The definitions for the available symbols are normally stored in a file called `symbols.4d` which is read in each time 12d Model opens an existing project or creates a new project. `Symbol.4d` is searched for in the standard set up paths, or is pointed to by the environment variable

```
SYMBOLS_4D filename
```

The definition of the symbols will be given in the following section 40.2.3 Symbol Definition.

Continue to 40.2.3 Symbol Definition or return to 40.2 Symbols.
40.2.3 Symbol Definition

The definition of a worldstyle symbol of a given name name is

```
worldstyle name {
    set_up_commands
    draw_commands
}
```

where the set_up_commands must be before the draw_commands.

The linestyle/paper/worldstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes ““.

The symbol itself is defined inside the braces where there can be zero or more set_up_commands from the list

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>value</td>
</tr>
<tr>
<td>group</td>
<td>name</td>
</tr>
<tr>
<td>factor</td>
<td>value</td>
</tr>
<tr>
<td>xorigin</td>
<td>value</td>
</tr>
<tr>
<td>yorigin</td>
<td>value</td>
</tr>
</tbody>
</table>

followed by zero or more draw_commands from the list

```
move  x-value y-value
draw   x-value y-value
rmove dx-value dy-value
rdraw dx-value dy-value
colour colour_name
circle radius
arc   radius start-angle end-angle
text "text" angle height "justification"
text "text" angle height "justification" "textstyle"
text "text" angle height "justification" "textstyle" xfactor slant offset_width offset_height
```

The repeat command is a positive integer num_repeats

```
repeat num_repeats {
    repeat_commands repeat_draw_commands
}
```

and zero or more repeat_commands from the list

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpos</td>
<td>x-value</td>
</tr>
<tr>
<td>ypos</td>
<td>y-value</td>
</tr>
<tr>
<td>rfactor</td>
<td>value</td>
</tr>
</tbody>
</table>

and zero or more repeat_draw_commands where repeat_draw_commands include all the draw_commands except repeat.

The set_up commands for symbols will now be described followed by the draw_commands.

See

40.2.3.1 set_up_commands for symbols
40.2.3.2 Description of the draw_commands for Symbols

Or return to 40.2 Symbols
40.2.3.1 set_up_commands for symbols

**group**

The *group* is used to associate symbols in pop-up menus.

If the group is not defined, the symbol is placed in a default (blank) group.

If the group name includes imbedded spaces, then it must be enclosed in double quotes ".

**factor**

This command factors up/down the drawing co-ordinates, heights and radii.

**xorigin, yorigin**

The default origin of the symbol is defined to be the midpoint of the bounding box of the line style. The bounding box includes the points moved to and drawn to but does not automatically include (0,0). Hence the calculated origin may not be (0,0).

The *xorigin* and *yorigin* commands are used to override the default origin of the symbol.

**length**

If length is omitted, then *length* is taken to be the horizontal size of the calculated bounding box of the symbol.

The *length* must always be positive but it can be larger or smaller than the symbols calculated horizontal size.

The origin of the symbol and the length are both used in positioning and sizing of the symbol.

**Examples**

```
// Floodlight
worldstyle FLOODLIGHT {
  group "Energex"
  mode vertex
  xorigin 0
  yorigin 0
  colour "yellow"
  circle 0.225
  move -.45 0
  draw -0.225 0
  move 0.45 0
  draw 0.225 0
  move 0 -.45
  draw -0.225
  move 0 0.45
  draw 0 0.225
  move -.159 0.159
  draw -0.318 0.318
  move 0.159 0.159
  draw 0.318 0.318
```
move 0.159 -0.159
draw 0.318 -0.318
move -0.159 -0.159
draw -0.318 -0.318
move 0 0.8
text "FL" 0 0.5 "centre-middle"
}

Continue to 40.2.3.2 Description of the draw commands for Symbols or return to 40.2.3 Symbol Definition or 40.2 Symbols.
40.2.3.2 Description of the draw_commands for Symbols

**move** \(x\text{-value} \ y\text{-value}\)
move the pen from the current pen position to the new position \(x\text{-value}, y\text{-value}\).

**draw** \(x\text{-value} \ y\text{-value}\)
draw from the current pen position to the new position \(x\text{-value}, y\text{-value}\).

**rmove** \(dx\text{-value} \ dy\text{-value}\)
move relative from the current pen position through the distance \(dx\text{-value}, dy\text{-value}\).

**rdraw** \(dx\text{-value} \ dy\text{-value}\)
draw relative from the current pen position through the distance \(dx\text{-value}, dy\text{-value}\).

**colour** \(colour\text{-name}\)
change colour (line styles can contain more than one colour).
If colour is not defined, the symbol is drawn in the colour of the string that the symbol is applied to. If the colour-name includes imbedded spaces, then it must be enclosed within double quotes ".

**circle** \(radius\)
draw a circle of the given radius at the current pen position.
After drawing a circle, the current pen position is left at the centre of the circle.

**arc** \(radius \ start\text{-angle} \ end\text{-angle}\)
draw an arc of the given radius from the start angle to the end angle. A positive radius denotes that the arc is drawn in a clockwise direction, a negative radius means anti-clockwise. Angles are given in degrees, minutes and seconds in the ddd.mmssfff format.
After drawing an arc, the current pen position is left at the centre of the arc.

**text** \(text \ angle \ height \ "justification"\)
the characters \text are drawn at the current pen position with the given angle, height, justification and possibly textstyle, xfactor, slant, offset_width and offset_height. Angle and slant are given in degrees, minutes and seconds in the ddd.mmssfff format. Slant is between -45 and 45 degrees.
The allowed justifications are

- top-left
- top-centre
- top-right
- middle-left
- middle-centre
- middle-right
- bottom-left
- bottom-centre
- bottom-right
and the value is enclosed inside double quotes (").
After drawing text, the current pen position is left where it was before the text was drawn.

**repeat** \(num\text{-repeats}\) \{ \(repeat\_commands\ \ repeat\_draw\_commands\) \}
The repeat command allows the set of repeat\_draw\_commands inside the braces (the repeat-style) to be re-drawn a number of times \(num\text{-repeats}\), and with each redraw, the size of the repeat-style is modified.
In the definition of repeat, there can be zero or more repeat\_commands from the list

**xpos** \(x\text{-value}\)
and zero or repeat_draw_commands where repeat_draw_commands include all draw_commands except repeat.

Unlike symbol, the repeat-style is defined in terms of a local origin at (0,0). The repeat-style is actually drawn with this origin at the position given by the values of xpos and ypos.

The repeat-style is drawn \textit{num_repeats} times and on each redraw, the distances, heights and radii are factored by the amount

\[ \text{repeat_factor} = (1 - i \times \text{rfactor}) \]

where \( i = 0, 1, \ldots, \text{num_repeats}-1 \)

If rfactor is not specified, it is given the default value of \( 1/\text{num_repeats} \). The factor is then

\[ \text{repeat_factor} = (\text{num_repeats} - i)/\text{num_repeats} \]

where \( i = 0, 1, \ldots, \text{num_repeats}-1 \)

\textbf{Examples of the Repeat Command}

1. To produce circles of radius 10,9,8,...1 about the origin.
   
   \[ \text{repeat 10 \{ circle 10 \}} \]

2. To produce circles of radius 10,9.5,9,...5.5 about the origin
   
   \[ \text{repeat 10 \{ rfactor 0.05 circle 10 \}} \]

\textbf{More Examples of World Styles}

1. draw a circle of radius 20. The origin of the style is (0,0)
   
   \[ \text{worldstyle "circle" \{ move 0 0 \text{circle 20} \}} \]

2. draw a circle of radius 20. The origin of the style is (100,100)
   
   \[ \text{worldstyle "circle" \{ move 100 100 \text{circle 20} \}} \]

3. draw a circle of radius 20. The origin of the style is (0,0)
   
   \[ \text{worldstyle "circle" \{ xorigin 0 yorigin 0 move 100 100 \text{circle 20} \}} \]

4. draw concentric circles of centre (0,0) inside a box
   
   \[ \text{worldstyle "dot" \{ xorigin 0 yorigin 0 move -5 -5 \text{draw -5 25} \text{draw 25 25} \}} \]
draw 25 -5
draw -5 -5
repeat 10 {
    move 0 0
    circle 10
}

5. draw an arc of absolute radius 10 in the clockwise direction from the angle 45 to the angle -45.

    worldstyle "arc" {
        move 0 0
        arc 10 45 -45
    }

6. draw an arc of absolute radius 10 in the anti-clockwise direction from the angle 45 to the angle -45.

    worldstyle "arc 1" {
        move 0 0
        arc -10 45 -45
    }

7. top-left justified text with a circle centred on the actual text position

    worldstyle "top-left" {
        group text
        move 0 0
        circle 4
        text "<top left>" 0 10 "top-left"
    }

Return to 40.2.3 Symbol Definition or 40.2 Symbols.
40.3 Textstyles and Fonts

Users can define any number of textstyles and specify how they are mapped to AutoCAD style names or Microstation (DGN, Intergraph) font numbers.

There is one fixed spaced textstyle called "1" (the default) which is identical to the textstyle used in earlier versions of 12d Model.

Each textstyle has a font definition (or font 1 as the default) which defines the stroking for each character in the font. True Type fonts are supported and most AutoCAD SHP files can be used to define the fonts.

Textstyles using True Type fonts or shape file which do not use arcs in their font definition, can also have a slant and a x_factor.

Textstyles can be used in text strings, 4d strings, super strings, linestyles, plots and user defined title blocks.

For further information about Textstyles and Fonts, see

40.3.1 Textstyles Definitions File
40.3.2 Fonts Definitions File
40.3.1 Textstyles Definitions File

Textstyles can be created/edited using the Create/Edit Textstyle panel which is brought up by double clicking on Create textstyle in the Textstyles expansion of the Project Tree (see 7.9.6 Textstyles) brought up by the Project => Tree option.

The Create/Edit Textstyle panel acts as an interactive editor to a text file which contains the textstyle definitions. The full description of the text file will now be given.

The definitions for the available textstyles are normally stored in a file called textstyl.4d which is read in each time 12d Model opens an existing project or created a new project. Textstyl.4d is searched for in the standard set up paths, or is pointed to by the environment variable TEXTSTYLES_4D filename

Inside textstyl.4d, a textstyle of a given name is defined by

```
  textstyle    textstyle_name    {
    textstyle commands
  }
```

Each textstyle must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes " ".

The textstyle itself is defined inside the braces where there can be zero or textstyle commands from the list

```
  font_name    text
  hardware_text_dxf
  stroked_text_dxf
```

The commands for reading and writing dxf files are similar to those for dgn except that dxf has font numbers.

```
output_name_dxf     text
input_name_dxf     text

or

hardware_text_dxf
stroked_text_dxf

output_name_dgn     integer
input_name_dgn     integer

hardware_text_model
stroked_text_model

or

stroked_text
hardware_text

fixed_height     value
variable_height

fixed_slant     value
variable_slant

fixed_xfactor     value
variable_xfactor
```

The description of each command is

```
font_name     text
```

Name of the font to be used to draw the characters of the textstyle. The stroking of the font characters can be defined in the file fonts.4d. If no font_name is given, or the stroking is not given in the font file, then the standard 12d Model font is used ("1").

```
hardware_text_dxf     or stroked_text_dxf
```

If stroked_text_dxf appears, then any text in this textstyle written out to dxf will be stroked - that is, broken into straights, lines and curves.

If hardware_text_dxf is in the file, then any text in this textstyle sent to dxf will be given as actual dxf text (not stroked).

```
output_name_dxf     dxf_style_name
```

If text is sent to dxf as hardware text, the dxf style of the text will be dxf_style_name.

```
input_name_dxf     dxf_style_name
```

When reading in dxf files, any text of style dxf_style_name will be given the 12d Model textstyle name textstyle_name.

The commands for reading and writing dgn files are similar to those for dxf except that dgn has font numbers.

```
output_name_dgn     dgn_font_number
input_name_dgn     dgn_font_number

hardware_text_model     or stroked_text_model
```

Similarly, when writing out to a 12d Model model. For hardware_text_model, text will be sent to text with the same textstyle.

```
stroked_text     or hardware_text
```

If stroked_text appears in the definition and there is no other hardware_text flag set, then the text will be stroked - that is, broken into straights, lines and curves.

If hardware_text appears in the definition, then the text is written out as hardware text.
By default, the height, slant and xfactor for the text can be set when text is defined however it is possible to set each of height, slant and xfactor to a fixed value.

\[ \text{fixed_height \hspace{0.5cm}} \text{value} \]

or

\[ \text{variable_height} \]

If fixed_height and a value are specified, then all text in this textstyle is drawn at a fixed height. If fixed_height is missing or variable_height (the default) appears, then each text string in the textstyle has its own height.

\[ \text{fixed_slant \hspace{0.5cm}} \text{value} \]

or

\[ \text{variable_slant} \]

If fixed_slant and a value are specified, then all text in this textstyle is drawn at a fixed slant. If fixed_slant is missing or variable_slant (the default) appears, then each text string in the textstyle has its own slant. Slant is given in degrees, minutes and seconds in the ddd.mmssfff format and must be between -45 and 45 degrees.

\[ \text{fixed_xfactor \hspace{0.5cm}} \text{value} \]

or

\[ \text{variable_xfactor} \]

If fixed_xfactor and a value are specified, then all text in this textstyle is drawn at a fixed xfactor. If fixed_xfactor is missing or variable_xfactor (the default) appears, then each text string in the textstyle has its own xfactor.

**Example of a Textstyle File**

textstyle "1" { // DGN FONT 0 ACAD FONT STANDARD
  output_name_dxf STANDARD
  input_name_dxf STANDARD
  input_name_dgn "0"
  output_name_dgn "0"
  stroked_text
  hardware_text_model
  hardware_text_dgn
  hardware_text_dxf
}

textstyle ISO { // DGN FONT 1 ACAD FONT ISO
  font_name ISO
  input_name_dxf ISO
  output_name_dxf ISO
  input_name_dgn "1"
  output_name_dgn "1"
  stroked_text
  hardware_text_model
  hardware_text_dgn
  hardware_text_dxf
}

textstyle MONO { // DGN FONT 2 ACAD FONT MONO
  font_name MONO
  output_name_dxf MONOTXT
  input_name_dxf MONOTXT
  input_name_dgn "2"
  output_name_dgn "2"
  stroked_text
  hardware_text_model
  hardware_text_dgn

hardware_text_dxf

}
textstyle SCRIPT { // DGN FONT 3 ACAD FONT

font_name SCRIPT
output_name_dxf SCRIPTC
input_name_dxf SRCIPTC
input_name_dgn "3"
output_name_dgn "3"
stroked_text
hardware_text_model
hardware_text_dgn
hardware_text_dxf

}

Continue to the next section 40.3.2 Fonts Definitions File for a description of the fonts file, or return to 40.3 Textstyles and Fonts.
40.3.2 Fonts Definitions File

The definition of any fonts referred to in the textstyl.4d file are given in the fonts.4d file which is searched for in the standard 12d Model set up paths, or is pointed to by the environment variable

```plaintext
FONTS_4D filename
```

The stroking for each character in the font (which is used when drawing the text on the screen and when required, stroking the text for outputs and plots) can be given in a separate file in the Autocad shape file format.

Inside fonts.4d, a font of a given name is defined by

```plaintext
class   font_name {     
    font commands
}
```

Each font must have a name and if the name includes imbedded spaces, it must be enclosed in double quotes " ".

The font itself is defined inside the braces where there can be zero or more font commands from the list

```plaintext
stroke_file filename
proportional
fixed
```

The description of each command is

```plaintext
stroke_file stroke_file_name
```

The name of the file containing the stroking for each character in the font in AutoCAD ascii shape file format (.shp). The stroke_file_name is searched for in the standard 12d Model set up paths. If the stroking for a character is not defined, the standard 12d Model character is used instead.

```plaintext
proportional
fixed
```

If a stroke file is not given, then the font could be a fixed (mono) or proportional font.

**Example of a Font File**

```plaintext
font ISO {
    proportional
    stroke_file "ISO"
}
font GOTHIC {
    proportional
    stroke_file "GOTHICE.SHP"
}
font MONO {
    proportional
    stroke_file "MONOTXT.SHP"
}
```
Continue to the next section 40.3.2 Fonts Definitions File for a description of the fonts file, or return to 40.3 Textstyles and Fonts.

Return to 40.3 Textstyles and Fonts or 40 Linestyles, Symbols, Textstyles & Patterns.
40.4 Patterns

12d Pattern Fills provide the definitions of the patterns used for filling Super Strings.

The definitions of patterns are stored in a file called patterns.4d and users can add their own patterns to this file. See 40.4.1 Patterns.4d.

If a patterns file has been read, the pop-up for the Pattern field in the Pattern tab of the Change Super String Filling panel will list the patterns read from the file. See 14.12.9.5 Fills.

Any groups in the pattern file will be displayed as Folders in the pop-up list.
there are two patterns star and solid dot without a group and group called BCC with one pattern Cement.

Continue to 40.4.2 12d Patterns Definitions File or return to 40.4 Patterns.
40.4.1 Patterns.4d

Some patterns are installed with 12d Model and users can also define their own patterns.

The definitions of the available 12d patterns are stored in a file called patterns.4d which is read in each time 12d Model opens an existing project or creates a new project.

patterns.4d is searched for in the standard set up paths, or the full path of file to use can be given by the environment variable

```
    PATTERNS_4D    path_name_of_file
```

The definition of the 12d patterns is given in the section 40.4.2 12d Patterns Definitions File.

Continue to 40.4.2 12d Patterns Definitions File or return to 40.4 Patterns.
40.4.2 12d Patterns Definitions File

The definitions for the available patterns is stored in a file called `patterns.4d` which is read in each time 12d Model opens an existing project or created a new project. `Patterns.4d` is searched for in the standard set up paths, or is pointed to by the environment variable `PATTERNS_4D` filename.

There is no inbuilt 12d editor for patterns.4d and a text editor is used to create it. The full description of the text file will now be given.

The `patterns.4d` file consists of the word `patterns` followed by at least one space and the an open brace `{`, then the definitions of each pattern and finally a closing brace `}`.

That is,

```
patterns  
  { 
    definition_of_pattern_group_1 
    definition_of_pattern_group_2 
    . . . 
    definition_of_pattern_group_n 
  } 
```

where each `definition_pattern_group_i` is the definition of a group of patterns.

The format of each `definition_of_pattern_group_i` is

(a) group `{ 
  name  group_name 
  definition_of_pattern_1 
  definition_of_pattern_2 
  . . . 
  definition_of_pattern_n 
}

where `group_name` is the name of the group for all the patterns defined inside the `definition_of_pattern_group_1`, and `definition_of_pattern_i` is the definition of an individual pattern or just

(b) `definition_of_pattern_i`

where `definition_of_pattern_i` is the definition of an individual pattern. In this case the pattern does not belong to any group.

data defining how the pattern draws (looks like).

Each `definition_of_pattern_i` is the definition of a single pattern and its format is

```
pattern  
  { 
    name  pattern_name 
    pattern_data_1 
    pattern_data_2 
    . . . 
    pattern_data_n 
  } 
```

where `pattern_name` is the name of the pattern and each `pattern_data_i` is the data defining
how part of the pattern draws (looks like).
Each pattern_name must be unique within the patterns.4d file and if the name includes
imbedded spaces then the name must be enclosed in double quotes ".

The format of pattern_data_i is that of a super string (without pattern fills) in 12da format except
that in the super string definition:

    string super {

is replaced by

    data {

The super strings must not include any patterns.
For the 12da format of a super string, see 34.4.8 Super String.

So a definition_of_pattern_i consists of a a unique name and the drawing sections of 0 or
more super strings.

An example of patterns and the patterns.4d file defining them is:

![Patterns Diagram]

Patterns
41 Functions Keys, Menus, Toolbars

This appendix contains information about how user defined function keys, menus and toolbars are defined and used in 12d Model.

See
41.1 User Defined Function Keys
41.2 User Defined Menus
41.3 User Defined Toolbars

41.1 User Defined Function Keys

The user can define function keys (with possible modifiers) to be used to
(a) bring up most 12d Model menus or panels
(b) toggle certain snaps on or off.
(c) start some geometry snaps
(d) read a layout file
(e) execute a batch file or a program (system call).
(f) run 12d Model 12dPL’s (macros) or chains

The function key definitions are given in the file

userkeys.4d

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or is pointed to by the environment variable

FUNCTION KEYS_4D file // function key definitions

The format of the function_keys file is simply a list of function key definitions with only one per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

The function key definition is

MODIFIERS FUNCTION_KEY OPERATION

where MODIFIERS can be totally missing or any combination of

shift
close
or
alt

FUNCTION_KEY is one of

f1, f2,...f12 (f7 should be avoided since it is used in 12d Model for typed input,
f1 & f10 should be avoided since they are reserved by Windows NT)

and OPERATION is one of

menu menu_name // raise a menu
panel panel_name // raise a panel
snap toggle_snap // list of toggle_snaps given below
snap cogo_snap // list of cogo_snaps given below
cogo_command // list of cogo_commands given below
layout layout_file_name // run a screen layout file
system batch_file // run a batch file
system program // run a program
or for macros

```
    macro    options          user_macro_name      macro_arguments
```

where the macros options are:

- **-no_console**  // don’t display macro console
- **-close_on_exit**  // remove console when macro terminates
- **-buttons**  // have buttons for finish, restart and quit on console
- **-allow_defaults**  // allow default answers for console questions

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

**For information on how to use each item with function keys, see**

- Menus and Panels
- View Menus and Panels
- View Toggle Menus
- Available Snaps to be Toggled
- Available Cogo Snaps
- Available Cogo Commands
- Layout Files
- System Calls
- 12dPLs (Macros)
- Chains

For using $LIB and $User_Lib, see $LIB and $USER_LIB.
For an example of userkeys.4d, see Example of a User Function Key File.

**Menus and Panels**

Menus and panels can be programmed by functions keys by simply giving the name of the menu and panel after the `panel` command.

For example,

```
f5    panel       "String Inquire"       // this is a panel
f6    panel       "String Create"       // this is a menu
```

**Note**: the names for each menus and panel (together) must have unique names so there is no confusion about what is to be run by just giving the name after the command `panel`.

**View Menus and Panels**

Menus and panels for views can be programmed by functions keys by substituting the text `$PLAN_VIEW`, `$SECTION_VIEW` or `$PERSPECTIVE_VIEW` in place of the view name in the panel name or menu name.

For example,

```
f9    panel       "Plan Plot $PLAN_VIEW"
```

A panel for each view type can be programmed for the same modifier and function key combination. If the cursor is over the appropriate view type when the function key is selected, then the panel is fired up.

For example, the three definitions for f5

```
f5    panel       "Section Plot $SECTION_VIEW"
f5    panel       "Plan Plot $PLAN_VIEW"
f5    panel       "Perspective Plot $PERSPECTIVE_VIEW"
```

means that a panel will come up when f5 is selected over any of the three view types.
View Toggle Menus

The **toggle menus** available on each view can be set to a function key by

<table>
<thead>
<tr>
<th>MODIFIERS</th>
<th>FUNCTION_KEY</th>
<th>menu</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>FUNCTION_KEY</td>
<td>menu</td>
<td>&quot;Toggle PLAN_VIEW&quot;</td>
</tr>
<tr>
<td></td>
<td>FUNCTION_KEY</td>
<td>menu</td>
<td>&quot;Toggle SECTION_VIEW&quot;</td>
</tr>
<tr>
<td></td>
<td>FUNCTION_KEY</td>
<td>menu</td>
<td>&quot;Toggle PERSPECTIVE_VIEW&quot;</td>
</tr>
</tbody>
</table>

As for the view menus, the cursor must be over the appropriate view type when the function key is selected.

For example,

```
shift f8 menu "Toggle $PLAN_VIEW"
```

brings up the plan view toggle menu if shift f8 is selected when in a plan view.

**Available Snaps to be Toggled**

- toggle_point_snap
- toggle_line_snap
- toggle_grid_snap
- toggle_cursor_snap
- toggle_tin_snap
- toggle_input_height_snap
- toggle_show_information

For example,

```
control f2 toggle_point_snap
```

**Available Cogo Snaps**

- snap create_edit
- snap line_create_edit
- snap tangent_items_edit
- snap fillet_3_points_edit
- snap fillet_item_item_cp_edit
- snap fillet_item_item_radius_cp_edit
- snap locate_divide_edit
- snap locate_divide_distance_edit
- snap parallel_edit
- snap intersect_edit
- snap intersect_offset_edit
- snap bearings_intersect_edit
- snap between_points_edit
- snap locate_edit
- snap locate_chainage_edit
- snap locate_offset_edit
- snap locate_deflection_edit
- snap locate_drop_perpendicular_edit
- snap locate_projection_edit
- snap locate_two_point_distances_edit

For example,

```
shift f1 snap locate_chainage_edit
```

**Available Cogo Commands**

All the new cogo commands can be activated by a function key.

- create_edit
- line_create_edit
- tangent_items_edit
- fillet_3_points_edit
- fillet_item_item_cp_edit
- fillet_item_item_radius_cp_edit
locate_divide_edit
locate_divide_distance_edit
parallel_edit
intersect_edit
intersect_offset_edit
bearings_intersect_edit
between_points_edit
locate_edit
locate_chainage_edit
locate_offset_edit
locate_deflection_edit
locate_drop_perpendicular_edit
locate_projection_edit
locate_two_point_distances_edit

For example,

```
f2 between_points_edit
```

**Layout Files**

Layout files can be called up using the `layout` command.

For example,

```
f8 layout "temp/contours.slf"
```

**System Calls**

Programs and batch files can be called up using the `system` command. The directories defined by the environment variables `$LIB_4D` and `$USER_4D` are included in the PATH environment variables so that any batch files or executables in these areas will be accessible without including any path name in the system call.

For example,

```
f4 system special.exe // run the program special.exe
shift f4 system batch.bat // run a batch file
control f4 system "start cmd /k dir" // do a dir in a command shell
```

**12dPLs (Macros)**

12d supplied and User 12dPLs (macros) can be run and the macros brought up with or without buttons, and with leaving or removing the macro console when the macro has finished.

The macro command structure and options are:

```
macro options user_macro_name macro_arguments
```

where the macros options are:

- `-no_console` // don't display macro console
- `-close_on_exit` // remove console when macro terminates
- `-buttons` // have buttons for `finish`, `restart` and `quit` on console
- `-allow_defaults` // allow default answers for console questions

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For example,

```
f8 macro -no_console -close_on_exit"/area/drape_align.4do"
f9 macro -buttons"/games/lots.4do"
```

For compatibility with earlier versions of **12d Model**, the following macro commands are also supported:

```
macro user_macro_name // run macro without buttons,
```
macrow user_macro_name // leave console panel on exit
macrow_with_buttons user_macro_name // run macro without buttons,
// remove console panel on exit
macrow_with_buttons_2 user_macro_name // run macro with buttons,
// leave console panel on exit

Chains
12d supplied and User chains can be run by using the chain command.
    chain chain_name
For example,
    f8 chain "tri_cont_label.chain"

$LIB and $USER_LIB
The variable $LIB and $USER_LIB can be used as part of the layout_file_name and
user_macro_name to pick up files from either the library or user library.
For example,
    f7 macro "$LIB/drape_align.4do"
    f8 macro "$USER_LIB/lots.4do"
    f9 layout "$LIB/contours.slf"
Note - if $LIB_4D is not defined, then 12dmodel/6.00/library is used. If $USER_LIB_4D is not
defined, then 12dmodel/6.00/user_lib is used

Example of a User Function Key File
// File to define function key usage
// Note: f1, f6 & f10 are reserved by Windows NT
// f7 is reserved by 4D Solutions for typed input
// Available function key modifiers are
// shift control alt
// Note: some alt key combinations are reserved by Windows NT
// Some sample lines may be
// f5  toggle_point_snap
// shift f5  toggle_line_snap
// control shift f7  toggle_input_height_snap
// Note that all function key modifiers must come before the function key itself.
// -----------------------------------------------------
// snaps
f3  toggle_point_snap
f4  toggle_line_snap
f5  toggle_grid_snap
f5  toggle_cursor_snap
f8  toggle_input_height_snap
// snaps cogo
f9  snap intersect_offset_edit
f11  snap locate_chainage_edit
f12  snap locate_drop_perpendicular_edit
// panels
f2       panel "String Inquire"
shift f1 panel "Edit String"
shift f2 panel "String Delete"
shift f3 panel "Clean Model"
shift f4 panel "Delete Model"
shift f5 panel "Strings Edit Ops"
shift f6 panel "Points Edit Ops"
shift f7 panel "String Attributes"
shift f8 panel "Toggle $PLAN\_VIEW"

// layout files
control f4 layout "$LIB/tri_contour_clean.slf"

// user macros
control f5 macro -no_console -close_on_exit "$LIB/Culd.4do"

// -----------------------------------------------------

Continue to the next section 41.2 User Defined Menus or return to 41 Functions Keys, Menus, Toolbars.
41.2 User Defined Menus

To help customise 12d Model, there is a pull down menu User on the Main menu and User menus on each of the pull down menus on the Main menu, and some other Menus.

The User menus can run 12d Model macros, external programs, chains, and bring up 12d Model screen layout files, panels and menus.

User menus can have walk-right menus, and any walk-right menus can have further walk-right menus so User menus can be used to build sophisticated tailored additions to 12d Model. Each of the User Defined menus are also floating (tear away) menus just like standard 12d Model menus.

All the User menus are defined in the two files: Usermenu.4d, which is created by the user, and Xtramenu.4d, which supplied by 12d Solutions.

When displayed, each User menu is divided into two sections with menu options supplied by User in the file Xtramenu.4d on the top, and any options supplied by the user (in the file Usermenu.4d) underneath.

The default name for the User Defined Menus definition file is

```
usermenu.4d
```

which is searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable

```
USER_OPTIONS_4D file // Customers User menu definition
```

The default name for the 12d Solutions definition file which includes some macro for User is

```
xtramenu.4d
```

which is also searched for in the standard set up areas (local, USER_4D, user, set_ups etc.) or set by the environment variable
EXTRA_OPTIONS_4D file // 12D Solutions User menu definitions

The format for the User Defined Manu’s file is given in the next section 41.2.1 Full Definition of User Menus.

**Important Note**

The file `xtramenu.4d` is for use by **12d Solutions** only. Please do not modify it because it may be overwritten in future updates. The file `usermenu.4d` is for Customer use.

See

- 41.2.1 Full Definition of User Menus
- 41.2.2 Using `$LIB` and `$USER_LIB` in User Menus
- 41.2.3 Placing User Defined Menus on User and Other 12d Menus
- 41.2.5 Example of a User Defined Menu
41.2.1 Full Definition of User Menus

The User Defined Menus are made up of buttons which have text on them and when the left hand mouse button (LB) is pushed down and released on a button, a command is executed.

A button can also have a walk-right menu which appears when the left hand mouse button (LB) is moved over the arrow on the right hand side of the button. Walk-right menus can have walk-right menus.

The text for each button in the User menus, plus the action taken when the button is selected, is user specified. Any of the buttons can include further walk-right menus.

When a button is selected, the action can be to

(a) run a 12d Model macro
(b) run a 12d Model chain
(c) bring up a 12d Model menu or User Defined menu
(d) bring up a 12d Model panel
(e) read a screen layout file
(f) execute a batch file or program (system call)

In the Usermenu.4d file, a menu is defined by:

```plaintext
Menu menu_name {
    button_1
    button_2
    ...
    button_n
}
```
where a button can include one or both of the keywords *Command* and *Walk_Right*, and the syntax for a button is

Button *button_name* {
   Walk_Right *menu_name_1*
   and/or Command *command_name*
}

The text displayed on the button is *button_name* and the definitions of the *Walk_Right* and *Command* commands are:

**Walk_Right Menu for Buttons**

The *Walk_Right* keyword specifies that there is a walk-right menu for the button and gives the name of the menu that is displayed when LB is moved over the walk-right arrow on the button.

The *Walk_Right* command consists of the word *Walk_Right* followed by one or more spaces and then the name of the menu that is displayed when over the walk-right arrow.

```
Walk_Right *menu_name*
```

where *menu_name* is the name of another menu defined elsewhere in the *usermenu.4d* file.

When the *Walk_Right* keyword exists, a walk-right arrow is created on the button.

If there is no *Walk_Right* keyword, then there is no walk right arrow on the button.

A *Walk_Right* line is optional.

**NOTE** - walk-right menus can contain walk-right menus.

**Commands for Buttons**

The *Command* keyword defines what action occurs if LB is clicked on the button.

The *Command* consists of the word *Command* followed by one or more spaces and then the name of the command and any arguments it requires.

```
Command "*command_name* *command_arguments*"
```

The *command_name* and *command_arguments* can do any of:

(a) Run a User Defined or 12d Supplied 12d Model 12dPL (Macro)

Command "*macro* *macro_options* *user_macro_name* *macro_parameters*" // run macro

where the *macros_options* are:

```
-no_console // don’t display macro console
-close_on_exit // remove console when macro terminates
-buttons // have buttons for finish, restart and quit on console
-allow_defaults // allow default answers for console questions
```

The default when there are no macro options is to run the macro with a console but without buttons, and to leave the macro console on the screen when the macro terminates.

For example

```
Button "Write Levels" {
   Command "macro Tinval.4do"
}

Button "ADAC - show attributed/not attributed" {
   Command "macro -no_console -close_on_exit Adac_show_panel.4do"
```
(b) Run a chain

Command "chain chain_file_name"

It is also possible to pass a chain parameter value file (pvf) to be used by the chain through to the chain. The command is

Command "chain -pvf pvf_file_name chain_file_name"

where pvf_file_name is the name of the pvf file to use when the chain chain_file_name is run.

For example

Button "Survey to ADAC 41 chain" {
  Command "chain -pvf $USER/BCC/ADAC_BCC_41.pvf $LIB/ADAC_survey_base.chain"
}

Also see 28.3.5.4 Running Chains from User Menus and Toolbars

(c) Bring up a 12d Model menu and/or a User Defined Menu

Command "12d_model_menu_name"

or

Command "user_defined_menu_name"

The 12d_model_menu_name is simply the name on the top of the 12d Model menu. The user_defined_menu_name is the name of a User Defined menu that is defined further down in the usermenu.4d file.

For example, for the menu called "Model Utilities", the

Button "Bring up the Model Utilities menu" {
  Command "Model Utilities"
}

Notice that for a menu, only the menu name in quotes follows the keyword Command.

Note: - this works because all the names must be unique amongst the 12d Model menus, 12d Model panels and User Defined menus.

A menu can occur as a Walk_Right menu and/or as a Command.

(d) Bring up a 12d Model panel

Command "12d_model_panel_name"

Every 12d Model menu and panel has a unique name and the 12d_model_panel_name is simply the name on the top of the panel.

For example, for the menu called "Test Helmert 2d (Advanced) panel", the

Button "Bring up a Helmert panel" {
  Command "Test Helmert 2d (Advanced)"
}

Notice that for a panel, only the panel name in quotes follows the keyword Command.

Note: - this works because all the names must be unique amongst the 12d Model menus, 12d Model panels and User Defined menus.

(e) Run a User Defined screen layout file
Command "layout  layout_file_name"

For example

Button "Generate ADAC Tree Spreadsheet" {
    Command "layout ADAC_Tree_Report.slx"
}

(f) Execute a batch file or program

Command "system  program_or_batch_file_name"

Notes
1. A Command Line is optional
2. A button can have both a Walk_Right and a Command defined for it.
3. If there is only a Walk_Right menu and no Command, clicking on the button will bring up the Walk_Right menu.
4. Both Walk_Right and Command can be left out.
   For example
   
   Button "-----------------------------" {
   }
   Button "" {
   }
will create a button with the text "-----------------------------" on it and a button with no text on it.
5. In the usermenu.4d file, blank lines are ignored and anything on a line after a // is a comment

Continue to the next section 41.2.2 Using $LIB and $USER_LIB in User Menus or return to 41.2 User Defined Menus.
41.2.2 Using $LIB and $USER_LIB in User Menus

The variable $LIB and $USER_LIB can be used in Commands as part of the user_macro_name, chain_file_name, layout_file_name and programe_or_batch_file_name to pick up files from either the 12d Library or the User library.

**Note**

If $LIB_4D is not defined, then 12dmodel/version_number.00/library is used.
If $USER_LIB_4D is not defined, then 12dmodel/version_number.00/user_lib is used

For example, the definition of a menu called "Lots" could be:

```plaintext
Menu "Lots" {
  Button "Create lots" { // button called "Create lots" which
    Command "macro -close_on_exit $USER_LIB/subdiv.4do" // fires up a 12d Model macro
  }
  Button "Roads" { // button with walk-right menu "Roads" and layout file
    Walk_Right "Roads" // walk-right menu "Roads"
    Command "layout $USER_LIB/road.slx" // button invokes a layout file if selected
  }
}
```

Continue to the next section 41.2.3 Placing User Defined Menus on User and Other 12d Menus or return to 41.2 User Defined Menus.
41.2.3 Placing User Defined Menus on User and Other 12d Menus

User Defined Buttons on Main User Menu

The place buttons or menus in the bottom of the User menu on the Main menu, put the buttons in a menu called User in the usermenu.4d file.

For example

```
Menu "User" {
    Button "Triangulate" { // button called Triangulate which brings up
        Command "Triangulate a View" // the "Triangulate a View" panel
    }
    Button "Lots" {  // button called Lots with its
        Walk_Right "Lots"  // own walk-right menu called Lots
        Command "Triangulate a View"  // plus clicking on the button brings up the
    }  // the "Triangulate a View" pane
}
```

User Defined Menus on Other 12d Menus

It is also possible to define a User submenu on any 12d Model menus or submenu.

In 12d Model, all menus and sub-menus on the Main menu have a unique name. So a User menu is defined for any of them by simply having a menu called "User menu_name" in the usermenu.4d file.

For example, the menu for the option Strings=>Create is called String Create (String not Strings) so a User menu for Strings=>Create would be called "User String Create":

```
Menu "User String Create" {
    Button "Create 4d strings" { // button called Create 4d strings which brings up
        Command "macro -close_on_exit $USER_LIB/ref_points.4do"
    }
    Button "Create point strings" {
        Command "macro -close_on_exit $USER_LIB/x_sects.4do"
    }
}
```
Chapter 41  Functions Keys, Menus, Toolbars

User Defined Menus
41.2.4 Names for User Defined Menus

Apart from the names of the special User menus just mentioned, all other menu names in `usermenu.4d` are user defined so they can be easily used in user defined walk-right menus.

And menu referred to in the file `usermenu.4d` that is not one of the special User menus, **must be defined** somewhere in the `usermenu.4d` file.

And remember, all the names must be unique amongst the 12d Model menus, 12d Model panels, special User menu and user named User Defined menus.

Continue to the next section 41.2.5 Example of a User Defined Menu or return to 41.2 User Defined Menus.
41.2.5 Example of a User Defined Menu

// the definition of buttons to go on the Main menu option "User"
Menu "User" { // User menu on Main menu
    Button "Triangulate" { // button called Triangulate which brings up
        Command "Triangulate a View" // the "Triangulate a View" panel
    }
    Button "Lots" { // button called Lots with its
        Walk_Right "Lots" // own walk-right menu called Lots
    }
    Button "Roads" { // button with walk-right menu "Roads"
        Walk_Right "Roads"
        Command "layout $LIB/road.slp" // button invokes a layout file if selected
    }
}

// the definition of the walk-right menu Lots
Menu "Lots" {
    Button "Create lots" {
        Command "macro $LIB/subdiv9.4do"
    }
    Button "Label lots" {
        Command "macro $LIB/subnum3.4do"
    }
    Button "Write Lot Levels" {
        Command "macro $LIB/Tinval.4do"
    }
}

// the definition of the walk-right menu Roads
Menu "Roads" {
    Button "Roundabout" {
        Command "macro $LIB/Round.4do"
    }
    Button "Culdesac bulb" {
        Command "macro $LIB/Culd.4do"
    }
    Button "Drape alignment string" {
        Command "macro $LIB/Drape_al.4do"
    }
    Button "Create Table drain" {
        Command "macro $LIB/Table_dr.4do"
    }
}

// the definition of User on the Main menu option Strings=>Create"
Menu "User String Create" { // User menu on option Strings=>Create
    Button "Create ref points" {
        Command "macro -close_on_exit $LIB/ref_points.4do"
    }
    Button "Create X-sections" {
        Command "macro -close_on_exit $LIB/x-Sects.4do"
    }
}

Continue to the next section 41.3 User Defined Toolbars or return to 41.2 User Defined Menus.
41.3 User Defined Toolbars

A toolbar is made up of buttons which can have a picture on them (icons) and when the left hand mouse button (LB) is pushed down and released on the button, a command is executed.

A button can also have a flyout toolbar which appears when the left hand mouse button (LB) is held down on the button (note that there can only be one level of flyouts).

Toolbars can be turned on and off, and their positions are remembered when 12d Model is saved. See 4.3.5 Toolbars and Controlbars.

The definitions for toolbars in 12d Model are stored in two files - user_toolbars.4d and toolbars.4d. When 12d Model is installed, toolbars.4d is installed in the 12d Model folder Set_Ups. user_toolbars.4d is for user defined toolbars and is created by the user and should be stored in the folder User.

So any user defined toolbars and simply added to user_toolbars.4d and saved in the folder Users.

The icon for each button on a toolbar, plus the action taken when the button is selected is user specified. A button can include a fly-out toolbar but flyouts can only be to one level (i.e. no flyouts on flyouts).

When a button is selected, the action can be to
(a) run a 12d Model12dPL (macro) or chain
(b) bring up a 12d Model menu
(c) bring up a 12d Model panel
(d) read a layout file
(e) execute a batch file or program (system call)

When 12d Model starts up, any toolbars defined in toolbars.4d and user_toolbars.4d that are not called as flyouts by another toolbar in toolbars.4d or user_toolbars.4d, are displayed in the main toolbar on the left hand side of the 12d Model screen.

When a toolbars is moved around, its position is saved when 12d Model is saved so the toolbars are in the same final position when the project is reopened.

Go to the next section 41.3.1 Full Definition of Toolbars.
41.3.1 Full Definition of Toolbars

The definition for Toolbars is given in the files called

---

**Toolbars.4d** and **user_toolbars.4d**

---

which are searched for in the standard set up areas (local, USER_4D, user, set_ups etc.)

Or instead of **toolbars.4d**, it can be defined and set by the environment variable

---

TOOLBARS_4D file  // Toolbars definition

---

In the **toolbars.4d** and **user_toolbars.4d** files, a **toolbar** is defined by:

---

**Toolbar** toolbar_name {
  button_1
  button_2
  ...
  button_n
}

---

where a button can include none or more the commands **Icon**, **Command** and **Flyout**, and the syntax for button is:

---

**Button** button_name {
  Icon icon_name_1
  Command command_name_1
  Flyout toolbar_name_1 // only used if a flyout toolbar is required
}

---

For the definitions of the **Icon**, **Command** and **Flyout** commands see:

---

41.3.1.1 **Icons for Toolbars**
41.3.1.2 **Command for Toolbars**
41.3.1.3 **Flyout for Toolbars**

---

41.3.1.1 Icons for Toolbars

The **Icon** command defines the bitmap that is displayed for the button in the toolbar. The format of the bitmap is a bmp file (.bmp) of size 16x16. The **Icon** command consists of the word **Icon** followed by one or more spaces and then the name of the bitmap, **icon_name**.

---

**Icon** icon_name

---

The **icon_name** can include a pathname but if no pathname is present, the bitmap is searched for in the folder **Images** under the folders **User** or **Set_Ups**.

If the **Icon** command is missing then a default **Icon** command is used with the **icon_name**

---

**button_name.bmp**

---

**Icon** button_name.bmp

---

Go to the next section 41.3.1.2 **Command for Toolbars** or return to 41.3.1 Full Definition of Toolbars

41.3.1.2 Command for Toolbars

The **Command** command defines what action occurs if LB is clicked on the button. The **Command** command consists of the word **Command** followed by one or more spaces and then the name of the command and any arguments it requires.

---

**Command** command_name

---

The Commands are the same as those for a **User Defined Menu**. See Commands for Buttons
If the Command command is missing then a default Command is used with the command name **button_name** with no arguments

\[
\text{Command button_name}
\]

Go to the next section 41.3.1.3 Flyout for Toolbars or return to 41.3.1 Full Definition of Toolbars

### 41.3.1.3 Flyout for Toolbars

The **Flyout** command defines what toolbar is displayed when LB is help down on the button. The **Flyout** command consists of the word **Flyout** followed by one or more spaces and then the name of the toolbar that is displayed.

\[
\text{Flyout flyout_toolbar_name}
\]

where **flyout_toolbar_name** is the name of another toolbar defined elsewhere in the toolbars file.

When the **Flyout** command exists, **Icon** and **Command** are not required and if they are present, are ignored.

The icon on the **Flyout** button is the **Icon** from the first button in the flyout toolbar.

The command executed if LB is pressed and released on the Flyout button is the **Command** from the first button in the flyout toolbar.

**NOTE** - flyouts can not be nested so the toolbar **flyout_toolbar_name** can not contain a **Flyout** command.

**NOTE** - when 12d Model starts up, any toolbars defined in toolbars.4d that are not called as flyouts by another toolbar in toolbars.4d, are displayed in the main toolbar on the left hand side of the 12d Model screen.

### Example of a User Defined Toolbar

// ---------------------------------------------
// WARNING: you cannot have the same command using different icons
// ALSO: when using a flyout, the Command & Icon are ignored
// and the details are taken from the first button
// on the flyout
// ---------------------------------------------

Toolbar "Cad" {
  Button "Points" {
    Command "Create Point" // this is ignore since it is a flyout
    Icon "Create Point.bmp" // this is ignore since it is a flyout
    Flyout "Cad Points"
  }
  Button "Change String" {
    Flyout "Change String"
  }
}

Toolbar "Cad Points" {
  // used as a flyout toolbar
  Button "Create Point" {
    Command "Create Point"
    Icon "Create Point.bmp"
  }
  Button "Chainage" {
    Command "Locate Chainage"
    Icon "Chainage.bmp"
  }
} // end of "Cad Points" toolbar
Toolbar "Change String" { // used as a flyout toolbar
    Button "String Close" {
        Command "String Close"
        Icon "String Close.bmp"
    }
    Button "String Reverse" {
        Command "String Reverse"
        Icon "String Reverse.bmp"
    }
    Button "String Trim" {
        Command "String Trim"
        Icon "String Trim.bmp"
    }
} // end of "Change String" toolbar

$LIB and $USER_LIB

As they were for Commands in User Defined menus, the variables $LIB and $USER_LIB can be used in Commands as part of the user_macro_name, chain_file_name, layout_file_name and program_or_batch_file_name to pick up files from either the 12d Library or the User library. See 41.2.2 Using $LIB and $USER_LIB in User Menus.

For example, the definition of a toolbar called "Lots" could be:

```
Toolbar "Lots" {
    Button "Create lots" { // button called "Create lots" which
        Command "macro -close_on_exit $USER_LIB/subdiv.4do" // fires up a 12d Model macro
    }
    Button "Roads" { // button with walk-right menu "Roads" and layout file
        Walk_Right "Roads" // walk-right menu "Roads"
        Command "layout $USER_LIB/road.slf" // button invokes a layout file if selected
    }
}
```

Notes

(a) The variables $LIB and $USER_LIB can be used as part of the layout_file_name and user_macro_name to pick up files from either of the libraries.

(b) blank lines in the toolbars file are ignored and anything on a line after a // is a comment

Another Example of a Toolbar

```
Toolbar "Cogo" {
    // in this case, the Command is assumed to be "Create Line"
    // the icon is "Create Line.bmp"
    // Command is normally the name of the panel/menu
        Button "Create Line" {
        }
    // this is a spacer
        Button "" {
        }
    // this is a command and also has a flyout capability
```

User Defined Toolbars
// calling the toolbar called Flyout
// flyouts cannot be nested
Button "Create Fillet by radius" {
  Command "Create Fillet by radius"
  Icon "Create Fillet by radius.bmp"
  Flyout "Flyout"
}

// The flyout toolbar for above (and a normal toolbar as well)
Toolbar "Flyout" {
  Button "Create Line" {
  }
  Button "" {
  }
  Button "Create Arc by Centre Radius" {
    Command "Create Arc by Centre Radius End Points"
    Icon "Create Arc by Centre Radius End Points.bmp"
  }
  Button "Create Fillet by radius" {
    Command "Create Fillet by radius"
    Icon "Create Fillet by radius.bmp"
  }
}

Return to [41.3.1 Full Definition of Toolbars](#) or [41 Functions Keys, Menus, Toolbars](#).
42 Special File Formats

42.1 Default File Ending

In any panel pop-up requiring a file name to be displayed, default file endings are used to restrict the names of the files selected from the current folder and if they exist, from the library and user library areas.

Whilst a panel is up, the extension being searched for can be changed by typing say ".xyz" into the panel field requiring a file name, and then pressing <enter>. The list of files ending in ".xyz" will be displayed and clicking B3 in the panel field will also bring up a list of all files ending in ".xyz". When a new panel is created, the panel fields revert to the default file ending.

A list of the default files used in 12d Model pop-ups and their endings is:

<table>

**Note**

This list is for the default files used in 12d Model panel fields. It does not include 12d Model setup files which are given in the appendix [39 Setting Up & Configuring 12d](#).
42.2 Special 12d Solutions File Formats

12d Solutions has a number of special file formats, most of which have already been specified. The remaining formats will now be given.

In any of the files, blank lines ignored and any information after // until the end of that line is ignored. Hence comments can easily be inserted into the files by preceding them by //.

Unless enclosed in quotes ("), more than one consecutive space or tab are treated as one space.
42.2.1 Eagle Map File

An eagle map file is a user created file consisting of a list of 12d Model colours and the Eagle pen, dash style, pen thickness and frag to be used for the colour.

The map file is set out with one 12d Model colour per line. The line begins with the 12d Model colour followed by the Eagle pen number, dash style, thickness and frag to be used for the 12d Model colour. Each item is separated by one or more spaces.

For example, if the 12d Model colour red is to be mapped to Eagle pen 3, dash style 4, thickness 2 and frag 1, then the line in the eagle map file would be

```
red 3 4 2 1
```

An eagle map file can be used for writing out three dimensional data to Eagle, or when producing plots in Eagle format.

For plotting, the map file must be called `eagleplt.emf`.

When writing three dimensional data out to Eagle, a user specified file name is allowed.

In the output case, as each string is written out, the map file is searched sequentially until a colour match is made. If no match is found, the colour of the string is used as a pen number and default values used for dash, thickness and frag.

Comments can be included in the map file by preceding the comment with a double forward slash (i.e. `//`). Anything on the line following the `//` will be ignored.

An example of an Eagle map file is,

```
//12d Model colour to Eagle mapping file
//
//12d Model colour  eagle pen   dash  thickness  frag
black          0     1 1 1 1
red            2     0 1 5
green          4     1 1 1
blue           4     2 1 11
cyan           5     1 1 1
yellow         6     1 1 1
magenta        7     1 1 1
white          1     1 1 1
orange         15    1 1 1
purple         14    1 1 1
grey           13    1 1 1
"dark green"   12    1 1 1
"dark red"     11    1 1 1
"off yellow"   4     1 1 1
"dark blue"    8     1 1 1
brown          11    1 1 1
```

```
42.2.2 Template File

The 12d Solutions Template file format is a simple text file definition for reading and writing out template definitions for use in the apply options in 12d Model.

The template definition begins with the key word `template` followed by the template name and then the definitions of

\[ \text{fixed, cut, fill and final parts of the template} \]

\[ \text{or fixed and decision parts} \]

all enclosed within curly braces `{ }`.

\[
\text{template fred} \{ \\
\text{fixed} \{ \\
\text{... or } \\
\} \\
\text{cut} \{ \\
\text{... decisional } \\
\} \\
\text{fill} \{ \\
\text{... } \\
\} \\
\text{final} \{ \\
\text{... } \\
\}
\]

The definition of the `fixed` part of the template begins with the key word `fixed` followed by a list of the links enclosed in curly braces `{ }`.

The links are defined one per line in order from the centre-line. Each link begins with the keyword `link` followed by the width, percent cross-fall, colour and name for each link. For the percent cross-fall, positive means up, negative is down and zero horizontal.

For example,

\[
\text{fixed} \{ \\
\text{link 3.5 -3 cyan kerb } \\
\text{link 1 -4 magenta shoulder } \\
\text{link 2 -5 blue verge } \\
\}
\]

describes a fixed template with three links, the first of width 3.5 with a 3% cross-fall downwards, the next link of width 1 with 4% cross-fall downwards and the third link of width 2 and 5% cross-fall downwards.

The definition of the `cut` part of the template begins with the key word `cut` followed by a list of the links enclosed in curly braces `{ }`.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword `link` followed by the width, one in slope, colour and name for each link. For cut, the one in slope is positive for up, negative for down, and zero for horizontal.
For example,

```
cut {
    link 3 2 yellow a
    link 2 0 magenta b
    link 3 -1 yellow c
    link 2 0 magenta d
}
```

describes a cut template with four links, the first of width 3 with 1:2 slope upwards, the next link of width 2 horizontally, the third link of width 3 and 1:1 slope downwards and width 2 horizontally.

The definition of the **fill** part of the template begins with the key word **fill** followed by a list of the links enclosed in curly braces `{}`.

The links are defined one per line in order from the end of the fixed template (or centre-line if no fixed part exists). Each link begins with the keyword **link** followed by the width, one in slope, colour and name for each link. For fill, the one in slope is positive for down, negative for up, and zero for horizontal. Please note that this is the opposite to **cut**.

For example,

```
fill {
    link 5 2 yellow e
    link 1 0 magenta f
    link 10 -1 yellow g
}
```

describes a fill template with three links, the first of width 5 with 1:2 slope downwards, the next link of width 1 horizontally, and the third link of width 10 and 1:1 slope upwards.

The definition of the **final** part of the template begins with the key word **final** followed the cut slope, fill slope and search distance enclosed in curly braces `{}`. The key words for the three values are cut_slope, fill_slope and search_distance.

For example,

```
final {
    cut_slope 1  fill_slope 2  search_distance 100
}
```

describes a final cut slope of 1:1 (upwards), fill slope of 1:2 downwards and template with three links, the first of width 5 with 1:2 slope downwards, both going for a maximum distance of 100.

The definition of the **decisions** part of the template begins with the key word **decisional** followed by a list of the decision commands enclosed in curly braces `{}`.

The decision commands are defined one per line and have the format:

- **Fixed Xfall**: Width value Height value XFall value Name text Colour colour
- **Fixed Slope**: Width value Height value Slope value Name text Colour colour
- **Tin Width**: tin_name Strip value width value Name text Colour colour
- **String Offset**: string_name Strip value Offset value Name text Colour colour
- **Batter**: tin_name Strip value Width value Height value Slope value Name text Colour colour Goto label
- **Tin Decision**: tin_name Offset value Min value Max value Goto label
- **Label**: label_name
**Goto** label\_name

**End**

For example,

template "std" {
  fixed {
    link 3 unknown -3 cyan "kerb"
    link 1 unknown -4 magenta "shoulder"
    link 2 unknown -5 purple "verge"
  }
  decisional {
    Tin\_Decision "rock" 0 0 1000 "cut\_rock"
    Tin\_Decision "shale" 0 0 1000 "cut\_shale"
    Tin\_Decision "terrain" 0 0 1000 "cut\_terrain"
    Label "fill\_terrain"
    Batter "terrain" 0 8 unknown -3 "f1" blue "alldone"
    Batter "terrain" 0 1 unknown 0 "f2" "dark green" "alldone"
    Goto "fill\_terrain"
    Label "cut\_rock"
    Tin\_Decision "rock" 0 0 0.3 "cut\_rock\_done"
    Batter "rock" 0.3 5 unknown 0.5 "r1" cyan "cut\_rock\_done"
    Batter "rock" 0 2.5 unknown 0 "r2" yellow "cut\_rock\_done"
    Goto "cut\_rock"
    Label "cut\_rock\_done"
    Tin\_Decision "shale" 0 0 1000 "cut\_shale"
    Goto "cut\_shale\_done"
    Label "cut\_shale"
    Tin\_Decision "shale" 0 0 0.6 "cut\_shale\_done"
    Batter "shale" 0.6 6 unknown 1 "s1" magenta "cut\_shale\_done"
    Batter "shale" 0 3 unknown 0 "s2" "dark red" "cut\_shale\_done"
    Goto "cut\_shale"
    Label "cut\_shale\_done"
    Tin\_Decision "terrain" 0 0 1000 "cut\_terrain"
    Goto "alldone"
    Label "cut\_terrain"
    Batter "terrain" 0 3 unknown 1.5 "t1" red "alldone"
    Batter "terrain" 0 2 unknown 0 "t2" green "alldone"
    Goto "cut\_terrain"
    Label "alldone"
  }
}

**Notes**

1. spaces in text - any text string that includes spaces or only numbers, must be enclosed in double quotes "".
2. comments - anything after // until the end of the line is ignored.
3. blank lines - blank lines are ignored
42.2.3 Screen Layout File

The 12d Model screen layout file contains a simple text file definition for 12d Model panels and menus in either the pre-V10 format (slf) or the V10 XML format (slx).

The definition includes a screen position for the panel or menu, and for panels, values for any of the panel fields.

At any time, the layout of the menus and panels on the screen in a 12d Model session can be written out using the menu option

`File i/o=>Layouts =>Layout output`

Also, the layout for an individual panel or menu can be created by clicking RB in the menu/view title area and selecting the dump option to bring up the Menu/Panel Dump panel.

Note: If a screen layout file is created and added to the layout.4d file (by selecting layout.4d as the file name and selecting Append), then the menu/panel will appear whenever a project is opened. See layout.4d

A screen layout file can be read in using the menu options

`File i/o=>Layouts =>Layout input or File i/o=>Layouts =>Layout input files`

Also when a project starts up, the layout file layout.4d is read in and any menus and panels described in the file are placed on the screen (see 39.2.3 Setup Files Used for New and Existing Projects).

An example of a screen layout file for 'Read x y z s Data' in the V10 format is:

```xml
<?xml version="1.0"?>
<meta_data>
<brm>
<units>
<metric>
<linear>metre</linear>
<area>square metre</area>
<volume>cubic metre</volume>
<temperature>celsius</temperature>
<presure>millibars</presure>
<angular>decimal degrees</angular>
<direction>decimal degrees</direction>
</metric>
</units>
</meta_data>
<application>
<name>12d Model</name>
<manufacturer>12d Solutions Pty Ltd</manufacturer>
<manufacturer_url>www.12d.com</manufacturer_url>
<application>12d Model 10.0C1i Doco - Not For Production</application>
```
42.2.4 Map File for 12d Model V4.0

Up to 12d Model V4.0, the map file format consisted of one or more lines. Each line begins with a key (entity-mask) followed by a string name, model name, colour, breakline type (point or line), and line style separated by one or more spaces. The key can contain wild cards (*) and wild characters (?).

When a string is read in and satisfies a key, the key's corresponding string name, model, colour, breakline type and style is used for that string.

For example, any entity name beginning with 31 can be created as a 12d Model string with the name picket, colour cyan, breakline type line, line style 1 and model fences by the map file line

```
31* picket fences cyan line 1
```

If a map file is used, as each entity is read in, the map file is searched sequentially until a match with a key is made and the key's name, colour etc. used. If no match is found, the default colours and model (given in the read panel) are used.

Notes
1. If the entity-name is to be used as the new string name, use an asterisk (*) in place of the string name. For example,

```
fred * fences cyan line 1
```

2. If the default model for the reader is to be used as the model name, use an asterisk in place of the model name. For example,

```
31 31 * cyan line 1
```

3. A * for colour, breakline type and linestyle means that if the entity has a colour, breakline style or linestyle, then it is used rather than be mapped to another one.

4. All model names used in the map file can be given an extra (common) prefix by typing the prefix into the prefix for models field in the read panel.

5. If any information includes a space, then it must be enclosed in quotes ". For example, the model name may be "trial 1" or a style "large tanks".

6. Comments can be included in the map file by preceding them with a double forward slash //.

An example of a 12d Model map file is

```
// 12d Model map file
// key    name    model    colour    pt-line    linestyle
102      break   breaks   red       line       solid
305      fence   caddast  green     point      dash
998      bdry    bound    cyan      line       solid
spots    *       spot     yellow    point      1
PS*      *       *        yellow    point      1
```

Map File for 12d Model V5.0 and Above

For 12d Model V5.0, the map file was extended to allow for defining properties such as tinability, symbols at vertices, vertex and segment text and pipe and culverts.

To allow for all the different type of mapping in the one file, the map file is broken up into sections (one section for each tab of the map file editor) and each section begins with a header record which is the section name enclosed in braces ({}). For example, the symbols section has the
Inside each section, the data is similar to the V4.0 map file with lines consisting of a key (entity-mask) followed by the data required for that section. The key can contain wild cards (*) and wild characters (?).

The exact format for the map file is not required since they are created and edited from within 12d Model by the option

File i/o => Map file
42.2.5 12d Patterns File

See 40.4 Patterns
43 Plotters and Plotting

The method of creating plots and sending them to a plotter, or to a pdf, or a Cad system such as AutoCad or Microstation, varies from site to site.

So 12d Model provides tools to enable the user to tailor the plotting system, especially the defining of Plotters and Plotter Mapping Files which are described in this chapter.

See

43.1 12d Model Plotters
43.2 Defining Plotters - Plotters.4d
43.3 Mapping 12d Colours to Pens and RGBs
43.4 Sending Plots to a Plotter
43.5 Sheet Sizes
43.6 Text Units in Plots
43.1 12d Model Plotters

When creating a plot, 12d Model has a variety of options about where the potting data goes to.

The user can:

(a) drive the plotters directly using Windows printer drivers, raster plotter drivers, hp plotter commands etc.

(b) plot indirectly by creating a computer disk file (the plot file) in a variety of formats containing the relevant plotter instructions for producing the plot. The formats include pdf, XPS, DWG and DGN.

(c) plot indirectly to a 12d Model model

Once the plotting device (plotter engine) the decided, there will still be a variety of ways that the 12d Model colours are to appear on the plot.

For example, for some plots you may want all the colours to be plotted as black and shades of grey rather than actual colours. Or for white to be plotted as black.

To control how a colour is plotted on a particular plot device, there are various user definable parameters and the most flexible for controlling colours is the plotter mapping file (pmf file).

There are a number of pmf files installed with 12d Model and/or users can also define their own.

So an 12d Model plotter consists of a

1. Unique name for the Plotter
2. The Plot Engine (plot device)
3. Other Parameters to control the plot engine and outputs

The definitions for each of the 12d Model plotters is given in the file plotters.4d and it is the list of plotter names from this file that is displayed as the choice list in the when the Select Plotter pop-up menu.

The list of 12d Model plotters installed with 12d Model is:
From the list you will see that there can be a number of Plotters using the same plot device (e.g. windows or pdf) and these will differ in one or more of the other plot parameters. For example, having a different plotter mapping file.

When a plot file is created, it can be passed to a user specified program or batch file which can do things like automatically directing the plot file to a plotter. See 43.3 Mapping 12d Colours to Pens and RGBs.

For information on plotters.4d, see 43.2 Defining Plotters - Plotters.4d
43.2 Defining Plotters - Plotters.4d

The file `plotters.4d` defines the names of the plotters that appear in the plotter type panel field, and the properties of each of these named plotters.

On opening a 12d Model project, if the environment variable `PLOTTERS_4D` exists then it has the pathname to the file that defines the plotters otherwise, the file `plotters.4d` is searched for in the standard set up paths. See `PLOTTER_4D` and 39.2.4 Folders Searched for Setup Files).

The pop-up list for the `plotters.4d` file shipped with 12d Model is:

![Select Plotter](image)

but users can delete plotters from this and/or add their own plotters to the file.

For each plotter in `plotters.4d`, it is possible to customize:

(a) the name of the plotter
(b) the plot device (plot engine)
(c) any plotter mapping for mapping colours
(d) a start and end sequence that is sent to a physical plotter
In the plotter file, the definition of a *plotter* of a given name *plotter_name* is set out as:

```
plotter  plotter_name {
    set_up_command_1
    set_up_command_2
    ...
    set_up_command_n
}
```

*plotter_name* must not be blank, and if it includes imbedded spaces then the name must be enclosed in double quotes "".

Each *plotter_name* in the file must be unique in the file.

There can be zero or more *set up commands* inside the braces {} and each *set up command* is from the list:

- group
- engine
- extension
- map_file
- map_pens
- output_cmd
- colour
- header
- footer

These *set up commands* are documented in the next section 43.2.1 *Plotter Set Up Commands*.

For a description of some of the Plotters in the default plotters.4d file, see 43.2.2 *Some Plotters in the Default Plotters.4d File*.

For an example of a *plotters.4d* file, see 43.2.3 *Example of a Plotters.4d File*. 
43.2.1 Plotter Set Up Commands

**group**

although all the *plotter names* have to be different, rather than just listing them in a flat list, the plotter names can be displayed in a tree structure.

The **group** command gives the levels in the tree for the plotter name in the pop up list. Each level is separated by a forward slash `/`

For example, if the plotter name was **PDF black** and **group PDF/Full Scale** then it will show up in the pop-up list as:

![Select Plotter](image)

**engine**

the device that the plot is being created for. For example, model, pdf_12d, xps_writer, dwg_2010, dgn, dgn_v8, postscript and hpgl.

For a complete list of engines, see **43.2.1 Plotter Engines**.

**extension** "*.xxx"

the extension added to the file name used for the plot file written out by this plotter.

**map_file** *plotter_mapping_file_name*

if **map_file exists**, it exists then it points to the *plotter mapping file* which is used to define each 12d *Model colour* what **pen number** it is mapped to, and for each **pen number**, its **rgb** and **weight** (width).

If **map_file does not exist**, and a global mapping file is specified, then it will be used as the plotter mapping file. Otherwise the pen mapping in Colours.4d is used.

If the **engine** is any of the **dwg/dxf/dbx** variants, then the **map_file** is an **Autocad mapping file** with the extension of **.amf**, the plotter will use the **colour number** being plotted as the **key** in the Autocad mapping file. This allows the mapping from colour number directly into layer name, Autocad colour and linestyle. Note that if Autocad colour or linetype is BYLAYER, then 12d Model uses the correct values in Autocad. The '*' character means that the field is ignored. For an example of an amf file, see **43.2.1.3 Definition and Example of a .amf File**.

If the **engine** is **dgn/dgn_v8** then the **map_file** is a **table file** with the extension of **.tbl**. The plotter will use the **colour number** being plotted as the **key** in the **table file**. This allows the mapping from the colour number directly into dgn level, weight, style and colour. For an example of a tbl file, see **43.3 Mapping 12d Colours to Pens and RGBs**.

**map_pens** true or false
if `map_pens` is `true`, it uses the specified `map_file`.

If `map_pens` is `false`, it doesn't use any mappings (map_file, global plotter mapping file or pen mapping table). It leaves the pen number untouched.

`smap_pens` is ignored when

(a) the `map_file` is used as a tbl file (plotter engine is dgn and the map_file has an extension of .dgn. In this case any mapping is occurring via the tbl file where colour is the key.

(b) the map_file is used as a amf file (plotter engine is dxf or dwg and the map_file has an extension of .dxf. In this case, any mapping is occurring via the .dxf file where colour is the key.

`output_cmd` path to a script or program

for this plotter, the given script or program is used on the created plot file. This replaces the PLOTTER_4D definition of script or program for this plotter.

`colour` true or false

This is only used in hpgl2 and postscript.

If `false`, then

- for postscript don’t send the rgb for colours
- for hpgl2, don’t send down the block of information with the number of pens and the rgb for each pen.

That is, if false, it stops hpgl2 and postscript writing out the colour definition commands.

`header` and `footer`

The `header` information is placed in the plot file before any plot commands and the `footer` information is placed at the end of plot file after all the plot commands.

The format for the `header` or `footer` is:

```plaintext
header {// this information in placed in the plot file before any plot commands
    lines of text which can include plotter variables
}
```

or

```plaintext
footer {// this information is placed at the end of the plot file, after the plot commands
    lines of text which can include plotter variables
}
```

Each line of text is surrounded by quotes. For example, "this is some stuff".

The `plotter_variables` used in the `header` or `footer` are:

- username
- filename
- date
- time
- sheet_width
- sheet_height
- page_number - not used
- minimum_x, minimum_y// plotter dependent
- maximum_x, maximum_y// plotter dependent

and are included in the text by preceding them by a + and also following them by a cross if more text follows. For example:
"the user is " + username + " of 4D Solutions"

The appropriate information is substituted for the plotter_variables when a plot is created.

Hence

"the user is " + username + " of 12d Solutions"

would give

"the user is fred of 12d Solutions"

A plotter_variable may not be appropriate for a particular plotter and if a plotter_variable is specified but not used for a plotter, it is substituted by blank.

If header or footer is not specified, then appropriate default information for the plotter is used.

The header and footer set_up_commands are not used by all plotters. If they are not used for a particular plotter, the header or footer command is ignored.

At present, only the plotters hpgl, hpgl2, postscript and dxf use header and footer.

minimum_x etc for postscript, it is the extent of the plot in mm

sheet_width, sheet_height for postscript in mm

For hpgl2

sheet_width, sheet_height in mm/40.

Continue to the next section 43.2.1.1 Plotter Engines or return to 43.2 Defining Plotters - Plotters.4d.
43.2.1.1 Plotter Engines

When creating a plot, 12d Model can either use a Windows printer driver to plot directly, or instead of driving the plotter directly, create a computer disk file (the plot file) containing the relevant plotter instructions for producing the plot (which is then sent to the plotter), or in the case of the plotter type model, create a 12d Model model.

The available Plotter Engines are:

<table>

43.2.1.3 Definition and Example of a .amf File

An example of an AutoCad output mapping file for use with an Autocad plotter:

```
// File: acadplot.amf
// -------------
// column 1     match colour  - can include wild cards * and wild characters ?
// column 2     new name      - not output to DXF
// column 3     ACD layer     -
// column 4     ACD colour    - * for 12d Model colour (mapped to ACD),
//                        BYLAYER for ACD BYLAYER
// column 5     ACD line type- * for 12d Model linestyle,
//                        BYLAYER for ACD BYLAYER
// column 6     ACD text style- not yet used, * for 12d Model text style
//
// Notes:
// 1. column 5 (ACD colour) can only be a number between 0 and 256, or * or BYLAYER
// 2. The DWG/DXF file produced needs to be loaded into an existing Autocad drawing
//    which has the ACD layers and linestyles defined.
//
// column 1        2              3          4                          5                           6
//
// 1     CONT       ljg1        1                          1                         *
// 2     TOP          ljg2        2                    CONTINUOUS
// 3     TOP          *           3                         *                           *
// 4     TOP          ljg4        *                      BYLAYER
// 5     TOP          ljg5      BYLAYER         DASH                   *
```

Continue to the section 43.2.2 Some Plotters in the Default Plotters.4d File or return to 43.2 Defining Plotters - Plotters.4d.
43.2.2 Some Plotters in the Default Plotters.4d File

**Full Scale >PDF black**
- The 12d standard **colour numbers 1-15 & 316** plot with **0.25mm black** pens.
- The "pen*" (400 series) colour numbers plot with **black pens** of **specific weights**.
- All "ppf*" (900 series) colour numbers plot with black/grey scale pens of specific weights.

**Full Scale >PDF black string weight**
- If the string has no weight then it is the same as **Full Scale >PDF black** but if the string has a weight then the string weight is used.
- So if a non standard weight is required for a particular string then you set the weight for that string. Otherwise do not give the string a weight.

**Full Scale >PDF colour**
- The 12d standard **colour numbers 1-15 & 316** plot with **0.25mm pens** of the matching colour, except:
  a) **white** (7) plots to **black**,
  b) **yellow** (5) plots to a **darker yellow**.
- The "pen*" (400 series) colour numbers plot with **black pens** of **specific weights**.
- All "ppf*" (900 series) colour numbers plot with **black/grey scale pens** of **specific weights**.

**Full Scale >PDF colour string weights**
- If the string has no weight then it is the same as **Full Scale >PDF colour** but if the string has a weight then the string weight is used.
- So if a non standard weight is required for a particular string then you set the weight for that string. Otherwise do not give the string a weight.

**Half Scale >PDF black, Half Scale >PDF black string weight**
**Half Scale >PDF colour, Half Scale >PDF colour string weight**
- These are the same the Full Scale plotters EXCEPT that the **pen width is 0.125mm**

    map_file "pmf_colour.pmf"
}

Continue to the section 43.3 Mapping 12d Colours to Pens and RGBs or return to 43.2 Defining Plotters - Plotters.4d.
43.3 Mapping 12d Colours to Pens and RGBs

**12d Model** uses up to 10,240 different colours and when it comes to plotting, it must be decided how these colours are mapped for the particular plotter device being used.

Some physical plotters may print colours and others only black. And even on a colour plotter, sometimes you may want to print out in black, or black and grey scale.

When plotting to devices such as PDF, or CAD systems such as AutoCad and Microstation, no physical plot is created but the plot image may need to be send colours to special colours, layers and styles in the other system.

For plotting to actual plotters, there are two methods of specifying the colour to pen mappings.

(a) **pen mapping using Colours.4d**

A simple "colour to pen number" mapping which is mainly used for older pen plotters that only had a fixed number of pens that could be used. It also provides the default pen numbers if they are not mentioned in the *plotters.4d* file. See 43.3.1 Pen Mapping in Colours.4d.

(b) **plotter mapping - Plotters.4d**

An extended colour to pen number mapping is more often used which not only maps colour numbers to pens but can also include a weight (thickness) in millimetres for each pen (pen_mapping).

Plus the red, green, blue definition for the pen numbers used on the plotter (pen_colour)

This is for the physical plotters such as laser, electrostatic, inkjet and bubblejet plotters, and the non-physical plotters such as pdf. See 43.3.2 Plotter Mapping File.

So for a plotter mapping

```
Colour number in 12d Model  |   pen_mapping   | Pen number and weight |  pen_colour  | RGB for Pen number
```

As Plotter mapping is an extension of pen mapping, only one of the two is used for a plot. See

43.3.1 Pen Mapping in Colours.4d.

43.3.2 Plotter Mapping File.

Or return to 43 Plotters and Plotting.
43.3.1 Pen Mapping in Colours.4d

The *colours.4d* file defines the rgb for drawing the colours on a view and also defines the default plotter pen associated with the colour numbers.

The Plots=>Pen mapping option or any other option that brings up the Edit Colours panel can be used to define the correspondence between 12d Model colours. See 39.2.7.2 Colours File (*colours.4d*).

Continue to 43.3.2 Plotter Mapping File or return to 43.3 Mapping 12d Colours to Pens and RGBs.
43.3.2 Plotter Mapping File

The plotter mapping file can be used with pen plotters but is more specifically designed for laser, electrostatic and inject plotters and allows the user to:

(a) map 12d Model colours to particular plotter pens and also specify a width (thickness or weight) to be used for the pen.

and

(b) specify the red, green and blue mix for the pens.

The plotter mapping file to be used can be set by either

1. by the environment variable PLOTTER_MAPPING_4D, or is the file pmf.4d found in the standard set up areas.

2. defined for a particular plotter in the Plotters.4d file. See 43.2 Defining Plotters - Plotters.4d

There are also two special formats of the plotter mapping file which are used for plotting to Autocad dwg/dxf and Microstation dgn. The special mapping files use the 12d Model colour number as a key to tables which control how the information is passed to DWG/DXF and DGN.

3. .tbl file used with plotting to Microstation dgn

4. .amf used with plotting to Autocad dwg, dxf or dxb

And a superseded method using a plotter mapping file in the Plotter Mapping Table panel.

5. Now superseded - the option Plots =>Plotting setups =>Plotter mapping. See 25.8.13 Plotter Mapping Table.

The definition of the Plotter Mapping File (pmf file) is given in the next section 43.3.2.1 Definition of a Plotter Mapping File and the initiation performed before the pmf file is used is described in 43.3.2.2 Initialisation of the Plotter Mapping File.
43.3.2.1 Definition of a Plotter Mapping File

The plotter mapping file (.pmf) consists of two default values followed by the two sections pen_mapping and pen_colours:

(a) the **default_weight** command that goes before the pen_mapping or pen_colours sections and which is used as the weight for any colour number that is mapped to a pen number but not given a weight in the pen_mapping section.

```
default_weight weight
```

(b) the **default_colour** command that also goes before the pen_mapping or pen_colours sections and which defines the default red, green and blue for any pens used but not set in the pen_colours section.

```
default_colour red green blue
```

(c) **pen_mapping** section which defines which pen a colour number is mapped to, and the weight for the pen.

The pen_mapping section consists of the key word **pen_mapping** followed by { and then one line for each colour number being mapped with the colour number, then the plotter pen number and finally the pen weight that the colour number is mapped to. This is finished with a }.

```
pen_mapping {
  // pen mapping and weight table
  // 12d plotter weight
  // colour pen no for pen
  0 1 0.15
  1 2 0.25
  3 1 0.5
  // etc.
}
```

(d) **pen_colours** section which defines the red, green and blue values to be used for the pens on the plotter.

The pen_colours section consists of the key word **pen_colours** followed by { and then one line for each plotter pen having the rgb defined with the plotter pen number followed by the red, green and blue values for the plotter pen. This is finished with a }.

```
pen_colours {
  // pen colours table
  // plotter
  // pen red green blue values 0-255 for red, green and blue
  0 0 0 0 // pen 0 is black
  1 255 0 0 // pen 1 is red
  // etc.
}
```

Continue to the section 43.3.2.2 Initialisation of the Plotter Mapping File or return to 43.3.2 Plotter Mapping File or 43.3 Mapping 12d Colours to Pens and RGBs.
43.3.2.2 Initialisation of the Plotter Mapping File

Before the plotter mapping file is used

(a) a default pen_mapping table is constructed from the colours in the colours.4d file by:
   
   colour n  goes to  pen n  default_weight
   
   where default weight is the default_weight if one is given in the specified plotter mapping file or zero if the default_weight does not exist.

(b) a default pen_colours table for pens 0 to 10,240 is set up by:

   pen n  default_red  default_green  default_blue

   where default_red, default_green, default_blue are the red, green and blue of the default_colour if one is given in the specified plotter mapping file, or rgb 0 0 0 if the default_colour does not exist.

The plotter mapping file is then processed and over writes any of the above initial mapping values.

This initialisation sequence means that if a colour number is not listed in the pen_mapping section of the pmf file, then the pen mapping as given for that colour number in the colours.4d file is used. Hence the pen_number in the colours.4d file is the default pen number.

Continue to the next section 43.4 Sending Plots to a Plotter or return to 43.3.2 Plotter Mapping File or 43.3 Mapping 12d Colours to Pens and RGBs.
43.4 Sending Plots to a Plotter

When the plot file is created, it can be passed to a user specified program or batch file that can
do things like automatically direct the plot file to a specific plotter.

The mechanism is that as plots are created, 12d Model can fire up a user supplied batch file/
program with the plot file as the first argument.

By checking the plot name suffix, the batch file could for example, decide which plotter the plot
must be sent to.

The environment variable

\texttt{PLOTTER\_4D} \textit{points to batch file/program}

points to the batch file/program which can be fired up whenever a plot is generated. The name of
the plot is given as the first parameter of the batch file.

If the tick box \textbf{Send plots} in the panel tab \textbf{System Settings} of the panel \textbf{Defaults} (given by the
menu option \textit{Utilities} \rightarrow \textbf{Default}) is set to on, the batch file/program is run as each plot is created.

If more than one plot is created by an option (e.g. x plot) then the batch file/program is called
separately for each of the plots.

An example of a batch file to send the plot to port lpt1 for Windows would be

\begin{verbatim}
@echo off
copy %1 lpt1
\end{verbatim}

An example for Windows which looks out for hp files is

\begin{verbatim}
@echo off
echo.
\echo -----------------------------
:next_file
if "%1" == "" goto done
\echo %1 | find /I ".hp" > nul
if ERRORLEVEL 0 if not ERRORLEVEL 1 goto hp_plotter
\echo Plotting file %1
shift
\echo Plotting %1 to HP plotter
\echo %1 to HP plotter
\copy %1 \server_name\printer_name
shift
\echo -----------------------------
\echo
\end{verbatim}

Continue to the next section \textbf{43.5 Sheet Sizes} or return to \textbf{43 Plotters and Plotting}. 
43.5 Sheet Sizes

For plot frames, long and x plots, the overall size of the plot sheet can be given by a pop-up containing defined sheet size.

The sheet size names, width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable SHEET_SIZES_4D.

The layout of the sheet sizes file is given in the section 39.2.7.4 Sheet Sizes File (sheets.4d).

Continue to the next section 43.6 Text Units in Plots or return to 43 Plotters and Plotting.
43.6 Text Units in Plots

Text occurs in 12d Model plots in a number of ways -

- plotting **text strings**, text in super strings and other strings.
- automatic text such as grid values, x-section and long-section plot annotation.
- text within linestyles.

The most difficult thing about text is that because of the different uses of text, there needs to be more than one systems of **units** to define text heights.

The height of text for a given textstyle is defined to be the height of a capital A. However, in **12d Model**, there are three methods of defining the units for measuring this height.

- world units - the units used for data
- screen units - pixels
- plot paper units - millimetres.

**World Units**

World units are the units of user data. For most users, the base unit for user data is metres. However 12d Model is a almost a dimensionless system and the base unit is totally dependent on the user.

The height of world text when displayed in a view depends upon on the **text height** and the **scale** of the view.

When plotted, the height that world text appears on a plot sheet is the same as for any data defined in world units - the height depends on the **scale** used for the plot.

Text heights that are only given in world units have (w) after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a (u) after them.

**Screen Units - Pixels**

When screen units (pixels) are used, the text is a fixed height on the screen. If the user zooms in on text given in pixels, the text remains the same height.

To have a height on a plot, screen unit text needs a height defined in millimetres.

For some screen text, both a pixel and a millimetre height is supplied when the text is defined.

For text with only a pixel height, there is a plotting multiplication parameter called **pixels-to-millimetres** which is used to convert pixel heights to plot paper heights. The value of pixels-to-millimetres is set using the **Plots => Plotting setups => Pixels to mm** option and is stored for the project. See **25.7.5 Pixels to mm**.

Text heights that are only given in pixels have (pix) or (p) after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a (u) after them.

**Plot Paper Units - Millimetres**

Text defined in plot paper units (millimetres) has a well defined height on a plot sheet.

Text heights that are only given in millimetres have (mm) after them.

For some text, the choice of units is either world, pixel or paper units. The text parameters then have a (u) after them.

Return to 43 Plotters and Plotting.
44 Text Plot Parameters

IMPORTANT WARNING

This information on the text version of the plot parameters only includes those parameters needed up to 12d Model 7 and is only included for those users still working with old text pff files. Text PPFs have been replaced by the PPF Editors - see 26 PPF Editors.

This appendix contains information about the definitions in the text versions of the plot parameter files. The text plot parameter files are not normally seen by users because the Plot Parameter editors create binary plot parameter files.

See
44.1 Plot Frame Plot Parameter File
44.2 Cross Section Plot Parameter File
44.3 Long Section Plot Parameter File
44.4 Pipeline Plot Parameter File
44.5 #Include in Plot Parameter Files

44.1 Plot Frame Plot Parameter File

The plot frame section plot parameters are placed in a file with ending .ppf
Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.
Anything on a line after a double forward slash // is considered to be a comment.
The set of all parameters for the plot frame plot is enclosed within a set of curly brackets { } with the header

    plot_frame_plot  "plot set name"

before the curly brackets.
That is,

    plot_frame_plot  "plot set name"  {
        plot parameters
        one per line
    }

If there is more than one plot_frame_plot parameter set in the file, only the first set is used.
There may also be parameter sets for other plot types such as section_long_plot in the same file.
The other sets will be ignored when doing plot frame plots.
The only parameters not connected with title block file are

view_name       view_name       // name of view used for information
                 // on the plot
single_frames   frame_name      // name of plot frame to be plotted
model_of_frames model_name      // model of plot frames which may be
// plotted as a group

Both these parameters exist in the `plot frames plot` panel and when the parameter file is first read, if either of these parameters exist in the plot parameter file then they will be used to replace the corresponding parameters in the panel.

However, if the parameters are subsequently modified in the panel, the new panel value will be the value used for plotting.
44.1.1 Title Block Information

A plot frame plot can have a standard 12d Model title block or a user defined title block.

For a user defined title block, the title block drawing commands are kept in a file whose name is given by the user when setting up the plot frame. The title block drawing commands are almost identical to the linestyle drawing commands.

If a user defined title block has been set for the plot frame, plot frame parameters can be used to pass information though to the title block.

User Title Block

Some of the plot parameters are used to pass information down to variables in a user defined title block specified in the plot frame.

The parameters are:

- **time_format**
  - text
  - // format for $time

- **title_1**
  - text
  - // passed down to $title_1

- **title_2**
  - text
  - // passed down to $title_2

- **user_text_n**
  - text
  - // where n = 1,2,... 1000
  - // passed down to $user_text_n

- **start_page_number**
  - integer
  - // used as the starting value for $page_number.
  - // if missing, $page_number starts at 1.

- **start_drawing_number**
  - integer
  - // added to $drawing_number in title block file
  - // if missing, $drawing_number starts at 1.

- **drawing_number_prefix**
  - text
  - // passed down to $drawing_number_prefix

- **drawing_number_postfix**
  - text
  - // passed down to $drawing_number_postfix

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a pff.

Please continue to the next section 44.2 Cross Section Plot Parameter File.
44.2 Cross Section Plot Parameter File

The cross section plot parameters are placed in a file with ending .ppf. Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line. Anything on a line after a double forward slash // is considered to be a comment. The set of all parameters for the cross section plot is enclosed within a set of curly brackets { } with the header

```
section_x_plot "plot set name"
```

before the curly brackets.

That is,

```
section_x_plot "plot set name" {
    plot parameters
    one per line
}
```

If there is more than one section_x_plot parameter set in the file, only the first set is used. There may also be parameter sets for other plot types such as section_long_plot in the same file. The other sets will be ignored when doing cross section plots.

The plot parameters are documented in following groups:

For the Plot Sheet layout, please continue to the section 44.2.1 Plot Sheet Layout.

Boxes and datum area, please continue to the section 44.2.2 Boxes and Datum Area.

Only for the Centre line case:

Datum area, please continue to the section Datum Line.

Labelling the centreline, style etc., please continue to the section Labelling the Centreline Chainage.

Only for the Boxes case:

Datum area, please continue to the section Datum Line.

Labelling the centreline chainages, please continue to the section Labelling the Centreline Chainage.

Defining boxes and what is labelled in them, please continue to the section 44.2.5 Defining Boxes.

For Both the Centre Line and Boxes case:

Graph area parameters, please continue to the section 44.2.6 Graph Area.

Grade labelling, please continue to the section 44.2.7 Grade Labelling.

Labelling points on x-sections, please continue to the section 44.2.8 Labelling Points of the X-Sections.

Labelling cuts, please continue to the section 44.2.9 Labelling Cuts of X-Sections Through Strings in a Model.

Hatching cut/fill, please continue to the section 44.2.10 Hatching Cut and Fill Areas.

Drawing extra x-sections, please continue to the section 44.2.11 Extra Models of X-Sections.

Sorting x-sections, please continue to the section 44.2.12 Sorting X-Sections by Chainage.

Title block information, please continue to the section 44.2.13 Title Block Information.

Panel modifying parameters, please continue to the section 44.2.14 Parameters that Modify Fields In the Cross Plot Panel.

Example, please continue to the section 44.2.16 Example of a Cross Section Plot Parameter File.
44.2.1 Plot Sheet Layout

X-sections are normally generated at chainages along a given centreline. This centreline chainage is stored with each x-section string.

The chainages of the actual x-sections are referred to as offsets from the centreline position rather than x-section chainages. The offsets of the x-section are set up so that the zero offset occurs where the x-section crossed the centreline string.

The x-sections along the centreline are stored in the one model (the primary model) which is then used to generate the cross section plot.

\[ \text{model} \to \text{plot} \]

Each x-section from the primary model of x-sections generates its own sub-plot for which the x-section is the primary string. Hence the cross section plot consists of many individual plots drawn on one or more plot sheets.

Each plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

\[ \text{sheet} \size \]

The sheet size name, width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable SHEET_SIZES_4D file

The plotting area is restricted to within the plot sheet by giving margins which are:

If a User Defined Title Block is used:

\[ \text{left} \margin \, \text{mm} \]
\[ \text{right} \margin \, \text{mm} \]
\[ \text{top} \margin \, \text{mm} \]
\[ \text{bottom} \margin \, \text{mm} \]

If the default 12d title block is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the bottom_border_gap is added to the calculated height of the bottom of the title block.

\[ \text{left} \border_gap \, \text{mm} \]
\[ \text{right} \border_gap \, \text{mm} \]
\[ \text{top} \border_gap \, \text{mm} \]
\[ \text{bottom} \border_gap \, \text{mm} \]

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margin and gap parameters can exist in the one plot parameter file.
The x-sections are plotted in the order they occur in the x-section model and start being plotted at the bottom left hand corner of the cross section plotting area.

The individual x-section plots are then drawn going up the column, and when the column is full, start from the bottom of the next column.

When a sheet is full, a follow on sheet is created.

Each individual x-section sub-plot is positioned with the surrounding gaps:

- `left_sub_plot_gap` mm
- `right_sub_plot_gap` mm
- `top_sub_plot_gap` mm
- `bottom_sub_plot_gap` mm
Definition of Plotting Areas for User Defined Title Blocks

(top_margin, 0)

(left_sub_plot_gap, top_sub_plot_gap)

(right_sub_plot_gap, top_sub_plot_gap)

(right_margin, 0)

(bottom_sub_plot_gap, 0)

((left_margin, bottom_margin), (right_margin, bottom_margin))

(bottom_sub_plot_gap, bottom_sub_plot_gap)

(cross_section plot area)

(bottom_sub_plot_gap, bottom_sub_plot_gap)

(sheet height)

(sheet width)

left_margin

right_margin

bottom_margin

left_sub_plot_gap

right_sub_plot_gap

top_sub_plot_gap

bottom_sub_plot_gap
If required, all the sub-plots in a column can be automatically positioned up so that the zero offsets (the centrelines) of each x-section line up.

```
line_up_cl yes/no  // yes - line up zero offsets
```

The width of the plot can be a fixed distance left or right of the centre line (zero offset) or for the full section plus an extra left and right distance:

```
absolute_extensions yes  // The section goes from the left_extension offset on the left to the right_extension offset on the right.
no  // The section goes for the entire section length plus the left and right extension distances.
```

```
left_extension world-units  // left extension value
right_extension world-units  // right extension value
```

The x-section can be drawn and labelled with either

(a) centreline case - the x-section is plotted and an upright, and the offset and height value at the zero offset (normally the centre line position)

(b) boxes case - the x-section is plotted and the heights of the x-section and the tins at all the x-section points are labelled in boxes under the plot of the x-section.
The x-section sub-plot itself consists of the three regions - graph, datum and boxes.

The **graph area** is the area where the actual plots of the strings are drawn. This exists for both the centreline and boxes case.

The **datum area** is the region between graph area and the datum line. This exists for both the centreline and boxes cases.

The **boxes area** is where the offset values and the heights for the strings drawn on the x-section plot are labelled. This only exists for the boxes case.

For both cases, the x-section sub-plot can be labelled with other information such as:

(a) grades across the x-section

(b) points across the x-section

(c) cuts the x-section makes through strings

(d) cut and fill areas

All the required parameters will be described in the following sections.

Please continue to the next section [44.2.2 Boxes and Datum Area](#).
44.2.2 Boxes and Datum Area

The x-section can be labelled with either

(a) an upright, and the offset and height value at the zero offset (normally the centre line position)

(b) the heights of the x-section and the tins at all the x-section points.

The choice is given by the parameter `label_type`:

- `label_type "centre line"` // type (a)
- `boxes` // type (b)

A datum line exists for both cases.

For the boxes case, a box area for the offset and heights is created below the datum line. The available parameters for tailoring the box area will be given after describing the datum line parameters.

For the centre line case, the centre line and offset and height of the centre line are shown.

In both cases, the actual cross section plot is drawn above the datum line in the graph area.

Please continue to the next section **44.2.3 Centre Line Case** for the centre line parameters.

Please continue to the section **44.2.4 Boxes Case** for the boxes parameters.
44.2.3 Centre Line Case

**Datum Line**

Each x-section sub-plot can be labelled with the datum value for the plot of the x-section string. This DATUM INFO label is made up of the text strings:

"datum_name" followed by the *datum-value*

and is above the datum line.

For the centreline case, the graph area is positioned the distance $\text{datum_above_gap_cl}$ above the datum line.

The $\text{datum_above_gap_cl}$ can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

The datum value can be placed on the left, centre or right side of the datum line.

- $\text{datum_roundoff}$
  - 1.0 // value to roundoff the datum value to
  - e.g. 0.5, 0.2, 1.0 (default 1.0)

- $\text{datum_decimals}$
  - integer // number of decimal places to display
  - the datum value (default 1).
  - If $>0$, trailing zeros are removed after the decimal point.
  - If $<0$, the absolute value is taken as the number of decimal places to report
  - i.e. no trailing zeros are removed

- $\text{datum_side_cl}$
  - 0 // datum text in middle of datum line
  - 1 // **""** left of datum line (default)
  - 2 // **""** right of datum line

- $\text{datum_linestyle}$
  - linestyle // datum line linestyle (default solid)

- $\text{datum_name}$
  - text // text to write before the datum value

- $\text{datum_textstyle}$
  - text // textstyle for datum information

- $\text{datum_text_size}$
  - mm // size of datum text and value

- $\text{datum_colour}$
  - colour // colour of the datum text

- $\text{datum_line_colour}$
  - colour // colour of the datum line
datum_text_justification_cl just // justification for datum text
// NOTE - this is not normally required since
// by default the text justification is set to
// match datum_side_cl

datum_x_cl mm // distance to move the datum text
// along the datum line

datum_y_cl mm // distance to raise the datum text
// above the datum line (used to be
// called datum_offset)

The datum_x_cl and datum_y_cl can be positive, zero or negative.

Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string.

This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the chainage-value

and is drawn under the datum line.

The chainage value can be placed on the left, centre of right side of the datum line.

chainage_side_cl 0 // text in middle of datum line (default)
1 // " " " left of datum line
2 // " " " right of datum line

The parameters controlling the labelling are:

chainage_label 0/1 // 1 = label sub-plot with centreline
// chainage, 0 don’t label.
chainage_title text // text before the chainage value
chainage_decimals integer // number of decimals in the chainage
// value. If <0, the absolute value
// is taken as the number of decimal
// places i.e. no trailing zeros are
// removed for the values in the
// chainage values.
chainage_colour colour // colour of the text
chainage\_size \hspace{1cm} mm \hspace{1cm} // size of the text
chainage\_textstyle \hspace{1cm} colour \hspace{1cm} // textstyle for the chainage label
chainage\_text\_justification\_cl \hspace{1cm} just \hspace{1cm} // justification of the chainage text
chainage\_x\_offset \hspace{1cm} mm \hspace{1cm} // x position of text
chainage\_y\_offset \hspace{1cm} mm \hspace{1cm} // y position of text

The \texttt{chainage\_x\_offset} is measured from the beginning of the datum line.

The \texttt{chainage\_y\_offset} is measured from the bottom of the datum line with positive being \textbf{down}.

\textbf{Centre Line Linestyle}

The upright at the centre line position can have its own linestyle.

\texttt{cl\_linestyle \hspace{1cm} linestyle \hspace{1cm} //linestyle for centreline}
Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the primary string (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

\[
\text{pre_text} \ \text{value} \ \text{post_text}
\]

where value is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.

Parameters for labelling the X Co-ordinate at Zero Offset:

- **primary_x0_draw_mode**: 0 // don’t draw the label -default
  1 // draw the label

- **primary_x0_position**: 0 // label in middle of datum line (default)
  1 // " " " " left of datum line
  2 // " " " " right of datum line

- **primary_x0_pre_text**: text // pre-text for label - def " 

- **primary_x0_post_text**: text // post-text for label - def " 

- **primary_x0_decimals**: integer // number of decimal places to display - def 1
  // If > 0, trailing zeros are removed after 
  // the decimal point
  // If < 0, the absolute value is taken as the 
  // number of decimal places to report
  // i.e. no trailing zeros are removed

- **primary_x0_x**: mm // x adjustment to position of label - def 0

- **primary_x0_y**: mm // y adjustment to position of label - def 0

- **primary_x0_angle**: degrees // angle of the label - def 0

- **primary_x0_colour**: colour // colour of the label

- **primary_x0_size**: mm // size (in mm) of the label

- **primary_x0_textstyle**: textstyle // textstyle of the label

- **primary_x0_justify**: just // justification for text

Parameters for Labelling the Y Co-ordinate at Zero Offset:

- **primary_y0_draw_mode**: 0 // don’t draw the label -default
  1 // draw the label

- **primary_y0_position**: 0 // label in middle of datum line (default)
  1 // " " " " left of datum line
Chapter 44  Text Plot Parameters

Cross Section Plot Parameter File  Page 7351

Parameters for Labelling the Height of Primary String at Zero Offset:

primary_height_draw_mode 0 // don’t draw the label -default
1 // draw the label
primary_height_position 0 // label in middle of datum line (default)
1 // " " " left of datum line
2 // " " " right of datum line
primary_height_pre_text text // pre-text for label - def " "
primary_height_post_text text // post-text for label - def " "
primary_height_decimals integer // number of decimal places to display - def 1
// If > 0, trailing zeros are removed after
// the decimal point
// If < 0, the absolute value is taken as the
// number of decimal places to report
// i.e. no trailing zeros are removed
primary_height_x mm // x adjustment to position of label - def 0
primary_height_y mm // y adjustment to position of label - def 0
primary_height_angle degrees // angle of the label - def 0
primary_height_colour colour // colour of the label
primary_height_size mm // size (in mm) of the label
primary_height_textstyle textstyle // textstyle of the label
primary_height_justify just // justification for text

Parameters for Placing Some Text:

extra_text_draw_mode 0 // don’t draw the label -default
1 // draw the label
extra_text_position 0 // label in middle of datum line (default)
1 // " " " left of datum line
2 // " " " right of datum line
extra_text text // text for label - def " "
extra_text_x mm // x adjustment to position of label - def 0
extra_text_y mm // y adjustment to position of label - def 0
extra_text_angle degrees // angle of the label - def 0
extra_text_colour colour // colour of the label
extra_text_size mm // size (in mm) of the label
extra_text_textstyle textstyle // textstyle of the label
extra_text_justify just // justification for text

Parameters for Labelling the Height of a Tin at Zero Offset:

A section along the primary string through each tin on the section view is automatically drawn on
the cross section plot but the user can specify whether the tin height at the zero offset is labelled or not.

Hence although there may be a number of tins drawn on the section plot, not all of them need to have their height at zero offset labelled.

The default order for labelling the tins is the order that they were added to the view but it is possible to specify which tin is used for labelling by giving the tin name rather than just using the tin on the section view.

In fact, it is possible to use any tin in the project to label the height at zero offset, not just those drawn on the section view.

If a tin of the name given by *tin_n_name* does not exist, then the plot is not produced and an error message is given.

The parameters for labelling the height of the tin at zero offset are:

```
tin_n_name text // n=1, ... no of tins on the section view.
// use the tin called text to label the nth row of tin heights.
```

The parameters for labelling the height of the tin at zero offset are:

- **tin_n_name**
  - text
  - // n=1, ... no of tins on the section view.
  - // use the tin called text to label the nth row of tin heights.
  - // if a tin of the name given by *tin_n_name* does not exist, then the plot is not produced and an error message is given.

The parameters for labelling the height of the tin at zero offset are:

- **tin_n_height_draw_mode**
  - 0 // don’t draw the label -default
  - 1 // draw the label

- **tin_n_height_position**
  - 0 // label in middle of datum line (default)
  - 1 // " " " left of datum line
  - 2 // " " " right of datum line

- **tin_n_height_pre_text**
  - text // pre-text for label - def " "

- **tin_n_height_post_text**
  - text // post-text for label - def " "

- **tin_n_height_decimals**
  - integer // number of decimal places to display - def 1
  - // If > 0, trailing zeros are removed after the decimal point
  - // If < 0, the absolute value is taken as the number of decimal places to report
  - // i.e. no trailing zeros are removed

- **tin_n_height_x**
  - mm // x adjustment to position of label - def 0

- **tin_n_height_y**
  - mm // y adjustment to position of label - def 0

- **tin_n_height_angle**
  - degrees // angle of the label - def 0

- **tin_n_height_colour**
  - colour // colour of the label

- **tin_n_height_size**
  - mm // size (in mm) of the label

- **tin_n_height_textstyle**
  - textstyle // textstyle of the label
Labelling the Centre Line Offset and Height

In the centre line case, the value of the height of the primary string (usually the design cross section) at the zero offset can be labelled. This is normally where the alignment string cuts the cross section.

The label is made up of the texts:

```
primary_title  offset_title  offset_value  height_text  height_value
```

NOTE: These parameters have now been superseded. The parameters for labelling the height of the primary string at zero offset covers this case. To use the zero offset parameters instead, the primary_height_pre_text would include all text required for the Primary_title, offset_title, offset_value and height_text (offset_value is always 0.0).

The parameter primary_mode_cl controls whether the primary_title is included in the label.

```
primary_mode_cl  0  // don’t include primary_title, primary_value
                 1  // incl. primary_title, primary_value default
```

The parameter height_mode_cl controls whether the height_title and height_value are included in the label.

```
height_mode_cl  0  // don’t include height_title, height_value
                1  // include height_title, height_value default
```

The parameter offset_mode_cl controls whether the offset_title and offset_value are included in the label.

```
offset_mode_cl  0  // don’t include offset_title, offset_value
                1  // include offset_title, offset_value default
```

The label can be placed on the left, centre, of right side of the datum line.

```
offset_height_side_cl  0  // text in middle of datum line (default)
                      1  // " " " left of datum line
                      2  // " " " right of datum line
```

The size, colour, text justification and text style for the label is given by:

```
primary_title  text  //primary title
offset_title   text  // offset label (default "Offset")
height_text    text  // height text label (default "Height")
primary_textstyle  textstyle  // textstyle used for offset and height label
primary_colour  colour // colour for offset and height label
primary_size    mm //size of the offset and height label
offset_height_text_justification_cl  justif // text justification
                                      // NOTE - this is not normally required since
                                      // by default the text justification is set to
                                      // match offset_height_side_cl
```

The number of decimals in the offset-value and height-value is controlled by:

```
number_of_decimals  integer  // number of decimal places in the offset,
                      // height boxes. If <0, the absolute value
                      // is taken as the number of decimal
                      // places i.e. no trailing zeros are
                      // removed for the values in the offset,
                      // heights area.
```

The label is placed an distance offset_x_cl along the datum line and a distance offset_y_cl
below the datum line of the plot.

- **offset_x_cl** \( mm \) // distance to move the text along the datum line
- **offset_y_cl** \( mm \) // distance to shift the text below the datum line

The **offset_y_cl** is measured from the datum line with positive being **down**.

Please continue to the next section **44.2.4 Boxes Case** for the boxes parameters.

Please continue to the section **44.2.6 Graph Area** if you are not using boxes parameters.
44.2.4 Boxes Case

Datum Line

For the boxes case, the datum line is positioned the distance datum_below_gap above the top of the boxes area and the graph area is then positioned the distance datum_above_gap above the datum line.

Hence the graph area is distance (datum_below_gap + datum_above_gap) above the top of the boxes area.

datum_above_gap  mm     // dist from datum line to bottom of the
                    // graph area
datum_below_gap  mm     // dist from datum line to top of the
                       // boxes
datum_linestyle  linestyle //linestyle for the datum line

The datum_below_gap and datum_above_gap can be zero or positive.

The roundoff for the datum value is specified by the user (default 1.0) and the datum is automatically calculated for each sub-plot, and labelled.

datum_roundoff  1.0     // value to roundoff the datum value to
                    // e.g. 0.5, 0.2, 1.0 (default 1.0)
datum_decimals  integer // number of decimal places to display
                       // the datum value (default 1).
                    // If > 0, trailing zeros are removed after
                       // the decimal point.
                    // If <0, the absolute value is taken as the
                       // number of decimal places to report
                    // i.e. no trailing zeros are removed

datum_name      text     // text to write before the datum value
datum_textstyle text     // textstyle for datum information
datum_text_size mm      // size of datum text and value
datum_colour    colour   // colour of the datum text
datum_line_colour colour   // colour of the datum line
datum_x         mm      // distance to move the datum text
                    // along the datum line
                    // called datum_offset

datum_y         mm      // distance to raise the datum text
                    // above the datum line (used to be
                       // called datum_offset)

The datum_x and datum_y can be positive, zero or negative.

Labelling the Centreline Chainage

Each x-section sub-plot can be labelled with the centreline chainage of the x-section string.

This CHAINAGE INFO label is made up of the text strings:

"chainage_title" followed by the chainage-value

and is drawn under the boxes area.

The parameters controlling the labelling are:

chainage_label  0/1     // 1 = label sub-plot with centreline
                    // chainage, 0 don’t label.
chainage_title text    // text before the chainage value
chainage_decimals integer // number of decimals in the chainage
                       // value. If <0, the absolute value
                       // is taken as the number of decimal
                       // places i.e. no trailing zeros are
                       // removed for the values in the
The chainage_x_offset is measured from the beginning of the height boxes.

If chainage_x_offset is omitted, the text is centred on heights area.

The chainage_y_offset is measured from the bottom of the box area with positive being down.
44.2.5 Defining Boxes

When boxes is selected for label_type, the primary string (usually the design cross section) and each tin in the x-section sub-plot can be labelled with one or two lines of title, and the height at the offset position for each point in the primary string.

The title for the strings, is drawn in the title area of the boxes area.

The offsets/heights are drawn in the heights area of the boxes area.

Consequently the boxes area is made up of rows of text consisting of:

- string/tin titles followed by the offset/height values across the string/tin.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is

(a) offset title and values
(b) tin title and heights - natural surface etc. (optional)
(c) primary string title and heights - design x-section (optional)

The title area starts at the relative position (left_sub_plot_gap,bottom_sub_plot_gap).

The size of the title text is given by the title_box_text_size parameter.

The width of the title area is either given by the space_for_titles parameter, or if omitted, the required width is automatically calculated.

- title_box_text_size mm // size of the titles in the boxes
- space_for_titles mm // calculated if omitted

There can be two lines of title text and the title text, textstyle and colour can be set independently for the primary string and each tin.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

- box_titles_x mm // distance to move the title text from the left hand side of the boxes

The heights area starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (box_text_justification).

The number of decimal places and the size of the heights text can also be specified.

The height of each individual box area is either given by the horizontal_line_spacing parameter, or if omitted, the required height is automatically calculated.

- number_of_decimals integer // number of decimal places in the height boxes. If <0, the absolute value
The total height of the boxes area is simply given by number of boxes drawn multiplied by the height of one box (they all have the same height).

The width of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

Hence the total width of the boxes area is the width of the labels area plus the width of the heights area.

Many distance definitions in the plot parameter file are given in terms of distance above the top of the boxes area.

The text in the title area is the same for each cross section plot on the sheet so it is possible to restrict the title area to be only on the first cross section on the sheet or the first column of cross sections.

The drawing of the box line work is user defined. This has been extended from V3.1 although draw_box_mode has been left in for upward compatibility.
For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters `draw_box_side_n` and `box_side_colour_n`, and the separation lines inside the boxes are controlled by the parameters `box_line_draw_mode` and `box_line_mode_n` where the box numbering, n, starts from the bottom box.

**Note:** The following parameters are only used if `draw_box_mode` is set to 3.

```
draw_box_side_1 1 // draw the left side of the title area (def)
0 // don’t draw the left side
box_side_colour_1 colour // colour to draw left side of title area
// default box_colour
draw_box_side_2 1 // draw top of the title area (default)
0 // don’t draw the top
box_side_colour_2 colour // colour to draw top of title area
// default box_colour
draw_box_side_4 1 // draw bottom of the title area (default)
0 // don’t draw the bottom
box_side_colour_4 colour // colour to draw bottom of title area
// default box_colour
draw_box_side_5 1 // draw left side of the heights area (def)
0 // don’t draw the left side
box_side_colour_5 colour // colour to draw left side of heights area
// default box_colour
draw_box_side_6 1 // draw top of the heights area (default)
0 // don’t draw the top
box_side_colour_6 colour // colour to draw top of heights area
// default box_colour
draw_box_side_7 1 // draw right side of the heights area def
0 // don’t draw the right side
box_side_colour_7 colour // colour for right side of heights area
// default box_colour
draw_box_side_8 1 // draw bottom of the heights area (def)
0 // don’t draw the bottom
box_side_colour_8 colour // colour for bottom of heights area
// default box_colour
```

The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters `box_line_draw_mode` and `box_line_mode_n`.

The separation lines can be drawn just in the title area, just in the heights area or in both areas.

The parameter `box_line_draw_mode` can be set to control all the separation lines but there are
additional parameters, `box_line_mode_n`, which override `box_line_draw_mode` for each of the individual boxes where \( n = 1, \ldots, \) number of boxes -1.

The top of the top box is not controlled by `box_line_mode_n` but is controlled by the parameters `draw_box_side_2` and `draw_box_side_6`.

```
box_line_draw_mode 0 // don’t draw any separation lines inside
                    // the title and heights areas
1 // draw the separation lines inside the
    // title and heights areas (default)
2 // draw the separation lines inside the
    // title area only
3 // draw the separation lines inside the
    // heights area only

box_line_mode_n 0 // for the nth box, don’t draw any
                  // line at the top of the box for either
                  // the title or the heights areas
1 // for the nth box, draw the line at the
    // top of the box for both the
    // title and heights areas
2 // for the nth box, draw the line at the
    // top of the box for the title area only
3 // for the nth box, draw the line at the
    // top of the box for the heights area only
```

```
<table>
<thead>
<tr>
<th>title area</th>
<th>heights area</th>
</tr>
</thead>
<tbody>
<tr>
<td>draw this line for <code>box_line_mode_2 = 1</code> or <code>3</code></td>
<td></td>
</tr>
<tr>
<td>draw this line for <code>box_line_mode_1 = 1</code> or <code>3</code></td>
<td></td>
</tr>
</tbody>
</table>

values for `box_line_mode_n`
```

Finally, the right hand end of the boxes can stop at the end of the design x-section or extend to the end of the `right_extension` distance.

```
box_extension_mode 0 // default - stop right end of boxes at the
                     // end of design x-section
1 // extend right end of boxes to the end of
    // the right_extension distance.
```
if box_extension_mode = 1 then the boxes extend to the end of the right extension
Offset Titles and Values

If the label_type is set to boxes, the offsets of the points across the primary string (usually the design cross section) are always labelled.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>offset_title</td>
<td>text</td>
<td>// first line of offset title (def offsets)</td>
</tr>
<tr>
<td>offset_title_2</td>
<td>text</td>
<td>// second line of offset title</td>

<td>mm</td>
<td>// size for offset values</td>
</tr>
</tbody>
</table>

Example of Offset Titles Parameters

```plaintext
// offset titles and values
offset_title            "Offset"
offset_title_2          "metres"
offset_title_colour     grey
```

Primary String Titles and Heights

Sometimes the primary string (the design cross section) is only required to define the offset positions to label and the section line for the tin sections. In this case, the primary string would not be drawn on the cross section plot.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter primary_string.

If the primary string is drawn, by default a row of labelling is included in the boxes area with up to two lines of title information and heights for each point across the cross section.

<table>

</tbody>
</table>

Example of Labelling Primary String Titles
primary_title                           "Design"
// primary_title_2                          "primary2" // not being used - commented out
primary_colour                           "purple"
primary_title_colour                     "red"
**Tin Titles, Heights and Depths**

A section along the primary string through each tin on the section view is automatically drawn on the cross section plot, but the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that they were added to the view but it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use any tin in the project to label a row, not just those drawn on the section view.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tin_n_name</td>

<tr>
<td>tin_n_depth_title_2</td>
<td>text</td>
<td>// second line of tin depth title</td>
</tr>
<tr>
<td>tin_n_depth_textstyle</td>
<td>textstyle</td>
<td>// textstyle of the tin depth titles</td>
</tr>
</tbody>
</table>

If a tin of the name given by tin_n_name does not exist, then the plot is not produced and an error message is given.

For the following parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth tin on the section view or if tin_n_name is set, by the tin specified by tin_n_name.
### Cross Section Plot Parameter File

  - // box for the tin heights.

### Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin, at a particular offset is defined as

\[
\text{depth} = \text{tin height value} - \text{height of the primary string}
\]

That is, the depth that the primary string is below the tin.

Before plotting, the value of depth is multiplied by either the `depth_positive_factor` or `depth_negative_factor`.

- if (depth >= 0) \( \text{plotted_depth_value} = \text{depth} * \text{depth_positive_factor} \)
- if (depth < 0) \( \text{plotted_depth_value} = \text{depth} * \text{depth_negative_factor} \)

Hence the definition of depth can be modified by the parameters:

- `depth_positive_factor` value // multiplier for positive depths
- `depth_negative_factor` value // multiplier for negative depths

For example, if the opposite sign is required for depth, that is,

\[
\text{depth} = \text{height of the primary string} - \text{tin height value}
\]

simply set

- `depth_positive_factor` -1
- `depth_negative_factor` 1

### Example of Labelling Tins

// tin label 1 for on
// 0 for off

- `tin_1_label` 1
- `tin_1_title` “Natural”
- `tin_1_colour` grey
- `tin_1_title_colour` red
Labelling the Design Height, X and Y Co-ordinates and Tin Heights at Offset Zero

The values of the height and X and Y co-ordinates of the primary string (usually the design cross section) at the zero offset can be labelled. Note that zero offset is normally where the alignment string cuts the cross section.

The heights of any tins (such as the natural surface) at the zero offset can also be labelled.

The labels are made up of:

\[ \text{pre_text} \quad \text{value} \quad \text{post_text} \]

where value is either a height or a co-ordinate.

The label is positioned at either the left, right or middle of the datum line, with an x and y adjustment and a rotation.

extra_text_size mm // size (in mm) of the label
extra_text_textstyle textstyle // textstyle of the label
extra_text_justify just // justification for text
Offset Selection for Uprights and Staggering of Heights

For each sub-plot, the offsets of the points across the x-section string (primary string) are used for positioning uprights (leader lines), and the offset and height labels for the uprights.

By default, there is an upright at each point across the primary string.

However, if the primary string is a 4d string, then the text at the points on the 4d string can be used as a key to suppress the labelling and upright at that point.

The parameters to stop labelling and uprights are:

\[ \text{mask\_name\_n} \quad \text{4d\_string\_point\_text} \quad \text{where} \quad n=1,100 \]

**Note** - the text \( 4d\_string\_point\_text \) can include wild cards (*) and characters (?).

After any name masks have been applied, it is often desirable to weed out offset values that are too close together before doing any labelling.

\[ \text{offset\_label\_tolerance} \quad \text{value} \quad // \text{weed out offset values closer together} \]
\[ \quad \text{// (in offset units) than this value} \]

If the real offset position is used for the horizontal position of the offset/height text, text overwriting can easily occur. To prevent overwriting, the text is automatically staggered.

When staggering occurs, the real offset position is then indicated by the offset markers which are drawn at the top of the text boxes from the staggered text position back to the actual offset position of the text.

The size and position of the staggers are given by:

\[ \text{stagger\_gap\_top} \quad \text{mm} \quad // \text{distance from boxes to top of stagger} \]
\[ \quad \text{// distance from boxes to bottom of stagger} \]
\[ \quad \text{// stagger} \]
\[ \text{stagger\_gap\_bottom} \quad \text{mm} \quad // \text{distance between staggers is} \]
\[ \quad \text{// box\_text\_size \times \text{stagger\_gap\_factor}} \]

When staggering occurs, it is possible for the heights area to be wider than the graph area.
Uprights

Uprights (leader lines) can be drawn from the top of the staggers to strings drawn on the plot.

The height of the uprights is given by the `uprights_draw_mode`:

- `uprights_draw_mode`: 0 // none
- 1 // to maximum string height at that chainage
- 2 // ticks, to stagger height
- 3 // to `uprights_y` above the boxes
- 100 // to the primary string
- 101-500 // to tin1 or tin2 etc.

- `uprights_y`: `mm` // distance to draw the uprights for mode 3
- `uprights_colour`: `colour` // uprights colour (def boxes colour)

The uprights can go below the top of the boxes.

- `uprights_bottom_mode`: 0 // stop at top of boxes (default)
- 1 // draw to bottom of boxes
- 2 // draw to `uprights_bottom_y` below the top of the boxes
- 3 // draw to `uprights_bottom_y` above the bottom of the boxes
- 4 // ticks at chainage

- `uprights_bottom_y`: `mm` // distance
- `uprights_text_offset_factor`: `value` // move the text by this factor*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.
Please continue to the next section 44.2.6 Graph Area.
44.2.6 Graph Area

The graph area for each section sub-plot is the area where the actual plot of the x-section string is drawn.

The width of the graph area is determined by the width of the x-section string being plotted, the left and right extensions and horizontal scale (scale) given by parameters or in the section x plot panel, and the vertical exaggeration given by the section view or a parameter.

- `view_name` text // default is section view in panel.
- `vertical_exaggeration` value // default is vertical exag for view
- `scale` value // 1:value - horizontal scale, default is
  - `scale 1:` in panel.
- `left_extension` world-units // left extension value
- `right_extension` world-units // right extension value

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The height of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The size of the graph area can also be extended to allow for symbols by the parameters:

- `extra_space_units` 0 // extra space values are world units - default
- `extra_space_left` units // " " " are millimetres on plot page
- `extra_space_right` units // add to right of plot area, default 0
- `extra_space_top` units // add to top of plot area, default 0
- `extra_space_bottom` units // default 0

The types of strings that are drawn in the graph area of a cross section plot are:

(a) primary string the x-section string from the x-section model that is being drawn. Called the primary string and is usually the design x-section.

(b) tins sections of the primary string through any tins either in models on the section view or in corridor models.

(c) services parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The colour of the strings in the plot is the actual string colour for cases (a) and (c), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are...
labelled with heights.

**Primary String (Design Cross Section)**

The primary string (the design cross section) is used to define
(a) the design cross section
(b) the chainage of the section
(c) the offset positions for labelling heights and drawing uprights
(d) the section line used for sectioning through tins
(e) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the cross section plot, it doesn't have to be drawn on the cross section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter `primary_string` which was described earlier.

The **colour** of the primary string in the plot is the actual primary string colour.

**Tins**

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The **colour** and **linestyle** of the tin section in the plot is the actual tin colour and tin linestyle.

Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

**Corridor and Services**

A corridor around the primary string is defined by giving a left and right corridor width and a left and right extension.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the cross section plot.

Strings do not have to cross the primary string, but just be in the corridor.

---

The corridor defining parameters are
left_extension  world-units  // left extension value
right_extension  world-units  // right extension value
corridor_width_left  world-units  // corridor left and right widths
corridor_width_right  world-units  // defaults are the section view values
corridor_overlap_left  world-units  // corridor left and right overlaps.
corridor_overlap_right  world-units  // defaults are the section view values
corridor_chord_arc  world-units  // chord-arc tolerance used to
                           // approximate arcs in the corridor.
                           // default is the section view value

The models containing tins for sectioning and strings for services are taken from the section view
or given by the parameters
corridor_model_n  model  // n = 1, 2 ... 100
                       // models containing tins and service
                       // strings to be drawn on the view.

If any corridor_model_n parameters are defined, then only the models given by the parameters
are used. If no corridor_model_n parameters are set, then the models added to the given section
view are used.

That is, either the corridor_model_n parameters are used or if none exist, then the models added
to the section view are used for tins and service strings.

The colour and diameter of the service strings drawn in the plot are the actual strings colour
and diameter.

Please continue to the next section 44.2.7 Grade Labelling.
44.2.7 Grade Labelling

The plot of the x-section string is made up of straight lines joining the individual points of the x-section.

The grades of these lines can be labelled:

- `grade_label 0` // don’t label grades (default)
- `grade_label 1` // label grades

Either the individual lines can be used as the segments to be labelled for grade, or adjacent lines of the same grade can be considered to be just one segment and labelled only once.

Hence the segments to be labelled for grade can be the individual lines of the x-section, or the segments defined by changes of grade.

- `grade_change_only 0` // label individual lines
- `grade_change_only 1` // label change of grade segments

It is also possible to ignore segments smaller than a given minimum width on the plot.

- `grade_minimum_width mm` // segments smaller are not labelled

The grade labels are drawn parallel to the segment, centred about the segments end points, and a distance `grade_offset` above the segment. The size, colour and number of decimal places can all be set.

- `grade_decimals integer` // number of decimal places in grade
- `grade_size mm` // size of the grade label
- `grade_textstyle text` // textstyle of the grade label
- `grade_colour colour` // colour of the grade label
- `grade_offset mm` // distance above the segment for label
- `grade_signed yes` // default - grades are signed
- `grade_signed no` // absolute value of grades

The grade can be labelled as percent cross-fall, 1 in slope, m/m or VicRoads x:1.

Also a threshold value can be set and any grades whose absolute value are below the threshold can be labelled in one way, and those above the threshold labelled a different way.

Hence, if the absolute value of the grade is less than or equal to the absolute value of `grade_threshold`, then `grade_mode` is used, otherwise `grade_upper_mode` is used.

- `grade_mode 0` // % grade
- `grade_mode 1` // 1 in
- `grade_mode 2` // m/m
- `grade_mode 3` // VicRoads x:1

- `grade_threshold value` // grade threshold for type of grade labelling

- `grade_threshold_mode 0-3` // type of grade value given in grade_threshold types are the same as `grade_mode`

- `grade_upper_mode 0` // % grade
- `grade_upper_mode 1` // 1 in
- `grade_upper_mode 2` // m/m
- `grade_upper_mode 3` // VicRoads x:1

- `grade_upper_decimals integer` // number dec places in grades above threshold value
Example of Grade Labelling

```plaintext
grade_label                            1 // turn grade labels on
grade_mode                             0 // percent grade
grade_decimals                         1 // one decimal place, no trailing zeros
grade_change_only                     1 // only label when change of grade

// text size for grade annotations
grade_size                                 2
grade_colour                            yellow

// how far the annotation is (perpendicularly)
// from the string itself
grade_offset                               1

// label all annotations separated by more than
// the minimum width in plot units
grade_minimum_width                0

// threshold and threshold mode describe the value
// at which the grade labelling changes
// mode to grade_upper_mode
grade_threshold                          7 // change labelling when over 7%
grade_threshold_mode                0 // units for threshold - %
grade_upper_mode                      1 // label as 1:x
```

Please continue to the next section 44.2.8 Labelling Points of the X-Sections.
44.2.8 Labelling Points of the X-Sections

The points across each x-section can be automatically labelled on the x-section plots.

The **height**, **offset** and **name** of the point can be labelled as well as a **symbol** drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the point.

The height position for the labelling can be specified as the

(a) top of the boxes for the x-section
(b) above the maximum height of the strings on the plot
(c) height of the point on the x-section string (primary string)
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the point on the cross section string. For all other cases, only the offset of the cut string is used.

Other heights, for example, the height of the tin at that offset can be used as the height (case (d)).

Text justification refers to the actual position and is given by

```
"top-left"  "top-centre"  "top-right"
"middle-left"  "middle-centre"  "middle-right"
"bottom-left"  "bottom-centre"  "bottom-right"
```

A choice of six special symbols and/or any of the 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

```
+  |  |  [  △  ○
```

Up to twenty five (25) separate sets of points can be labelled.
Parameters for Labelling Points of X-Sections

The points of the x-section to be labelled for the nth set of parameters is restricted to all the points whose name satisfying the `points_n_mask`:

```
points_n_mask     point_names         // points to be labelled
```

where `point_names` is a text string containing the name masks, each separated by one or more spaces, to test the point name against. Each mask can include wild cards and wild characters.

For example

```
points_1_mask     "ke**
```

or

```
points_1_mask     "?bank**
```

or, if both masks are required,

```
points_1_mask     "ke*  ?bank**
```

The parameters for drawing a symbol are

```
points_symbol_n_mode  0 // cross
1 // up from centre of box
2 // up and down from centre of box
3 // square
4 // triangle, base at bottom
5 // circle
6 // use a 12d symbol
```

If `points_symbol_n_mode` is 6, then the plot symbol is given by

```
points_symbol_n_style  plotsymbol // name of the 12d symbol to draw at point
```

**Important Note**

The plot symbol of name `plotsymbol` is defined in the file given by:

(a) the parameter `plot_symbols` in the ppf file

```
plot_symbols     filename
```

or if `plot_symbols is not defined`, then

(b) in the file pointed to by the environment variable `PLOT_SYMBOLS_4D`

```
PLOT_SYMBOLS_4D     filename       // default plotsym.4d
```

or if `PLOT_SYMBOLS_4D is not defined`, then

(c) in the file `plotsym.4d`

which is searched for in the standard set up file sequence

**If none of the above files are defined**, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable `SYMBOLS_4D`

```
SYMBOLS_4D     filename       // default symbols.4d
```

or if the environment variable `SYMBOLS_4D` does not exist, in the file, `symbols.4d`
The position of the symbol is given by:

points_symbol_n_position
1 // above point height value
3 // above top of boxes
4 // above top of graph area but not including
    // the extra_space_top
100 // to primary string (same as 1)
101-500 // to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

points_symbol_n_x    mm // offset adjustment to position
points_symbol_n_y    mm // height adjustment to position
points_symbol_n_angle degrees // rotation about point
points_symbol_n_colour colour // colour of symbol

and for all values of points_symbol_n_mode other than 6:

points_symbol_n_size mm // size of symbol, 0 don't draw

The value of the offset of the point can be labelled using the parameters:

points_offset_n_position
1 // above point height value
3 // above top of boxes
4 // above top of graph area but not including
    // the extra_space_top
100 // to primary string
101-500 // to tin1 or tin2 etc.

points_offset_n_x    mm // offset adjustment to position
points_offset_n_y    mm // height adjustment to position
points_offset_n_angle degrees // rotation about point
points_offset_n_size mm // size of text, 0 don't label
points_offset_n_colour colour // colour of text
points_offset_n_textstyle textstyle // textstyle to use for points offset text.
points_offset_n_pre_text text // text before the offset value
points_offset_n_post_text text // text after the offset value
points_offset_n_justification justification // justification of the text
points_offset_n_no_decimals integer // number of decimals in offset

The value of a height at the offset of the point can be calculated and labelled using the parameters:

points_height_n_mode
1 // use height of point itself
3 // use real world height of position
    // above boxes
100 // height of primary string (same as 1)
101-500 // use height of to tin1 or tin2 etc.

points_height_n_position
1 // at points position
3 // above top of boxes
4 // above top of graph area but not including
    // the extra_space_top
100 // to primary string (same as 1)
101-500 // to tin1 or tin2 etc.

points_height_n_x    mm // offset adjustment to position
points_height_n_y    mm // height adjustment to position
points_height_n_angle degrees // rotation about point
points_height_n_size mm // size of text, 0 don't label
points_height_n_colour colour // colour of text
<table>

Please continue to the next section 44.2.9 Labelling Cuts of X-Sections Through Strings in a Model.
44.2.9 Labelling Cuts of X-Sections Through Strings in a Model

The cuts that each x-section string makes though any strings in user given models can be automatically labelled on the x-section plots.

The height, offset and name of the cut string can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled.

The offset position for the labelling is the offset of the cut string.

The height position for the labelling can be specified as the
(a) top of the boxes on the x-section
(b) above the maximum height of the strings on the plot
(c) height value of the cut string
(d) height of the x-section string (the primary string)
(e) height of a tin.

The actual position of the label is defined relative to the above point.

Note:
Only case (b) involves the actual height of the cut string. For all other cases, only the offset of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the offset is required and the height of the tin at that offset can be used as the height (case (d)).

Text justification refers to the actual position and is given by
“top-left” “top-centre” “top-right”
“middle-left” “middle-centre” “middle-right”
“bottom-left” “bottom-centre” “bottom-right”

A choice of six special symbols and/or or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.
Parameters for Labelling Cuts of X-Sections Through Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the model which contains the strings, and then a name mask which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the nth set (where n can be from 1 to 25) of cuts of the x-sections with the strings in the model are given by:

- `cuts_n_model`  
  model_name  
  // model of strings to be cut

The selection of the strings from the model `model_name` whose cut points are to be labelled is all the strings whose name satisfies the name mask `cuts_n_mask`:

- `cuts_n_mask`  
  name_mask  
  // strings to check for cuts
  // and if a cut occurs,
  // parameters show how to
  // label the cut

where `name_mask` is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

- `cuts_1_mask "ke*"`
- `cuts_1_mask "?bank*"`
- or, if both masks are required,
  - `cuts_1_mask "ke* ?bank*"`

If `cuts_n_mask` is missing, then all strings in the model are used. This is equivalent to `name_mask` being "*".

All strings in the model `cuts_n_model` whose name satisfy the name mask `cuts_n_mask` are then checked for cuts with the x-sections, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the nth set.

The parameters for drawing a symbol at the cut points are:

- `cuts_symbol_n_mode`  
  0  
  1  
  2  
  3  
  4  
  5  
  6  
  // cross  
  // up from centre of box  
  // up and down from centre of box  
  // square  
  // triangle, base at bottom  
  // circle  
  // use a 12d symbol

If `cuts_symbol_n_mode` is 6, then the plot symbol is given by

- `cuts_symbol_n_style`  
  plotsymbol  
  // 12d symbol to draw at cut

Important Note

The plot symbol of name `plotsymbol` is defined in the file given by:

(a) the parameter `plot_symbols` in the ppf file

- `plot_symbols filename`
or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D
   PLOT_SYMBOLS_4D filename // default plotsym.4d

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file plotsym.4d
   which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it
will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D
   SYMBOLS_4D filename // default symbols.4d
   or if the environment variable SYMBOLS_4D does not exist, in the file, symbols.4d

The position of the symbol is given by:

- cuts_symbol_n_position
  - 1 // above point height value
  - 3 // above top of boxes
  - 4 // above top of graph area but not including
    // the extra_space_top
  - 100 // to primary string
  - 101-500 // to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

- cuts_symbol_n_x mm // offset adjustment to position
- cuts_symbol_n_y mm // height adjustment to position
- cuts_symbol_n_angle degrees // rotation about point
- cuts_symbol_n_colour colour // colour of symbol

and for all values of cuts_symbol_n_mode other than 6:

- cuts_symbol_n_size mm // size of symbol, 0 don't draw

The value of the offset of the cut string can be labelled using the parameters:

- cuts_offset_n_position
  - 1 // above cut strings height value
  - 3 // above top of boxes
  - 4 // above top of graph area but not including
    // the extra_space_top
  - 100 // to primary string
  - 101-500 // to tin1 or tin2 etc.

- cuts_offset_n_x mm // offset adjustment to position
- cuts_offset_n_y mm // height adjustment to position
- cuts_offset_n_angle degrees // rotation about point
- cuts_offset_n_size mm // size of text, 0 don't label
- cuts_offset_n_colour colour // colour of text
- cuts_offset_n_textstyle textstyle // textstyle to use for cuts offset text.
- cuts_offset_n_pre_text text // text before the offset value
- cuts_offset_n_post_text text // text after the offset value
- cuts_offset_n_justification justification // justification of the text
- cuts_offset_n_no_decimals integer // number of decimals in offset

The value of a height at the offset of the point can be calculated and labelled using the parameters:

- cuts_height_n_mode
  - 1 // use height of cut point itself
  - 3 // use real world height of position
A label which can include the name of the cut string is drawn by using the parameters:

- **cuts_label_n_position**: The position of the label relative to the cut point.
  - 1: Above the cut strings height value.
  - 3: Above top of boxes.
  - 4: Above top of graph area but not including the extra_space_top.
  - 100: To primary string.
  - 101-500: To tin1 or tin2 etc.

- **cuts_label_n_mode**: The mode for including the cut string name.
  - 0: Don't include cut string name.
  - 1: Include cut string name in label.

- **cuts_label_n_x**, **cuts_label_n_y**, **cuts_label_n_angle**, **cuts_label_n_size**, **cuts_label_n_colour**, **cuts_label_n_textstyle**, **cuts_label_n_pre_text**, **cuts_label_n_post_text**, **cuts_label_n_justification**: Parameters for adjusting the position, angle, size, colour, style, and justification of the label text.

The cut point can be labelled with:
- **offset** of the cut point
- **height** of the cut point
- **height** of the x-section or tins at this offset
- **name** of the string for the cut point

User defined symbols can also be drawn at the cut point.
Please continue to the next section 44.2.10 Hatching Cut and Fill Areas.
44.2.10 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hatch_original_tin_n</td>
<td>tin_name for original surface</td>
</tr>
<tr>
<td>hatch_new_tin_n</td>
<td>tin_name for final surface</td>
</tr>
<tr>
<td>hatch_cut_separation_n</td>
<td>mm</td>
</tr>
<tr>
<td>hatch_cut_angle_n</td>
<td>degrees</td>
</tr>
<tr>
<td>hatch_cut_colour_n</td>
<td>colour</td>
</tr>
<tr>
<td>hatch_cut_linestyle_n</td>
<td>linestyle</td>
</tr>
<tr>
<td>hatch_cut_draw_sides_n</td>
<td>1/0</td>
</tr>
<tr>
<td>hatch_cut_draw_original_n</td>
<td>1/0</td>
</tr>
<tr>
<td>hatch_cut_draw_new_n</td>
<td>1/0</td>
</tr>
<tr>
<td>hatch_fill_separation_n</td>
<td>mm</td>
</tr>
<tr>
<td>hatch_fill_angle_n</td>
<td>degrees</td>
</tr>
<tr>
<td>hatch_fill_colour_n</td>
<td>colour</td>
</tr>
<tr>
<td>hatch_fill_linestyle_n</td>
<td>linestyle</td>
</tr>
<tr>
<td>hatch_fill_draw_sides_n</td>
<td>1/0</td>
</tr>
<tr>
<td>hatch_fill_draw_original_n</td>
<td>1/0</td>
</tr>
<tr>
<td>hatch_fill_draw_new_n</td>
<td>1/0</td>
</tr>
</tbody>
</table>

Notes

(a) cut is when the new tin is below the original tin.
    fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
    fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.
44.2.11 Extra Models of X-Sections

The order and centreline chainages of the x-section subplots for the x-section plot are defined by the sections from the primary model of cross sections.

The sections through any specified triangulations and service models, and offsets for labelling are fully defined by these primary x-sections.

However it is also possible to plot extra x-sections on each of the sub-plots by supplying extra models of x-sections which are at the same plan positions as the primary x-section strings.

Only those x-sections from the extra models that are within a user specified tolerance of a primary x-section are plotted.

The extra models of x-sections and the plan tolerance for checking that the extra cross-sections are the same position as the primary x-sections are

```plaintext
extra_model_tolerance_1 value // tolerance in 12d Model units
extra_model_n model_name // where n=1, ... 100
                  // extra models of x-sections
```

The actual colour of the extra x-sections is used as their plotting colour.

Please continue to the next section 44.2.12 Sorting X-Sections by Chainage.
44.2.12 Sorting X-Sections by Chainage

The chainage on the design string that the x-section is created at is stored with the cross-section. When the x-sections are created by the apply functions, they are created in the order of increasing chainage and added to the model for sections in that order. Hence if the cross sections are plotted, the natural order would be in increasing chainage order. However, it is possible to upset the order in the model by manually adding in extra sections. Hence there is a parameter in both the section x plot panel and the plot parameter file to ensure that the cross sections are sorted in increasing chainage order before they are plotted.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sort_sections</td>
<td>1</td>
<td>sort sections by design chainage</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>use order of sections in model</td>
</tr>
</tbody>
</table>

Please continue to the next section 44.2.13 Title Block Information.
44.2.13 Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

Standard Title Block

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter plot_border.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_border</td>
<td>yes/no // yes plots a standard title block</td>
</tr>
<tr>
<td></td>
<td>// default yes</td>
</tr>
<tr>
<td>title_1</td>
<td>text</td>
</tr>
<tr>
<td>title_2</td>
<td>text</td>
</tr>
<tr>
<td>title_text_size</td>
<td>value</td>
</tr>
<tr>
<td>title_colour</td>
<td>colour</td>
</tr>
</tbody>
</table>

User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The plot_border parameter should also be set to no so that the standard title block is not also drawn.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>use_title_file</td>
<td>yes/no // yes draws the title block given in title_file</td>
</tr>
<tr>
<td></td>
<td>// default no</td>
</tr>
<tr>
<td>title_file</td>
<td>filename</td>
</tr>
<tr>
<td>plot_border</td>
<td>no // turn off standard title block</td>
</tr>
</tbody>
</table>

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters user_text_n (n = 1,2,... 1000)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_text_n</td>
<td>text</td>
</tr>
</tbody>
</table>

The special plot parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time_format</td>
<td>text // format for $time</td>
</tr>
<tr>
<td>user_text_n</td>
<td>text // where n = 1,2,... 1000</td>
</tr>
<tr>
<td></td>
<td>// passed down to $user_text_n</td>
</tr>
<tr>
<td>title_1</td>
<td>text // passed down to $title_1</td>
</tr>
<tr>
<td>title_2</td>
<td>text // passed down to $title_2</td>
</tr>
<tr>
<td>start_page_number</td>
<td>integer // used as the starting value for</td>
</tr>
<tr>
<td></td>
<td>// $page_number. If missing,</td>
</tr>
<tr>
<td></td>
<td>// $page_number starts at 1.</td>
</tr>
<tr>
<td>start.Drawing_number</td>
<td>integer // added to $drawing_number in title</td>
</tr>
<tr>
<td></td>
<td>// block file. If missing,</td>
</tr>
<tr>
<td></td>
<td>// $drawing_number starts at 1.</td>
</tr>
<tr>
<td>drawing_number_prefix</td>
<td>text // passed down to</td>
</tr>
<tr>
<td></td>
<td>// $drawing_number_prefix</td>
</tr>
<tr>
<td>drawing_number_postfix</td>
<td>text // passed down to</td>
</tr>
<tr>
<td></td>
<td>// $drawing_number_postfix</td>
</tr>
</tbody>
</table>

Please continue to the next section 44.2.14 Parameters that Modify Fields In the Cross Plot Panel.
44.2.14 Parameters that Modify Fields In the Cross Plot Panel

A number of parameters match those in the section x plot panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters in the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the section x plot panel are:

- view_name: text
- plotter_type: text
- model_to_plot: text
- plot_stem: text
- start_chainage: chainage
- end_chainage: chainage
- sheet_size: text or “width height”
- scale: value
- absolute_extensions: yes/no
- left_extension: world-units
- right_extension: world-units
- line_up_cl: yes/no
- primary_string: yes/no
- label_type: yes/no
- box_colour: colour
- text_size: mm
- sort_sections: yes/no
- use_title_file: yes/no
- title_file: filename
- plot_border: yes/no
- title_1: text
- title_2: text
- title_text_size: value
- title_colour: colour
- global_textstyle: textstyle

Please continue to the next section 44.2.15 Generating Cross Section Plots Without a View.
44.2.15 Generating Cross Section Plots Without a View

The cross section plot parameters are comprehensive enough that it is possible to completely generate a cross section plot without referencing a section view, or even using the section X plot panel.

Such a ppf can be run using the plots=>plot a ppf option or from the 4D Solutions programming language, 4DL.

When generating a cross section plot using the section X plot panel, a plot parameter file containing all the parameters needed to regenerate the plot using plots=>plot a ppf can be written out by simply giving a name for the ppf file in the plot parameters write field of the section X plot panel.

Notes

1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section 44.2.16 Example of a Cross Section Plot Parameter File.
44.2.16 Example of a Cross Section Plot Parameter File
// ppf file to generate x-section example

section_x_plot "plot 2" {

Please continue to the next section 44.3 Long Section Plot Parameter File.
44.3 Long Section Plot Parameter File

The long section plot parameters are placed in a file with ending .ppf. Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line. Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the long section plot is enclosed within a set of curly brackets { } with the header

\[ \text{section} \_\text{long} \_\text{plot} \quad \text{“plot set name”} \]

before the curly brackets.

That is,

\[ \text{section} \_\text{long} \_\text{plot} \quad \text{“plot set name”} \quad \{ \]

\quad \text{plot parameters} \\
\quad \text{one per line} \\
\}

If there is more than one section_long_plot parameter set in the file, only the first set is used. There may also be parameter sets for other plot types such as section_x_plot in the same file. The other sets will be ignored when doing a long section plot.

The plot parameters are documented in following groups:

- Defining chainage range
- Breaking the plot into pages
- Plot Sheet layout
- Boxes area
- Defining chainages and staggering
- Defining uprights
- Datum area
- Graph (drawing)
- Defining bubbles
- Quick HG
- Extensive HG
- Quick VG
- Extensive VG
- Labelling heights
- Labelling with scale
- Title block information
- Panel modifying parameters
- Labelling string name
- Example

- 44.3.23 Example of a Long Section Plot Parameter File
44.3.1 Possible Chainage Range

In the panel, the field **Use HG VG for min, max** determines whether the horizontal geometry (HG) and the vertical geometry (VG) are both used to determine the minimum and maximum chainages for drawing. This allows the vertical geometry to be plotted when it is outside the horizontal geometry (e.g. kerb returns).

The equivalent parameter in the pfp is

```
use_vg_hg_for_min_max 1 // the chainage range available for plotting
// is from the minimum of the horizontal
// geometry (HG) and the vertical geometry
// (VG) to the maximum of the HG and VG
// This is useful for kerb returns

use_vg_hg_for_min_max 0 // the chainage range available for
// plotting is from the minimum of the
// horizontal geometry (HG) to the
// maximum of the HG.
```
44.3.2 Pagination

If the long section plot is too long to fit on one page, it can be broken into a number of pages (sheets).

The parameter, \textit{pagination\_length}, controls the amount of new chainage length on each plot page. Each page of the long section plot can also include a set chainage amount from the end of the previous plot.

Hence apart from the first page and possibly the last page, the plot will have a chainage length given by the sum of the \textit{pagination\_length} and \textit{pagination\_overlap}.

- \texttt{pagination}\hspace{1em} yes/no \hspace{1em} // if yes, then break the plot into pages
- \texttt{pagination\_mode}\hspace{1em} chainage \hspace{1em} // length and overlap in chainage units
- \hspace{1em} millimetre \hspace{1em} // length and overlap in millimetres
- \texttt{pagination\_length}\hspace{1em} chainage \hspace{1em} // new chainage range on each page
- \hspace{1em} millimetres \hspace{1em} // overlap between pages

\textbf{Note}

The \textit{pagination\_length} and \textit{pagination\_overlap} are given in chainage units or millimetres. The user must choose values which will fit on the selected sheet size or the end of each plot will be truncated by the sheet.
44.3.3 Plot Sheet Layout

The plot page or sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```
sheet_size text // sheet name, or
"mm mm" // sheet size: width height
```

The sheet size name and width and heights can be specified by the user in a file named sheets.4d which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D file // file of plotter sheets sizes
```

The plotting area is restricted to within the plot sheet by giving margins which are:

If a User Defined Title Block is used:

```
left_margin mm
right_margin mm
top_margin mm
bottom_margin mm
```

If the default 12d title block is used, then the size of the bottom of title block depends on the text size. The following parameters are used in the default title block case and the bottom_border_gap is added to the calculated height of the bottom of the title block.

```
left_border_gap mm
right_border_gap mm
top_border_gap mm
bottom_border_gap mm
```

Because the user can easily select from the plotting panel whether a User Defined Title Block or the default 12d title block is used, both sets of margins and gap parameters can exist in the one plot parameter file.
The long plot itself consists of the three regions - boxes, datum and graph areas.

The **boxes area** is where the titles and the chainage values and the heights/depths for the strings drawn on the long plot are labelled.

The **datum area** is the region between the boxes area and the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

Apart from information labelled in the boxes area, the long section plot can label other information such as:

(a) horizontal geometry
(b) vertical geometry
(c) chainage, heights at special points
(d) symbols at special points
(e) bubbles at special chainages
(f) cuts the design string makes through strings
(g) cut and fill areas
The size of the graph area can also be extended to allow for plot symbols by the parameters:

- `extra_space_units`: 0 // extra space values are world units - default
- `extra_space_left`: units // " " are millimetres on plot page
- `extra_space_right`: units // subtract from left of plot area, def 0
- `extra_space_top`: units // add to right of plot area, default 0
- `extra_space_bottom`: units // add to top of plot area, default 0
- `extra_space_top`: units // subtract from bottom of plot area, // default 0

Please continue to the next section 44.3.4 Boxes Area.
44.3.4 Boxes Area

Each string in the long section plot can be labelled with one or two lines of title, and the chainages/heights/depths at the user specified chainages for the strings.

The title for the strings, is drawn in the title area of the boxes area. The chainages/heights/depths are drawn in the heights area of the boxes area. Consequently the boxes area is made up of rows of text consisting of:

- string/tin titles followed by the chainage/height/depth values along the string.

Each row is surrounded by lines to form a box.

The default order of the boxes from the bottom up is:

- (a) optional super-elevation diagram
- (b) chainage values
- (c) can be primary string heights - user choice
- (d) tin heights and depths
- (e) offset heights and depths
- (f) optional volumes or earth works
- (g) can be primary string heights - user choice
- (h) zero or more blank boxes

The blank boxes are used to place other information in (such as horizontal or vertical geometry) or for other user supplied information.

Placing the primary string label before the bank boxes or just after the chainage box in controlled by the parameter primary_label_mode.

number_of_blank_boxes integer // integer > 0
primary_label_mode 0 //put primary string labels in last box
// before blank boxes
1 // or first box above the chainages

Although the order of the boxes may appear to be fixed, in practice they can be in any order. This is possible because for each box, there is a parameter to set the height in millimetres from the bottom of all the boxes that the text in the box is drawn at (the _y_pos parameters).

The title area starts at the co-ordinate (left_margin,bottom_margin). The size of the title text is given by the title_box_text_size parameter.
The width of the title area is either given by the space_for_titles parameter, or if omitted, the required width is automatically calculated.

- title_box_text_size \text{mm}  // size of the title text for boxes
- space_for_titles \text{mm}  // calculated if omitted

There can be two lines of title text and the title text, textstyle and colour can be set independently for each box.

The x position of the title text is the same for all the lines of title text and can be set to be a fixed distance from the left hand side of the boxes.

- box_titles_x \text{mm}  // distance to move the title text from the left hand side of the boxes

The y position of the title text can be set separately for each type of title. The parameters are given later under each of the title types (e.g. chainages, primary string, tins, depths etc.).

After the title area there can be a user defined gap, followed by the heights area

- box_gap \text{mm}  // blank area between the title area and the heights area default 0

The heights area starts at the end of the title area.

The height text is written at right angles to the bottom of the boxes. It can be either top or bottom justified with respect to the box (box_text_justification).

The number of decimal places (number_of_decimals), and the size of the heights text (box_text_size) can be specified globally but there is a parameter for each box which overrides these defaults for each box of heights.

- box_text_justification 0  // bottom of individual boxes
- box_text_justification 1  // top of individual boxes
- number_of_decimals integer  // number of decimal places in the height boxes. If <0, the absolute value is taken as the number of decimal places i.e. no trailing zeros are removed for the values in the heights area.
- box_text_size \text{mm}  // size of the height text values

A global height for the individual boxes is either given by the horizontal_line_spacing parameter, or if omitted, a height to fit the largest height or depth value is calculated and used as the default box height.

- horizontal_line_spacing \text{mm}  // calculated if omitted

However, the height of each box can be individually set by parameters box_size_n where the boxing numbering, n. starts from the bottom box. The value of horizontal_line_spacing is used for any of the box_size_n parameters not specified.

- box_size_n \text{mm}  // height of the nth box, numbered from bottom up.

The total height of the boxes area is simply given by the sum of the heights of each box.
The width of the heights area is determined by the number of chainages to be labelled and whether the values are staggered to prevent overwriting.

Hence the total width of the boxes area is the width of the title area plus box_gap, plus the width of the heights area.

Many distance definitions in the plot parameter file are given in terms of distance above the top of the boxes area so that the distances are independent of the number of boxes and box sizes.

The drawing of the box line work, the box colour, the position of the primary string labels and the number of blank boxes are all set by parameters.

First, all the line work for the box itself is user defined. This has been extended from V3.1 although draw_box_mode has been left in for upward compatibility.

\[
\begin{align*}
\text{draw_box_mode} & \quad 0 & \text{// don't draw box lines} \\
& \quad 1 & \text{// draw box lines around heights area} \\
& \quad 2 & \text{// draw box lines around title and heights areas} \\
& \quad 3 & \text{// use draw_box_side_n, box_line_draw_mode and box_line_mode_n}
\end{align*}
\]

\[
\text{box_colour} \quad \text{colour} \quad \text{// colour of the boxes}
\]

For V3.2, the line work for the outside of the title and heights boxes is controlled by the parameters draw_box_side_n and box_side_colour_n, and the separation lines inside the boxes are controlled by the parameters box_line_draw_mode and box_line_mode_n where the box numbering, n, starts from the bottom box.

Note: The following parameters are only used if draw_box_mode is set to 3.

\[
\begin{align*}
\text{draw_box_side_1} & \quad 1 & \text{// draw the left side of the title area (def)} \\
& \quad 0 & \text{// don't draw the left side} \\
\text{box_side_colour_1} & \quad \text{colour} & \text{// colour to draw left side of title area} \\
& \quad \text{default box_colour}
\end{align*}
\]

\[
\begin{align*}
\text{draw_box_side_2} & \quad 1 & \text{// draw top of the title area (default)} \\
& \quad 0 & \text{// don’t draw the top} \\
\text{box_side_colour_2} & \quad \text{colour} & \text{// colour to draw top of title area} \\
& \quad \text{default box_colour}
\end{align*}
\]

\[
\begin{align*}
\text{draw_box_side_3} & \quad 1 & \text{// draw right side of the title area}
\end{align*}
\]
The lines at the top of the individual boxes inside the title area and heights area (separation lines) are controlled by the parameters `box_line_draw_mode` and `box_line_mode_n`.

The separation lines can be drawn in just the title area, just the heights area or in both areas.

The parameter `box_line_draw_mode` can be set to control all the separation lines but there are additional parameters, `box_line_mode_n`, which override `box_line_draw_mode` for each of the individual boxes where n = 1, ... number of boxes -1.

The top of the top box is not controlled by `box_line_mode_n` but is controlled by the parameters `draw_box_side_2` and `draw_box_side_6`.

```plaintext
// (default if box_gap is non-zero)
0 // don’t draw the right side
// (default if box_gap is zero)

box_side_colour_3 colour // colour to draw right side of title area
// default box_colour
draw_box_side_4 1 // draw bottom of the title area (default)
0 // don’t draw the bottom
box_side_colour_4 colour // colour to draw bottom of title area
// default box_colour
draw_box_side_5 1 // draw left side of the heights area (def)
0 // don’t draw the left side
box_side_colour_5 colour // colour to draw left side of heights area
// default box_colour
draw_box_side_6 1 // draw top of the heights area (default)
0 // don’t draw the top
box_side_colour_6 colour // colour to draw top of heights area
// default box_colour
draw_box_side_7 1 // draw right side of the heights area def
0 // don’t draw the right side
box_side_colour_7 colour // colour for right side of heights area
// default box_colour
draw_box_side_8 1 // draw bottom of the heights area (def)
0 // don’t draw the bottom
box_side_colour_8 colour // colour for bottom of heights area
// default box_colour
```

The lines to draw for `draw_box_side_1` to `draw_box_side_8` are controlled by the parameter `box_line_draw_mode` and `box_line_mode_n`.

The separation lines can be drawn in just the title area, just the heights area or in both areas.

The parameter `box_line_draw_mode` can be set to control all the separation lines but there are additional parameters, `box_line_mode_n`, which override `box_line_draw_mode` for each of the individual boxes where n = 1, ... number of boxes -1.

The top of the top box is not controlled by `box_line_mode_n` but is controlled by the parameters `draw_box_side_2` and `draw_box_side_6`.
### Chainage Titles and Values

The chainages are always labelled

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chainage_title</td>
<td>First line of chainage title</td>
</tr>
<tr>
<td>chainage_title_2</td>
<td>Second line of chainage title</td>
</tr>
<tr>
<td>chainage_title_textstyle</td>
<td>Text style of the chainage title</td>
</tr>
<tr>
<td>chainage_title_colour</td>
<td>Default chainage title colour</td>
</tr>
<tr>
<td>chainage_title_size</td>
<td>Default chainage title size</td>
</tr>
<tr>
<td>chainage_title_y_pos</td>
<td>Height in mm above the bottom of all the boxes that the chainage title text is drawn.</td>
</tr>
<tr>
<td>chainage_decimals</td>
<td>Number of decimal places for chainages</td>
</tr>
<tr>
<td>chainage_textstyle</td>
<td>Text style of the chainage values</td>
</tr>
<tr>
<td>chainage_colour</td>

</tr>
<tr>
<td>chainage_size</td>
<td>Size of chainages, def is box_text_size</td>
</tr>
<tr>
<td>chainage_y_pos</td>
<td>Height in mm above the bottom of all the boxes that the chainage values text is drawn.</td>
</tr>
</tbody>
</table>

**Example of Chainage Titles**

- chainage_title: “DESIGN”
- chainage_title_2: “CHAINAGE”
chainage_title_colour          "yellow"
chainage_colour                   "grey" // colour of chainage text
chainage_decimals               -3 // 3 decimal places - leave trailing zeros
Primary String Title and Heights

Sometimes the primary string is only required to define chainages or the horizontal path for tin sections. In this case, the primary string would not be drawn on the long section plot.

If the primary string is drawn, it is automatically labelled.

Also the drawing of crosses at the vertical intersection points can be controlled from the ppf file.

```plaintext
primary_draw_vips 1 // draw crosses at VIPS (default)
0 // don’t draw VIP crosses

The position of the primary string label box can be either straight after the chainage box, or after the tin and offset boxes but before the blank boxes.

```plaintext
primary_string yes // draw and label the primary string
no // don’t draw or label the primary string
primary_label_mode 0 // last box before blank boxes
1 // first box above the chainages

primary_title text // first line of string title
primary_title_2 text // second line of string title, default is the primary string name.
primary_title_textstyle textstyle // textstyle of the primary string titles
primary_title_colour colour // colour of the string titles
primary_title_size mm // default primary title size
primary_title_y_pos mm // if set, the height in mm above the bottom of all the boxes that the primary string title text is drawn.
// If not set, then the text is placed at a height that puts it inside the default box for the primary string.

primary_decimals integer // number of decimal places
primary_textstyle textstyle // textstyle of the primary string heights
primary_colour colour // colour of the heights
primary_size mm // if set, the height in mm above the bottom of all the boxes that the primary string height text is drawn.
// If not set, then the text is placed at a height that puts it inside the default box for the primary string.
primary_y_pos mm // if set, the height in mm above the bottom of all the boxes that the primary_string_height text is drawn.

primary_ch_tolerance mm // for a given chainage, if no z value exists,
// this distance is added to/subtracted from the chainage to search for a valid z value.
```

Example of Primary String Titles

```plaintext
primary_title "DESIGN"
primary_title_2 "CENTRELINE"
primary_title_colour "yellow"
primary_colour "grey" // colour of height text
primary_decimals -2 // 2 decimal places - leave trailing zeros
```
Tin Titles and Heights

A section along the primary string through each tin on the section view can be automatically drawn on the long plot, and the user can specify whether the tin heights and depths are labelled or not in the boxes area.

Hence although there may be a number of tins drawn on the section plot, not all of them need to be labelled or have their depths labelled.

The default order for labelling the tins and depths is the order that the tins were added to the view however it is possible to specify which tin is used for labelling each row of tin heights and depths by giving the tin name rather than just using the tin order on the section view.

In fact, it is possible to use any tin in the project to label a row, not just those drawn on the section view.

The parameter to define the nth tin by name is \( \text{tin}_n\text{\_name} \):

\[
\text{tin}_n\text{\_name} \quad \text{text} \\
// n=1, \ldots \text{no of tins on the section view.} \\
// \text{use the tin named text to label the nth row of tin heights and depths.}
\]

If a tin of the name \( \text{tin}_n\text{\_name} \) does not exist, then the plot is not produced and an error message is given.

For the following parameters, \( n \) takes the value 1 to 100 and specifies that the parameter set applies to the nth tin on the section view, or if \( \text{tin}_n\text{\_name} \) is set, for the tin specified by \( \text{tin}_n\text{\_name} \).

\[
\begin{align*}
\text{tin}_n\text{\_draw\_mode} & \quad 1 \quad // \text{draw the nth tin (default)} \\
& \quad 0 \quad // \text{don't draw the nth tin} \\
\text{tin}_n\text{\_draw\_colour} & \quad \text{colour} \quad // \text{colour to draw the nth tin.} \\
& \quad // \text{If omitted, then use the tin colour} \\
\text{tin}_n\text{\_label} & \quad 1 \quad // \text{label the tin's heights (default)} \\
& \quad 0 \quad // \text{don't label the tin's heights} \\
\text{tin}_n\text{\_title} & \quad \text{text} \quad // \text{first line of tin title} \\
\text{tin}_n\text{\_title\_2} & \quad \text{text} \quad // \text{second line of tin title} \\
\text{tin}_n\text{\_textstyle} & \quad \text{textstyle} \quad // \text{textstyle of the tin titles} \\
\text{tin}_n\text{\_colour} & \quad \text{colour} \quad // \text{colour for titles of heights} \\
\text{tin}_n\text{\_size} & \quad \text{mm} \quad // \text{default nth tin's title size} \\
\text{tin}_n\text{\_y\_pos} & \quad \text{mm} \quad // \text{if set, the height in mm above the bottom of all the boxes that the tin title text is drawn.} \\
& \quad // \text{If not set, then the text is placed at a height that puts it inside the default box for the tin heights.} \\
\text{tin}_n\text{\_decimals} & \quad \text{integer} \quad // \text{number of dec places in tin height} \\
\text{tin}_n\text{\_textstyle} & \quad \text{textstyle} \quad // \text{textstyle of the tin heights} \\
\text{tin}_n\text{\_colour} & \quad \text{colour} \quad // \text{colour for heights and depths} \\
\text{tin}_n\text{\_size} & \quad \text{mm} \quad // \text{default nth tin's title size} \\
\text{tin}_n\text{\_y\_pos} & \quad \text{mm} \quad // \text{if set, the height in mm above the bottom of all the boxes that the tin height text is drawn.} \\
& \quad // \text{If not set, then the text is placed at a height that puts it inside the default box for the tin heights.} \\
\text{tin}_n\text{\_depth\_label} & \quad 1/0 \quad // 1 to label, 0 don't label depths \\
\text{tin}_n\text{\_depth\_title} & \quad \text{text} \quad // \text{first line of tin depth title} \\
\text{tin}_n\text{\_depth\_title\_2} & \quad \text{text} \quad // \text{second line of tin depth title} \\
\text{tin}_n\text{\_depth\_textstyle} & \quad \text{textstyle} \quad // \text{textstyle of the tin depth titles} \\
\text{tin}_n\text{\_depth\_colour} & \quad \text{colour} \quad // \text{colour for titles of depths}
\end{align*}
\]
### Offset Model Titles and Heights

For **12d Model V3.2**, each string in the offset model given in the *section long plot* panel can be automatically projected onto the primary string and drawn on the long section plot.

For **12d Model V4.0**, the idea of an offset model has been modified to allow strings to be projected onto the primary string to be specified by model and name, rather than just projecting all the strings in a given model. The string can also be labelled with either the string name, its model name or both.

The string is specified by

```plaintext
offset_n_mask "model_name->string_name"
```

For each n, a set of plot parameters determine if the string’s heights and/or depths from the primary string are labelled in the boxes area.

If only the `string_name` is given, then the model given in the Offset model field of the Section Long Plot panel.

If there is **more than one string** with the given model and name, then it will be considered to be one string and at any primary string chainage, the closest of the strings will be the part used for projecting. For example, strings of the same name on either side of a road intersection will be considered to be the one string for projecting.

If any `offset_n_mask` is used, then the Offset option expects all the strings to be specified by an `offset_n_mask`. Then if no mask exists for any value of n, then that parameter set is ignored and no string projected.

If no offset masks are used (that is, no `offset_n_mask`’s are used), then the Offset option works as it did in **12d Model V3.0**. That is, plot parameters determine whether each string in the offset model is drawn, and if the string’s heights and depths from the primary string are labelled in the boxes area. The order that the strings are then plotted and labelled is the same as the order of the strings in the Offset model.

For the following sets of parameters, n takes the value 1 to 100 and specifies that the parameter set applies to the nth string given by `offset_n_mask` or, if no offset masks are given, the nth string in the Offset model.

```plaintext
offset_n_mask "model_name->string_name"
offset_n_draw_mode 1 // draw the nth offset string (default)
```

</tbody>
</table>
Chapter 44 Text Plot Parameters

The default title for each set each parameter set, is the string name but this can be changed to just the model name or the model and string name:

offset_title_mode  
0 // label with string name (default)  
1 // label with model name  
2 // label with model->string as name

or, for any set, the offset_title_mode can be replaced by two lines of user defined title:

offset_n_title text // first line of title  
offset_n_title_2 text // second line of title  
offset_n_title_textstyle textstyle // textstyle of the offset titles

The rest of the parameters for the set are:

offset_n_title_colour colour // colour for titles of heights  
offset_n_title_size size // size for heights  
offset_n_title_y_pos mm // height in mm above the
offset n_decimals integer // number of dec places in offset height  
offset_n_textstyle textstyle // textstyle of the offset heights  
offset_n_colour colour // colour for heights  
offset_n_size size // size for heights  
offset_n_y_pos mm // height in mm above the
offset_n_depth_label 1/0 // 1 to label, 0 don't label depths  
offset_n_depth_title text // first line of offset depth title  
offset_n_depth_title_2 text // second line of offset depth title  
offset_n_depth_title_textstyle textstyle // textstyle of the offset depth titles  
offset_n_depth_title_colour colour // colour for titles of depths  
offset_n_depth_title_size mm // size for titles of depths  
offset_n_depth_title_y_pos mm // height in mm above the

Chainages of Offset Strings - Offset Chainages

For a string other than the primary string, it is possible to label the chainages that are obtained from the other string by going out perpendicular to the primary string at a chainage, cutting the other string and then calculating the chainage from the other string at the cut point.

The other string is known as an offset string and the chainage from the offset string corresponding to a primary chainage is called the offset chainage.

Up to twenty sets of offset chainages can be labelled - each is defined by its own set of parameters:

**Note** no box is automatically created for the offset chainages. An empty box must be defined and the appropriate values set for `chainage_n_title_y_pos` and `chainage_n_y_pos`.

</tbody>
</table>

**Example of Offset Chainage and Titles**

- `chainage_1_offset_string` = “Design->RKERB"
- `chainage_1_title` = “RIGHT KERB”
- `chainage_1_title_2` = “CHAINAGE”
- `chainage_1_title_colour` = “yellow”
- `chainage_1_colour` = “grey” // colour of offset chainage text
- `chainage_1_decimals` = -3 // 3 decimal places - leave trailing zeros
Definition of Depth to a Tin or to Offset Strings

The depth from the primary string to a tin or to a string from the offset model, at a particular chainage is defined as

\[ \text{depth} = \text{tin height value} - \text{height of the primary string} \]

or

\[ \text{depth} = \text{offset string height value} - \text{height of the primary string} \]

That is, the depth that the primary string is below the tin or a string from the offset model.

Before plotting, the value of depth is multiplied by either the `depth_positive_factor` or `depth_negative_factor`.

If \( \text{depth} \geq 0 \)
\[ \text{plotted_depth_value} = \text{depth} \times \text{depth_positive_factor} \]

If \( \text{depth} < 0 \)
\[ \text{plotted_depth_value} = \text{depth} \times \text{depth_negative_factor} \]

Hence the definition of depth can be modified by the parameters:

- `depth_positive_factor` value // multiplier for positive depths
- `depth_negative_factor` value // multiplier for negative depths

For example, if the opposite sign is required for depth, that is,

\[ \text{depth} = \text{height of the primary string} - \text{tin/offset string height value} \]

simply set

`depth_positive_factor` -1
`depth_negative_factor` -1
Super-Elevation Diagram

The optional super-elevation diagram draws the values of the cross-fall (x-fall) between two strings using the primary string as the reference string. The cross-fall at a given chainage on the primary string is calculated by sectioning perpendicular to the reference string at that chainage and cutting the two strings. The cross-fall is defined as the cross-fall between the two cuts points on the strings.

The diagram has levels for the cross fall for a pair of strings on the left of the primary string, and a pair of strings on the right of the primary string. The diagram also has uprights in the super-elevation box with chainage values at the change of super values.

For the left hand side, the cross-fall is calculated at right angles to the primary string between the user given left hinge string and the left edge string.

There are plot parameters to control all aspects of the super diagram.

- `super_draw_mode`: 0 // default, don’t draw a super diagram  
  1 // draw super using `super_sample_interval`  
  2 // sample super using chainages of x-sections  
  3 // sample super using chainages from a string

- `super_sample_interval`: value // if `super_draw_mode = 1`, default 20 // chainage distance to sample x-fall

- `super_sample_name`: model_name // if `super_draw_mode = 2` model_name->string_name // if `super_draw_mode = 3`

- `super_tolerance`: value // If `super_draw_mode` is 1, the change of super is greater than `super_tolerance`, // draw uprights

- `super_title`: text // first line of super title // def Super elevation

- `super_title_textstyle`: textstyle // textstyle of the super titles

- `super_title_colour`: colour // super title colour, def `box_colour`

- `super_title_size`: mm // super title size, def `label_text_size`

- `super_title_y_pos`: mm // if set, the height in mm above the // bottom of all the boxes that the // super title text is drawn. // If not set, then the text is placed at a // height that puts it inside the default // box for the super.

- `super_xfall_textstyle`: textstyle // textstyle of the super x-fall labels

- `super_xfall_colour`: colour // super x-fall colour, def `box_colour`

- `super_xfall_size`: mm // super x-fall size, def `label_text_size`

- `super_xfall_x`: mm // def 0

- `super_xfall_y`: mm // def 0.5

- `super_ch_textstyle`: textstyle // textstyle of the super chainages

- `super_ch_colour`: colour // super chainage colour, def `box_colour`

- `super_ch_size`: mm // super chainage size, def `label_text_size`

- `super_ch_x`: mm // def 0

- `super_ch_y`: mm // def -1

- `super_ch_decimals`: integer // number decimal places in chainage // def `number_of_decimals`

- `super_hinge_name_left`: model_name->string_name // left hinge string

- `super_edge_name_left`: model_name->string_name // left edge string

- `super_left_linestyle`: linestyle // default DASHED

- `super_left_line_colour`: colour // default `box_colour`

- `super_left_decimals`: integer // number decimal places in left x-fall // def 0

- `super_left_pre`: text // text before left x-fall value

- `super_left_post`: text // text after left x-fall value

- `super_hinge_name_right`: model_name->string_name // right hinge string

Volume Cut and Fill Values

The values of calculated cut and fill volumes (cut and fill earth works) can be read from a file and then interpolated to produce cut and fill volumes for a given interval along the primary string.

There are plot parameters to control all aspects of the volume diagram.

- **volume_draw_mode**: 0 // default, don’t draw a volume diagram
  1 // draw a volume diagram

- **volume_text_centre_mode**: 0 // default, the text of cut and fill are labelled along the uprights
  1 // the text are centred in between the uprights

- **volume_sample_interval**: value // interval to display volumes, default 20

- **volume_file_name**: file_name // the volumes report file

- **volume_y_pos**: mm // if set, the volume box is positioned at this height from the bottom of the first box

- **volume_box_size**: mm // if set, the uprights and volume and titles are plotted in accordance with this heights

- **volume_title**: text // first line of volume title
  // default Earthworks

- **volume_title_textstyle**: textstyle // textstyle of the volume titles

- **volume_title_colour**: colour // volume title colour, def box_colour

- **volume_title_size**: mm // volume title size, def label_text_size

- **volume_title_y_pos**: mm // if set, the height in mm above the bottom of all the boxes that the volume title text is drawn.
  // If not set, then the text is placed at a height that puts it inside the default box for the volumes.

- **volume_cut_title**: text // first line of volume sub title
  // default cut

- **volume_cut_title_textstyle**: textstyle // textstyle of the cut volume titles

- **volume_cut_title_colour**: colour // cut volume title colour, def box_colour

- **volume_cut_title_size**: mm // cut volume title size, def label_text_size

- **volume_cut_title_y**: mm // if set, the height in mm above the default position.
  // If not set, then the text is placed at a height that puts it inside the default box for the cut volumes.

- **volume_fill_title**: text // first line of volume sub title
  // default fill

- **volume_fill_title_textstyle**: textstyle // textstyle of the fill volume titles

- **volume_fill_title_colour**: colour // fill volume title colour, def box_colour

- **volume_fill_title_size**: mm // fill volume title size, def label_text_size

- **volume_fill_title_y**: mm // if set, the height in mm above the default position.
  // If not set, then the text is placed at a height that puts it inside the default box for the fill volumes.

- **volume_cut_textstyle**: textstyle // textstyle of the cut values

- **volume_cut_text_colour**: colour // cut value colour, def box_colour

- **volume_cut_text_size**: mm // cut value size, def label_text_size

- **volume_cut_text_x**: mm // the x distance to move the cut text from the default cut text position, def 0, it is not used if volume_text_centre_mode=1

- **volume_cut_text_y**: mm // the y distance to move the cut text from the default cut text position, def 0

- **volume_cut_decimals**: integer // number decimal places in cut values
  // def number_of_decimals
volume_fill_textstyle    textstyle       // textstyle of the fill values
volume_fill_text_colour  colour        // fill value colour, def box_colour
volume_fill_text_size    mm           // fill value size, def label_text_size
volume_fill_text_x       mm           // the x distance to move the fill text from the
                                   // default fill text position, def 0, it is not used
                                   // if volume_text_centre_mode=1
volume_fill_text_y       mm           // the y distance to move the fill text from the
                                   // default fill text position, def 0
volume_fill_decimals     integer      // number decimal places in fill values
                                   // def number_of_decimals
volume_cl_linestyle      linestyle     // linestyle of horizontal cut/fill dividing line
volume_cl_line_colour    colour       // colour of horizontal cut/fill dividing line
volume_uprights_draw_mode 0            // default, don’t draw cut/fill uprights
                                   // draw cut/fill uprights
volume_uprights_line_colour 1            // colour of uprights
volume_sub_upright_colour    colour     // colour of sub uprights line
volume_sub_uprights_x     mm           // the distance to move from the default
                                   // sub uprights position, def 0
volume_sub_title_x        mm           // the distance to move the sub title text
                                   // from the volume sub uprights

X,Y Values

The values of the X and Y coordinate for selected chainages can be labelled as separate boxes. The chainages specified are limited to the base set of chainages already defined in the chainage selection and staggering section, i.e. an upright must exist for the X and Y value to be labelled. Not all of the uprights have to be labelled, just those specified in this section.

There are plot parameters to control all aspects of the X and Y labelling.

Chainages are used for positioning X and Y labels.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

```
xy_order 0 // 0 = X on bottom, Y on top
1 // 1 = Y on bottom, X on top
xy_chord_arc 0 // don't use chord/arc chainages
1 // include chainages for chord/arc
xy_start_chainage value // start chainage of labelling range
xy_end_chainage value // end chainage of labelling range
xy_interval value // regular interval (0 = no regulars)
xy_label_hcp 0/1 // 1 = include tangents, spirals
xy_label_hip 0/1 // 1 = include hip points
xy_label_vip 0/1 // 1 = include vip points
xy_label_vtp 0/1 // 1 = include tangent points
xy_label_crest 0/1 // 1 = include crest points
xy_label_sag 0/1 // 1 = include sag points
xy_label_grade_change 0/1 // 1 = include change of vertical grade
xy_special_n_file filename // n = 1 to 20 - include chainages from the file (one chainage per line)
xy_label_tolerance value // > 0 use as weeding tolerance
// <= 0, don't weed
```

For X parameters:

```
x_label 0/1 // 0 = Don’t label X values/titles
1 // 1 = Label X values/titles
x_title text // first line of X title
// (default "Easting")
x_title_2 text // second line of X title
x_title_textstyle textstyle // textstyle of the X titles
x_title_colour colour // default X title colour
x_title_size mm // default X title size
x_title_y_pos mm // if set, the height in mm above the bottom of all the boxes that the X title text is drawn.
// If not set, then the text is placed at a height that puts it inside the default box for the X.

x_label_decimals integer // number of decim places for X values
x_label_textstyle textstyle // textstyle of the X values
x_label_colour colour // colour of X values, def is box_colour
x_label_size mm // size of X values, def is box_text_size
x_label_y_pos mm // if set, the height in mm above the bottom of all the boxes that the X value text is drawn.
// If not set, then the text is placed at a height that puts it inside the default box for the X value.
```
For Y parameters:

- **y_label**: 0/1
  - 0 = Don’t label Y values/titles
  - 1 = Label Y values/titles

- **y_title**: text
  - first line of Y title
  - (default “Eastings”)

- **y_title_2**: text
  - second line of Y title

- **y_title_textstyle**: textstyle
  - textstyle of the Y titles

- **y_title_colour**: colour
  - default Y title colour

- **y_title_size**: mm
  - default Y title size

- **y_title_y_pos**: mm
  - if set, the height in mm above the bottom of all the boxes that the Y title text is drawn.
  - If not set, then the text is placed at a height that puts it inside the default box for the Y.

- **y_label_decimals**: integer
  - number of decim places for Y values

- **y_label_textstyle**: textstyle
  - textstyle of the Y values

- **y_label_colour**: colour
  - colour of Y values, def is box_colour

- **y_label_size**: mm
  - size of Y values, def is box_text_size

- **y_label_y_pos**: mm
  - if set, the height in mm above the bottom of all the boxes that the Y value text is drawn.
  - If not set, then the text is placed at a height that puts it inside the default box for the Y value.

Please continue to the next section **44.3.5 Chainage Selection and Staggering**.
44.3.5 Chainage Selection and Staggering

Chainages are used for positioning height labels, uprights (leader lines) and bubbles.

The chainages for the long section plot relate to the primary string and are controlled by a set of parameters.

- **chord_arc**
  - Value: 0 // don't use chord/arc chainages
  - Value: 1 // include chainages for chord/arc

- **chainage_interval**
  - Value: // regular interval (0 = no regulars)

- **chainage_label_ends**
  - Value: 0/1 // 1 = include start and end chainages

- **chainage_label_hip**
  - Value: 0/1 // 1 = include hip points

- **chainage_label_vip**
  - Value: 0/1 // 1 = include vip points

- **chainage_label_vtp**
  - Value: 0/1 // 1 = include tangent points

- **chainage_label_crest**
  - Value: 0/1 // 1 = include crest points

- **chainage_label_sag**
  - Value: 0/1 // 1 = include sag points

- **chainage_label_grade_change**
  - Value: 0/1 // 1 = include change of vertical grade

- **chainage_special_n_file**
  - Value: filename // n = 1 to 20 - include chainages from the file (one chainage per line)

- **chainage_label_tolerance**
  - Value: // > 0 use as weeding tolerance
  - Value: <= 0, don't weed

- **chainage_merge_bubbles**
  - Value: 0/1 // 1 = merge in the bubble chainages

- **chainage_merge_tolerance**
  - Value: // > 0, weeding tol after bubble merge
  - Value: <= 0, don't weed after merge

Default values

- **chainage_label_tolerance** = 1.0 exp -4 (world units)
- **chainage_merge_tolerance** = 1.0 exp -8 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a chainage special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

If the real chainage position is used for the horizontal position of the chainage/height/depth text, text over writing can easily occur.

To prevent over writing, the text can be **staggered**.

If the **stagger_mode** parameter is set to 1, the text position is adjusted so that the text does not over write.

The real chainage position is then indicated by the chainage markers which are drawn at the top of the text boxes from the staggered text position back to the actual chainage position of the text.

- **stagger_mode**
  - Value: 0 // no staggering, allow over writing
  - Value: 1 // stagger text to prevent over writing

- **stagger_gap_top**
  - Value: mm // distance from boxes to top of stagger

- **stagger_gap_bottom**
  - Value: mm // distance from boxes to bottom of stagger

- **stagger_gap_factor**
  - Value: // distance between staggers is
  - Value: box_text_size * stagger_gap_factor

When staggering occurs, it is possible for the heights area to be longer than the graph area.
Please continue to the next section 44.3.6 Uprights.
### 44.3.6 Uprights

Uprights, or leader lines, can be drawn from the top of the staggers to the strings drawn on the plot.

The height of the uprights is given by the `uprights_draw_mode`:

<table>
<thead>
<tr>
<th><code>uprights_draw_mode</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>none</td>
</tr>
<tr>
<td>1</td>
<td>to maximum string height at that chainage</td>
</tr>
<tr>
<td>2</td>
<td>ticks, to stagger height</td>
</tr>
<tr>
<td>3</td>
<td>to <code>uprights_y</code> above the boxes</td>
</tr>
<tr>
<td>100</td>
<td>to the primary string</td>
</tr>
<tr>
<td>101-500</td>
<td>to <code>tin1</code> or <code>tin2</code> etc.</td>
</tr>
<tr>
<td>501-900</td>
<td>to <code>offset1</code> or <code>offset2</code> etc.</td>
</tr>
</tbody>
</table>

- `uprights_y mm`: distance to draw the uprights for mode 3
- `uprights_colour colour`: uprights colour (default `boxes_colour`

The uprights can go below the top of the boxes.

<table>
<thead>
<tr>
<th><code>uprights_bottom_mode</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>stop at top of boxes (default)</td>
</tr>
<tr>
<td>1</td>
<td>draw to bottom of boxes</td>
</tr>
<tr>
<td>2</td>
<td>draw to <code>uprights_bottom_y</code> below the top of the boxes</td>
</tr>
<tr>
<td>3</td>
<td>draw to <code>uprights_bottom_y</code> above the bottom of the boxes</td>
</tr>
<tr>
<td>4</td>
<td>ticks at chainage</td>
</tr>
</tbody>
</table>

- `uprights_bottom_y mm`: distance
- `uprights_text_offset_factor value`: move the text by this factor\*size

When uprights go below the top of the boxes, the height and offset text is moved to the left so that the upright does not go through the text. The left hand side of the heights boxes also moves to the left to leave room for the height text.
Please continue to the next section 44.3.7 Datum Area.
44.3.7 Datum Area

The **datum area** is the region between the boxes area and the graph area. The **datum line** is positioned the distance `datum_below_gap` above the top of the boxes area and the graph area is positioned the distance `datum_above_gap` above the datum line. Hence the graph area is distance `(datum_below_gap + datum_above_gap)` above the top of the boxes area.

- `datum_above_gap` \(\text{mm}\) // distance from datum line to the bottom of the graph area
- `datum_below_gap` \(\text{mm}\) // distance from datum line to the top of the boxes
- `datum_linestyle` \(\text{linestyle}\) // linestyle for datum line (default solid)

The `datum_below_gap` and `datum_above_gap` can be zero or positive. A value for the datum can be specified by the parameter `datum_value` or if the `datum_value` is not set, a datum value is automatically calculated for the long section using a roundoff specified by the user (default 1.0).

- `datum_value` \(\text{value}\) // if set, the value to use for datum. // If not set, the datum is automatically calculated (using `datum_roundoff`)
- `datum_roundoff` \(1.0\) // value to roundoff the datum value to // e.g. 0.5, 0.2, 1.0 (default 1.0)
- `datum_decimals` \(\text{integer}\) // number of decimal places to display // the datum value (default 1). // If > 0, trailing zeros are removed after // the decimal point. // If <0, the absolute value is taken as the // number of decimal places to report // i.e. no trailing zeros are removed

- `datum_name` \(\text{text}\) // text to write before the datum value
- `datum_textstyle` \(\text{textstyle}\) // textstyle for the datum text
- `datum_text_size` \(\text{mm}\) // size of datum text and value
- `datum_colour` \(\text{colour}\) // colour of the datum text and line
- `datum_x` \(\text{mm}\) // distance to move the datum text // along the datum line
- `datum_y` \(\text{mm}\) // distance to raise the datum text // above the datum line (used to be // called `datum_offset`)

Please continue to the next section 44.3.8 Graph Area.
44.3.8 Graph Area

The graph area is the area where the actual plots of the strings are drawn.

The string used to define the horizontal position and chainage of the plot is called the primary string and is either

(a) the string being profiled on the given section view
or
(b) the string given by the parameter

```
string_to_plot "model->string_name" // name of string to profile
```

When the primary string is being written out to a plot parameter file by 12d Model, a string_to_plot parameter and special parameters recording the internal id’s for the string and it’s model are all written out.

```
primary_model_id integer // internal 12d Model parameter
primary_string_id integer // internal 12d Model parameter
```

The length of the graph area is determined by the length of the primary string being plotted (restricted to the specified start and end chainages) and the horizontal scale (scale) given by parameters or in the section long plot panel, and the vertical exaggeration given by the section view or a parameter.

```
view_name text // default is section view in panel.
vertical_exaggeration value // default is vertical exag for the view
scale value // 1:value - horizontal scale, default is // scale 1: in panel
start_chainage value // ““ means use start of primary string
end_chainage value // ““ means use end of primary string
```

The vertical scale is determined by the horizontal scale and the vertical exaggeration.

The height of the graph area is determined by the vertical scale (given by the horizontal scale and the vertical exaggeration) and the minimum and maximum values of the data being plotted. Hence the graph height is a calculated rather than a given value.

The types of strings that can be drawn in the graph area of a long section plot are:

(a) primary string the string being profiled (usually the design string).
(b) tins sections of the primary string through any tins either in models on the section view or in corridor models.
(c) offset strings strings in the offset model that are projected back onto the primary string
(d) services parts of strings (from either models on the section view or in corridor models) that cut the defined corridor.

The colour of the strings in the plot is the actual string colour for cases (a), (c) and (d), and the colour of the tin used for the section in case (b).

Although all the strings are plotted, the plot parameter file can be used to select which ones are labelled with heights and/or depths.

Primary String (Design String)

The primary string (the design string) is used to define

(a) the design long section
(b) the chainage positions for labelling heights and drawing uprights
(c) the section line used for sectioning through tins
(d) the section line for defining the corridor for services

Although the primary string is used to set up most of the information for the long section plot, it
doesn’t have to be drawn on the long section.

The drawing or not drawing of the primary string on each cross section plot is controlled by the parameter `primary_string` which was described earlier.

The colour of the primary string in the plot is the actual primary string colour.

**Tins**

A section along the primary string through each tin on the specified section view is automatically drawn on the cross section plot.

The colour and linestyle of the tin section in the plot is the actual tin colour and tin linestyle.

Whether the tin heights are labelled or not in the boxes area is controlled by parameters and has been described earlier

**Corridor and Services**

A corridor around the primary string is defined by giving a left and right corridor width.

Any string in a model added to the section view is checked to see if it appears in the corridor, and if it does, then it is drawn on the long section plot.

To be drawn, strings do not have to cross the primary string, but just be in the corridor.

```
strings (no diameter)

pipe string

primary string
(design long section)

plan view

corridor_width_left

corridor_width_right

corridor_overlap_left

corridor_overlap_right

corridor_chord_arc

/ world-units

// chord-arc tolerance used to approximate arcs in the corridor.
// default is the section view value

The corridor defining parameters are

corridor_width_left  world-units  // corridor left and right widths

corridor_width_right  world-units  // defaults are the section view values

corridor_overlap_left  world-units  // corridor left and right overlaps.

corridor_overlap_right  world-units  // defaults are the section view values

corridor_chord_arc  world-units  // chord-arc tolerance used to approximate arcs in the corridor.
// default is the section view value

The models containing tins for sectioning and strings for services are taken from the section view or given by the parameters

corridor_model_n  model  // n = 1, 2 ... 100
// models containing tins and service
// strings to be drawn on the view.

If any `corridor_model_n` parameters are defined, then only the models given by the parameters
are used. If no corridor_model_n parameters are set, then the models added to the given section view are used.

That is, either the corridor_model_n parameters are used or if none exist, then the models added to the section view are used for tins and service strings.

The colour and diameter of the service strings drawn in the plot are the actual strings colour and diameter.

The graph area sits on top of the boxes and datum areas, so there may not be enough room left on the sheet for the full plot height. In this case, the plot will be truncated at the top of the allowed graph area.

Please continue to the next section 44.3.9 Bubbles Definitions.
44.3.9 Bubbles Definitions

Circles with the string name and a unique number (bubbles) can be drawn on the long section plot. Bubbles are normally used for lip profiles.

The chainages used for the bubbles are given by a set of parameters similar to the chainage parameters. The resulting set of bubbles are sequentially numbered (starting with one) in chainage order.

Although many bubbles can be defined by the bubble parameters, a bubble is only drawn on the plot if there is a labelled chainage to draw it above.

Hence not all bubbles given by the bubble chainage parameters are drawn but for the ones that are drawn, the bubble number is taken from the full bubble set.

chainage_bubbles 0 // don't drawn bubbles
1 // draw bubbles

bubble_radius mm // radius of the bubbles
bubble_colour // colour for the bubbles

bubble_text_string_name_mode 0 // do not label with string name
1 // label string name
2 // label with model->string name

bubble_pre_text text
bubble_post_text text
bubble_textstyle textstyle
bubble_text_size mm
bubble_text_offset mm

bubble_upright_distance mm // distance bubbles are above boxes/uprights
bubble_mode 0 // bubble_upright_distance is above boxes
1 // bubble_upright_distance is above uprights

bubble_draw_upright 0/1 // 1 = draw extra upright if bubble_mode = 1

bubble_start_chainage value // start chainage for bubbles
bubble_end_chainage value // end chainage for bubbles
bubble_chord_arc 0/1 // 1 = use chord-arc chainages
bubble_interval value // include regular interval
// (0 = no regulars)

bubble_label_ends 0/1 // 1 = include start and end chainages
bubble_label_hcp 0/1 // 1 = include tangents, spirals
bubble_label_hip 0/1 // 1 = include hip points
bubble_label_vip 0/1 // 1 = include hip points
bubble_label_vtp 0/1 // 1 = include tangent points
bubble_label_crest 0/1 // 1 = include crests
bubble_label_sag 0/1 // 1 = include sags
bubble_label_grade_change 0/1 // 1 = include change of grade
bubble_special_n_file filename // n = 1 to 20 include chainages from the file

bubble_label_tolerance value // > 0 use as weeding tolerance
// <= 0, don't weed

Defaults

bubble_label_tolerance = 1.0 exp -4 (world units)

If a tolerance is zero or negative, no weeding is performed.

The format of a bubble special file is simply a list of chainage values, one value per lines. Blank lines in the file are ignored and anything on a line after a // is a comment.

Please continue to the next section 44.3.11 Extensive Horizontal Geometry Labelling.
44.3.11 Extensive Horizontal Geometry Labelling

For complicated horizontal geometry labelling, there are sets of horizontal geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the horizontal geometry of alignment strings other than the primary string. To plot such a string on the same plot, the chainage position of the horizontal geometry for the non-primary alignment strings is projected onto the primary string to give a primary string chainage for plotting. The values of the horizontal geometry (such as radius and spiral length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting horizontal geometry, the user can give up to twenty sets of these labels and they can be used to label spirals, curves and tangent information for the primary string and/or additional alignment strings.

Each label set consists of three parts:
(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

For the following parameters, n takes the value 1 to 20 and specifies the nth parameter set.

\[
\begin{align*}
\text{h}_g_n\_type & \quad 0 \quad \text{// label spirals} \\
& \quad 1 \quad \text{// label horizontal curves} \\
& \quad 2 \quad \text{// label horizontal tangents} \\
\text{h}_g_n\_value\_mode & \quad \text{for spiral labelling} \quad 0 \quad \text{// nothing} \\
& \quad 1 \quad \text{// length} \\
& \quad \text{for curve labelling} \quad 0 \quad \text{// nothing} \\
& \quad 1 \quad \text{// length} \\
& \quad 2 \quad \text{// radius} \\
& \quad \text{for tangent labelling} \quad 0 \quad \text{// nothing} \\
& \quad 1 \quad \text{// length} \\
& \quad \text{for spiral labelling} \quad 0 \quad \text{// nothing} \\
& \quad 1 \quad \text{// length} \\
& \quad 2 \quad \text{// radius*length} \\
\text{h}_g_n\_label\_y & \quad \text{mm} \quad \text{// distance of arrow line above the top of} \\
& \quad \text{// the boxes} \\
\text{h}_g_n\_label\_x & \quad \text{mm} \quad \text{// distance from the left hand side of the} \\
& \quad \text{// labels area} \\
\text{h}_g_n\_label\_offset & \quad \text{mm} \quad \text{// distance to raise the label\_text above} \\
& \quad \text{// arrow line} \\
\text{h}_g_n\_label\_text\_size & \quad \text{mm} \\
\text{h}_g_n\_label\_text\_colour & \quad \text{colour} \\
\text{h}_g_n\_label\_text & \quad \text{text} \\
\text{h}_g_n\_label\_text\_style & \quad \text{textstyle} \quad \text{// textstyle used} \\
\text{h}_g_n\_draw\_mode & \quad 0 \quad \text{// no arrow} \\
& \quad 1 \quad \text{// arrow} \\
& \quad 2 \quad \text{// line} \\
& \quad 3 \quad \text{// line with uprights at ends} \\
& \quad 4 \quad \text{// uprights, no line}
\end{align*}
\]
5  // line with downrights
6  // downrights, no line
7  // line with up and downrights at ends
8  // up and downrights, no line
9  // draw curve
11 // radius*length curve

\begin{tabular}{|c|c|c|}
\hline
0 & 4 & 8 \\
\hline
1 & 5 & 9 \\
\hline
2 & 6 & \\
\hline
3 & 7 & 11 \\
\hline
\end{tabular}

- \texttt{h\_g\_n\_left\_gap} \hspace{2mm} \texttt{mm} // size of gap for left side of arrow
- \texttt{h\_g\_n\_right\_gap} \hspace{2mm} \texttt{mm} // size of gap for right side of arrow
- \texttt{h\_g\_n\_colour} \hspace{2mm} \texttt{colour} // colour of the arrow
- \texttt{h\_g\_n\_height} \hspace{2mm} \texttt{mm} // height of the arrow
- \texttt{h\_g\_n\_gap} \hspace{2mm} 0 // no gap
  \hspace{2mm} 1 // leave gap in arrow for text

Parameters for text on the arrows:

- \texttt{h\_g\_n\_text\_colour} \hspace{2mm} \texttt{colour} // colour of the text
- \texttt{h\_g\_n\_text\_size} \hspace{2mm} \texttt{mm} // size of the text
- \texttt{h\_g\_n\_text\_offset} \hspace{2mm} \texttt{mm} // distance to raise the text above the arrow line
- \texttt{h\_g\_n\_pre\_text} \hspace{2mm} \texttt{text} // text before the arrow text
- \texttt{h\_g\_n\_post\_text} \hspace{2mm} \texttt{text} // text after the arrow text
- \texttt{h\_g\_n\_textstyle} \hspace{2mm} \texttt{textstyle} // textstyle used
- \texttt{h\_g\_n\_no\_decimals} \hspace{2mm} \texttt{integer} // number of decimal places in arrow text.
  // If > 0, all trailing zeros after the decimal place are removed.
  // If < 0, the absolute value is taken as the number of decimal places and no trailing zeros are removed after the decimal point.
- \texttt{h\_g\_n\_rotate} \hspace{2mm} \texttt{mm} // if ticked, the text on the arrows will be rotated to fit.

If the set of parameters is to apply to the horizontal geometry of an alignment string other than the primary string, then simply add the following parameter to define the other alignment string:

\texttt{h\_g\_n\_offset\_string} \hspace{2mm} "model->string\_name"

or

\texttt{h\_g\_n\_offset\_string} \hspace{2mm} "string\_name"

and the model is the Offsets model from the \texttt{Section Long Plot} panel.

If the \texttt{h\_g\_n\_offset\_string} parameter does not exist, then the set of horizontal geometry
parameters is applied to the primary string.

Example of Extensive Horizontal Geometry

// Parameter to stop the drawing of the quick horizontal geometry
horizontal_geometry_y 0

// Set 1 - Extensive Horizontal Geometry Labelling - label the horizontal curve radius
h_g_1_type 1 // label horizontal curve
h_g_1_value_mode 2 // if this param is missing then set is ignored
h_g_1_label_y 45
h_g_1_label_x 0
h_g_1_label_offset 2
h_g_1_label_text_size 4
h_g_1_label_textcolour YELLOW
h_g_1_label_text "Horiz Curve Data"

// Parameters for arrow type
h_g_1_draw_mode 1
h_g_1_colour "white"
h_g_1_height 1.5
h_g_1_gap 0

// Parameters for text on the arrows
h_g_1_text_colour GREEN
h_g_1_text_size 3.5
h_g_1_text_offset 2.5
h_g_1_pre_text "R"
h_g_1_post_text "m"
h_g_1_no_decimals 2

Example of Extensive Horizontal Geometry for use with a Non-primary Alignment String

// Set 2 labels the horizontal curves radii of the kerb string projected onto primary string
h_g_2_offset_string "left offsets->kerb" // non-primary string to do VG of

h_g_2_type 1 // label horizontal curve
h_g_2_value_mode 2 // if this param is missing then set is ignored
h_g_2_label_y 55
h_g_2_label_x 0
h_g_2_label_offset 2
h_g_2_label_text_size 4
h_g_2_label_textcolour GREEN
h_g_2_label_text "Left Kerb - Horiz Curve Data"

// Parameters for arrow type
h_g_2_draw_mode 1
h_g_2_colour "white"
h_g_2_height 1.5
h_g_2_gap 0

// Parameters for text on the arrows
h_g_2_text_colour GREEN
h_g_2_text_size 3.5
h_g_2_text_offset 2.5
h_g_2_pre_text                        "R"

h_g_2_post_text                      "m"

h_g_2_no_decimals                2

Please continue to the next section 44.3.13 Extensive Vertical Geometry Labelling.
44.3.13 Extensive Vertical Geometry Labelling

For complicated vertical geometry labelling of the primary alignment string, there are sets of vertical geometry labelling parameters which give tight control over the position and types of labels.

It is also possible to label the vertical geometry of alignment strings other than the primary string. To plot such a string on the same plot, the chainage position of the vertical geometry for the non-primary alignment strings is projected onto the primary string to give a primary string chainage for plotting. The values of the vertical geometry (such as grade and curve length) that are plotted are taken from the other string. Independently graded offset strings (such as a left and right kerbs) are the type of additional alignment strings that may need to be plotted on the same long section plot as the reference string (primary string).

For plotting vertical geometry, the user can give up to twenty sets of these labels and they can be used to label grades or vertical curve information for the primary string and/or additional alignment strings.

Each label set consists of three parts:
(a) a text label on the left hand side of the plot
(b) an arrow
(c) text on the arrows.

For the following parameters, n takes the value 1 to 20 and specifies the nth parameter set.

v.g.n_type
0  // labelling grades
1  // labelling vg curve information

If v.g.n_type is missing, then the entire nth set is ignored.

The interpretation of the value of the parameter v.g.n_value_mode depends on whether the set is being used for grade labelling or curve labelling:

v.g.n_value_mode
for grade labelling
0  // nothing
1  // % grade
2  // 1 in grade
3  // m/m grade
4  // chainage length between vertical
// curve points
5  // per chord - Queensland Rail

for curve labelling
0  // nothing
1  // length - chainage for parabolic vc's
// arc length for circular vc's
2  // radius
3  // K value
5  // curve constant - Queensland Rail

Vertical curve points to draw the arrows between (for grade labelling only)
v.g.n_between_mode
0  // between chainages at the vip's
1  // between chainages at the vtp's

Position of the Arrow Line
v.g.n_label.y  mm
// distance of arrow line above the top of
// the boxes this can be negative
Parameters for the left hand label of the whole line of the vg arrows:

- `v_g_n_label_x mm` // distance from the left hand side of the labels area
- `v_g_n_label_offset mm` // distance to raise the label_text above arrow line
- `v_g_n_label_text text`
- `v_g_n_label_textstyle textstyle`
- `v_g_n_label_text_size mm`
- `v_g_n_label_text_colour colour`

Parameters for arrow type

- `v_g_n_draw_mode` 0 // no arrow
- `v_g_n_draw_mode` 1// arrow
- `v_g_n_draw_mode` 2 // line
- `v_g_n_draw_mode` 3 // line with uprights at ends
- `v_g_n_draw_mode` 4 // uprights, no line
- `v_g_n_draw_mode` 5 // line with downrights
- `v_g_n_draw_mode` 6 // downrights, no line
- `v_g_n_draw_mode` 7 // line with up and downrights at ends
- `v_g_n_draw_mode` 8 // up and down rights, no line
- `v_g_n_draw_mode` 9 // draw curve
- `v_g_n_draw_mode` 10 // draw grade

Parameters for text on the arrows

- `v_g_n_text_colour colour` // colour of the text
- `v_g_n_text_size mm` // size of the text
- `v_g_n_text_offset mm` // distance to raise the text above the arrow line
- `v_g_n_pre_text text` // text before the arrow text
- `v_g_n_post_text text` // text after the arrow text
- `v_g_n_textstyle textstyle` // textstyle used
- `v_g_n_no_decimals integer` // number of decimal places in arrow text.
- `v_g_n_no_decimals integer` // If > 0, all trailing zeros after the decimal place are removed.
- `v_g_n_no_decimals integer` // If < 0, the absolute value is taken as the number of decimal places and no
If the set of parameters is to apply to the vertical geometry of an alignment string other than the primary string, then simply add the following parameter to define the other alignment string

```plaintext
v_g_n_offset_string "model->string_name"
or
v_g_n_offset_string "string_name"
```

and the model is the Offsets model from the Section Long Plot panel.

If the `v_g_n_offset_string` parameter does not exist, then the set of vertical geometry parameters is applied to the primary string.

**Example of Extensive Vertical Geometry**

// Parameter to not to draw the quick vertical geometry
vertical_geometry_grade_y 0

// Set 1 labels the vertical curves with length
v_g_1_type 1 // curve
v_g_1_value_mode 1 // chainage length
v_g_1_label_y 45
v_g_1_height 4
v_g_1_label_offset -2
v_g_1_label_text "VG Curves"
v_g_1_text_offset 2
v_g_1_label_text_size 6
v_g_1_pre_text ""
v_g_1_post_text " L"
v_g_1_gap 0
v_g_1_draw_mode 8
v_g_1_text_size 4

// Set 2 labels the vertical curves with K value
v_g_2_type 1 // curve
v_g_2_value_mode 3 // K value
v_g_2_label_y 45
v_g_2_height 1.5
v_g_2_label_text ""
v_g_2_text_offset -5
v_g_2_pre_text ""
v_g_2_post_text " K"
v_g_2_gap 0
v_g_2_draw_mode 1
v_g_2_text_size 4

**Example of Extensive Vertical Geometry for use with a Non-primary Alignment String**
// Set 3 labels the vertical curves with length with the kerb string projected onto primary stings

v_g_3_offset_string               "left offsets->kerb"                 // non-primary string to do VG of
v_g_3_type                    1    // curve
v_g_3_value_mode        1    // chainage length
v_g_3_label_y                  55
v_g_3_height                      4
v_g_3_label_offset            -2
v_g_3_label_text              "Left kerb - VG Curves"
v_g_3_text_offset               2
v_g_3_label_text_size         6
v_g_3_pre_text                 "".v_g_3_post_text            " L"
v_g_3_gap                         0
v_g_3_draw_mode             8
v_g_3_text_size                  4

Please continue to the next section 44.3.14 Labelling Chainages and Heights in the Graph Area.
44.3.14 Labelling Chainages and Heights in the Graph Area

The chainage and/or height values for certain points (given by label_n_type) can be labelled. Up to twenty sets of chainage/height labels can be done.

- label_n_type: 0 // chainage of vip, height of vip
- 1 // chainage of vip, height of primary
- 2 // crest
- 3 // sag
- 4 // vtp
- 5 // hcp
- 6 // change of grade
- 7 // mid-ordinate of the vertical curve

If label_n_type is missing, then the set is ignored.

- label_n_y_mode: 0 // height in mm above boxes
- 1 // above height value (default)
- 2 // above primary height
- label_n_y: mm // distance above point
- label_n_angle: degrees // rotation about point
- label_n_x: mm // distance along from point
- label_n_offset: mm // text raise height
- label_n_justification: 0 // left end
- 1 // middle
- 2 // end
- label_n_size: mm
- label_n_colour: size
- label_n_textstyle: textstyle
- label_n_value_mode: 0 // no values labelled
- 1 // val 1 = chainage
- 2 // val 1 = height
- 3 // val 1 = chainage, val 2 = height
- 4 // val 1 = height, val 2 = chainage
- label_n_pre_text: text
- label_n_mid_text: text
- label_n_post_text: text
- label_n_textstyle: textstyle // textstyle to use
- label_n_no_decimals_1: integer // number of decimal places in val 1
- label_n_no_decimals_2: integer // number of decimal places in val 2

If the number of decimal places is greater than zero (> 0), then any trailing zeros after the decimal point are removed.

If the number of decimal places is less than zero (< 0), the absolute value is taken as the number of decimal places and no trailing zeros after the decimal point are removed.

Example of Labelling Chainage and Heights

// label the crests with chainage on one line
// and height (elevation) on the next
label_1_type: 2 // crest
label_1_y_mode: 2 // above string
label_1_y: 10
label_1_angle: 0
label_1_justification: 1 // centre
label_1_size: 4
label_1_colour: red
label_1_value_mode: 1 // chainage
label_1_pre_text               “CH “
label_1_no_decimals_1          1

label_2_type                   2    // crest
label_2_y_mode                 2    // above string
label_2_y                      2
label_2_angle                  0
label_2_justification          1    // centre
label_2_size                   4
label_2_colour                 red
label_2_value_mode             2    // height
label_2_pre_text               “EL “
label_2_no_decimals_1          1

Please continue to the next section 44.3.15 Labelling With Symbols.
44.3.15 Labelling With Symbols

Symbols can be placed at certain points given by symbol_n_type.

The symbol is drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

Up to twenty sets of symbol labelling can be done.

```
symbol_n_type  0 // chainage of vip, height of vip
               1 // chainage of vip, height of primary
               2 // crest
               3 // sag
               4 // vtp
               5 // hcp
               6 // change of grade
```

If symbol_n_type is missing, then the set is ignored.

```
symbol_n_y_mode  0 // height in mm above boxes
                  1 // above height value (default)
                  2 // above primary height

symbol_n_y  mm // distance above point given by mode
symbol_n_angle  degrees // rotation about point
symbol_n_x  mm // distance along from point
symbol_n_size  mm //
symbol_n_colour  colour // colour of symbol
symbol_n_draw_mode  0 // cross
                      1 // upright from centre of box
                      2 // up and downright from centre of box
                      3 // square
                      4 // triangle, base at bottom
                      5 // circle
```

Example of Labelling with Symbols

```
// draw a triangle symbol at the crest
symbol_1_type  2 // crest
symbol_1_y_mode  2 // above string
symbol_1_y  0
symbol_1_angle  0
symbol_1_size  2
symbol_1_colour  red
symbol_1_draw_mode  4 // triangle
```

Please continue to the next section 44.3.16 Hatching Cut and Fill Areas.
44.3.16 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

- `hatch_original_tin_n` // tin_name for original surface
- `hatch_new_tin_n` // tin_name for final surface
- `hatch_cut_separation_n` // distance between cut hatch lines
- `hatch_cut_angle_n` // angle in degrees of cut hatching
- `hatch_cut_colour_n` // colour of the cut hatching
- `hatch_cut_linestyle_n` // linestyle for cut hatching
- `hatch_cut_draw_sides_n` // 1 = draw sides of cut regions
- `hatch_cut_draw_original_n` // 1 = draw original tin in cut regions
- `hatch_cut_draw_new_n` // 1 = draw new tin in cut regions
- `hatch_fill_separation_n` // distance between fill hatch line
- `hatch_fill_angle_n` // angle in degrees of fill hatching
- `hatch_fill_colour_n` // colour of the fill hatching
- `hatch_fill_linestyle_n` // linestyle for fill hatching
- `hatch_fill_draw_sides_n` // 1 = draw sides of fill regions
- `hatch_fill_draw_original_n` // 1 = draw original tin in fill regions
- `hatch_fill_draw_new_n` // 1 = draw new tin in fill regions

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.

Please continue to the next section 44.3.17 Labelling Cuts of Design Through Strings in a Model.
44.3.17 Labelling Cuts of Design Through Strings in a Model

The cuts that the primary string (design line) makes though any strings in user given models can be automatically labelled on the long section plots.

The height, chainage and name of the cut string can be labelled as well as a symbol. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the

(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

Text justification refers to the actual position and is given by

“top-left” “top-centre” “top-right”
“middle-left” “middle-centre” “middle-right”
“bottom-left” “bottom-centre” “bottom-right”

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.
Parameters for Labelling Where the Design Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the *model* which contains the strings, and then a *name mask* which is used to restrict the strings in the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets can be labelled in different ways.

The parameters for selecting and labelling the nth set (where n can be from 1 to 25) of cuts of the design string with the strings in the model are given by:

```
cuts_n_model  model_name  // model of strings to be cut
```

The selection of the strings from the model *model_name* whose cut points are to be labelled is all the strings whose name satisfies the name mask *cuts_n_mask*:

```
cuts_n_mask  name_mask  // strings to check for cuts
```

where *name_mask* is a text string containing the name masks, each separated by one or more spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example

```
cuts_1_mask  "ke*"
```

or

```
cuts_1_mask  "?bank*"
```

or, if both masks are required,

```
cuts_1_mask  "ke* ?bank*"
```

If *cuts_n_mask* is missing, then all strings in the model are used. This is equivalent to *name_mask* being "***".

All strings in the model *cuts_n_model* whose name satisfy the name mask *cuts_n_mask* are then checked for cuts with the design string, and if a cut occurs, the cut point will be labelled according to the rest of the parameters in the nth set.

The parameters for drawing a *symbol* at the cut points are

```
cuts_symbol_n_mode  0  // cross
1  // up from centre of box
2  // up and down from centre of box
3  // square
4  // triangle, base at bottom
5  // circle
6  // use a 12d symbol
```

![Predefined Symbols](image.png)

If *cuts_symbol_n_mode* is 6, then the 12d symbol is given by

```
cuts_symbol_n_style  plotsymbol  // plot symbol to draw at cut
```

**Important Note**

The plot symbol of name *plotsymbol* is defined in the file given by:

(a) the parameter *plot_symbols* in the ppf file
plot_symbols filename

or if plot_symbols is not defined, then
(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D
PLOT_SYMBOLS_4D filename // default plotsym.4d

or if PLOT_SYMBOLS_4D is not defined, then
(c) in the file plotsym.4d

which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:
(d) either pointed to by the environment variable SYMBOLS_4D
SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, symbols.4d

The position of the symbol is given by:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cuts_symbol_n_position</td>
<td>1</td>
<td>// above point height value</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>// above top of boxes</td>
</tr>
<tr>
<td></td>
<td>100</td>
<td>// to primary string</td>
</tr>
<tr>
<td></td>
<td>101-500</td>
<td>// to tin1 or tin2 etc.</td>
</tr>
</tbody>
</table>

The symbol can be adjusted by the parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cuts_symbol_n_x</td>
<td>mm</td>
<td>// offset adjustment to position</td>
</tr>
<tr>
<td>cuts_symbol_n_y</td>
<td>mm</td>
<td>// height adjustment to position</td>
</tr>
<tr>
<td>cuts_symbol_n_angle</td>
<td>degrees</td>
<td>// rotation about point</td>
</tr>
<tr>
<td>cuts_symbol_n_colour</td>
<td>colour</td>
<td>// colour of symbol</td>
</tr>
</tbody>
</table>

and for all values of cuts_symbol_n_mode other than 6:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cuts_symbol_n_size</td>
<td>mm</td>
<td>// size of symbol, 0 don't draw</td>
</tr>
</tbody>
</table>

The value of the chainage of the cut string can be labelled using the parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cuts_chainage_n_position</td>
<td>1</td>
<td>// above cut strings height value</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>// above top of boxes</td>
</tr>
<tr>
<td></td>
<td>100</td>
<td>// to primary string</td>
</tr>
<tr>
<td></td>
<td>101-500</td>
<td>// to tin1 or tin2 etc.</td>
</tr>
<tr>
<td>cuts_chainage_n_x</td>
<td>mm</td>
<td>// chainage adjustment to position</td>
</tr>
<tr>
<td>cuts_chainage_n_y</td>
<td>mm</td>
<td>// height adjustment to position</td>
</tr>
<tr>
<td>cuts_chainage_n_angle</td>
<td>degrees</td>
<td>// rotation about point</td>
</tr>
<tr>
<td>cuts_chainage_n_size</td>
<td>mm</td>
<td>// size of text, 0 don't label</td>
</tr>
<tr>
<td>cuts_chainage_n_colour</td>
<td>colour</td>
<td>// colour of text</td>
</tr>
<tr>
<td>cuts_chainage_n_textstyle</td>
<td>text</td>
<td>// textstyle of textchainage</td>
</tr>
<tr>
<td>cuts_chainage_n_pre_text</td>
<td>text</td>
<td>// text before the chainage value</td>
</tr>
<tr>
<td>cuts_chainage_n_post_text</td>
<td>text</td>
<td>// text after the chainage value</td>
</tr>
<tr>
<td>cuts_chainage_n_justification</td>
<td>justification</td>
<td>// justification of the text</td>
</tr>
<tr>
<td>cuts_chainage_n_no_decimals</td>
<td>integer</td>
<td>// number of decimals in chainage</td>
</tr>
</tbody>
</table>
The value of a **height** at the chainage of the point can be calculated and labelled using the parameters:

- `cuts_height_n_mode`
  - 1: use height of cut point itself
  - 3: use real world height of the position of the label above the boxes
  - 100: height of primary string
  - 101-500: use height of to tin1 or tin2 etc.

- `cuts_height_n_position`
  - 1: at points position
  - 3: above top of boxes
  - 100: to primary string
  - 101-500: to tin1 or tin2 etc.

- `cuts_height_n_x`: mm
  - Chainage adjustment to position
- `cuts_height_n_y`: mm
  - Height adjustment to position
- `cuts_height_n_angle`: degrees
  - Rotation about point
- `cuts_height_n_size`: mm
  - Size of text, 0 don't label
- `cuts_height_n_colour`: colour
  - Colour of text
- `cuts_height_n_textstyle`: text
  - Textstyle of text height
- `cuts_height_n_pre_text`: text
  - Text before the height value
- `cuts_height_n_post_text`: text
  - Text after the height value
- `cuts_height_n_justification`: justification
  - Justification of the text
- `cuts_height_n_no_decimals`: integer
  - Number of decimals in height

A **label** which can include the **name** of the cut string is drawn by using the parameters:

- `cuts_label_n_position`
  - 1: above cut strings height value
  - 3: above top of boxes
  - 100: to primary string
  - 101-500: to tin1 or tin2 etc.

- `cuts_label_n_mode`
  - 0: don't include cut string name
  - 1: include cut string name in label

- `cuts_label_n_x`: mm
  - Chainage adjustment to position
- `cuts_label_n_y`: mm
  - Height adjustment to position
- `cuts_label_n_angle`: degrees
  - Rotation about point
- `cuts_label_n_size`: mm
  - Size of text, 0 don't label
- `cuts_label_n_colour`: colour
  - Colour of text
- `cuts_label_n_textstyle`: text
  - Textstyle of text label
- `cuts_label_n_pre_text`: text
  - Text before the string name
- `cuts_label_n_post_text`: text
  - Text after the string name
- `cuts_label_n_justification`: justification
  - Justification of the text
The cut point can be labelled with:

- **chainage** of the cut point
- **height** of the cut point
- **height** of the x-section or tins at this offset
- **name** of the string for the cut point

---

Please continue to the next section 44.3.18 Labelling the Primary String Name on the Plot.
44.3.18 Labelling the Primary String Name on the Plot

The plot can be labelled with a name under the boxes area. The name is made up of concatenation the text strings:

\[
\begin{array}{ccc}
\text{plot\_name\_pre\_text} & \text{primary-string-name} & \text{plot\_name\_post\_text} \\
\end{array}
\]

The plot name is positioned under the boxes.

\[
\begin{array}{c}
\text{plot\_name\_string\_name} \\
\text{plot\_name\_pre\_text} \\
\text{plot\_name\_post\_text} \\
\text{plot\_name\_textstyle} \\
\text{plot\_name\_size} \\
\text{plot\_name\_colour} \\
\text{plot\_name\_x\_offset} \\
\text{plot\_name\_y\_offset} \\
\end{array}
\]

The \text{plot\_name\_x\_offset} is measured from the beginning of the height boxes.

The default for \text{plot\_name\_x\_offset} is centred on heights area.

The \text{plot\_name\_y\_offset} is measured from the bottom of the box area with positive being \text{down}.

Example of Labelling Primary String Name

\[
\begin{array}{c}
\text{plot\_name\_pre\_text} \quad \text{“Long Section Plot for String”} \\
\text{plot\_name\_post\_text} \quad \text{“”} \\
\text{plot\_name\_size} \quad 15 \\
\text{plot\_name\_colour} \quad \text{red} \\
\text{plot\_name\_string\_name} \quad 1 \\
\text{plot\_name\_y\_offset} \quad 30 \\
\end{array}
\]

Please continue to the next section \text{44.3.19 Labelling the Scale on the Plot}. 
44.3.19 Labelling the Scale on the Plot

The plot can be labelled with the horizontal and vertical scale under the boxes area.

The scale label is made up of concatenation the text strings:

- `scale_horizontal_pre_text` followed by the horizontal scale value, then followed by `scale_horizontal_post_text`
- `scale_vertical_pre_text` followed by the vertical scale value, then followed by `scale_vertical_post_text`

The horizontal scale value is the value given by the scale parameter.

The vertical scale value is calculated from the horizontal scale and the vertical exaggeration for the section view.

The scales are positioned under the boxes.

- `scale_horizontal_pre_text`
- `scale_horizontal_post_text`
- `scale_horizontal_textstyle`
- `scale_horizontal_size` in mm
- `scale_horizontal_colour`
- `scale_horizontal_x_offset` in mm
- `scale_horizontal_y_offset` in mm
- `scale_horizontal_decimals`

- `scale_vertical_pre_text`
- `scale_vertical_post_text`
- `scale_vertical_textstyle`
- `scale_vertical_size` in mm
- `scale_vertical_colour`
- `scale_vertical_x_offset` in mm
- `scale_vertical_y_offset` in mm
- `scale_vertical_decimals`

The `scale_vertical_x_offset` and `scale_horizontal_x_offset` are measured from the beginning of the heights area.

The default for `scale_vertical_x_offset` and `scale_horizontal_x_offset` are centred on the heights area.

The `scale_vertical_y_offset` and `scale_horizontal_y_offset` are measured from the bottom of the box area with positive being down.

If the number of decimal places is greater than zero (> 0), then any trailing zeros after the decimal point are removed.

If the number of decimal places is less than zero (< 0), the absolute value is taken as the number of decimal places and no trailing zeros after the decimal point are removed.
Example of Labelling Horizontal and Vertical Scales

```
scale_horizontal_pre_text         "Horizontal Scale 1:"
scale_horizontal_post_text             ""
scale_horizontal_size                     15
scale_horizontal_colour             yellow
scale_horizontal_y_offset              60

scale_vertical_pre_text          "Vertical Scale 1:"
scale_vertical_post_text           ""
scale_vertical_size                        15
scale_vertical_colour                green
scale_vertical_y_offset                 90
```

Please continue to the next section 44.3.20 Title Block Information.
44.3.20 Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

**Standard Title Block**

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter `plot_border`.

```
plot_border  yes/no  // yes plots a standard title block
            // default yes

title_1     text

title_2     text

title_text_size value

title_colour  colour
```

**User Title Block**

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of this chapter.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The `plot_border` parameter should also be set to `no` so that the standard title block is not also drawn.

```
use_title_file yes/no  // yes draws the title block given in title_file
                 // default no

title_file     filename

plot_border    no  // turn off standard title block
```

Some special plot parameters are used to pass information down to variables in a user defined title block. For example, inside the title block file it is possible to have runtime user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters `user_text_n` (n = 1,2,... 1000)

```
user_text_n    text
```

The special plot parameters are:

```
time_format   text  // format for $time

user_text_n   text  // where n = 1,2,... 1000
               // passed down to $user_text_n

title_1       text  // passed down to $title_1

title_2       text  // passed down to $title_2

start_page_number integer  // used as the starting value for $page_number. If missing,
                           // $page_number starts at 1.

start_drawing_number integer  // added to $drawing_number in title block file. If missing,
                               // $drawing_number starts at 1.

drawing_number_prefix text  // passed down to $drawing_number_prefix

drawing_number_postfix text  // passed down to $drawing_number_postfix
```

Please continue to the next section 44.3.21 Parameters that Modify Fields In the Long Plot Panel.
44.3.21 Parameters that Modify Fields In the Long Plot Panel

A number of parameters match those in the section long plot panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for any plots.

The plot parameters that also occur in the section long plot panel are:

- `scale` value
- `start_chainage` value
- `end_chainage` value
- `chainage_interval` value
- `chord_arc` 0/1
- `plotter_type` text
- `plot_file` text
- `view_name` text
- `offset_model` text
- `plot_border` yes/no
- `label_depths` yes/no
- `primary_string` yes/no
- `datum_value` value
- `sheet_size` text or “width height”
- `box_text_size` mm
- `box_colour` colour
- `use_title_file` yes/no
- `title_file` filename
- `plot_border` yes/no
- `title_1` text
- `title_2` text
- `title_text_size` value
- `title_colour` colour
- `pagination` yes/no
- `pagination_length` value
- `pagination_overlap` value
- `global_textstyle` textstyle

Please continue to the next section 44.3.22 Generating Long Section Plots Without a View.
44.3.22 Generating Long Section Plots Without a View

The long section plot parameters are comprehensive enough that it is possible to completely generate a long section plot without referencing a section view, or even using the section long plot panel.

Such a ppf can be run using the plots=>plot a ppf option or from the 4D Solutions programming language, 4DML.

When a long section plot is being generated entirely from a file, an extra parameter is needed to specify whether the datum value is calculated or the datum_value parameter is used.

```
manual_datum 1 // use the datum_value parameter for the datum
              0 // ignore the datum_value and let 12d Model calculate the datum.
```

When generating a long section plot using the section long plot panel, a plot parameter file containing all the parameters needed to regenerate the plot using plots=>plot a ppf can be written out by simply giving a name for the ppf file in the plot parameters write field of the section long plot panel.

Notes
1. A warning is given if the keyword in a plot parameter file does not exist.
2. A warning is also given if the key word pair is defined more than once in a ppf.

Please continue to the next section 44.3.23 Example of a Long Section Plot Parameter File.

Please continue to the next section 44.5 #Include in Plot Parameter Files.
44.4 Pipeline Plot Parameter File

The pipeline plot option is used to make special long section plots for a network of pipeline strings.

Some of the look of the pipeline long section plot can be controlled from the plot pipeline network panel itself, however a wider selection of control parameters is available by using a pipeline long plot, plot parameter file.

The pipeline long section plot parameters are placed in a file with ending .ppf. Each parameter consists of a parameter name followed by one or more spaces and then the parameter value. There is only one parameter per line.

Anything on a line after a double forward slash // is considered to be a comment.

The set of all parameters for the pipeline long section plot is enclosed within a set of curly brackets {} with the header

```
pipeline_long_plot     "plot set name"
```

before the curly brackets.

That is,

```
pipeline_long_plot     "plot set name" {
    plot parameters
    one per line
}
```

If there is more than one pipeline_long_plot parameter set in the file, only the first set is used. There may also be parameter sets for other plot types such as section_x_plot in the same file. The other sets will be ignored when doing a pipeline long section plot.

44.4.0.1 Plot Sheet Layout

The plot sheet is considered to have only positive co-ordinates with the origin (0,0) in the left hand corner. The units for the plot are millimetres.

The overall size of the plot sheet is given by either a defined sheet size, or by the width and height of the plot given in millimetres and separated by one or more spaces.

```
sheet_size       text     // sheet name, or
        "mm     mm"     // sheet size: width     height
```

The sheet size name and width and heights can be specified by the user in a file named sheet_sizes_definitions which is in the normal set up areas, or is pointed to by the environment variable

```
SHEET_SIZES_4D       file     // file of plotter sheets sizes
```

The long plot is then positioned within the plot sheet by giving the margins

```
left_margin       mm
right_margin      mm
top_margin        mm
bottom_margin     mm
```

The (left_margin,bottom_margin) defines the left hand corner position of the long plot on the plot sheet.

The right_margin and top_margin need not be set and if missing, will be calculated from the other plot parameters defining the plot layout.

The pipeline long section plot will break an individual plot up if it doesn't fit across the sheet. There can be one or more rows of plot on the same sheet.
The top row is done first, followed by the second top row, then the third and so on until the bottom row. If there is only one row, it is considered to be the bottom row.

When a sheet is full, a follow on sheet is created.

As soon as one pipeline string is completed, the next pipeline string in the network model is plotted beginning on the same row as the previous pipeline string and with a horizontal gap of size \texttt{horizontal_plot_gap} between the plots. If there is not enough room on the row to start the next plot, it will begin on a new row.

The position of the left hand bottom corner of the first plot in the bottom row is given by the parameters, \texttt{left_margin} and \texttt{bottom_margin}.

If there are two or more rows of plots, the position of the first plot in each row is given by adding multiples of the \texttt{(plot_height+vertical_plot_gap)} to the \texttt{bottom_margin}.

\begin{verbatim}
    network_model text // model of pipeline strings
    left_margin mm // Position of the left hand bottom
    bottom_margin mm // corner of first plot in the bottom row.
    only_one_line 0 // more than one row on a sheet
    1 // only one row of plot on a sheet
    plot_height mm // total height of a plot row. It doesn't
    // includes the vertical_plot_gap.
    horizontal_plot_gap mm // gap between plots on same row
    vertical_plot_gap mm // gap between rows of plots
\end{verbatim}

The pipeline long plot itself consists of seven areas. From the bottom up, they are boxes, below datum, bottom stagger, graph, top stagger, arrow 4 area and top.

The boxes area is where the chainages and various values for the pipeline strings are labelled.

The below datum area is a region between the boxes area and the datum line.
The **bottom stagger area** is where the upright line staggers occur before going up from the boxes area to the graph area.

The **graph area** is the area where the actual plots of the strings are drawn.

The **top stagger area** is where the upright line staggers occur above the graph area.

The **arrow 4 area** is an extension of the uprights above the top stagger area to allow for the drawing of arrows where the arrows go between the staggered uprights above the graph area.

The **top area** is an annotation area above the arrow 4 area (the top of the plot) and is used for pegs and deflection angles.

Apart from information labelled in the boxes and top areas, the pipeline long section plot can place arrows between ips for other information such as

(a) pipe grade  
(b) vertical geometry  
(c) horizontal geometry

Also the chainages where services cross the pipeline line are automatically labelled.

### 44.4.0.2 Chainages, Staggering and Uprights

For the pipeline plot, the labelling of pipe invert levels, pipe invert, depth to invert, pipe grade and natural surface level are done at the chainages:

(a) pegs given by the peg_interval  
(b) horizontal and vertical deflection points  
(c) points in the specials model  
(d) crossing services

The points in the specials model are projected onto the pipeline string and the chainages used for labelling. If the point is a 4d string, then the text at the point is used as a text label at the top of the plot.
The peg interval and specials model are given by the parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>peg_interval</td>
<td>world-units // distance between pegs</td>
</tr>
<tr>
<td>specials_model</td>
<td>text // model name</td>
</tr>
</tbody>
</table>

Uprights, or leader lines, are drawn from the values at the bottom of the plot to the top of the plot for cases (a), (b) and (c), or to the crossing service in the graph area for case (d).

If the text values are placed at the real chainage positions at the bottom of the plot, text overwriting can easily occur if the chainages are very close together.

To prevent such overwriting, the text can be staggered.

That is, if the text is going to overwrite a previous text value, the next text value is actually moved along until there is no overwriting.

Since the text is no longer at the correct chainage position, the uprights to the pegs and services start at the text position and then bend back to the correct chainage position on the plot. The region where the bending occurs is called the stagger area.

For the pipeline plot, there is an area below the graph where the uprights bend backwards from the staggered text position to the real chainage position (bottom stagger area).

There is a second area above the graph where the uprights bend forwards from the real chainage position to the staggered text position (top stagger area).

Hence annotation above the top stagger area will line up with the staggered values below the bottom stagger area.

The stagger area below the graph area is defined by

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stagger_height_1</td>
<td>mm // distance from the top of datum to the</td>
</tr>
<tr>
<td></td>
<td>// start of the staggers</td>
</tr>
<tr>
<td>stagger_height_2</td>
<td>mm // distance over which stagger occurs</td>
</tr>
<tr>
<td>stagger_gap_bottom</td>
<td>mm // distance from end of staggers to the</td>
</tr>
<tr>
<td></td>
<td>// bottom of the graph area</td>
</tr>
</tbody>
</table>

The stagger area above the graph area is defined

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stagger_gap_top</td>
<td>mm // distance from top of the graph area to</td>
</tr>
<tr>
<td></td>
<td>// the start of the staggers</td>
</tr>
<tr>
<td>stagger_height_3</td>
<td>mm // distance over which stagger occurs</td>
</tr>
<tr>
<td>stagger_height_4</td>
<td>mm // distance from end of staggers to the</td>
</tr>
<tr>
<td></td>
<td>// bottom of above upper staggers area</td>
</tr>
</tbody>
</table>

The distance to be left for text to avoid overwriting is:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>horizontal_text_gap</td>
<td>mm // minimum distance to leave for text</td>
</tr>
<tr>
<td></td>
<td>// after peg values</td>
</tr>
<tr>
<td>services_text_gap</td>
<td>mm // minimum distance to leave for text</td>
</tr>
<tr>
<td></td>
<td>// after service values</td>
</tr>
</tbody>
</table>

When staggering occurs, it is possible for the values area to be longer than the graph area.

For the uprights that are drawn from the text to the pegs, specials and services:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>line_colour</td>
<td>colour // colour of uprights to the pegs and</td>
</tr>
<tr>
<td></td>
<td>// specials</td>
</tr>
<tr>
<td>service_line_colour</td>
<td>colour // colour of upright to the crossing</td>
</tr>
<tr>
<td></td>
<td>// services</td>
</tr>
<tr>
<td>service_text_colour</td>
<td>colour // colour of the name of the service.</td>
</tr>
<tr>
<td>service_text_size</td>
<td>mm // size of the service text.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_il_text_size</td>
<td>mm // size of the service invert level text.</td>
</tr>
</tbody>
</table>
service_il_textstyle text // textstyle of the service il text  
service_il_text_colour colour // colour of the service il text  

Label vertical geometry:  
v_g_text_size mm // size of the vertical geometry text  
v_g_textstyle text // text style of the vertical geometry text  
v_g_text_colour colour // colour of the vertical geometry text  

Label horizontal geometry:  
h_g_text_size mm // size of the horizontal geometry text  
h_g_textstyle text // textstyle of the horizontal geometry text  
h_g_text_colour colour // colour of the horizontal geometry text  

Label pegs:  
peg_text_size mm // size of the peg label  
peg_textstyle text // text style of the peg label  
peg_text_colour colour // colour of the peg label  

Label special chainage:  
chainage_special_text_size mm // size of the special chainage text  
chainage_special_textstyle text // textstyle of the special chainage text  
chainage_special_text_colour colour // colour of the special chainage text  

### 44.4.0.3 Boxes Area

The pipeline string values of chainage, invert level, depth to pipe invert or depth to top of pipe, grade and natural surface level can be labelled in the pipeline long section plot with one line of title, and the actual values given at the chainage of each peg in the pipeline string.

The **titles** for the string values, are drawn in the **titles area** of the **boxes area** and the values are drawn in the **values area** of the **boxes area**.

Consequently the boxes area is made up of rows of text consisting of:

- **title** followed by the **values** along the string.

Each row is surrounded by lines to form a box.

The **titles area** for the left plot in the bottom row starts at the co-ordinate (left_margin, bottom_margin) and each row is begun by adding the distance (plot_height + vertical_plot_gap) to the bottom_margin.

The width of the title box is given by the **plot_title_width** parameter and the height of each box is given by **plot_title_height**.

- **plot_title_width** mm // width of the label boxes.  
- **plot_title_height** mm // height of each box  
- **box_titles_x** mm // the distance between the left of the  
  // title box and the title

The **values area** starts at the end of the label area and the values text is written at right angles to the bottom of the boxes.
The colour of the box line work is given by:

`plot_title_line_colour` colour  // colour of the lines in the boxes

A default text size and colour can be specified for the title text, and the size and colour of the values. These can be overridden by parameters (given later in this section).

`plot_title_text_size` mm  // size of label text in boxes
`plot_title_text_colour` colour  // colour of label text in boxes
`text_size` mm  // size of value text
`text_colour` colour  // colour of values in boxes

The width of the **values** area is determined by the number of chainages to be labelled and whether the values are staggered to prevent over writing.

The total width of the boxes area is the width of the labels area plus the width of the values area which depends on the amount of staggering that occurs.

The order of drawing and labelling the boxes from the bottom up is

(a) chainage values
(b) natural surface heights
(c) pipe invert levels
(d) depth to invert or depth to top of pipe
(e) grade of pipeline
The text, size, textstyle and colour for the title text and values text for each box can be set by:

(a) pipeline string chainages

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
44.4.0.4 Below Datum Area

The **below datum area** is the region between the boxes area and the arrow_1 area. The datum line is drawn at the top of the below datum area.

The size of the below datum area is
**44.4.0.5 Graph Area**

The **graph area** is the area where the actual plots of the pipeline strings are drawn.

The length of the graph area is determined by the length of the pipelines string to be plotted (given by the start and end chainages) and the horizontal scale (given by scale) of the plot.

\[
\text{scale} \quad \text{value} \quad // \quad 1:\text{value} - \text{horizontal scale} \\
\text{start\_chainage} \quad \text{value} \quad // \quad \"*\" \text{means use start of pipeline strings} \\
\text{end\_chainage} \quad \text{value} \quad // \quad \"*\" \text{means use end of pipeline strings}
\]

The vertical exaggeration is taken from the section view specified for the plot by the parameter:

\[
\text{view\_name} \quad \text{text}
\]

The tins to be sectioned through by the pipeline strings and any service models and corridor settings for the graph area are also taken from the specified section view.

The height of the graph is calculated by subtracting the height of the first five areas (i.e. don't include the top area) from the plot height.

If the plot will not fit horizontally into a row on the sheet, then the plot will be broken at an appropriate peg and the plot continued on another row.

Datum breaks at pegs are used to try and fit the plot vertically into the graph area but if the plot still cannot fit, then it will be truncated at the bottom.

The types of strings that can be drawn in the graph area of the pipeline long section plot are:

(a) **pipeline string** the strings from the network model
(b) **tins** sections of the pipeline string through any tins on the section view.
(c) **services** parts of strings from any models on the section view that cut the corridor for the section view.

The **colour** of the strings in the plot is the actual string colour for cases (a) and (c), the colour of the tin used for the section in case (b).

**44.4.0.6 Arrow 4 Area**

This is just an extension of the stagger lines before the top of the plot. It leaves an area that can be used for extra annotation after the plot is produced.
The height of the area is

```
plot_title_top_height    mm    // height of the arrow 4 area
```

### 44.4.0.7 Top Area

The *top area* is an annotation area at the top of the plot (above the arrow 4d area). It can be used for peg names and horizontal and vertical deflection angles in the pipeline.

The height of the top area is given by

```
vertical_plot_gap    mm    // size of the top area. If it is not large enough, the text will overwrite the plot in the row above.
```

### 44.4.0.8 Change of Direction At Intersection Points

If there is a horizontal or vertical intersection point without a curve on it, the deflection angle at the intersection point is drawn in the top area.

The text is drawn at the distance *angled_text_offset* above the top of the plot and if there is more than one angle, they are spaced horizontally by the distance *angled_text_gap* to the right.

The size and colour of the deflections is given by *text_size* and *text_colour*.

```
angled_text_offset    mm    // distance of direction text above top of the plot
angled_text_gap       mm    // distance of direction text to the right of previous text.
angled_text_angle     value // angle of direction text
```
44.4.0.9 Hatching Cut and Fill Areas

This option is used to hatch cut and/or fill areas between sets of tins.

For each set, the name of the two tins, the hatch linestyle, colour and separation and whether cut and/or fill regions are required are all user definable.

Up to twenty (20) separate sets of tins be hatched.

The parameters for labelling cuts and/or fill regions between tins are given by:

- `hatch_original_tin_n` for the name of the original surface
- `hatch_new_tin_n` for the name of the final surface
- `hatch_cut_separation_n` for the separation between hatch lines (mm)
- `hatch_cut_angle_n` for the angle of cut hatching (degrees)
- `hatch_cut_colour_n` for the colour of cut hatching
- `hatch_cut_linestyle_n` for the linestyle of cut hatching
- `hatch_cut_draw_sides_n` for drawing sides of cut regions (1 = draw sides, 0 = don't draw)
- `hatch_cut_draw_original_n` for drawing the original tin in cut regions (1 = draw, 0 = don't draw)
- `hatch_cut_draw_new_n` for drawing the new tin in cut regions (1 = draw, 0 = don't draw)
- `hatch_fill_separation_n` for the separation between fill hatch lines (mm)
- `hatch_fill_angle_n` for the angle of fill hatching (degrees)
- `hatch_fill_colour_n` for the colour of fill hatching
- `hatch_fill_linestyle_n` for the linestyle of fill hatching
- `hatch_fill_draw_sides_n` for drawing sides of fill regions (1 = draw sides, 0 = don't draw)
- `hatch_fill_draw_original_n` for drawing the original tin in fill regions (1 = draw, 0 = don't draw)
- `hatch_fill_draw_new_n` for drawing the new tin in fill regions (1 = draw, 0 = don't draw)

Notes

(a) cut is when the new tin is below the original tin.
fill is when the new tin is above the original tin.

(b) cut hatching is turned off by setting `hatch_cut_separation_n` to 0.0.
fill hatching is turned off by setting `hatch_fill_separation_n` to 0.0.
44.4.0.10 Labelling Cuts of Pipeline Through Strings in a Model

The cuts that the pipeline string makes though any strings in user given models can be automatically labelled on the long section plots.

The height, chainage and name of the cut string can be labelled as well as a symbol drawn. The height of tins at the same offset value can also be labelled.

The chainage position for the labelling is the chainage of the cut string.

The height position for the labelling can be specified as the

(a) top of the boxes on the long section
(b) height value of the cut string
(c) height of the primary string
(d) height of a tin.

The actual position of the label is defined relative to the above point.

Note:

Only case (b) involves the actual height of the cut string. For all other cases, only the chainage of the cut string is used. Hence for all cases except (b), the string does need to have a sensible height to be used for cuts through strings.

For example, a boundary string may have null heights but only the chainage is required and the height of the tin at that chainage can be used as the height (case (d)).

Text justification refers to the actual position and is given by

“top-left” “top-centre” “top-right”
“middle-left” “middle-centre” “middle-right”
“bottom-left” “bottom-centre” “bottom-right”

A choice of six special symbols and/or any 12d symbols can be drawn at the cut point.

The special 12d Model symbols of size one millimetre are drawn in a square box centred on (0,0) with sides of length two millimetres. That is, the box co-ordinates are (-1,-1), (1,1), (1,-1), (-1,-1).

The six special shapes are

Up to twenty five (25) separate models of strings can be cut and labelled.
44.4.0.11 Parameters for Labelling Where the Pipeline Cuts Strings in a Model

The method for specifying which strings are to be checked for cuts is by first specifying the
model which contains the strings, and then a name mask which is used to restrict the strings in
the model to only those whose name matches the name mask.

Up to twenty five different sets of models and name masks can be used so that different cut sets
can be labelled in different ways.

The parameters for selecting and labelling the n'th set (where n can be from 1 to 25) of cuts of
the design string with the strings in the model are given by:

```
cuts_n_model  model_name  // model of strings to be cut
```

The selection of the strings from the model model_name whose cut points are to be labelled is all
the strings whose name satisfies the name mask cuts_n_mask:

```
cuts_n_mask  name_mask  // strings to check for cuts
```

where name_mask is a text string containing the name masks, each separated by one or more
spaces, to test the string name against. Each mask can include wild cards and wild characters.

For example
```
cuts_1_mask  "ke*"
```
or
```
cuts_1_mask  "?bank*"
```
or, if both masks are required,
```
cuts_1_mask  "ke*  ?bank*"
```

If cuts_n_mask is missing, then all strings in the model are used. This is equivalent to
name_mask being "**".

All strings in the model cuts_n_model whose name satisfy the name mask cuts_n_mask are then
checked for cuts with the design string, and if a cut occurs, the cut point will be labelled according
to the rest of the parameters in the n'th set.

The parameters for drawing a symbol at the cut points are

```
cuts_symbol_n_mode  0  // cross
1  // up from centre of box
2  // up and down from centre of box
3  // square
4  // triangle, base at bottom
5  // circle
6  // use a 12d symbol
```

```
0 + 1 1 2 3 4 5 6  
|  |  |  |   |   |
predefined symbols for cut_symbol_n_modes 0 to 5
```

If cuts_symbol_n_mode is 6, then the 12d symbol is given by
```
cuts_symbol_n_style  plotsymbol  // 12d symbol to draw at cut
```

**Important Note**

The plot symbol of name plotsymbol is defined in the file given by:

(a) the parameter plot_symbols in the ppf file
plot_symbols filename

or if plot_symbols is not defined, then

(b) in the file pointed to by the environment variable PLOT_SYMBOLS_4D
PLOT_SYMBOLS_4D filename // default plotsym.4d

or if PLOT_SYMBOLS_4D is not defined, then

(c) in the file plotsym.4d
which is searched for in the standard set up file sequence

If none of the above files are defined, or if the symbol does not exist in the above files, then it will be searched for in the standard 12d symbols file which is:

(d) either pointed to by the environment variable SYMBOLS_4D
SYMBOLS_4D filename // default symbols.4d

or if the environment variable SYMBOLS_4D does not exist, in the file, symbols.4d

The position of the symbol is given by:

cuts_symbol_n_position 1 // above point height value
3 // above top of boxes
100 // to primary string
101-500 // to tin1 or tin2 etc.

The symbol can be adjusted by the parameters:

cuts_symbol_n_x mm // offset adjustment to position
cuts_symbol_n_y mm // height adjustment to position
cuts_symbol_n_angle degrees // rotation about point
cuts_symbol_n_colour colour // colour of symbol

and for all values of cuts_symbol_n_mode other than 6:

cuts_symbol_n_size mm // size of symbol, 0 don't draw

The value of the chainage of the cut string can be labelled using the parameters

cuts_chainage_n_position1 // above cut strings height value
3 // above top of boxes
100 // to primary string
101-500 // to tin1 or tin2 etc.

cuts_chainage_n_x mm // chainage adjustment to position
cuts_chainage_n_y mm // height adjustment to position
cuts_chainage_n_angle degrees // rotation about point
cuts_chainage_n_size mm // size of text, 0 don't label
cuts_chainage_n_colour colour // colour of text
cuts_chainage_n_textstyle text // textstyle of text chainage
cuts_chainage_n_pre_text text // text before the chainage value
cuts_chainage_n_post_text text // text after the chainage value
cuts_chainage_n_justification justification // justification of the text

cuts_chainage_n_no_decimals integer // number of decimals in chainage
The value of a **height** at the chainage of the point can be calculated and labelled using the parameters

```plaintext
cuts_height_n_mode 1 // use height of cut point itself
                    3 // use real world height of position
                    // above boxes
                    100 // height of primary string
                    101-500 // use height of to tin1 or tin2 etc.

cuts_height_n_position 1 // at points position
                         3 // above top of boxes
                         100 // to primary string
                         101-500 // to tin1 or tin2 etc.

cuts_height_n_x     mm // chainage adjustment to position

cuts_height_n_y     mm // height adjustment to position

cuts_height_n_angle degrees // rotation about point

cuts_height_n_size  mm // size of text, 0 don't label

cuts_height_n_colour colour // colour of text

cuts_height_n_textstyle text // textstyle of text height

cuts_height_n_pre_text text // text before the height value

cuts_height_n_post_text text // text after the height value

cuts_height_n_justification justification // justification of the text

cuts_height_n_no_decimals integer // number of decimals in height
```

A **label** which can include the **name** of the cut string is drawn by using the parameters

```plaintext
cuts_label_n_position 1 // above cut strings height value
                    3 // above top of boxes
                    100 // to primary string
                    101-500 // to tin1 or tin2 etc.

cuts_label_n_mode 0 // don't include cut string name
                    1 // include cut string name in label

cuts_label_n_x     mm // chainage adjustment to position

cuts_label_n_y     mm // height adjustment to position

cuts_label_n_angle degrees // rotation about point

cuts_label_n_size  mm // size of text, 0 don't label

cuts_label_n_colour colour // colour of text

cuts_label_n_textstyle text // textstyle of text label

cuts_label_n_pre_text text // text before the string name

cuts_label_n_post_text text // text after the string name

cuts_label_n_justification justification // justification of the text
```
44.4.0.12 Title Block Information

The plot can have a standard 12d Model title block or a user defined title block.

The standard title block consists of a simple border around the plot and two lines of text in a box underneath the plot. For a user defined title block, all the line work and text is defined by the user.

44.4.0.12.1 Standard Title Block

For the standard 12d Model title block, there are extra parameters for two lines of text and text size and colour. The standard title block is turned on or off by the parameter `plot_border`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plot_border</td>
<td>yes/no // yes plots a standard title block</td>
</tr>
<tr>
<td>title_1</td>
<td>text</td>
</tr>
<tr>
<td>title_2</td>
<td>text</td>
</tr>
<tr>
<td>title_text_size</td>
<td>value</td>
</tr>
<tr>
<td>title_colour</td>
<td>colour</td>
</tr>
</tbody>
</table>

44.4.0.12.2 User Title Block

For the user defined title block, the title block drawing commands are kept in a file whose name is supplied by the user. The title block drawing commands are almost identical to the linestyle drawing commands and is given at the beginning of 44 Text Plot Parameters.

Hence for a user defined title block, there are just two parameters - one to say a title block file is being used and the other to give the name of the title block file. The `plot_border` parameter should also be set to no so that the standard title block is not also drawn.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>use_title_file</td>
<td>yes/no // yes draws the title block given in title_file</td>
</tr>
<tr>
<td>title_file</td>
<td>filename</td>
</tr>
<tr>
<td>plot_border</td>
<td>no // turn off standard title block</td>
</tr>
</tbody>
</table>

Some special plot parameters are used to pass information down to variables in a user defined title block.

For example, inside the title block file it is possible to have run time user defined text variables. The actual text values for these text variables are passed down to the title block file from the plot parameter file via the parameters `user_text_n` (n = 1,2,... 1000)

```
user_text_n text
```

The special plot parameters are:
time_format text // format for $time
user_text_n text // where n = 1,2,... 1000
// passed down to $user_text_n
title_1 text // passed down to $title_1
title_2 text // passed down to $title_2
start_page_number integer // used as the starting value for
// $page_number. If missing,
// $page_number starts at 1.
start_drawing_number integer // added to $drawing_number in title
// block file. If missing,
// $drawing_number starts at 1.
drawing_number_prefix text // passed down to
// $drawing_number_prefix
drawing_number_postfix text // passed down to
// $drawing_number_postfix

44.4.0.13 Parameters that Modify Fields In the Plot Pipeline Network Panel

A number of parameters match those in the plot pipeline network panel.

When the plot parameter file is first read, any parameters in the panel will be replaced by the values of any corresponding parameters from the parameter file.

However, if the parameter is subsequently modified in the panel, the panel value will be the value used for the parameter.

The plot parameters that also occur in the plot pipeline network panel are:

network_model text
plotter_type text
plot_stem text
view_name text // name of section view for tins, services,
// vertical exaggeration etc.
specials_model text
peg_interval world-units
scale value
sheet_size text or “width height”
plot_height mm
start_chainage world-units
end_chainage world-units
left_margin mm
right_margin mm
top_margin mm
bottom_margin mm
plot_border yes/no

title_1 text
title_2 text

title_text_size value
title_text_colour colour
use_title_file yes/no
title_file filename
44.5 #Include in Plot Parameter Files

The plot parameter file also recognizes the CCCP preprocessor rules including #include which can be used to include other files in the plot parameter file.

The format of the #include command is:

```
#include file_name
```

Hence a block of plot parameters can be set up in a file and included in another file using #include rather than typing them all in again.

Any number of #include's can be placed in the plot parameter file.

To return to the beginning of this appendix, click on 44 Text Plot Parameters.
45 Glossary

Glossary of Common Terms

Arc

Part of the circumference of a circle.

Affine Transformation 2D

A two dimensional transformation where one set of points is fitted to another. The transformation is a six parameter transformation, i.e., x displacement, y displacement, x scale factor, y scale factor, a x-rotation and y-rotation. If more variables exist than degrees of freedom, i.e., more than three control points are used, a least squares solution is calculated.

AGD

Australian Geodetic Datum.

AGD66

Australian Geodetic Datum 1966.

AGD84

Australian Geodetic Datum 1984.

AMG

Australian Map Grid.

Angle, Cartesian Angle, Mathematical Angle

The angle of a point is the counter-clockwise angle from the x-axis (horizontal or East line) to the line joining the point to the origin.

The angle of a line is the counter-clockwise angle measured from the x-axis to the line.

Batter

A steeply sloping surface (usually the wall of an earth bank).

Bearing

The bearing of a point is the clockwise angle from the y-axis (vertical or North line) to the line joining the point to the origin.

The bearing of a line is the clockwise angle measured from the y-axis to the line.

Blend

Use to define how opaque/translucent/transparent the fill of a polygon, face or tin is.
The value of blend is between 0 and 1.  
0 means the fill is totally transparent (and hence invisible) and 1 means that the fill is opaque (non-translucent) and can’t be seen through at all.

**Breakline**

A line on a surface joining a series of points on a common change-of-grade line. For example, the ridge top or spur, top or toe of batter, creek bank. See also *tinable segment*.

**Cartesian Angle**

See Angle.

**Chainage**

Chainage is a measure of the plan length along a string. The chainage at a point on a string is the start chainage of the string plus the plan length of the string from the beginning of the string to that point.

**Circular Curve**

Curves defined as an arc.

**Cross Fall**

The lateral grade or slope of a surface (particularly of a road pavement); usually expressed as a percentage of the proportion of metres vertically to metres horizontally.

**End Chainage**

The chainage of the last point of a string.

**Eye-Point**

For a perspective view, it is the point where the observer of the perspective view looks from.

**GDA**

Geocentric Datum of Australia.

**GDA94**

**GPS**

Global Positioning System.

**Grade**

The longitudinal slope of a surface (particularly of road pavement). Usually expressed as a cross fall percentage or as a ratio of one unit vertically to a number of units horizontally. For example, 3% or 1:10.
GRS80

Helmert Transformation 2D
A two dimensional transformation where one set of points is fitted to another. The transformation is a four parameter transformation, i.e., x displacement, y displacement, scale factor and rotation. If more variables exist than degrees of freedom, i.e., more than two control points are used, a least squares solution is calculated.

Helmert Transformation 3D
A three dimensional transformation where one set of points is fitted to another. The transformation is a seven parameter transformation, i.e., x displacement, y displacement, z displacement, scale factor and three rotations. If more variables exist than degrees of freedom, i.e., more than two control points are used, a least squares solution is calculated.

Hidden Line
Lines that are hidden between protruding landforms, etc. in perspective views.

Horizontal Alignment
The plan position of an alignment string (centre line) defined by intersection points, spirals and arcs.

Intersection Point (IP)
The point where two lines intersect. Usually horizontal intersection points (HIP) or vertical intersection points (VIP)

Invert
The lower inner surface of a drain or sewer pipe.

ISG
Integrated Survey Grid (NSW Australia).

MGA, MGA94
Map Grid of Australia 1994.

NTv2
National Transform Version 2. Special grid file format used in Australia, NZ and Canada for converting longitude and latitude.

Null Value
In three dimensional data, it is possible that a point can have a valid plan position but an undefined height. In 12d Model, there is a special null value which is used internally when height is undefined (-9.9e29).
Obvert
The upper inner surface of a drain or sewer pipe.

Parabolic Curve
Curves defined as a parabola.

Plot File
A file of plotting instructions in a format to suit a particular plotter. In 12d Model, HPGL is the default format for plot files.

Polygon
A string where the first point and the last point have the same plan co-ordinate. That is, the string closes on itself.

Screen Units
The unit of resolution for the computer screen - usually called pixels.

Shade
For a shade for a perspective view, the colour of all triangle faces are adjusted depending on the angle they make with a specified light source.

Slope
The inclination or grade of a surface or line, usually expressed as a ratio between one unit vertically to a number of units horizontally. For example, 1:10.

Snapping
A process where the element to be selected does not have to be exactly located. A tolerance is specified (the snap tolerance) and if the cursor is placed within the tolerance distance of the element then the cursor is moved directly ("snaps") to the element.

Different snap settings determine what parts of the element are considered for snapping to. For example, points on the string (point snap), drop perpendicular on the lines of an element (line snap) and grid points (grid snap).

Spiral
The special type of curve used for transitioning between straights and arcs in an alignment string (centre line). Also known as a transition curve or transition spiral.

Start Chainage
The chainage of the first point of a string.

String
A string is an ordered series of points.
Apart from the first and last point in a string, each point in a string has a unique next point (successor) and a unique previous point (predecessor). The previous and next points for a point
are called its string neighbours. The lines joining a point with its neighbours are called string links.

A string which has the same first and last point is called a closed string otherwise a string is said to be open.

Strings are very useful in the modelling of terrain and design surfaces. 12d Model uses a number of different types of strings which as defined in the Tools and Concepts.

Sweep Angle

For an arc, the sweep angle is the angle, measured in the clockwise direction, between the line joining the arc start point to the arc centre and the line joining the arc end point to the arc centre.

Tangent Point

A point at which a curve touches a line or another curve such that the tangent vector at that point is the same for the two touching items.

Target-Point

For a perspective view, it is the point that the observer is looking at.

Template

Standardized cross-section which is applied to a string at defined chainage points.

MTF Modifiers

12d Model commands which modify the definition of a template, as well as create and modify strings without them even being in a template. MTF Modifiers are used in preference to defining hundreds of different templates.

TIN

Triangulated Irregular Network. A TIN is a set of triangles which do not non-overlap in plan. Each vertex of a triangle has a z-value so that the TIN represents a surface in three dimensional space made up of triangular faces. When a TIN is created from a data set, the triangles are formed so that all non-null points are vertices of triangles. If breaklines are preserved in the TIN, then triangles are constrained so that any link from a breakline string is a side of a triangle.

Tinable vertex or point

If a vertex or point is tinable, then the vertex/point is included in triangulations. If the vertex/point is not tinable, then the vertex/point is ignored when triangulating.

Tinable segment or line

If a segment or line is tinable (and both the vertices at the ends of the segment/line are tinable and the z-values not null), then the segment/line is used as a side of a triangle during triangulation. This may not be possible if there are crossing tinable segments/lines.

A tinable segment is also known as a breakline.

Note that for a segment/line to be used as a side of a triangle, then its end vertices must be tinable and the z-values not null.
Triangulation
A set triangles, which do not overlap in a plan view, created from a set of data points. See TIN.

UTM
Universal Transverse Mercator.

View
The area in 12d Model used for displaying (drawing) graphical information. In 12d Model there are three types of views - plan, section and perspective.

Vertical Alignment
The long section position of an alignment string (centre line) defined by vertical intersection points (VIP’s) and parabolic or circular curves.

WGS84

World Units
The fundamental units used in 12d Model - usually metres.
